CONFORMAL NETS IV: THE 3-CATEGORY

ARTHUR BARTELS, CHRISTOPHER L. DOUGLAS, AND ANDRÉ HENRIQUES

Abstract. Conformal nets are a mathematical model for conformal field theory, and defects between conformal nets are a model for an interaction or phase transition between two conformal field theories. In the preceding paper [1], we introduced a notion of composition, called fusion, between defects. We also described a notion of sectors between defects, modeling an interaction among or transformation between phase transitions, and defined fusion composition operations for sectors. In this paper we prove that altogether the collection of conformal nets, defects, sectors, and intertwiners, equipped with the fusion of defects and fusion of sectors, forms a symmetric monoidal 3-category. This 3-category encodes the algebraic structure of the possible interactions among conformal field theories.

INTRODUCTION

This entire paper is devoted to the proof of the following result:

**Theorem.** Conformal nets, defects, sectors, and intertwiners form a symmetric monoidal 3-category.

Here, following [3], we take dicategories internal to the 2-category of symmetric monoidal categories as our specific model for symmetric monoidal 3-categories. A dicategory in symmetric monoidal categories consists of: [0-data] a symmetric monoidal category of objects, a symmetric monoidal category of 1-morphisms, and a symmetric monoidal category of 2-morphisms; [1-data] various symmetric monoidal functors between (fiber products of) these categories, encoding identity and composition operations; [2-data] various symmetric monoidal natural transformations between (products and composites of) these functors, encoding compatibility relationships between the operations; and [3-axioms] various axioms for these transformations, encoding coherences between the compatibility relationships. In the following, these pieces of structure are tracked by labels of the form [D0-x], [D1-x], [D2-x], [D3-x], following the same numbering scheme as in [3, Def. 3.3].

In our case, the category of objects [D0-0] is the (symmetric monoidal) category $\mathcal{CN}_0$ of finite conformal nets (finite direct sums of irreducible conformal nets with finite index), together with isomorphisms between them; the category of 1-morphisms [D0-1] is the (symmetric monoidal) category $\mathcal{CN}_1$ of defects (between finite conformal nets), together with isomorphisms of defects; and the category of 2-morphisms [D0-2] is the (symmetric monoidal) category $\mathcal{CN}_2$ of sectors (between defects between finite conformal nets), together with homomorphism of sectors (also called intertwiners) that cover isomorphisms of defects and of conformal nets; the intertwiners play the role of 3-morphisms in the overall 3-category. These categories of nets, defects, and sectors are discussed in Section 0 below.

The most important operation in the 3-category is the composition of 1-morphisms [D1-2], which here is a (symmetric monoidal) functor

$$\mathcal{CN}_1 \times_{\mathcal{CN}_0} \mathcal{CN}_1 \to \mathcal{CN}_1$$

given by the fusion of defects:

$$\left( A D_B, B E_C \right) \mapsto D \oplus_B E.$$

The existence of this fusion operation is proven in [1, Thm 1.44]. The vertical composition of 2-morphisms [D1-4] is a functor

$$\mathcal{CN}_2 \times_{\mathcal{CN}_1} \mathcal{CN}_2 \to \mathcal{CN}_2,$$

given by the vertical fusion of sectors:

$$\left( D H_E, E K_F \right) \mapsto H \boxtimes_E K.$$

This operation is defined in [1, Sec 2.C]. Horizontal composition of 2-morphisms is encoded indirectly using the vertical composition of 2-morphisms together with left and right whisker

---

1. A dicategory object differs from a bicategory object in that the associativity structures (but not the unital structures) are strict.

2. We have not compared our notion of dicategory internal to symmetric monoidal categories with other notions of symmetric monoidal 3-category that exist in the literature. Nevertheless, we think that it is plausible that every symmetric monoidal 3-category (in whatever sense) could be modeled as a dicategory or bicategory in symmetric monoidal categories, and that every dicategory or bicategory in symmetric monoidal categories could be modeled in any other (weak) notion of symmetric monoidal 3-categories.
operations \([D1-5, D1-6]\), which are functors
\[
\begin{align*}
\mathbb{C}N_2 \times_{\mathbb{C}N_0} \mathbb{C}N_1 &\to \mathbb{C}N_2, \\
\mathbb{C}N_1 \times_{\mathbb{C}N_0} \mathbb{C}N_2 &\to \mathbb{C}N_2.
\end{align*}
\]
These whisker functors are given by horizontal fusion with a vacuum sector (identity 2-morphism): for instance the right whisker is
\[
\left((\mathbb{A}(D_1)_\mathbb{B})H_{(\mathbb{A}(D_2)_\mathbb{B})}, \mathbb{B}E_\mathbb{C}\right) \mapsto H \boxtimes \mathbb{B}H_0(E),
\]
where \(H_0(E)\) is the vacuum sector of the defect \(E\). These various composition operations, and others, are presented in Section 1.

Compatibility transformations encode various relationships among the composition operations, for instance the associativity of vertical composition of 2-morphisms \([D2-3]\), the interaction of the horizontal whiskering operation and vertical composition \([D2-6, D2-7]\), and the associativity of the horizontal whiskering \([D2-9, D2-10, D2-11]\) and of the fusion of defects \([D2-12]\). The most important compatibility transformation is the switch transformation \([D2-8]\), which is a (symmetric monoidal) natural transformation
\[
\mathbb{C}N_2 \times_{\mathbb{C}N_0} \mathbb{C}N_2 \boxtimes \mathbb{C}N_2,
\]
between the two functors
\[
\left((\mathbb{A}(D_1)_\mathbb{B})H_{(\mathbb{A}(D_2)_\mathbb{B})}, (\mathbb{B}(E_1)_\mathbb{C}K_{(\mathbb{B}(E_2)_\mathbb{C})}) \mapsto (H \boxtimes B H_0(E_1)) \boxtimes (D_2 \boxtimes B E_1) (H_0(D_2) \boxtimes B K).
\]
These and other compatibility transformations are constructed in Section 2.

The compatibility transformations are subject to various coherence axioms, for instance pentagon conditions for vertical composition of 2-morphisms \([D3-4]\), and for horizontal whiskering \([D3-15, D3-16]\) and horizontal fusion of defects \([D3-17]\), along with conditions governing the interaction of vertical associativity with horizontal whiskering \([D3-7]\). Crucial coherence conditions are the one controlling the interaction of the switch transformation with vertical composition \([D3-8]\), and the ones controlling the interaction of the switch operation with horizontal whiskering \([D3-13, D3-14]\). These and other conditions are proven in Section 3.

0. Nets, defects, and sectors

[0-0] Conformal nets. By an interval, we shall mean a smooth oriented 1-manifold that is diffeomorphic to the standard interval \([0, 1]\). We let \(\mathbf{INT}\) denote the category whose objects are intervals and whose morphisms are embeddings (not necessarily orientation-preserving and not necessarily boundary preserving). Let \(\mathbf{VN}\) be the category whose objects are von Neumann algebras, and whose morphisms are \(\mathbb{C}\)-linear homomorphisms, and \(\mathbb{C}\)-linear antihomomorphisms. A net is a covariant functor
\[
\mathcal{A} : \mathbf{INT} \to \mathbf{VN}
\]

taking orientation-preserving embeddings to homomorphisms and orientation-reversing embeddings to antihomomorphisms. It is said to be isotonic if the induced maps for embeddings are injective. In this case, given a subinterval \(I \subseteq K\), we will often not distinguish between \(\mathcal{A}(I)\) and its image in \(\mathcal{A}(K)\). A conformal net \(\mathcal{A}\) is an isotonic net subject to a number of axioms [2 Def 1.1]. Conformal nets form a symmetric monoidal category, whose morphisms are natural transformations and whose tensor product is the tensor product of \(\mathbf{VN}\) applied objectwise. There is also the operation of direct sum of conformal nets; it is also defined
A conformal net \( \mathcal{A} \) is said to be irreducible if every algebra \( \mathcal{A}(I) \) is a factor. A direct sum of finitely many irreducible conformal nets is called semisimple. There is a notion of a finite semisimple conformal net (direct sum of conformal nets with finite \( \mu \)-index [3]), defined utilizing the minimal index from subfactor theory [2 Sec 3]. The object category \( \mathbf{CN}_0 \) of our 3-category \( \mathbf{CN} \) is the subcategory of the category of conformal nets whose objects are finite semisimple conformal nets and whose morphisms are natural isomorphisms. This subcategory is a symmetric monoidal subcategory [2 Sec 3]. From now on all nets will be finite and semisimple and will be simply referred to as conformal nets.

[0-1] **Defects.** A bicolored interval is an interval \( I \) (always oriented), equipped with a covering by two closed, connected, possibly empty subsets \( I_o, I_\bullet \subset I \) with disjoint interiors, along with a local coordinate in the neighborhood of \( I_o \cap I_\bullet \). We disallow the cases where \( I_o \) or \( I_\bullet \) consists of a single point. The local coordinate does not need to preserve the orientation, but is required to send \((-\varepsilon, 0]\) into \( I_o \) and \([0, \varepsilon) \) into \( I_\bullet \). If either \( I_o \) or \( I_\bullet \) is empty, then there is no local coordinate specified. An embedding \( f: J \to I \) of bicolored intervals is called color preserving if \( f^{-1}(I_o) = J_o \) and \( f^{-1}(I_\bullet) = J_\bullet \). The bicolored intervals form a category \( \mathbf{INT}_\bullet \), whose morphisms are the color preserving embeddings that preserve the local coordinate. Let \( \mathcal{A} \) and \( \mathcal{B} \) be conformal nets. A defect from \( \mathcal{A} \) to \( \mathcal{B} \) is a functor

\[
D: \mathbf{INT}_\bullet \to \mathbf{VN}
\]

that extends \( \mathcal{A} \) and \( \mathcal{B} \) in the following sense: if \( I = I_o \) then \( D(I) = \mathcal{A}(I_o) \); if \( I = I_\bullet \) then \( D(I) = \mathcal{B}(I_\bullet) \). Moreover, \( D \) is subject to a number of axioms [1 Def 1.7]. We often say \( D \) is an \( \mathcal{A}-\mathcal{B} \)-defect and write \( D = \mathcal{A}\mathcal{D}_B \). Direct sum and tensor product for defects can be defined objectwise, as for nets. As morphisms between defects we have again natural transformations. Such a natural transformation \( \mathcal{A}\mathcal{D}_B \to \mathcal{A}'\mathcal{D}'_B \) restricts to natural transformations \( \mathcal{A} \to \mathcal{A}' \) and \( \mathcal{B} \to \mathcal{B}' \). The 1-morphism category of our 3-category \( \mathbf{CN} \) is the symmetric monoidal category \( \mathbf{CN}_1 \) whose objects are defects between finite semisimple nets, and whose morphisms are natural isomorphisms. There are forgetful source and target functors \( s, t: \mathbf{CN}_1 \to \mathbf{CN}_0 \) defined by \( s(\mathcal{A}\mathcal{D}_B) = \mathcal{A} \) and \( t(\mathcal{A}\mathcal{D}_B) = \mathcal{B} \).

**Proposition.** The symmetric monoidal functor \( s \times t: \mathbf{CN}_1 \to \mathbf{CN}_0 \times \mathbf{CN}_0 \) is a fibration in the sense of [3 Def 2.1, Def 2.2].

**Proof.** Observe as follows that the underlying (non-monoidal) functor \( s \times t \) is a fibration of categories. Given finite semisimple conformal nets \( \mathcal{A}, \mathcal{B}, \mathcal{A}', \mathcal{B}' \), natural isomorphisms \( \phi: \mathcal{A} \to \mathcal{A}' \) and \( \psi: \mathcal{B} \to \mathcal{B}' \), and a finite semisimple defect \( \mathcal{A}\mathcal{D}'_B \), we must construct a defect \( \mathcal{A}\mathcal{D}_B \) and a natural isomorphism \( \mathcal{A}\mathcal{D}_B \to \mathcal{A}'\mathcal{D}'_B \). We may take \( D(I) = \mathcal{A}(I) \) when \( I \) is white, \( D(I) = \mathcal{B}(I) \) when \( I \) is black, and \( D(I) = D'(I) \) when \( I \) is genuinely bicolored, together with \( D(I \to J) = D'(I \to J) \circ \phi(I) \) when \( I \) is white and \( J \) is genuinely bicolored, and \( D(I \to J) = D'(I \to J) \circ \psi(I) \) when \( I \) is black and \( J \) is genuinely bicolored. The isomorphism \( D \to D' \) is the identity on genuinely bicolored intervals and is \( \phi \), respectively \( \psi \), on white and black intervals. That \( s \times t \) is in fact a fibration of symmetric monoidal categories is similarly straightforward.

Throughout this paper we will depend heavily on graphical notation. Defects will often be represented by a picture, thought of as a bicolored interval, as follows:

---

The four bullets on this interval indicate that this interval is of length three. The marked point \( x \) denotes the point where the color of the interval changes. We often call this marked point the defect point. Strictly speaking we should include an orientation of our interval, for
example from left to right. (Later our intervals will often sit on the boundary of 2-manifolds embedded in the plane. Such a 2-manifold inherits its orientation from the plane and the interval from the boundary of the 2-manifold.) For a defect $\mathcal{A}D_B$ we think of the above interval as representing a collection of von Neumann algebras indexed by subintervals of our interval. If $I$ is a subinterval to the left of $x$, then it represents the algebra $\mathcal{A}(I) = D(I)$; if $I$ is a subinterval containing $x$, then it represents $D(I)$; if $I$ is a subinterval to the right of $x$, then it represents $B(I) = D(I)$. Sometimes we will simplify our graphical notation and drop the marked point from the interval. If we need coordinates on the above interval, then we will identify it with $[0,3]$, where 0 corresponds to the left boundary point and 3 to the right boundary point. The defect point then has the coordinate 1.5.

**[0-2] Sectors.** Consider the standard regular hexagon with side length 1:

In this paper $S^1$ is defined to be the boundary of this hexagon. Sometimes we emphasize this and write $S^1_6$ for the boundary of this hexagon. Later we will also need the regular octagon with side length 1; we denote its boundary as $S^2_8$. The hexagon inherits an orientation from the plane; this also orients its boundary. We will pick the clockwise orientation of the plane; thus the circle is also clockwise oriented. We think of the above circle as bicolored: the left hand side is white •, while the right hand side is black ●. The two marked points are the points where the color changes. In particular, every subinterval of $S^1_6$ that contains at most one of the marked points (and none on the boundary) inherits a bicoloring.

Let $\mathcal{A}D_B$ and $\mathcal{A}E_B$ be defects. A $D$-$E$-sector is a Hilbert space $H$ equipped with actions of algebras represented by the bicolored subintervals of $S^1_6$ as follows: for every white subinterval $I \subseteq S^1_6$, the algebra $\mathcal{A}(I)$ acts; for every black subinterval $I \subseteq S^1_6$, the algebra $\mathcal{B}(I)$ acts; for every bicolored subinterval containing the upper defect point, the algebra $D(I)$ acts; for every bicolored subinterval containing the lower defect point, the algebra $E(I)$ acts. These actions are subject to compatibility axioms [1, Def 2.2]. We often write $H =_{D} H_{E}$ to emphasize that $H$ is a $D$-$E$ sector. For fixed $D$ and $E$, the $D$-$E$-sectors form a category whose morphisms are the bounded linear maps that commute with the actions associated to the bicolored subintervals of $S^1_6$. There is also a natural notion of morphism $f :_{D} H_{E} \rightarrow_{D'} H'_{E'}$. In this case $f$ includes morphisms $\mathcal{A} \rightarrow\mathcal{A}', \mathcal{B} \rightarrow\mathcal{B}', \mathcal{A}D_B \rightarrow\mathcal{A}'D'_B, \mathcal{A}E_B \rightarrow\mathcal{A}'E'_B$ and an operator $T : H \rightarrow H'$ that commutes with the induced maps $D(I) \rightarrow D'(I)$ and $E(I) \rightarrow E'(I)$. The tensor product of Hilbert space yields a symmetric monoidal structure on sectors. Thus we obtain the symmetric monodial category $\mathcal{CN}_2$ of sectors [1, Def 2.7]. This is the 2-morphism category of our 3-category $\mathcal{CN}$.

In the graphical notation we think of a sector $_{D} H_{E}$ as represented by the above hexagon. We then think of the upper defect point as the $D$ point and the lower defect point as the $E$ point. By definition every bicolored subinterval of $S^1_6$ corresponds then to a von Neumann algebra that acts on the sector $H$. (Later, other 2-manifolds will also be thought of as representing certain sectors.) Often we will drop the marked points from the picture. Moreover, we will often draw the hexagon in a rectilinear fashion, for example as one of the following:

\[
\begin{array}{cccccc}
\framebox{\phantom{0}} & \framebox{\phantom{0}} & \framebox{\phantom{0}} & \framebox{\phantom{0}} & \framebox{\phantom{0}} & \framebox{\phantom{0}} \\
\end{array}
\]

Despite their appearance, all these pictures refer to the standard regular hexagon with its two marked points as drawn.
Later it will sometimes be convenient to have coordinates on $S^1_0$ and $S^1_6$. Then we will identify $S^1 \cong \mathbb{R}/6\mathbb{Z}$ such that the coordinates of the corner points are $0, 1, \ldots, 5$, where we start on the left and proceed clockwise from there. The coordinate of the upper defect point is then $1.5$, and the coordinate of the lower defect point is $-1.5 \equiv 4.5$. In a similar fashion we will identify $S^1_3$ with $\mathbb{R}/8\mathbb{Z}$.

**Proposition.** The symmetric monoidal functor $s \times t : \text{CN}_2 \to \text{CN}_1 \times \text{CN}_0 \times \text{CN}_0 \times \text{CN}_1$ is a fibration in the sense of [3 Def 2.1, Def 2.2].

**Proof.** Observe as follows that the underlying (non-monoidal) functor $s \times t$ is a fibration of categories. Given finite semisimple conformal nets $\mathcal{A}$, $\mathcal{B}$, $\mathcal{A}'$, $\mathcal{B}'$, finite semisimple defects $\mathcal{A}D_B$, $\mathcal{A}E_B$, $\mathcal{A}'D_{B'}$, $\mathcal{A}'E_{B'}$, natural isomorphisms $\phi : D \to D'$ and $\psi : E \to E'$, and a sector $D_H E$ in the sense of [3, Def 2.1, Def 2.2] we can set $\phi$ as operators on $H$. Let $\mathcal{A}$ commute; in particular $\phi$ commutes. There is an associated automorphism $A$ such that $\mathcal{A}(\phi)(a) = U_{\phi} a U_{\phi}^*$. We then say that $U_{\phi}$ implements $\phi$ on $\mathcal{A}(I)$. Of course, $U_{\phi}$ is not unique. If $\alpha : \mathcal{A} \to \mathcal{B}$ is a morphism of $\text{CN}_0$, then $\alpha(I)(U_{\phi})$ is an implementation of $\phi$ on $\mathcal{B}(I)$.

Let $\mathcal{A}D_B$ and $\mathcal{A}E_B$ be defects and let $D_H E$ be a sector. Let $\phi : S^1_0 \to S^1_3$ be a diffeomorphism that fixes a neighborhood of both defect point. We can then pick subintervals $I_L$ of the left half of $S^1_0$ and $I_R$ of the right half of the circle $S^1_3$ such that $\phi$ is the identity on a neighborhood of the complement of $I_L \cup I_R$. In particular, $\phi$ restricts to diffeomorphisms $\phi_L$ and $\phi_R$ of $I_L$ and $I_R$. We obtain automorphisms $\mathcal{A}(\phi_L)$ of $\mathcal{A}(I_L)$ and $\mathcal{B}(\phi_R)$ of $\mathcal{B}(I_R)$. A unitary $U : H \to H$ is said to implement $\phi$ if

$$\mathcal{A}(\phi_L)(a) \circ U = U \circ a \quad \text{and} \quad \mathcal{B}(\phi_R)(b) \circ U = U \circ b$$

as operators on $H$ for all $a \in \mathcal{A}(I_L)$, $b \in \mathcal{B}(I_R)$. Such an implementation always exits; for example we can set $U := U_L \circ U_R$ where $U_L$ implements $\phi_L$ on $\mathcal{A}(I_L)$ and $U_R$ implements $\phi_R$ on $\mathcal{B}(I_R)$. (It is part of the axioms for sectors that the actions of $\mathcal{A}(I_L)$ and $\mathcal{B}(I_R)$ on $H$ commute; in particular $U_L$ is $\mathcal{B}(I_R)$-linear and $U_R$ is $\mathcal{A}(I_L)$-linear.)

1. Composition and identity operations

1.1. Horizontal identity and composition.

[1-1] Horizontal identity. Let $\mathcal{A} : \text{INT} \to \text{VN}$ be a conformal net. Then the identity defect $\text{id}_\mathcal{A}$ for $\mathcal{A}$ is defined by

$$\text{id}_\mathcal{A} = \mathcal{A} \circ \text{forget}$$

where $\text{forget} : \text{INT}\bullet \to \text{INT}$ is the functor that forgets the bicoloring. The 1-cell identity $\text{CN}_0 \to \text{CN}_1$ is defined to be the functor $\mathcal{A} \mapsto \text{id}_\mathcal{A}$. We will draw the identity defect as

[1-1]
where we use an equal sign (rotated) in the place of the usual $\times$ at the defect point. Sometimes we simplify this by dropping the defect marker altogether:

$$\text{[1-2] Horizontal composition.}$$

The horizontal composition is defined as the horizontal composition of defects as introduced in [1, Sec 1.E]. We write this horizontal composition functor $\text{CN}_1 \times \text{CN}_0 \to \text{CN}_1$ as $(A_D B_E) \mapsto D \otimes_B E$ and draw the composite of two defects as

Here the left defect point is associated to $D$ and the right defect point is associated to $E$. We will review horizontal composition of defects and explain the picture in more detail below in Section 1.c.

1.b. Vertical identity and composition.

$$\text{[1-3] Vertical identity.}$$

Let $D = A_D B$ be a defect, and let $S$ be a circle with a bicoloring-preserving automorphism that exchanges the two color change points—we refer to such an automorphism as a reflection. The vacuum sector $H_0(D, S) = D H_0(D, S)_D$ of $D$ on $S$ was introduced in [1, Sec 1.B]. If $S$ is the standard circle $S^1_6$, then the reflection along the horizontal axis is a canonical choice of a bicoloring-preserving reflection. (In coordinates the reflection is $t \mapsto 6 - t$.) We call $H_0(D) := H_0(D, S^1_6)$ the vacuum sector of $D$. The functor $D \mapsto H_0(D)$ defines the 2-cell identity $\text{CN}_1 \to \text{CN}_2$. The underlying Hilbert space of the vacuum sector is the standard form $L^2(D(I))$ of the von Neumann algebra $D(I)$, where $I$ is the upper half of the circle $S^1_6$. (This is also the interval of length 3 used earlier.) Pictorially we denote the vacuum sector as

In this picture, the gray shading indicates that the sector is a vacuum sector; an arbitrary sector would have no interior shading. The upper and the lower half of $S^1_6$ are both copies of our bicolored interval $I$ and correspond to the two actions of $D(I)$ on $L^2(D(I))$. Sometimes we will drop the defect points from our pictures. Moreover, we might draw the picture in a rectilinear fashion such as

We point out that whenever the boundary of the circle is split into two intervals each of which contains a defect point in the interior, then the corresponding algebras are commutants of each other [1, Prop 1.16].

$$\text{[1-4] Vertical composition.}$$

The vertical composition $\text{CN}_2 \times \text{CN}_1 \to \text{CN}_2$ is defined as the vertical fusion from [1, Sec 2.C]. Our picture for the vertical fusion is

Note that the boundary of this picture is canonically $S^1_6$. In particular, no boundary reparametrisation is needed in the definition of vertical fusion. Often the picture is simplified by omitting defect points and is drawn as a rectilinear equivalent
The underlying Hilbert space of the vertical fusion of sectors is the Connes fusion of the Hilbert spaces for the two sectors over the algebra associated to the horizontal interval of length 3 in the middle of the pictures. Sometimes will will draw this picture in the following different, but equivalent, forms

These versions will be helpful when we discuss the vertical fusion of three sectors.

1. **Horizontal whiskers.**

**Horizontal fusion.** The definition of a 3-category that we are using in this paper does not (for reasons of efficiency) directly include a notion of horizontal composition of 2-morphisms. Nevertheless, there is such a composition for our sectors called *horizontal fusion* of sectors and this operation will be the basis for many pieces of structure in our 3-category. Horizontal fusion is a functor $CN_2 \times CN_0 \to CN_2$ and is defined in [1, Sec 2.B]. In symbols, given defects $\mathcal{A}(D_1)\mathcal{B}$, $\mathcal{A}(D_2)\mathcal{B}$, $\mathcal{B}(E_1)\mathcal{C}$, and $\mathcal{B}(E_2)\mathcal{C}$, we will write the horizontal fusion functor as

$$(D_1 H_{D_2}, E_1 K_{E_2}) \mapsto (D_1 \otimes B E_1 (H \boxtimes B K) D_2 \otimes B E_2).$$

We draw $H \boxtimes B K$ as

The underlying Hilbert space is the Connes fusion of $H$ and $K$ along the algebra associated by $B$ to the vertical interval $I$ of length 2 in the middle of the picture. Note that $I$ inherits two different orientations from the two (deformed) hexagons. If we orient $I$ using the right hexagon (corresponding to $K$), then $B(I)$ acts on $K$, while $B(-I) = B(I)^{op}$ acts on $H$. It is exactly this situation that allows the use of Connes fusion (just as one may take the tensor product of a right module and a left module). Sometimes we drop defect points from the picture. Moreover, we often draw a rectilinear version of the picture,

We can now give a brief summary of the composition of defects. Let $\mathcal{A}D_B$ and $\mathcal{B}E_C$ be defects. Consider $H_0(D) \boxtimes B H_0(E)$, the horizontal composition of the vacuum sectors for $D$ and $E$,

The boundary of this picture is drawn as an irregular hexagon, but its boundary has length 8. Thus it can be identified with the octagon $S^3_2$, and the upper four segments of the boundary can be identified with the interval $I_4$ of length 4

The evaluation of the composed defects $D \otimes_B E$ on this interval is generated in the algebra of bounded operators on $H_0(D) \boxtimes B H_0(E)$ by the evaluation of $D$ on the first two segments and by the evaluation of $E$ on the last two segments. Similarly, we obtain an algebra acting on $H_0(D) \boxtimes B H_0(E)$ for any subinterval of $I_4$. The interval $I_4$ is not bicolored, but there is a map onto a bicolored interval $I_3$ of length 3 that collapses the two half segments between the two defect points to a single defect point, and this collapse map is used to view $D \otimes_B E$ as a functor on $\text{INT}_{S_4}$. The evaluation of $D \otimes_B E$ on a subinterval of $I_3$ is defined via its preimage in $I_4$ under the collapse map. In our pictures we never indicate this collapse map.
in any way. Thus the pictures remember more than just the structure of $D \oplus_B E$ as a defect: we see more subintervals to which we can associate algebras, for example we could consider a little neighborhood of the left (say) defect point. In a similar fashion our picture for the horizontal fusion remembers more than just the structure of a sector; it also encodes the actions of some additional algebras. If we compose more than two defects, then we obtain intervals of yet longer length with yet more defect points.

To formally define the horizontal fusion of sectors a similar collapse map $\pi: S^1_8 \to S^1_6$ is used. It collapses four half segments to two points. On the upper half this is just the collapse map used before, on the lower half this is the reflection of that collapse map.

[1-5] Right whisker. The right composition of a 1-cell with a 2-cell $\text{CN}_2 \times \text{CN}_0 \text{CN}_1 \to \text{CN}_2$ is defined using horizontal fusion and the vacuum sector. Let $\mathcal{A}$, $\mathcal{B}$, and $\mathcal{C}$ be nets, let $\mathcal{A}(D_1)_B$, $\mathcal{A}(D_2)_B$, and $\mathcal{B}E_C$ be defects, and let $D_1 H D_2$ be a sector. The right composition of $H$ with $E$ is defined as the horizontal fusion $H \boxtimes_B H_0(E)$. We draw this as

\[
\text{[1-5].}
\]

Again, often this is drawn as

\[
\text{[1-5].}
\]

Here we omitted defect points from the pictures, but sometimes we will include them for clarity.

[1-6] Left whisker. The left composition of a 1-cell with a 2-cell is defined similarly to the right composition, and is drawn as

\[
\text{[1-6].}
\]

The data discussed so far is part of the definition of both a 2-category object and a dicategory object (in the 2-category of symmetric monoidal categories). We remind the reader that our 3-category of conformal nets is a dicategory object; the next two pieces of data [1-7] and [1-8] are labeled $[D1-7]$ and $[D1-8]$ in $[3]$. 

1.1. Directional identity cells.

[1-7] Left identity. The (upper) left 2-cell identity is a functor $\text{CN}_1 \to \text{CN}_2$. Its role is to show that the composition of a defect with an identity defect is, at least in a weak sense, equivalent to the original defect.

Let $\mathcal{A}D_B$ be a defect. There is no canonical isomorphism between $\text{id}_{\mathcal{A}} \oplus_{\mathcal{A}} D$ and $D$ in $\text{CN}_1$. (For this reason our 3-category of conformal nets is not a 2-category object in symmetric monoidal categories.) There is however a canonical $(\text{id}_{\mathcal{A}} \oplus_{\mathcal{A}} D)$-$D$-sector, the left identity for $D$. Our picture of this left identity is

\[
\text{[1-7].}
\]

This sector is the vacuum sector $H_0(D)$ for $D$ (this is the box part of the picture), twisted by a diffeomorphism (indicated by the balloon in the picture). Details of this construction follow.

We begin by reviewing the defect $\text{id}_{\mathcal{A}} \oplus_{\mathcal{A}} D$. Consider the collapse map $\pi: S^1_8 \to S^1_6$ used earlier. This map is symmetric with respect to the reflection along the horizontal axis (in
coordinates the reflection is given by $x \mapsto -x$). The restriction of $\pi$ to the upper half of $S^1_8$ is a map $I_4 \to I_3$, which collapses $[1.5, 2.5] \subset I_4$ to $1.5 \in I_3$, sends $x \in [0, 1.5] \subset I_4$ to $x \in [0, 1.5]$, and sends $x \in [2.5, 4] \subset I_4$ to $x - 1 \in [1.5, 3] \subset I_3$. The evaluation of $\text{id}_{\mathcal{A} \otimes_{\mathcal{A}} D}$ on a bicolored subinterval $I$ of $I_3$ is the algebra $D(\pi^{-1}(I))$. (This algebra is isomorphic to $D(I)$, but there is no canonical isomorphism if $I$ contains the upper defect point 1.5.)

To construct the left identity we pick a diffeomorphism $\Phi_L: S^1_8 \to S^1_6$ such that $\Phi_L(x) = x$ on a neighborhood of $[0, 1]$ and $\Phi_L(x) = x - 1$ on a neighborhood of $[2.5, 4]$ and is symmetric with respect to the vertical reflection of the circles; that is, we require that $\Phi_L(-x) = -\Phi_L(x)$. In particular, $\Phi_L$ coincides with $\pi$ on $[0, 1] \cup [2.5, 4]$. (The structure of our 3-category depends on the choice of $\Phi_L$.) Now we start with the vacuum sector $H_0(D)$ for $D$:

$\phantom{i}.$

It is a $D$-$D$-sector. We can twist the upper $D$-action by the restriction of $\Phi_L$ to the upper half $I_3$ of $S^1_6$, turning $H_0(D)$ into an $(\text{id}_{\mathcal{A}} \otimes_{\mathcal{A}} D)$-$D$-sector. More precisely, if $I \subseteq S^1_6$ is a bicolored interval containing the upper defect point, then the action of $(\text{id}_{\mathcal{A}} \otimes_{\mathcal{A}} D)(I)$ on $H_0(D)$ is defined via the isomorphism

$$ (\text{id}_{\mathcal{A}} \otimes_{\mathcal{A}} D)(I) = D(\pi^{-1}(I)) \xrightarrow{D(\Phi_L|_{\pi^{-1}(I)})} D(\Phi_L(\pi^{-1}(I))). $$

Because $\Phi_L(x) = x$ on a neighborhood of $[0, 1]$ and $\Phi_L(x) = x - 1$ on a neighborhood of $[2.5, 4]$ it follows that this construction indeed defines a sector. We define the left identity for $D$ to be this sector. The small balloon in the above picture represents the restriction of $\Phi_L$ to $[1, 2.5] \to [1, 1.5]$. Occasionally we use the abbreviated notation

$\phantom{i}.$

or

$\phantom{i}.$

in which a small vertical tick indicates that the top is a composition of two defects, or, when there could be no confusion, simply by

$\phantom{i}.$

[1-8] Right identity. The right identity is defined similarly to the left identity; specifically the right identity is a horizontal reflection of the left identity. Thus we replace the diffeomorphism $\Phi_L$ by the diffeomorphism $\Phi_R: S^1_8 \to S^1_6$, $\Phi_R(x) := 3 - \Phi_L(4 - x)$. The pictures for the right identity are:

$\phantom{i}.$

$\phantom{i}.$

$\phantom{i}.$

$\phantom{i}.$

[1-8].

Lemma 1. The left and the right identity sectors are invertible with respect to vertical fusion of sectors, as required in [3].

Proof. An inverse for the left identity is given by a vertical reflection of the left identity. Similarly, an inverse for the right identity is given by a vertical reflection of the right identity. □
The procedure of twisting with a diffeomorphism as in the construction of the left identity [1-7] can be applied to other defects than the vacuum sector. We can twist any $A_{DB}, A_{EB}$-sector by a diffeomorphism to obtain an $(\text{id}_A \otimes_A D)$-sector. Varying the position of the diffeomorphism we can also produce a $(D \otimes_B \text{id}_B)\cdot E$-sector or a $D \cdot (\text{id}_A \otimes_A E)$-sector or a $D \cdot (E \otimes_B \text{id}_B)$-sector. Moreover this process can be reversed. For example given a $(\text{id}_A \otimes_A D)$-sector we can twist by the inverse of $\Phi_L$ to obtain a $D \cdot E$-sector. These constructions are inverse to each other. Also note that in vertical compositions we will often move the diffeomorphism from one sector to another, when this does not affect the resulting composite sector; for example the following pictures are interchangeable:

![Diagram](image)

2. Compatibility transformations for composition and identity operations

2.A. Transformations for vertical identity and composition.

[2-1] Top identity. There is a canonical natural isomorphism

![Diagram](image)

because the underlying Hilbert space of the identity defect on the left hand side is the standard form of the algebra associated to the interval of length 3 in the middle of the picture on the left hand side. This is the top identity.

[2-2] Bottom identity. The bottom identity is similarly depicted

![Diagram](image)

[2-3] Vertical associator. Connes fusion of bimodules over von Neumann algebras is not strictly associative, but there is a coherent associator for this operation (similar to the associator for the algebraic tensor product of bimodules over rings). Because vertical fusion is defined using fusion along the algebra corresponding to the upper, respectively lower, half of our standard circle, the associator for Connes fusion over von Neumann algebras is also an associator for vertical fusion of sectors. We will draw this associator as

![Diagram](image)

The little gap on the left hand side illustrates that here we first do the Connes fusion along the upper algebra; on the right hand side the gap illustrates that we first do the Connes fusion along the lower algebra. Because this associator just comes from the fact that Connes fusion over von Neumann algebras is not strictly associative we will henceforth very often
supress this isomorphism and treat the right hand and left hand side of the above picture as equal; we therefore simply draw this vertical fusion as

![Vertical Fusion Diagram](attachment:vertical_fusion.png)

2.B. Transformations for horizontal composition and whiskers.

1 $\boxtimes$ 1-isomorphism. Crucial for the construction of our 3-category is the 1 $\boxtimes$ 1-isomorphism from \([1 \text{ Thm } 6.2]\]. The 1 $\boxtimes$ 1-isomorphism provides a natural isomorphism between two \(\mathsf{CN}_1 \times \mathsf{CN}_1 \to \mathsf{CN}_2\) defined as follows. Let \(\mathcal{A} D_B\) and \(\mathcal{B} E_C\) be defects. The first functor sends \((D, E)\) to \(H_0(D) \otimes_B H_0(E)\) and the second functor sends \((D, E)\) to \(H_0(D \otimes_B E)\). Thus the 1 $\boxtimes$ 1 isomorphism shows in particular that the horizontal fusion of two vacuum sectors is again a vacuum sector. In pictures the 1 $\boxtimes$ 1-isomorphism is denoted

\[
\begin{array}{c}
\begin{array}{c}
\hline
| & | & | & \vspace{1cm} & | & | & | \\
\hline
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\hline
| & | & | & \vspace{1cm} & | & | & | \\
\hline
\end{array}
\end{array}
\]

\([2-4] \text{ and } [2-5] \text{ Right and left vertical identity expansion.}\) The right and left vertical identity expansions coincide and are both given by the 1 $\boxtimes$ 1-isomorphism. In pictures we have

\[
\begin{array}{c}
\begin{array}{c}
\hline
| & | & | & \vspace{1cm} & | & | & | \\
\hline
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\hline
| & | & | & \vspace{1cm} & | & | & | \\
\hline
\end{array}
\end{array}
\]

but often we will drop the defect points from the notation.

The categories \(\mathsf{CN}_{\sim 2}, \mathsf{CN}_{\sim} \text{ and } \mathsf{CN}_{\sim 2}\). We will later need variants of \(\mathsf{CN}_2\) that have more morphisms.

The following notation will be helpful. If \(\varphi : A \to B\) is a map of von Neumann algebras, \(H\) is an \(A\)-module, and \(K\) is a \(B\)-module, then we denote by \(\text{Hom}_\varphi(H, K)\) the space of all bounded linear maps \(T : H \to K\) that are \(\varphi\)-linear, that is such that for all \(a \in A\) and \(\xi \in H\) we have \(T(\varphi(a)\xi) = \varphi(a)T(\xi)\).

We start by recalling the precise definition of the morphisms in \(\mathsf{CN}_2\). For defects \(\mathcal{A} D_B, \mathcal{A} E_B, \mathcal{A} D_B', \mathcal{A} E_B'\), and sectors \(\mathcal{B} H_E\) and \(\mathcal{D} H_{E'}\), a morphism \(f : \mathcal{B} H_E \to \mathcal{D} H_{E'}\) is a triple \(f = (T, \delta, \varepsilon)\) where \(T: H \to H'\) is a bounded linear map and \(\delta: D \to D'\) and \(\varepsilon: E \to E'\) are morphisms from \(\mathsf{CN}_1\) such that \(s(\delta) = \varphi(a)\): \(A \to A'\) and \(t(\delta) = t(\varepsilon): B \to B'\). Moreover, \(T\) is required to be \(\delta(I)\)-linear for all bicolored subintervals \(I\) of \(S_4^1\) not containing the lower defect point, and to be \(\varepsilon(I)\)-linear for all bicolored subintervals not containing the upper defect points. (On subintervals not containing a defect point these two requirements coincide.)

Informally, the categories \(\mathsf{CN}_{\sim 2}, \mathsf{CN}_{\sim} \text{ and } \mathsf{CN}_{\sim 2}\) are obtained, respectively, by relaxing the linearity of morphisms around the lower defect point (for \(\mathsf{CN}_{\sim 2}\)), around the upper defect point (for \(\mathsf{CN}_{\sim}\)), or around both defect points (for \(\mathsf{CN}_{\sim 2}\)). In all three cases the objects coincide with the objects of \(\mathsf{CN}_2\). Morphisms are defined more formally as follows. We use the following subintervals of our standard circle \(S_4^1\):

\[
I_{\sim} := [4, 5], I_{\sim}^c := [-1, 4], I^\sim := [1, 2], I^\sim c := [2, 7], I_l := [-1, 1], \text{ and } I_r := [2, 4].
\]

Let \(\mathcal{A} D_B, \mathcal{A} E_B, \mathcal{A} D_B', \mathcal{A} E_B'\) be defects and let \(\mathcal{B} H_E\) and \(\mathcal{D} H_{E'}\) be sectors. A morphism \(f : H \to H'\) in \(\mathsf{CN}_{\sim 2}\) is a pair \(f = (T, \varepsilon)\) where \(\varepsilon: E \to E'\) is a morphism of \(\mathsf{CN}_1\) and \(T \in \text{Hom}_\varepsilon(I_{\sim}^c)(H, H')\). A morphism \(f : H \to H'\) in \(\mathsf{CN}_{\sim 2}\) is a pair \(f = (T, \delta)\)
where \( \delta : D \to D' \) is a morphism of \( \mathbb{C}N \) and \( T \in \text{Hom}_{\mathbb{C}N}(H, H') \). Finally, a morphism \( f : H \to H' \) in \( \mathbb{C}N \) is a triple \( (T, \alpha, \beta) \) where \( \alpha : A \to A' \), \( \beta : B \to B' \) are morphisms of \( \mathbb{C}N_0 \) and \( T : H \to H' \) belongs to both \( \text{Hom}_{\mathbb{C}N_0}(H, H') \) and \( \text{Hom}_{\mathbb{C}N_0}(H, H') \). Note that there are forgetful functors \( \mathbb{C}N_0 \to \mathbb{C}N_{\sim 2} \) and \( \mathbb{C}N \to \mathbb{C}N_{\sim 2} \) that are the identity on objects and for morphisms are defined by \( (T, \varepsilon) \mapsto (T, s(\varepsilon), t(\varepsilon)) \) and \( (T, \delta) \mapsto (T, s(\delta), t(\delta)) \).

We remark that many of our previous constructions extend to these variants of \( \mathbb{C}N \).

For example the vertical fusion [1-4] is natural for these more general morphisms and thus extends canonically to a functor \( \mathbb{C}N_0 \times \mathbb{C}N \to \mathbb{C}N_{\sim 2} \). As a rule of thumb: whenever we have a neighborhood of a defect point on the boundary of the picture describing one of our functors, we can canonically extend that functor, adding an appropriate \( \sim \) to source and target of the functor.

Homomorphisms in \( \mathbb{C}N_{\sim 2} \) (or \( \mathbb{C}N_{\sim 2} \)) between vacuum sectors can be more concretely described, as follows:

**Lemma 2.** Let \( \mathcal{A}^D_B, \mathcal{A}'^D_B \) be defects, and let \( \delta : D \to D' \) be an (iso)morphism of defects. Then there is an isomorphism of vector spaces from \( D'(I^-) \) to \( \text{Hom}_{\mathbb{C}N(I^-)}(H_0(D), H_0(D')) \) given by \( b \mapsto b \circ H_0(\delta) \). Here we use \( \sim \) to refer both to an algebra element and to the linear map given by multiplying by that element.

In particular, if we view \( H_0(D) \) and \( H_0(D') \) as objects of \( \mathbb{C}N_{\sim 2} \), then given a bounded linear map \( F : H_0(D) \to H_0(D') \), the pair \( F, \delta \) defines a morphism \( H_0(D) \to H_0(D') \) in \( \mathbb{C}N_{\sim 2} \) if and only if \( F = b \circ H_0(\delta) \) for some \( b \in D'(I^-) \).

**Proof.** Haag duality for defects [1 Prop 1.16] implies that \( \text{Hom}_{D'(I^-)}(H_0(D'), H_0(D)) = D'(I^-) \), i.e., every \( D'(I^-) \)-linear operator on \( H_0(D') \) is given by the action of a unique element in \( D'(I^-) \).

Now \( H_0(\delta) : H_0(D) \to H_0(D') \) is a \( \delta(K) \)-linear isomorphism for all intervals \( K \subseteq S^1_0 \). In particular it is \( \delta(I^-) \)-linear and induces an isomorphism \( D'(I^-) = \text{Hom}_{D'(I^-)}(H_0(D'), H_0(D')) \) as objects of \( \mathbb{C}N_{\sim 2} \).

The second statement follows from the first and the definition of \( \mathbb{C}N_{\sim 2} \).

The categories \( \mathbb{C}N_{\sim 2} \) and \( \mathbb{C}N_{\sim 2} \). We define \( \mathbb{C}N_{\sim 2} \) as the full subcategory of \( \mathbb{C}N_{\sim 2} \) on objects of the form \( H_0(D) \otimes \ell \), where \( \mathcal{A}^D_B \) is a defect and \( \ell \) is a separable Hilbert space. It is a monoidal subcategory. Similarly we obtain a monoidal subcategory \( \mathbb{C}N_{\sim 2} \) of \( \mathbb{C}N_{\sim 2} \).

**Proposition 3.** Every object from \( \mathbb{C}N \) is isomorphic in \( \mathbb{C}N_{\sim 2} \) (resp. in \( \mathbb{C}N_{\sim 2} \)) to a direct summand of an object from \( \mathbb{C}N_{\sim 2} \) (resp. from \( \mathbb{C}N_{\sim 2} \)).

**Proof.** Let \( \mathcal{A}^D_B \), \( \mathcal{A}'^D_B \) be defects and let \( D \leq K_2 \) be a sector (in other words, an object of \( \mathbb{C}N \)). In particular, \( K \) is an \( E(I) \)-module, where \( I = [2, 7] \) is the complement of the interval \( (1, 2) \) of our standard circle \( S^1_0 \). Observe that the vacuum sector \( H_0(E) \) is faithful as an \( E(I) \) module (in fact \( H_0(E) \) is isomorphic to the standard form \( L^2(E(I)) \)). Recall that whenever \( A \) is a separable von Neumann algebra acting on a separable Hilbert space \( H \) and acting faithfully on a separable Hilbert space \( H' \), then there is an \( A \)-linear isometric embedding \( H \otimes \ell \to H' \otimes \ell \), and in particular an isometric embedding \( H \to H' \otimes \ell \), where \( \ell \) is an infinite-dimensional Hilbert space. We can therefore find an \( E(I) \)-linear isometric embedding of \( K \) into \( H_0(E) \otimes \ell \) for some separable Hilbert space \( \ell \). By the definition of \( \mathbb{C}N_{\sim 2} \) this embedding defines a morphism \( K \to H_0(E) \otimes \ell \) in \( \mathbb{C}N_{\sim 2} \), as desired.

**Proposition 4.** Let \( \mathcal{A}^D_B \) and \( \mathcal{A}'^D_B \) be defects and let \( \ell \) and \( \ell' \) be separable Hilbert spaces. Consider \( X := H_0(D) \otimes \ell \) and \( X' := H_0(D') \otimes \ell' \) as objects of \( \mathbb{C}N_{\sim 2} \). Let \( f = (\bar{F}, \delta) : X \to X' \) be a morphism in \( \mathbb{C}N_{\sim 2} \). Let \( Y := H_0(D') \otimes \ell' \). Then \( f \) can be factored through \( Y \) as
\[ f = f_2 \circ f_1 \text{ in } \text{CN}^\sim_2 \text{ where } f_1 \text{ is induced by } \delta \text{ and } f_2 \text{ is the identity on } D'. \] More precisely we have

(i) \[ f_1 = (H_0(\delta) \otimes \text{id}_\ell, \delta) : X \to Y; \]

(ii) \[ f_2 = (T, \text{id}_{D'}) : Y \to X' \text{ where } T \in D'(I) \otimes \text{B}(\ell, \ell'), \text{ with } I = [1, 2]. \]

Here, the space \( \text{B}(\ell, \ell') \) of bounded linear maps \( \ell \to \ell' \) is a corner in the von Neumann algebra \( \text{B}(\ell \oplus \ell') \), and the tensor product \( D'(I) \otimes \text{B}(\ell, \ell') \) is defined to be the closure of the corresponding algebraic tensor product in the von Neumann algebra \( D'(I) \otimes \text{B}(\ell \oplus \ell') \).

**Proof of Proposition 4.** We have to find \( T \in D'(I^\sim) \otimes \text{B}(\ell, \ell') \) such that \( \tilde{F} = T \circ (H_0(\delta) \otimes \text{id}_\ell) \).

By the definition of \( \text{CN}^\sim_2 \) we have

\[ \tilde{F} \in \text{Hom}_\delta(I^\sim)(H_0(D) \otimes \ell, H_0(D') \otimes \ell') \cong \text{Hom}_\delta(I^\sim)(H_0(D), H_0(D')) \otimes \text{B}(\ell, \ell'). \]

By Lemma 2 the map \( T_0 \mapsto T_0 \circ H_0(\delta) \) gives an isomorphism

\[ D'(I^\sim) \cong \text{Hom}_\delta(I^\sim)(H_0(D), H_0(D')). \]

Therefore \( T' \mapsto \tilde{T} \circ (H_0(\delta) \otimes \text{id}_\ell) \) yields an isomorphism

\[ D'(I^\sim) \otimes \text{B}(\ell, \ell') \cong \text{Hom}_\delta(I^\sim)(H_0(D) \otimes \ell, H_0(D') \otimes \ell'). \]

The inverse image of \( \tilde{F} \) under this isomorphism provides the desired factorization. \( \square \)

\[ [2-6] \text{ Right dewhisker.} \] The right dewhisker is an isomorphism

\[ \begin{array}{c|c|c}
\hline
- & \hline
\hline
- & \hline
\hline
\end{array} \]

The left and right sides of the above picture describe functors

\[ L, R : \text{CN}_2 \times \text{CN}_1 \times \text{CN}_2 \times \text{CN}_1 \to \text{CN}_2 \]

and the right dewhisker is a natural isomorphism \( \tau : L \to R \). Its construction will be a bit involved. We will show that in order to construct \( \tau \) it suffices to define \( \tau \) on the image of the functor \( I : \text{CN}_1 \times \text{CN}_1 \to \text{CN}_2 \times \text{CN}_2 \times \text{CN}_1 \) defined by \( I(D_B \times D_E) = (H_0(D), H_0(D), E) \). Here the natural isomorphism \( \tau_0 : L \circ I \to R \circ I \) can be constructed as the following composition:

\[ \begin{array}{c|c|c|c|c}
\hline
- & \hline
\hline
\hline
\hline
\hline
\end{array} \]

The darker shading indicates that those sectors are assumed to be vacuum sectors in the definition of \( \tau_0 \), but will need to be replaced by arbitrary sectors in order to define \( \tau \). The first and third isomorphisms are given by the isomorphisms [2-1] or [2-2] (which are equivalent by axiom [3-1]). The second and fourth isomorphisms are given by the \( 1 \otimes 1 \)-isomorphism.
In order to promote \( \tau_0 \) to \( \tau \) we use the following diagram of functors.

\[
\begin{array}{ccc}
\text{CN}_{1} \times \text{CN}_{0} \text{CN}_{1} & \xrightarrow{I} & (\text{CN}_{2} \times \text{CN}_{1} \text{CN}_{2}) \times \text{CN}_{0} \text{CN}_{1} \\
\downarrow i_0 & & \downarrow i_1
\end{array}
\]

Here we use the variations of \( \text{CN}_{2} \) introduced earlier. The functors \( \hat{L} \) and \( \hat{R} \) are the canonical extensions of \( L \) and \( R \). The functor \( I \) applies the identity sector twice in the first entry and has already been defined. The vertical functors \( i_1 \) and \( i_2 \) are induced from the three inclusion of \( \text{CN}_{2} \) into \( \text{CN}_{\geq 2} \), \( \text{CN}_{\leq 2} \), and \( \text{CN}_{2} \). The functor \( \hat{I} \) is induced from the inclusions \( \text{CN}_{\geq 2} \to \text{CN}_{\geq 2} \) and \( \text{CN}_{\leq 2} \to \text{CN}_{\leq 2} \). The composition \( i_1 \circ I \) canonically factors as \( \hat{I} \circ i_0 \).

In the next step we use \( \tau_0 \) to construct a natural isomorphism \( \hat{\tau}_0 : \hat{L} \circ \hat{I} \to \hat{R} \circ \hat{I} \). Let \( X_0 := (D, E) \) be an object of \( \text{CN}_{1} \times \text{CN}_{0} \text{CN}_{1} \) and let \( X = (H_0(D) \otimes \ell, H_0(D) \otimes \ell', E) \) be an object from \( \text{CN}_{\geq 2} \times \text{CN}_{1} \text{CN}_{\geq 2} \times \text{CN}_{0} \text{CN}_{1} \). We have natural identifications \( \hat{L}(\hat{I}(X)) = L(I(X_0)) \otimes \ell \otimes \ell' \) and \( \hat{R}(\hat{I}(X)) = R(I(X_0)) \otimes \ell \otimes \ell' \). We set \( \hat{\tau}_0(X) := (\tau_0) \otimes \ell \otimes \ell' \). However, there are more morphisms in \( \text{CN}_{\geq 2} \times \text{CN}_{1} \text{CN}_{\geq 2} \times \text{CN}_{0} \text{CN}_{1} \) than there are in \( \text{CN}_{1} \times \text{CN}_{0} \text{CN}_{1} \), and we need to check that \( \hat{\tau}_0 \) is natural with respect to these extra morphisms. Note that \( \hat{\tau}_0 \) is natural for morphisms from \( \text{CN}_{1} \), because \( \tau_0 \) is. By Proposition 4 to check naturality with respect to morphisms in \( \text{CN}_{\geq 2} \), it suffices to consider morphisms of the form

(i) \( f_1 = (H_0(\delta) \otimes \text{id}_\ell, \delta) \), where \( \delta : D \to D' \), or

(ii) \( f_2 = (T, \text{id}_D) \) where \( T \in D(I) \otimes \mathcal{B}(\ell, \ell') \), for \( I = [1, 2] \).

Now \( \hat{\tau}_0 \) is natural with respect to morphisms of the first kind because \( \tau_0 \) is natural for the morphisms from \( \text{CN}_{1} \). As \( \tau_0 \) is equivariant for the action of \( D(I) \), it follows that \( \hat{\tau}_0 \) is also natural for morphisms of the second kind. Similarly, \( \hat{\tau}_0 \) is natural for morphisms from \( \text{CN}_{\leq 2} \).

Thus \( \hat{\tau}_0 \) is a natural transformation.

By Proposition 4, every object of \( \text{CN}_{\geq 2} \times \text{CN}_{1} \text{CN}_{\leq 2} \times \text{CN}_{0} \text{CN}_{1} \) can be embedded as a direct summand in an object of \( \text{CN}_{\geq 2} \times \text{CN}_{1} \text{CN}_{\geq 2} \times \text{CN}_{0} \text{CN}_{1} \). Thus we can extend \( \hat{\tau}_0 \) canonically to a natural transformation \( \hat{\tau} : \hat{L} \to \hat{R} \).

Let \( X \) be an object from \( \text{CN}_{2} \times \text{CN}_{1} \text{CN}_{2} \times \text{CN}_{0} \text{CN}_{1} \). Then

\[
\hat{\tau}_i(X) : \hat{L}(i_1(X)) \to \hat{R}(i_1(X))
\]

is a morphism in \( \text{CN}_{\leq 2} \). In fact we will see that \( \hat{\tau}_i(X) \) is a morphism in \( \text{CN}_{2} \), and so we can define \( \tau_X := \hat{\tau}_i(X) \) and obtain the desired natural isomorphism. To check that \( \hat{\tau}_i(X) \) is in \( \text{CN}_{2} \), we write \( X = (D \cdot D', D' \cdot D'' \cdot E) \), where \( D, D' \), and \( D'' \) are \( A \cdot B \)-defects and \( E \) is a \( B \cdot C \)-defect. For convenience we ignore the collapse map \( S_0^1 \to S_0^2 \) and think of the \( (D \otimes_B E)\)-\( (D'' \otimes_B E) \)-sectors \( L(X) \) and \( R(X) \) as defined on \( S_0^1 \) instead of on \( S_0^2 \). We have to show that \( \hat{\tau}_i(X) \) is equivariant for the actions of \( D(I^-) \) and \( D''(I^-) \), where we now view \( I^- = [1, 2] \) and \( I^- = [0, 7] \) as subintervals of \( S_0^1 \). Elements of \( D(I^-) \) and \( D''(I^-) \) can be viewed as morphisms in \( \text{CN}_{\geq 2} \) and \( \text{CN}_{\leq 2} \), and therefore as morphisms in \( \text{CN}_{\geq 2} \times \text{CN}_{\leq 2} \times \text{CN}_{\leq 2} \). Therefore the required equivariance of \( \hat{\tau}_i(X) \) follows from the naturality of \( \hat{\tau} \). This finishes the construction of the right dewhisker.
[2-7] Left dewhisker. The left dewhisker is defined analogously to the right dewhisker and is drawn as

\[ \text{Diagram} \]

[2-7].

[2-8] Switch. The switch isomorphism is a composite of two isomorphisms

\[ \text{Diagram} \]

[2-8].

Each of those two isomorphisms is referred to as a half-switch. Arguing as in the construction of the right dewhisker it suffices to construct these isomorphisms in the cases where all sectors are vacuum sectors. In this case the first half switch is defined as

\[ \text{Diagram} \].

Here the first and third isomorphisms are both the $1 \boxtimes 1$-isomorphism and the second is $[2-1]$ (which agrees in this case with [2-2]). The second half-switch is defined analogously.

2.c. Transformations for horizontal associators.

[2-9], [2-10], and [2-11] Whisker associators. The associators for twice whiskered sectors are given, using the $1 \boxtimes 1$-isomorphism and the associativity of Connes fusion, as

\[ \text{Diagram} \]

[2-9],

\[ \text{Diagram} \]

[2-10],

\[ \text{Diagram} \]

[2-11].

As in the case of the vertical associator [2-3] we will also here often suppress the associator for Connes fusion. In particular, we will suppress [2-11].

[2-12] Horizontal associator. The associator for the composition of defects is induced from the associator for fusion (or fiber product) of von Neumann algebras and is discussed in [1 Eq 1.55]. Here we will suppress this isomorphism.

In [1 Prop 4.32] we proved that the $1 \boxtimes 1$-isomorphism is associative in the following sense.

**Lemma L.** The $1 \boxtimes 1$-isomorphism is associative for the composition of defects, that is the following diagram commutes:

\[ \text{Diagram} \].
We point out that in the upper left corner of the diagram in this lemma, we have suppressed the morphism of sectors associated to the associator of horizontal fusion. Similarly, in the lower right corner of the diagram we have suppressed the morphism of sectors associated to the associator for fusion of defects.

2.d. **Transformations for horizontal identities.** The 2-data discussed so far is part of the definition of both a 2-category object and a dicategory object (in the 2-category of symmetric monoidal categories). We remind the reader that our 3-category of conformal nets is a dicategory object; the remaining pieces of data [2-13] to [2-18] are labeled [D2-13] to [D2-18] in [3].

*Left and right quasi-identity.* Let \( \mathcal{A}D_B \) and \( \mathcal{A}E_B \) be defects and let \( DH_E \) be a sector. There is no canonical isomorphism \( H_0(id_A) \boxtimes_A H \cong H \) in \( CN_2 \). In fact, \( H_0(id_A) \boxtimes_A H \) is an \( (id_A \otimes_A D)-(id_A \otimes_A E) \)-sector and not a \( D-E \)-sector. There is however such an isomorphism if we are willing to twist \( H \) on top and bottom by the diffeomorphism \( \Phi_L \) introduced in the construction of the left identity [1-7]. The left quasi-identity has been constructed in [1 Def 6.20] (where it was called the “left unitor” \( \hat{\Upsilon}_l \)), and will be draw as

![Left quasi-identity diagram]

Here the ballons on the right box signal that the \( D-E \)-sector structure on \( H \) has been twisted to an \( (id_A \otimes_A D)-(id_A \otimes_A E) \)-sector structure using \( \mathcal{A}(\Phi_L) \) at the indicated portions of the picture. Of course we can move one or two of the ballons to the left box by composing with the appropriate inverse diffeomorphism. For example we obtain from the left quasi-identity an isomorphism of \( (id_A \otimes_A D)-E \)-sectors drawn as

![Twisted sector diagram]

Similarly, there is a right quasi-identity using \( \Phi_R \) drawn as

![Right quasi-identity diagram]

The next two lemmas are proved respectively in [1 Eq 6.23] and in [1 Lem 6.21].

**Lemma M.** The following diagram commutes:

![Commutative diagram]
Lemma X. The $1 \boxtimes 1$-isomorphism is, in the following sense, natural with respect to the left quasi-identity—this diagram commutes:

Similarly, there are “right versions” of Lemma M and Lemma X for the right quasi-identity.

[2-13] Left identity pass. The pass through a left identity is defined as the following composite

For the first map observe that we can move the diffeomorphism from the lower defect to the horizontal composition of the two upper defects. The first map is then obtained by the bottom identity [2-2]. The second map is obtained from the left quasi-identity by applying the inverse of $\Phi_L$ on the lower half—this moves the lower bubble from the right hand picture to the left hand picture. The third map is the top identity [2-1].

[2-14] Right identity pass. The pass through a right identity is a reflection along a vertical axis of the pass through a left identity, and is defined similarly:

[2-15] Swap. The swap is an isomorphism

The construction of the swap depends on the flip and will be given after the construction of the flip below.

[2-16] Left identity expansion. The left identity expansion is obtained from the $1 \boxtimes 1$-isomorphism and is drawn as
Right identity expansion. The right identity expansion is a reflection along a vertical axis of the left identity expansion, and is defined similarly:

\[ \text{[2-17]} \]

Flip. The flip is an isomorphism

\[ \text{[2-18]} \]

and is defined as follows. Note that both the left and right hand side of the flip are obtained from the horizontal composition of two identity sectors

by two different diffeomorphism \( \phi_L, \phi_R \) from an interval of length 2 to an interval of length 1—the intervals under consideration are those between the non-identity defect points. Note that \( \phi_L \) and \( \phi_R \) coincide on a neighborhood of the boundary of this interval. In order to define the flip we need to implement the diffeomorphism \( \phi := \phi_R \circ (\phi_L)^{-1} \); this is possible, because \( \phi \) acts as the identity in a neighborhood of the boundary of the interval. However, there is no canonical implementation. In order to choose these implementations consistently we proceed as follows. The group \( \text{Diff}_0([0, 1]) \), of diffeomorphisms that are the identity on a neighborhood of the boundary, is perfect by \([5]\). Thus it admits a universal central extension \( \pi : \tilde{\text{Diff}}_0([0, 1]) \to \text{Diff}_0([0, 1]) \). For any net \( \mathcal{A} \) we can implement any \( \varphi \in \text{Diff}_0([0, 1]) \) by a unitary \( U_\varphi \in U(\mathcal{A}(I)) \); thus \( U_\varphi a U_\varphi^* = \mathcal{A}(\varphi)(a) \) for all \( a \in \mathcal{A}([0, 1]) \). Moreover, \( U_\varphi \) is unique modulo the center \( Z(\mathcal{A}([0, 1])) \). This induces a unique homomorphism \( U: \tilde{\text{Diff}}_0([0, 1]) \to \mathcal{A}([0, 1]) \) such that \( U_\varphi a U_\varphi^* = \mathcal{A}(\pi(\varphi))(a) \) for all \( a \in \mathcal{A}([0, 1]) \), and all \( \tilde{\varphi} \in \tilde{\text{Diff}}_0([0, 1]) \). The uniqueness of this map implies that it is compatible with tensor products of nets. Now we choose \( \tilde{\varphi} \) such that \( \pi(\tilde{\varphi}) = \phi \). (The structure of our 3-category depends on this choice.) The flip is the map induced by the action of \( U_{\tilde{\varphi}} \).

We note that \( U_{\tilde{\varphi}} \) also provides an isomorphism

for general sectors. This generalization of the flip will be helpful in Lemma Z below.

Construction of the swap [2-15]. The domain and target of the swap isomorphism are obtained by twisting the vacuum sector of the same identity defect with different diffeomorphisms. Using implementation of diffeomorphisms for the net in question we can implement the difference between these diffeomorphism (as in the construction of the flip [2-18]) and see that domain and target of the swap are indeed isomorphic. However, there is a priori no preferred implementation and therefore no canonical choice for the swap. Because every net can be canonically written as a direct sum of irreducible nets, it suffices to determine the swap for irreducible nets. In this case there is up to phase a unique implementation.
Therefore it remains to determine the phase of the swap in this case. Consider the diagram

Here the lower horizontal map is obtained by twisting the quasi-identity

while the left vertical map is obtained by applying the quasi-identity to the left identity

(In particular, for the lower horizontal map in the above square diagram, the inner diffeomorphism of the two upper diffeomorphisms in the lower left hand item is added by the quasi-identity; by contrast, for the left vertical map the outer of those two diffeomorphisms is added by the quasi-identity.) The phase of the swap is now fixed by requiring the above diagram to commute.

The defining diagram for the swap generalizes as follows.

**Lemma Z.** The following diagram commutes

Later we will only need Lemma Z for vacuum sectors, but the proof of the more general statement is a bit cleaner.

**Proof.** We denote the non-vacuum sector in the diagram by \( D H_E \). Here \( \Delta D_B \) and \( \Delta E_B \) are defects. If \( D = \text{id}_A \) and \( H = H_0(\text{id}_A) \), then the diagram commutes by the construction of the swap. This also implies that the diagram commutes if \( H = H_0(\text{id}_A) \otimes \ell \) for any Hilbert space \( \ell \). For \( \varepsilon > 0 \) we now use the subinterval \( I_\varepsilon = [-1.5 + \varepsilon, 1.5 - \varepsilon] \) of the circle \( S^1 \) bounding the non-vacuum sector. There exists an \( \mathcal{A}(I_\varepsilon) \)-linear isometry \( U_\varepsilon : H_0(\text{id}_A) \otimes \ell \rightarrow H \otimes \ell \). If \( \varepsilon \) is sufficiently small, then \( U_\varepsilon \) will commute with all four sides of the above diagram. Thus the square also commutes for \( H \otimes \ell \) and thus for \( H \) itself. \( \square \)

3. **Coherence axioms for compatibility transformations**

3.a. **Axioms for vertical identity and composition.**

**Proposition.** Axiom [3-1] is satisfied.
Proof. Axiom [3-1] asserts that top and bottom identity agree in the case where both sectors are vacuum sectors. This holds because the corresponding statement is already true for Connes fusion.

\[ \square \]

**Proposition.** Axioms [3-2] and [3-3] are satisfied.

*Proof.* Axioms [3-2] and [3-3] assert that top and bottom identity are compatible with the vertical associator. This holds because the corresponding statement is already true for Connes fusion.

\[ \square \]

**Proposition.** Axiom [3-4] is satisfied.

*Proof.* Axiom [3-4] asserts that the vertical associator satisfies the pentagon identity. This holds because the associator for Connes fusion satisfies the pentagon identity.

\[ \square \]

**Remark.** It is possible to base the definition of sectors on a square rather than a hexagon and to define vertical fusion using just a side of this square (rather than half of the hexagon). Then our pictures would become a little simpler, but vertical composition would require a diffeomorphism and the associator would then involve this diffeomorphism. Axioms [3-1] through [3-4] would be more cumbersome to prove in such a set-up.

3.b. Axioms for horizontal composition and whiskers.

**Proposition.** Axiom [3-5] is satisfied.

*Proof.* The argument is summarized by the following diagram.

```
\begin{center}
\begin{tikzpicture}
\node (D) at (0,0) {$D$};
\node (N) at (0,-2) {$N$};
\node (C) at (-2,-2) {$C$};
\node (identity) at (0,2) {identity};
\node (expand) at (-2,2) {expand};
\node (identity2) at (2,2) {identity};
\node (identity3) at (2,-2) {identity};
\draw (D) edge (identity)
      (N) edge (identity)
      (C) edge (identity)
      (identity) edge (identity2)
      (identity) edge (identity3)
      (D) edge (N)
      (D) edge (C)
      (N) edge (C);
\end{tikzpicture}
\end{center}
```

Each of the four corners of the diagram denotes a functor $\mathbf{CN}_2 \times \mathbf{CN}_0 \to \mathbf{CN}_1$. Each of the four lines on the boundary of the diagram denotes a natural isomorphism determined by its label. These four natural isomorphisms (simply referred to as *maps* for brevity) are explained in more detail as follows:

- The map labeled “whisker” is the “right dewhisker” [2-6].
- The horizontal map labeled “identity” is obtained by applying the top identity [2-1] to the left half of the item in the top left corner of the diagram.
- The right vertical map labeled “identity” is obtained by applying the top identity [2-1].
The horizontal map labeled “expand” is obtained by applying the left (or equivalently right) vertical identity expansion [2-4] to the top half of the item in the lower left corner of the diagram.

Axiom [3-5] asserts that the boundary of this diagram commutes, that is, if we start at some corner of the diagram and compose the four maps along the boundary of the diagram then we should obtain the identity natural transformation on the functor corresponding to the corner where we started. (We remark that in 3, the axiom is rotated by \(-\pi/2\) from the version depicted above.) Now observe that each corner of the diagram can also be viewed as determining a functor \(\mathbb{C}N_{\sim2} \times \mathbb{C}N_{\sim0} \to \mathbb{C}N_{\sim2}\). And similarly each map on the boundary describes a natural isomorphism between these functors. Moreover, the question whether the diagram commutes or not is invariant under this change from \(\mathbb{C}N_{\sim2}\) to \(\mathbb{C}N_{\sim2}\). But the \(\mathbb{C}N_{\sim2}\)-version has the advantage that because of Proposition 3, it suffices to check the commutativity of the diagram in the case when the darker shaded sector is an identity sector, not an arbitrary sector. Therefore we can and will assume that this sector is also an identity sector. Under this assumption, the internal maps and nodes of the diagram make sense. Axiom [3-5] will follow, once we have shown that the three cells in the interior commute.

The cell labeled “D”. The composition of the maps not labeled “whisker” around this cell is the definition of the map labeled “whisker”. Thus this cell commutes by definition. This is the reason for the label “D”.

The cell labeled “N”. The map that is counterclockwise after the map labeled “identity” is the left (or equivalently right) vertical identity expansion [2-4]. The map clockwise after the map labeled “identity” is the vertical fusion of the identity (on the top) and the left vertical identity expansion (on the bottom). The remaining map is a top identity (as is the map labeled identity). Thus this cell commutes by the naturality of the top identity map. This is the reason for the label “N”.

The cell labeled “C”. Consider the item in the lower left corner of the diagram. Here we can apply the left (or right) vertical identity expansion [2-4] to both the bottom and top half of this item. These applications do not interact with each other and can be done in any order or simultaneously. All three maps on the boundary of this cells are obtained from these commuting operations. The cell therefore commutes. We recorded this in the diagram by the label “C”, for commuting operations. □

Formally the proofs of the remaining axioms will be very similar to the proof of axiom [3-5]. We will however not repeat the arguments in every case in detail. In particular, we will trust the reader to determine the correct maps from our pictures. Moreover, the trick that allows us to assume that some sector is not an arbitrary sector but an identity sector (by replacing \(\mathbb{C}N_{\sim2}\) temporarily with \(\mathbb{C}N_{\sim2} \) or \(\mathbb{C}N_{\sim2}\)) will be used very often in the remainder of this paper. We will always refer to this as the corner trick and indicate the sector to which it is applied by a darker shading.

**Proposition.** Axiom [3-6] is satisfied.
Proof. This axiom asserts that the following diagram commutes

The diagonal maps are the two half-switches from the definition of the switch isomorphism [2-8]. Thus the cell labeled “D” commutes by definition. There is a mirror symmetry between the two remaining cells. Thus it suffices to prove that [3-6a] commutes: this is the content of the next lemma. □

Lemma. The diagram [3-6a] commutes.

Proof. The argument is similar to the proof of Axiom [3-5] and is summarized as

Proposition. Axiom [3-7] is satisfied.
Proof. The argument is summarized as

The boundary of this diagram is a square, not a hexagon as in [3], because we suppress the vertical associativity isomorphisms. To help the reader to decode the precise meaning of the items of this diagram we give a more detailed picture of the left top corner where the bullets are added (even though these can be reconstructed from the form of the picture).

Each cell of the diagram commutes for the reason indicated in the diagram. □

Proposition. Axiom [3-8] is satisfied.
**Proof.** Consider the diagram

Here, the left isomorphism labeled ∗ is defined using the corner trick (as in the construction of the right dewisker [2-6]) to be the following composite:

The second isomorphism labeled ∗ is defined similarly. There is a horizontal symmetry between the cells labeled [3-8a] and [3-8c]. Thus it suffices to prove that [3-8a] and [3-8b] commute. This is the content of the next two lemmas. □
**Lemma.** The diagram [3-8a] commutes.

*Proof.* Applying the corner trick twice, the cell [3-8a] can be filled as follows:
**Lemma.** The diagram [3-8b] commutes.

*Proof. Using the corner trick twice, we fill the cell [3-8b] as follows:

![Diagram](image)

**3.c. Axioms for horizontal associators.**

**Proposition.** Axioms [3-9] and [3-10] are satisfied.

*Proof. Both are a consequence of the associativity of the 1⊗1-isomorphism, in the form of Lemma L.*
**Proposition.** Axiom [3-11] is satisfied.

*Proof.* Using the corner trick this axiom is proved by this diagram:

![Diagram](image)

The cells labeled “L” commute by Lemma L. □

**Proposition.** Axiom [3-12] is satisfied.

*Proof.* The formulation of axiom [3-12] simplifies from a hexagon to a square because we suppress the whisker associator [2-11]. Using the corner trick we can fill in this square as
Proposition. Axiom [3-13] is satisfied.

Proof. The axiom follows from the commutativity of the following diagram:
There is a horizontal symmetry between the cells labeled [3-13a] and [3-13b]. Thus it remains to prove that [3-13a] commutes. This is the content of the next lemma.

**Lemma.** The diagram [3-13a] commutes.

*Proof.* Using the corner trick we can fill in the diamond as follows:

```
N L

| 3-5 |

\[\text{whisker} \quad \text{expand} \quad \text{half switch} \quad \text{half switch} \quad \text{expand} \]
```

**Proposition.** Axiom [3-14] is satisfied.

*Proof.* The axiom follows from the commutativity of the diagram

```
\[\text{expand} \quad \text{3-14a} \quad \text{3-14b} \quad \text{expand} \quad \text{D} \quad \text{D} \quad \text{expand} \]
```

There is a horizontal symmetry between the cells [3-14a] and [3-14b]. Thus it suffices to show that [3-14a] commutes. This is the content of the next lemma.
**Lemma.** The diagram [3-14a] commutes.

*Proof.* Using the corner trick twice we can fill in [3-14a] as follows:

![Diagram](image)

**Proposition.** Axiom [3-15] is satisfied.

*Proof.* This axiom follows from the associativity of the 1⊗1-isomorphism (Lemma L):

![Diagram](image)
**Proposition.** Axiom [3-16] is satisfied.

*Proof.* Upon suppression of horizontal associators, three of the nodes of the axiom reduce to the left hand picture below. The remaining two nodes reduce to the right hand picture; both edges between these sets of nodes are the indicated expansion:

![Diagram]

□

**Proposition.** Axiom [3-17] is satisfied.

*Proof.* This axiom asserts that the associator for defects [2-12] satisfies the pentagon identity. This holds because the corresponding statement is already true for fusion (or fiber product) of von Neumann algebras. □

3.d. **Axioms for horizontal identities.** The axioms [3-1] to [3-17] do not involve identity defects. These axioms are part of the definition of both a 2-category object and a dicategory object (in the 2-category of symmetric monoidal categories). The remaining axioms [3-18] to [3-26] are the axioms labeled [D3-18] to [D3-26] in [3].

**Proposition.** Axiom [3-18] is satisfied.

*Proof.* This axiom follows from the commutativity of this diagram:

![Diagram]

The cells labeled “N” and “D” commute by naturality and by definition. The remaining cell commutes for a reason that we have not yet encountered, namely by Lemma M. □
**Proposition.** Axiom [3-19] is satisfied.

**Proof.** Axiom [3-19] reduces to a square, because we are suppressing the vertical associator [2-3]. We can partially fill the square as follows. For readability and ease of comparison with a subsequent diagram, we use the abbreviated notation for the four corner configurations, and the full bullet and bubble notation for the interior configurations.

For the remaining cell we can use the corner trick and assume that the top left sector is an identity sector. This reduces axiom [3-19] to the case where only one of the sectors is not an identity sector. Using this additional assumption we can fill in Axiom [3-19] as follows.
(using the simpler notation that suppresses the bullets and bubbles for diffeomorphisms):
Proposition. Axiom [3-20] is satisfied.

Proof. We can fill in axiom [3-20] partially as follows:

Here we used the more precise notation using bullets and bubbles. The above diagram shows that axiom [3-20] is equivalent to the commutativity of the remaining hexagon. By the corner trick this hexagon commutes if and only if it commutes for the identity sector, and the hexagon with identity sector commutes if and only if axiom [3-20] commutes for the identity sector. Thus it suffices to establishes axiom [3-20] for the identity sector. This
follows from the following diagram (where we drop bullets and bubbles from the notation).
**Proposition.** Axiom [3-21] is satisfied.

*Proof.* We can partially fill Axiom [3-21] as follows.

Thus it remains to prove the commutativity of the cell [3-21a]. This is the content of the next Lemma. □

**Lemma.** Diagram [3-21a] commutes.

*Proof.* Using the corner trick, we can fill in [3-21a] as follows
Here we use Lemma X for the first time. It ensures that the cell labeled “X” commutes. The hexagon labeled N at the bottom of the diagram commutes by naturality of the bottom identity with respect to two applications of $1 \boxtimes 1$-isomorphisms. On one of the sides of this pentagon these two applications of the $1 \boxtimes 1$-isomorphism are denoted by just one map. □

**Proposition.** Axiom [3-22] is satisfied.

**Proof.** This follows from this diagram:

![Diagram](image)

Almost all of the axioms of a dicategory object assert that a diagram and a number of variants of the diagram commute. So far we have ignored the variants—their commutativity can always be established by a straightforward variation of the argument for the original diagram. The only exception to this is axiom [3-23]. Here our definition of the swap [2-15] was designed to ensure that [3-23L], the left hand version of [3-23], holds. For the right hand version [3-23R] we will have to use a different argument.
Proposition. Axiom [3-23L] is satisfied.

Proof. Axiom [3-23L] can be filled as follows:

![Diagram showing the filling of Axiom [3-23L]]

The inner square commutes by Lemma Z.

Proposition. Axiom [3-23R] is satisfied.

Proof. Consider again the diagram from the proof of [3-23L]. This diagram reduced [3-23L] to Lemma Z. The proof of Lemma Z in turn reduced to the case where all defects are identity defects. The same argument can be applied to [3-23R] to reduce to the case of identity defects: we therefore only need to prove [3-23R] in the case where all the defects are identity defects. In this case the following diagram reduces [3-23R] to [3-23L] (which is
already proved) and [3-24] (which we prove next):
Proposition. Axiom [3-24] is satisfied.

Proof. Axiom [3-24] can be filled as follows:

Proposition. Axiom [3-25] is satisfied.

Proof. This follows from the associativity of $1 \boxtimes 1$:
Proposition. Axiom [3-26] is satisfied.

Proof. This follows from the naturality of the flip, applied to the expand isomorphism:

\[
\begin{array}{c}
\text{flip} \\
\text{flip}
\end{array}
\quad
\begin{array}{c}
\text{expand} \\
\text{expand}
\end{array}
\quad
\frac{1}{N}
\]
