Extended Iterative Scheme for QCD: the Four-Gluon Vertex

L. Driesen and M. Stingl

Abstract: We study the self-consistency problem of the generalized Feynman rule (nonperturbatively modified vertex of zeroth perturbative order) for the 4-gluon vertex function in the framework of an extended perturbation scheme accounting for non-analytic coupling dependence through the $\Lambda$ scale. Tensorial structure is restricted to a minimal dynamically closed basis set. The self-consistency conditions are obtained at one loop, in Landau gauge, and at the lowest approximation level ($r = 1$) of interest for QCD. At this level, they are found to be linear in the nonperturbative 4-gluon coefficients, but strongly overdetermined due to the lack of manifest Bose symmetry in the relevant Dyson-Schwinger equation. The observed near decoupling from the 2-and-3-point conditions permits least-squares quasisolutions for given 2-and-3-point input within an effective one-parameter freedom. We present such solutions for $N_F = 2$ massless quarks and for the pure gluon theory, adapted to the 2-and-3-point coefficients determined previously.
1 The generalized Feynman rule $\Gamma^{[r,0]}_{4V}$

The present paper continues, and brings to a provisional stage of completion, the determination of generalized Feynman rules in an extended perturbation scheme for QCD \[1\], designed to account for the strongly nonanalytic coupling dependence of correlation functions through the renormalization-group invariant mass scale $\Lambda$. The generalized rules, denoted $\Gamma^{[r,0]}$, are proper vertex functions of zeroth perturbative order (no power corrections in the coupling $g^2$, as indicated by the index 0), but with a nonperturbative $\Lambda$ dependence which in turn is approximated systematically at a level characterized by the index $r$. In contrast to the ordinary Feynman rules, it is a nontrivial self-consistency problem for these extended rules to reproduce themselves in the integral equations for vertex functions. However, the divergence-related mechanism operative in the self-reproduction \[1\] does ensure that formation of $\Gamma^{[r,0]}$'s remains rigorously restricted to the small number of vertices corresponding to the ordinary Feynman rules – the superficially divergent vertices. In the companion paper \[2\], this self-consistency problem was set up and solved for the vertices with up to three external legs, on the lowest nontrivial approximation level ($r = 1$, and one loop) of interest for QCD.

Below, we complement this study by examining the highest superficially divergent amplitude, the 4-vector (4-gluon) vertex $\Gamma_{4V}$. There are several features that set this vertex function apart and motivate its separate treatment. One is its sheer kinematical complication, due partly to the large number of 6 Lorentz-scalar momentum variables, but mostly to the exorbitantly lengthy tensor decompositions implied by its 4 color and 4 Lorentz indices. In constructing the $r = 1$ approximant $\Gamma^{[r,0]}_{4V}$ (section 2), one is thereby forced to adopt a theoretically motivated simplification of the full tensor structure. Another special feature is that $\Gamma_{4V}$ represents the lowest QCD amplitude which in the nonperturbative context exhibits the phenomenon of compensating poles (or, in the terminology of \[3\], of negative shadow poles), first noted in Abelian models in \[4\]. While these poles can be inferred uniquely already from the “lower” DS equations for $\Gamma_{3V}$ and $\Gamma_{2V}$ by suitable residue-taking operations, it is now necessary to demonstrate that on the level of the 4-point equation they are in turn self-consistent (section 3). A natural by-product of this demonstration is then a “reduced” integral equation for the remainder vertex $V_{4V}$ defined by

$$\Gamma^{[r,0]}_{4V} = -(C_{1}^{[r]}_{1})_{2V,2V} - (C_{2}^{[r]}_{2})_{2V,2V} - (C_{3}^{[r]}_{3})_{2V,2V} + V_{4V}^{[r,0]},$$  \(1.1\)

where $C_{1,2,3}^{[r]}$ are the shadow-pole terms in the 3 channels of the 4-gluon amplitude. This amounts to rearranging the full connected-and-amputated 4-gluon correlation function as

$$T_{4V} = A_1' + A_2' + A_3' + V_{4V},$$  \(1.2\)

where $A_1', A_2', A_3'$ are “softened”, i.e. one-shadow-irreducible, one-gluon exchange diagrams formed by subtracting the shadow-pole term from the ordinary dressed-one-gluon-exchange diagram $A_{1,2,3}$ in each of the 3 channels. The object $V_{4V}^{[r,0]}$ depends on only four Lorentz-scalar variables, and establishing the self-consistency conditions for its nonperturbative coefficients (section 4) is simpler than for the full $\Gamma_{4V}$.

The latter conditions will exhibit a problem that presumably besets all approximate treatments of vertex equations with three or more external lines: if such vertices possess a symmetry among their
external legs such as Bose symmetry, their Dyson-Schwinger (DS) equations will in general not display this symmetry manifestly, and any approximation to them will produce unsymmetric terms. Forcing self-reproduction of a symmetric input by requiring these terms to vanish leads to overdetermination of the dynamical conditions. If this does not happen to be counteracted by underdetermination tendencies, as was the case for the $r = 1$ three-point conditions derived in [2], one must settle for a “compromise” solution in the sense of least-squares error minimization (section 5).– Technically, the self-consistency conditions will be derived at the $r = 1$ and one-loop ($l = 1$) levels, and in Landau gauge. The latter again provides considerable simplification because the two ghost vertices at $l = 1$ remain perturbative, and because in this gauge a closed DS system can be written for the amplitudes with only transverse (if any) gluon legs, whose tensorial complexity is significantly lower. A disadvantage, of course, is that the self-consistency (or lack of it) for statements concerning longitudinal-gluon amplitudes, such as Slavnov-Taylor identities, cannot be checked directly from such a system.

The 4-gluon vertex also occupies a special position in that it belongs both to the class of superficially divergent “basic” vertices having their own (ordinary or extended) Feynman rules, and to the class of amplitudes capable of developing bound-state (here, glueball) poles – a phenomenon otherwise restricted to the superficially convergent higher vertices. In the present paper we are exclusively concerned with the generalized Feynman rule, a zeroth-order quantity, which like its ordinary counterpart contains no information as yet about bound states. The latter, if present, arise from an infinite partial resummation of the higher-order, quasi-perturbative corrections

$$[g(\nu)^2]^p \cdot \Gamma_4^{[r,p]}(\{k\}, \Lambda, \nu) \quad (p = 1, 2, 3, \ldots). \quad (1.3)$$

As the notation recalls, these have their own nonperturbative $\Lambda$ dependences, which may be complemented by an inversely logarithmic “perturbative” dependence when reparametrizing the quasi-perturbative series in terms of $\alpha_s(k^2)$ rather than $g^2(\nu)$. Upon ladder or similar resummation, these may build up a pole in some Mandelstam variable (the squared sum of some subset of the momenta $\{k\}$) at some multiple of $\Lambda^2$ representing the square of a bound-state mass. Such a pole is accompanied by a pair of residue functions, each representing an infinite power series in $g^2$ starting at least with $p = 1$. It is therefore an example of nonperturbative $\Lambda$ dependence embedded in an otherwise quasi-perturbative term (starting at least at order $p = 2$) of the amplitude. These characteristics should prevent confusion between bound-state poles and the poles which in the present scheme arise as rational approximations to branch cuts in the squares of single-external-line momenta, and in zeroth quasi-perturbative order. The 4-gluon function is unique in exhibiting both phenomena. It is yet another matter (and not touched upon in this article) that in a confining theory the calculation of $S$-matrix elements will require a still larger set of generalized Feynman rules, comprising hadron-to-quarks and hadron-to-gluons bound-state vertices for the outer corners of $S$-matrix diagrams – vertices of an intrinsically hybrid nature, since their dependence on the squares of single-quark momenta would have to be determined and approximated consistently with the generalized Feynman rules for the internal lines and vertices, whereas their dependence on the total virtuality of the bound state is governed by “resummed-perturbative” bound-state dynamics.
2 Structure of the $r = 1$ approximant

Due to the large number of possible tensor structures of a four-gluon amplitude (e.g., $43$ independent Lorentz tensors for a fully transverse amplitude, each combined with $8$ independent color tensors for $SU(3)_C$), one is forced, at the present stage, to adopt some theoretically motivated restriction to a smaller subset of tensors. We briefly describe such a restricted form, partly repeating material from appendix A of [1] to keep the discussion self-contained. The amplitude

\[
\left( V_{\mu_4}^{r \lambda}(p_1, p_2, p_3, p_4) \right)_{\kappa \lambda \mu \nu}^{abcd} \quad (p_1 + p_2 + p_3 + p_4 = 0) \quad (2.1)
\]

is expanded over an $18$-member set of color $\otimes$ Lorentz tensors, of which $15$ are linearly independent. They are formed from building blocks

\[
C_{abcd}^{(i)} L_{(j)}^{\kappa \lambda \mu \nu} \quad (i = 1 \ldots 6, j = 1 \ldots 3), \quad (2.2)
\]

where the color tensors $C^{(i)}$, fourth-rank objects over the adjoint representation of $SU(3)_C$, are given by

\[
\begin{align*}
C_{abcd}^{(1)} &= \delta_{ab} \delta_{cd}, & C_{abcd}^{(2)} &= \delta_{ac} \delta_{db}, & C_{abcd}^{(3)} &= \delta_{ad} \delta_{bc}, \\
C_{abcd}^{(4)} &= f_{abc} f_{dcd}, & C_{abcd}^{(5)} &= f_{acn} f_{dbn}, & C_{abcd}^{(6)} &= f_{adn} f_{bcn},
\end{align*} \quad (2.3)
\]

in terms of the $SU(3)$ structure constants $f_{abc}$. Only five of these are linearly independent, since $C^{(4)} + C^{(5)} + C^{(6)} = 0$ by the Jacobi identity. As compared to the most general structure, this set omits three tensors containing a symmetric $SU(3)$ structure constant $d_{abc}$. The Lorentz-tensor building blocks $L_{(j)}$ are the three dimensionless ones,

\[
L_{(1)}^{\kappa \lambda \mu \nu} = \delta^{\kappa \lambda} \delta^{\mu \nu}, \quad L_{(2)}^{\kappa \lambda \mu \nu} = \delta^{\kappa \mu} \delta^{\nu \lambda}, \quad L_{(3)}^{\kappa \lambda \mu \nu} = \delta^{\kappa \nu} \delta^{\lambda \mu}, \quad (2.5)
\]

which are linearly independent. In obvious ways, all these fall into crossing triplets, where second and third members in each triplet arise from the first member by the crossing operations,

\[
\begin{align*}
\text{“} s \rightarrow u \text{”} : \quad (2, 3, 4) & \rightarrow (3, 4, 2), \\
\text{“} s \rightarrow t \text{”} : \quad (2, 3, 4) & \rightarrow (4, 2, 3),
\end{align*} \quad (2.6, 2.7)
\]

the $s$ channel being by convention the $(1 + 2) \leftrightarrow (3 + 4)$ channel. Here $2$ stands for the set $(p_2, \lambda, b)$, etc.

The set (2.2, 2.3) is distinguished in that it constitutes the smallest dynamically closed subset of the full tensor structure, i.e.: (i) It closes under Bethe-Salpeter (BS) iteration in each of the three channels of the amplitude, as exemplified by the $s$-channel, color-space multiplication,

\[
\left( C^{(i)} \cdot C^{(j)} \right)_{abcd} = \sum_{e, f = 1}^{8} C_{abcd}^{(i)} C_{efcd}^{(j)}, \quad (2.8)
\]

and closes also under iteration of DS interaction diagrams, provided the $3$-gluon vertices involved have $f_{abc}$ color structure only. We emphasized earlier [2] that with $4$-gluon color dependence restricted
to the five-dimensional basis $\{2.3/2.4\}$, it would be inconsistent to retain $d_{abc}$ color structure in the 3-gluon vertex, since the tensors omitted on the 4-gluon level would also contribute to that structure via the hierarchical coupling in the 3-gluon DS equation.

(ii) It closes under the crossing operations connecting the three channels, as given by (2.6) and (2.7).

(iii) It contains the perturbative zeroth-order vertex, namely,

$$\Gamma_{4V}^{(0)\text{pert}} = \frac{3}{2} C^{(4)} \left( L_{(2)} - L_{(3)} \right) + \frac{1}{2} \left( C^{(5)} - C^{(6)} \right) \left( -2L_{(1)} + L_{(2)} + L_{(3)} \right). \quad (2.9)$$

(Without this property, there would exist a still smaller dynamically closed set comprising only the tensors (2.3), but maintaining the perturbative limit calls for inclusion of (2.4).) All these statements are easy to verify by direct calculation.

For the choice (2.5) of Lorentz tensors, additional motivation comes from the observation that these are the only ones accompanied by invariant functions of zero mass dimension. The tensors omitted in (2.5) contain two or four powers of momentum, and are thus associated with invariant functions of mass dimensions $-2$ or $-4$. Together with the fact that their zeroth-order forms must have at least one power of $\Lambda^2$ in each term, this severely restricts possibilities for these functions to receive the divergent loop contributions required for self-reproduction, and it appears reasonable then to start with a basis omitting such tensors.

Invariant functions for the $V_{4V}$ amplitude, we recall, have zeroth-order rational structure only with respect to the variables $p_{12}^2 \ldots p_{42}^2$, since the entire zeroth-order rational structure with respect to $s$, $u$, $t$ variables is borne by the compensating-pole terms of eq. (1.1). Since our earlier demonstration of this applies, strictly speaking, only to the color-octet channels, we check in appendix A of this paper that in fact it holds generally. Thus at order $r = 1$, all invariant functions involve the same, fully symmetric denominator

$$\Delta^{[1,0]} = \left( p_{12}^2 + u_2^\prime \Lambda^2 \right) \left( p_{22}^2 + u_2^\prime \Lambda^2 \right) \left( p_{32}^2 + u_2^\prime \Lambda^2 \right) \left( p_{42}^2 + u_2^\prime \Lambda^2 \right). \quad (2.10)$$

Numerator polynomials in $\Lambda^2$ and the squared momenta, of mass dimension 8, must conform to the restrictions of naive asymptotic freedom. As seen in [2] in the example of the 3-gluon vertex, additional restrictions arise from the requirement that “softened” (one-shadow-irreducible) one-gluon exchange diagrams, which represent the physical one-gluon exchange mechanism, again should not generate higher-than-perturbative degrees of divergence when inserted in loops (for an example, see the righthand portion of diagram (A3) in Fig. 10): this excludes terms in the rational approximant in which any one squared momentum has a net positive power. Thus numerator polynomials should not contain $s$, $t$, $u$ either, nor should they have terms of type $\Lambda^2 p_i^6$ or $\Lambda^4 p_i^8$ still allowed by the primary restrictions. At level $r = 1$, all zeroth-order rational structure can then be expressed in terms of the single-pole quantities

$$\Pi_i = \frac{\Lambda^2}{p_i^2 + u_2^\prime \Lambda^2} \quad (i = 1, 2, 3, 4), \quad (2.11)$$

and the general $r = 1$ approximant, with full Bose symmetry among the four legs, turns out to involve seventeen dimensionless, real coefficients, each preceding a product of a tensor of type (2.2) and a combination of one or more quantities (2.11).
In the following we use two different representations for $V_4^{[1,0]}$. The first has building blocks with manifest Bose symmetry but involving linearly dependent color tensors internally; it uses and for our purpose defines the 17 independent coefficients. It is thus suitable for the presentation of the vertex as a generalized Feynman rule. This representation uses a color tensor

$$C_{abcd}^{(S)} = \text{tr} (t_at_b t_ct_d) + \text{tr} (t_at_ct_d)$$  \hspace{1cm} (2.12)$$

and its crossing partners $C^{(U)}, C^{(T)}$ obtained via (2.6) and (2.7), where $t_n$ are the generator matrices of $SU(3)_C$ normalized by $\text{tr}(t_m t_n) = \frac{1}{2} \delta_{mn}$. The latter trace is then used to supply another tensor triplet, proportional to (2.4),

$$\text{tr}(t_at_b) \text{tr}(t_ct_d) = \frac{1}{4} C_{abcd}^{(1)}$$  \hspace{1cm} (2.13)$$

plus crossing partners. $SU(3)$ representation algebra [3] gives the relation of (2.12) to (2.3) as

$$C^{(S)} = \frac{1}{12} \left[ C^{(1)} + C^{(2)} + C^{(3)} \right] + \frac{1}{6} \left[ C^{(5)} - C^{(6)} \right],$$  \hspace{1cm} (2.14)$$

with analogous relations for $C^{(U)}, C^{(T)}$. In this basis, which has been used e.g. in work on the operator-product expansion [3], the vertex with four transverse gluon legs is written

$$\left[ V_4^{[1,0]}(p_1 \ldots p_4) \right]_{\sigma\tau\omega}^{\rho\kappa\lambda} = t^{\rho\kappa}(p_1) t^{\sigma\lambda}(p_2) t^{\tau\mu}(p_3) t^{\omega\nu}(p_4)$$

$$\times \left\{ \left( \mathcal{G}_4^{(0)\text{pert}} \right)_{\kappa\lambda\mu \nu}^{\rho\sigma} + \sum_{n=1}^{17} \zeta_n \left( W_n^{[1,0]}(p_1^2 \ldots p_4^2; \Lambda^2) \right)_{\kappa\lambda\mu \nu}^{\rho\sigma} \right\},$$  \hspace{1cm} (2.15)$$

the $t$’s now denoting transverse projectors in the external momenta. Each of the building blocks $W_n$ comprises a color tensor (2.12) or (2.13) plus crossing partners, a combination of Lorentz tensors (2.7), and a combination of rational-function elements (2.11). Each therefore has at least one overall power of $\Lambda^2$ and vanishes in the perturbative limit, $\Lambda \to 0$. A full listing of these building blocks is relegated to appendix B.1; here we write out just one of them for illustration:

$$W_3^{[1,0]}(p_1^2 \ldots p_4^2; \Lambda^2) =$$

$$C^{(S)} \left( L_{(3)} - 2L_{(1)} + L_{(2)} \right) \left[ \Pi_1 \Pi_4 + \Pi_2 \Pi_3 - \Pi_3 \Pi_4 \right] + \left[ \Pi_1 \Pi_2 + \Pi_3 \Pi_4 \right]$$

$$+ C^{(U)} \left( L_{(1)} - 2L_{(2)} + L_{(3)} \right) \left[ \Pi_1 \Pi_2 + \Pi_3 \Pi_4 - \Pi_3 \Pi_4 \right] + \left[ \Pi_1 \Pi_2 + \Pi_3 \Pi_4 \right]$$

$$+ C^{(T)} \left( L_{(2)} - 2L_{(3)} + L_{(1)} \right) \left[ \Pi_1 \Pi_3 + \Pi_4 \Pi_2 - \Pi_3 \Pi_4 \right] + \left[ \Pi_1 \Pi_2 + \Pi_3 \Pi_4 \right]$$  \hspace{1cm} (2.16)$$

Note that these 17 building blocks are linearly independent of each other; the linear dependence of the basis tensors $C^{(SU,T)}$ affects only their internal structure, which upon rewriting in terms of independent tensors would lose its manifest crossing (and therefore Bose) symmetry. However, as a representation of the total $V_4$, (2.15) is based on dependent color tensors.

The second representation is more suitable for the self-consistency calculation of the zeroth-order vertex. To permit tensor-by-tensor comparison of the two sides of a DS equation, such a representation must employ linearly independent color tensors, and consequently forgo manifest Bose symmetry. However, since the way a $4V$ vertex appears in a DS interaction diagram singles out one of the three
channels (compare, e.g., the $4V$ vertex in diagrams (A3)$_A$ or (C2)$_A$ of Fig.10), it is useful to maintain partial symmetry properties within one channel. A basis of this kind, adapted to the $s$ channel, has color tensors

$$
C^{(A)} = C^{(1)}, \quad C^{(B)} = C^{(2)} + C^{(3)}, \quad C^{(C)} = C^{(2)} - C^{(3)}, \quad C^{(D)} = C^{(4)} \left( = -C^{(5)} - C^{(6)} \right),
$$

and Lorentz tensors (in $D = 4 - 2\epsilon$ Euclidean dimensions),

$$
L_{(0)} = \frac{1}{D} L_{(1)}, \quad L_{(+)} = \frac{1}{2} \left( L_{(2)} + L_{(3)} \right) - \frac{1}{D} L_{(1)},
$$

$$
L_{(-)} = \frac{1}{2} \left( L_{(2)} - L_{(3)} \right).
$$

The latter have been chosen to display, under $s$-channel tensor multiplication, the projector-like properties,

$$
L_{(m)}^{\kappa\lambda\rho\sigma} L_{(n)}^{\rho\sigma\mu\nu} = \delta_{mn} L_{(m)}^{\kappa\lambda\mu\nu} \quad (m, n = +, 0, -).
$$

If we denote by the symbol

$$
\{ \pi_{12}, \pi_{34}, \pi_{s} \} \quad \text{(each } \pi = +1 \text{ or } -1 \text{)}
$$

the class of four-point amplitudes having parities $\pi_{12}, \pi_{34}, \pi_{s}$ under the $1 \leftrightarrow 2$, $3 \leftrightarrow 4$, and $(1, 2) \leftrightarrow (3, 4)$ permutations respectively, then of the fifteen product tensors $C^{(i)} L_{(j)}$ formed from (2.17/2.18) and (2.19/2.20) there are eight in class $\{+, +; +\}$ and seven in class $\{-, -, +\}$. In the decomposition

$$
\left( V_{4T}^{[1,0]} (p_1 \ldots p_4) \right)^{\rho\sigma\tau\omega}_{abcd} = t^{\rho\kappa}(p_1) t^{\sigma\lambda}(p_2) t^{\tau\mu}(p_3) t^{\omega\nu}(p_4)
$$

$$
\times \sum_{i=A \ldots E} \sum_{j=+,-,0,-} C^{(i)}_{abcd} L_{(j)}^{\kappa\lambda\mu\nu} F_{i,j}^{[1,0]} (p_1^2 \ldots p_4^2; \Lambda^2),
$$

the invariant functions $F_{i,j}$ therefore come in two types,

$$
F_{i,j}^{[1,0]} \in \{+, +; +\} = \eta_{i,j,0} + \eta_{i,j,1} (\Pi_1 + \Pi_2 + \Pi_3 + \Pi_4) + \eta_{i,j,2} (\Pi_1 + \Pi_2) (\Pi_3 + \Pi_4)
$$

$$
+ \eta_{i,j,3} (\Pi_1 \Pi_2 + \Pi_3 \Pi_4) + \eta_{i,j,4} \left[ \Pi_1 \Pi_2 (\Pi_3 + \Pi_4) + (\Pi_1 + \Pi_2) \Pi_3 \Pi_4 \right]
$$

$$
+ \eta_{i,j,6} (\Pi_1 + \Pi_2) \Pi_3 \Pi_4 ;
$$

(2.24)

$$
F_{i,j}^{[1,0]} \in \{-, -, +\} = \eta_{i,j,3} \left( \Pi_1 - \Pi_2 \right) \left( \Pi_3 - \Pi_4 \right).
$$

(2.25)

The perturbative limit (2.3) fixes the coefficients $\eta_{i,j,0}$ of (2.24) as

$$
\eta_{i,j,0} = 3\delta_{i,D}\delta_{j,-} + \delta_{i,E} \left[ \delta_{j,+} - (D - 1)\delta_{j,0} \right].
$$

(2.26)

This representation then starts with a total of $8 \times 5 + 7 \times 1 = 47$ real, dimensionless coefficients. With no further restrictions on the latter, it would be adequate for quantities having partial Bose symmetry with respect to one distinguished channel, such as a two-particle irreducible kernel. For the full $V_{4V}$ amplitude, imposing complete Bose symmetry produces 30 relations between the $\eta$’s so they can ultimately be expressed linearly in terms of the 17 independent $\zeta$’s of (2.15). The listing of these linear conversion equations is relegated to appendix B.2.
The r.h.s. of a DS equation such as Fig.2 or Fig.10 below, which singles out the leftmost external leg in an unsymmetric way, does not even exhibit the reduced symmetry of (2.24/2.25) (although it does have a permutation symmetry between the three rightmost legs). Upon using (2.24/2.25) as input, the output therefore has still lower symmetry, and enforcing the self-reproduction of a symmetric vertex turns out to imply, in addition to 47 self-consistency conditions proper, 7 more conditions for the vanishing of terms excluded by the partial Bose symmetry, leading, after conversion of \( \eta \)'s to \( \zeta \)'s, to a total of 54 linear conditions on the 17 independent coefficients. Moreover, one finds that unwanted contributions to the eight constants (2.26) arise which represent low-\( r \) approximation errors in the perturbative renormalization constant, a phenomenon already encountered in [2] for the three-point vertices.

Finally note that with respect to any one of the four \( p_i^2 \), the reduced vertex permits a partial-fraction (p.f.) decomposition, such as

\[
V[^{[r,0]}_{4T}] = E[^{[r]}_{0,T}](p_2^2, p_3^2, p_4^2) + \sum_{n=1}^{r} \left( \frac{\Lambda^2}{p_1^2 + 2n\Lambda^2} \right) E[^{[r]}_{n,T}](p_2^2, p_3^2, p_4^2),
\]

where by omitting \( p_1^2 \) dependence in the \( E_0 \) term we have encoded the restriction of no net positive powers of \( p_1^2 \). Such a decomposition is useful technically in connection with the treatment of the compensating poles.

3 Self-consistency of compensating poles

It was demonstrated in [2] that from the lower (i.e., \( \Gamma_3V \) and \( \Gamma_2V \)) equations alone one may already infer the existence, and determine the residues, of certain pole terms in \( \Gamma_{4V} \) with respect to the three Mandelstam variables, and that these turn out (as did similar poles in longitudinal channels in the work of refs. [4]) to be compensating terms cancelling unphysical singularities ("shadow" poles) in the one-gluon reducible terms of \( T_{4V} \). The compensating poles are structures of tree topology which, since their internal shadow lines are not propagators of any of the elementary QCD fields, nevertheless can be present in the 1PI amplitude. This result is recalled in eq. (1.1) and in Fig.1(a), where each double-wiggly line, at level \([r,0]\), stands for a set of \( r \) shadow poles in the corresponding Mandelstam variable.

To understand the nature of these structures more fully, we now need to discuss how they reproduce self-consistently in the DS equation for \( \Gamma_{4V} \) itself. As with all zeroth-order nonperturbative terms, this will essentially occur through the hierarchical DS coupling, which transfers the building materials for the compensating terms down from the higher vertices in the equation. The argument is lengthy, but conveys an idea of how, by analogy, such terms establish themselves in still higher vertex functions. We therefore present it also in lieu of a general N-legs-amplitudes proof, whose length would be out of proportion to the insight gained. (The reader not interested in the details of this self-consistency result, and willing to accept it on faith, may proceed directly to the reduced DS equation for \( V_{4V} \) given diagrammatically in Fig.10, which is the starting point for sect.4.)

(1) The equation for \( \Gamma_{4V} \) is written diagrammatically in Fig.2, in a “hybrid” form in which interaction terms on the r.h.s. have not been resolved down to the level of proper vertices: the \( T' \)
amplitudes appearing there are amputated functions 1PI in the channels defined by their right-hand external legs, but otherwise still contain 1PR terms.

To keep technical complications to a minimum, we invoke all available simplifications: we disregard fermions, i.e. the term \((E)_{4}\) of Fig.2, and consider zeroth-order self-consistency only at one loop, where term \((D)_{4}\) does not yet contribute, and in Landau gauge, so that the ghost term \((B)_{4}\) may also be omitted. We are then dealing, first, with terms \((C)_{4}, (C')_{4}, (C'')_{4}\), involving the four-gluon function itself in the form of three \(T'_{4V}\) amplitudes, each one-gluon irreducible in the channel defined by its two right-hand external legs. The structure of such a \(T'_{4V}\) as following from Fig.1(a) is recalled in Fig.1(b): it has one compensating ( negative shadow ) pole in the distinguished channel, and “softened” ( one-shadow irreducible ) one-gluon exchanges in the two other channels.

\[ T'_{4V} \]

Second, we have term \((A)_{4}\) involving a five-gluon amplitude \(T'_{5V}\), which by definition is one-gluon irreducible in the four \(2V \leftrightarrow 3V\) channels accessible through its three right-hand external legs, namely the “horizontal” channel

\[ (5, 6) \leftrightarrow (2, 3, 4) \quad (i = 1), \]

and the three “tilted” channels

\[ (2, 3) \leftrightarrow (4, 5, 6) \quad (i = 2), \quad (3, 4) \leftrightarrow (5, 6, 2) \quad (i = 3), \quad (4, 2) \leftrightarrow (3, 5, 6) \quad (i = 4). \]

The integers \(i\) assigned refer, by convention, to a numbering \(i = 1 \ldots 10\) of the ten \(2V \leftrightarrow 3V\) channels of a five-point amplitude. Thus \(T'_{5V}\) has those one-gluon reducible terms removed that would produce a one-gluon reducible graph when introduced into term \((A)_{4}\). A representation of \(T'_{5V}\) suitable for our purpose is given diagrammatically in Fig.3; it is again hybrid in that it involves \(T'_{4V}\) amplitudes in addition to fully 1-gluon irreducible functions \(\Gamma_{4V}\) and \(\Gamma_{5V}\). The derivation of this representation is a technical matter that we relegate to appendix C. ( Its apparent asymmetry with respect to the \((5, 6)\) pair of legs is resolved by realizing that there exists an equivalent representation with the roles of \(\Gamma_{4V}\) and \(T'_{4V}\) interchanged ).

Insertion of Fig.3 into the \((A)_{4}\) term of Fig.2 then decomposes that term into a piece \((A)_{4,\Gamma}\) involving the 1-gluon irreducible \(\Gamma_{5V}\), plus six pieces with triangle-graph topology. We do not draw this decomposition separately.

Now take residues in the \(\Gamma_{4V}\) equation of Fig.2 with respect to the squared momentum, \(p_{12}^{2}\), of the leftmost external leg. This is entirely analogous to the residue comparison performed in [4] for the \(\Gamma_{3V}\) equation, and leads to the analogous conclusion: the zeroth-order pole terms in \(p_{12}^{2}\) of the r.h.s. can arise only from the term \((A)_{4,\Gamma}\), and the \(\Gamma_{5V}\) in that term must therefore contain zeroth-order poles \((s_{1} + u_{2n}A^{2})^{-1}\) in the Mandelstam variable of channel \((3.1)\),

\[ s_{1} = (-p_{5} - p_{6})^{2} = (p_{2} + p_{3} + p_{4})^{2}, \]

which equals \(p_{1}^{2}\) by momentum conservation. Note that terms with an inverse polynomial in \(p_{1}^{2}\) produced by the loop integration of term \((A)_{4,\Gamma}\), if any, would by the standard formulas of dimensional integration have to arise from convergent parts of the integral, and therefore would not trigger the self-consistency mechanism for zeroth-order terms; they would be part of the first-order, quasi-perturbative correction - a remark indeed applying to all instances of generation of zeroth-order terms.
The residues of $\Gamma_{5V}$ at those poles must be proportional to the residue functions $E_n^{[r]}(p_2, p_3, p_4)$ ($1 \leq n \leq r$) in the p.f. decomposition of $\Gamma_{4V}$ analogously to eq. (2.27). On the other side they must be proportional to the residue functions $B_n^{[r]}(p_5, p_6)$ ($1 \leq n \leq r$) of the three-point vertex $\Gamma_{3V}$; this follows e.g. from the way the same $\Gamma_{5V}$ amplitude enters in the two-DS-loops term of the three-point equation (term (D)$_3$ in Fig.1 of [2]). For these pole terms of $\Gamma_{5V}$, the loop of (A)$_4$ then turns into loops of self-energy type already encountered in the self-consistency problem of $\Gamma_{2V}$, which fixes the proportionality factors: the internal lines in the zeroth-order pole terms of $\Gamma_{5V}$ with respect to $s_1$ are associated with factors

$$- S_n^{[r]}(p_1) = \frac{1}{u_{r,2n+1}} \frac{t(p_1)}{p_1^2 + u_{r,2n} \Lambda^2} \quad (n = 1 \ldots r),$$

and therefore constitute minus a shadow line as defined in Fig.3(b) of [2].

(4) To demonstrate self-consistency of the three negative-shadow terms in eq.(1.1), we now feed the decomposition of Fig.1(a) into the various contributing terms on the r.h.s. of Fig.2 and verify that, upon appeal to information from the “lower” DS equations, those terms cooperate so that their sum splits off explicitly the same triplet of negative-shadow terms; after cancelling them from both sides of the equation, the remainder then constitutes a DS equation for the reduced amplitude $V_{4V}$.

The first place to feed in Fig.1(a) is the $\Gamma_{5V}$ poles just identified, with their $E_n^{[r]}$ residue functions. This turns each of them into a pole with the corresponding reduced $E_n^{[r]}$ instead, minus a triplet of terms with two shadow poles each, involving in addition to the $B_n^{[r]}$ ($n \geq 1$) a set of functions $B_{m,n}^{[r]}$ defined by further decomposition of these,

$$B_{m}^{[r]}(p, q) = B_{m,0}^{[r]}(q) + \sum_{n=1}^{r} \left( \frac{\Lambda^2}{p^2 + u_{r,2n} \Lambda^2} \right) B_{m,n}^{[r]}(q)$$

Invoking now the full Bose symmetry of $\Gamma_{5V}$, we see that this vertex has a shadow-poles structure given, in a condensed notation, by

$$\Gamma_{5V} = V_{5V}$$

$$- \sum_{i=1}^{10} \left\{ \sum_{n} B_n^{[r]} S_n^{[r]} E_n^{[r]} \right\}_i$$

$$+ \sum_{k=1}^{15} \left\{ \sum_{m,n} B_m^{[r]} S_m^{[r]} B_m^{[r]} B_{m,n}^{[r]} B_{n}^{[r]} \right\}_k,$$

where $i$ enumerates the 10 channels, while $k$ enumerates the 15 different 2+1+2 partitions of the 5 legs. This structure is shown diagrammatically in Fig.4. Note that the symmetrization is achieved with only 15, not 30, of the latter terms: since each of them has shadow lines in two different channels, these are enough to supply the triplet of contributions mentioned before to pole structure in all of the 10 Mandelstam variables. The amplitude $V_{5V}$ defined by eq.(3.6) will be referred to as the reduced 5-gluon vertex. As a superficially convergent vertex with all tree-like structures removed by construction, it consists only of superficially convergent loops. Since these, as emphasized repeatedly, do not support the self-reproduction of zeroth-order terms, it is an exact statement that

$$V_{5V}^{[r,0]} = 0 \quad (\text{all } r).$$
(5) The next place to feed in the assertion of Fig.1(a), or its consequence of Fig.1(b), is the six terms of triangle topology, arising from $(A)_4$ of Fig.2 upon insertion of the 1-gluon-reducible terms in the 2nd and 3rd lines of Fig.3. Together with eq.(3.6) and after some regrouping of terms, this is equivalent to using a new representation of the $T'_4 V$ amplitude given diagrammatically in Fig.5. We again relegate details of its derivation to appendix C and note only that this representation, apart from the fully one-shadow-irreducible gluon-exchange graphs in its 2nd and 3rd lines, has a shadow-line content isolated in four terms: the negative-shadow term in the first line, which is identical to the $i=1$ term in the 2nd line of eq.(3.6) and will play a special role by supplying in Fig.2 the singularities of $V_{4V}$ in its $p_{1}^2$ variable, and the 3 negative terms in the last two lines, which involve a 3-gluon-1-shadow auxiliary amplitude $\Xi_n$ as defined in Fig.7.

(6) Lastly, we should introduce Fig.1(b) into the $(C)_4$, $(C')_4$, and $(C'')_4$ terms of Fig.2. This will turn each of them into a graph having a $V_{4V}$ instead of $T_{4V}$, plus a pair of one-shadow-irreducible gluon-exchange terms giving equal contributions and for which the factor of $1/2$ therefore gets cancelled, plus a negative term with one shadow line, as displayed in Fig.8. (Note that an ordinary gluon line connecting to at least one bare vertex, such as the $\Gamma_{4V}^{(0)\text{pert}}$ in Fig.8, has no shadow content).

(7) In the crucial step of the argument, we now refer back to the three-point vertex equation, maintaining for consistency the simplifications analogous to those of step (1) above, and again feed the assertion of Fig.1 into the $T'_{4V}$ term of that equation (term $(A)_3$ in Fig.1 of [3], where the $T'_{4V}$ is denoted $T'_s$). We then take residues with respect to the squared momentum of one of the two external legs other than the “distinguished” leg entering from the left (one of the variables $p_1^2$ or $p_3^2$ in Fig.1 of [3]). Note that this kind of residue information stood unused so far, since in [2] we only exploited residue comparison with respect to the distinguished leg. The result is the diagrammatic relation of Fig.9, a DS equation of sorts for the partial amplitudes $B_n$ ($n \geq 1$) of $\Gamma_{3V}$. (If we do not invoke the simplifications, this relation of course gets additional ghost-loop, fermion-loop, and two-gluon-loops terms with their own $\Xi$-type amplitudes, as alluded to in the last line of Fig.9).

But this relation is precisely what is needed to turn the 3 negative shadow-line terms which arose in step (6) from the $(C)_4$ through $(C'')_4$ terms of Fig.2, plus the 3 negative $\Xi$ terms that arose from term $(A)_4$ upon insertion of the $\Xi$ graphs of Fig.5, into the 3 negative one-shadow terms on the r.h.s. of Fig.1(a). We have therefore attained our goal: we have shown that upon introducing the decomposition of Fig.1(a) with its 3 compensating-pole terms, either directly or through its immediate consequence of Fig.1(b), into wherever a four-point building block occurs in the interaction terms of Fig.2, these interaction terms cooperate so that their sum splits off explicitly those 3 compensating terms again. Note that in so doing we appealed to residue information not only from the lower (3-point and 2-point) DS equations, but now also from the 4-point equation itself, which led us to infer the shadow-reducibility structure (3.6) of the next higher, 5-gluon vertex.

We may now cancel the 3 compensating terms on both sides of the $\Gamma_{4V}$ equation and thus establish the DS equation of Fig.10 for the reduced vertex $V_{4V}$, which is the main result of this section.

(8) As a by-product, we may rewrite eq.(3.6) for the shadow content of $\Gamma_{5V}$. To each of the 10 terms with negative signs in the second line, we may add a triplet of terms of structure $\sum_m \Gamma_{3V} DB_m S_m B_m$, with one ordinary-gluon and one shadow line, such that the resulting quartet of
terms form precisely the set of compensating poles needed to cancel the four shadow lines present in the one-gluon-exchange diagram \( \{ \Gamma_3 V D \Gamma_4 V \} \) of the full connected-and-amputated 5-gluon amplitude \( T_{5V} \) ( one along the D propagator line, the other three hidden, by Fig.1(a), in the \( \Gamma_4 V \) vertex ). The same 30 terms, now regrouped into 15 suitable pairs, may then be subtracted from the 15 terms in the third line of (3.6), and it is straightforward to check with the aid of Fig.6(b) that each resulting triplet then forms the set of compensating poles needed to cancel the one two-shadows term and two single-shadow terms present in a double-gluon-exchange diagram \( \{ \Gamma_3 V D \Gamma_3 V D \Gamma_3 V \} \) of \( T_{5V} \). Since the total operation has not changed the equation, we conclude, with a view to eq. (C.1) of the appendix, that

\[
\Gamma_{5V} = V_{5V} + [ \text{complete set of compensating poles for all 25 one-gluon-reducible terms of } T_{5V}].
\] (3.8)

Thus the final result for the next higher amplitude is again simple: the full \( T_{5V} \) is completely one-shadow irreducible, consisting as it does of a \( V_{5V} \) with full extended irreducibility, plus 25 “softened” ( i.e. one-shadow irreducible ) but still one-gluon reducible diagrams.

(9) Finally note that term \((A1)_4\) of the reduced \( V_{4V} \) equation of Fig. 10, upon taking residues at its horizontal-channel shadow poles and invoking once again the \( \Gamma^{[r,0]}_{2V} \) self-consistency conditions, instantly reproduces the \( E_n^r \) terms with \( n \geq 1 \) of the p.f. decomposition (2.27). The remaining, further-reduced equation for the partial amplitude \( E_0^r \) of (2.27) at \( r = 1 \) is what we shall work with in practice; it should be kept in mind that this equation still has a term comprising the regular-at-poles remainders of \((A1)_4\) of Fig.10.

4 Self-consistency conditions

4.1 The overdetermined system

A glance at Fig.10 shows that the reduced DS equation for \( V_{4T} \), or for its \( E_{0,T} \) component, is linear in the four-point unknowns, though still nonlinear in the “lower”, 2-and-3-point vertices. This simplification results from (i) the restriction to a one-loop calculation and (ii) our use of the ordinary DS system without Bethe-Salpeter resummation. The self-consistency equations for the \( \zeta \) coefficients of eq. (2.15) will thus form a linear system but with a matrix ( determined by the divergent parts of diagrams \((A1)_4\), \((A3)_4\), and \((C2)_4\) of Fig.10 ) and with inhomogeneous terms ( determined by the divergent parts of the other diagrams of Fig.10 ) depending nonlinearly on the 2-point and 3-point coefficients.

As discussed in [2], the zeroth-order self-consistency system as a whole exhibits a scaling property, arising from the scheme- insensitive character of the self-reproduction mechanism. It implies that the system only determines ratios of the nonperturbative coefficients to certain fixed powers of one of them. The latter, by convention, was chosen to be \( x_1 \), a coefficient of the 3-transverse-gluons vertex. We need to maintain this convention for the 4-gluon quantities; thus for the parametrization (2.13)
we introduce rescaled parameters

\[ \tilde{\Lambda}^2 = |x_1|^2 \Lambda^2, \quad \tilde{\zeta}_i = \zeta_i/|x_1|^{n_i} \quad (i = 1 \ldots 17), \]

where the integers \( n_i \) are,

\[
\begin{align*}
n_1 &= n_7 = n_{13} = 1, \\
n_2 &= n_3 = n_6 = n_8 = n_9 = n_{12} = n_{14} = n_{17} = 2, \\
n_4 &= n_{10} = n_{15} = 3, \\
n_5 &= n_{11} = n_{16} = 4. \end{align*}
\]

All RG-invariant masses are obtained in terms of \( \tilde{\Lambda}^2 \) rather than \( \Lambda^2 \).

For the actual evaluation of the zeroth-order terms of diagrams \((A1)_4, (A3)_4, (C2)_4\) of Fig.10, one uses parametrization \((2.23)\) with its independent tensors and \( \eta \) coefficients. In contrast to what happens (at level \( r = 1 \)) in the 3-point systems, the immediate self-reproduction of the entire \( p_T^2\)-singular portion \( E_{1,T} \) of eq. \((2.27)\), achieved by extracting the pole term at \( p_T^2 = -u_2 \Lambda^2 = -\tilde{u}_2 \tilde{\Lambda}^2 \) from diagrams \((A1)_4\) and appealing to the 2-gluon self-consistency conditions, is found not to provide substantial relief for the overdetermination caused by the lack of manifest Bose symmetry. After reimposing the symmetry by expressing all \( \eta \)'s in terms of the \( \zeta \) coefficients of the fully Bose-symmetric form \((2.15)\), one is still faced with 54 linear equations for these 17 basic coefficients, with matrix elements and inhomogeneities depending nonlinearly (though polynomially) on the lower-vertex coefficients. The complete system is listed in Appendix D. To convey an impression of its structure, we write here just one typical equation: self-reproduction of the coefficient \( \eta_{A,0,4} \) in the invariant function \((2.24)\) associated with the \( C^{(A)} \otimes L_{(0)} \) tensor structure gives, after conversion to \( \zeta \)'s by means of appendix B.2 and multiplication by \( \beta_0 \) and \( u_3^2 \), the condition

\[
\begin{align*}
\frac{9}{2} \left( u_3^2 x_3 \right) \zeta_1 + \frac{9}{2} \left( \frac{3}{8} u_3^2 - u_3 x_4 \right) \zeta_2 + \frac{3}{2} \left( \left( \frac{9}{8} - \beta_0 \right) u_3^2 - \frac{3}{2} u_3 x_4 \right) \zeta_3 \\
+ \frac{27}{4} \left( u_3 x_1 \right) \zeta_4 + \frac{9}{4} \left( \frac{3}{2} u_3^2 + u_3 x_4 \right) \zeta_6 + \frac{3}{2} \left( \left( -\frac{9}{4} + \beta_0 \right) u_3^2 - \frac{3}{2} u_3 x_4 \right) \\
\times \left( \zeta_8 - 2\zeta_9 + 2\zeta_{12} - \zeta_{14} + \zeta_{17} \right) + u_3 \left( \frac{99}{4} x_1 - \frac{15}{8} x_3 - N_F z_3 \right) \left( \zeta_{10} - \zeta_{15} \right) = 9 \left( -\frac{3}{2} u_3^2 x_3^2 + 4 u_3 x_1 x_3 x_4 + \frac{1}{2} u_3 - x_2 \right) x_4^2 - 2 x_1 x_4 x_5 \\
+ N_F \left( \frac{u_3}{w_3} \right)^2 \frac{2}{\gamma_4} \left( w_3 z_1 z_3 - w_3 z_4 + z_1 z_5 - z_2 z_4 \right). \end{align*}
\]

Here \( N_F = 3 \) has been used. The \( N_F \) factors identify contributions from the quark-loop diagrams \((E1)_4, (E1')_4\) of Fig.10. Note that for the quark-vertex coefficients \( z_i \), the simplified numbering of eqs. \((4.6)\) of \([2]\) has been employed.

As far as we are aware, no presently existing mathematical software tool for nonlinear algebraic systems is capable of dealing directly with a system of this size and complicated, partially overdetermined structure. The only strategy currently practical for dealing with the total system is to take advantage of the “near decoupling” of the 4-point system: of the 17 \( \zeta \) coefficients, only two combinations, \( Z_1 \) and
Z_2, enter the 2-and-3-point system (through some of the 3-gluon vertex conditions). One then treats these as additional unknowns in the lower-vertices system and, after invoking the scaling property, determines them to within an one-parameter freedom. Subsequently, their definitions are appended to the linear system for the 4-point \(\zeta\)'s as two extra conditions, bringing the total to 56 equations: this represents only a minor increase in the anyway massive overdetermination of that system. The extra equations are, in rescaled form,

\[
\frac{15}{32} (3\tilde{\zeta}_1 - \tilde{\zeta}_7) = \tilde{Z}_1 = \frac{Z_1}{x_1},
\]

\[
\frac{15}{32} (3\tilde{\zeta}_2 + 3\tilde{\zeta}_3 - \tilde{\zeta}_8 - \tilde{\zeta}_9) = \tilde{Z}_2 = \frac{Z_2}{x_1^2},
\]

where the \(\tilde{Z}_1, \tilde{Z}_2\) on the r.h.s. stand for the values produced by the lower-vertices system. The structure of the four-point system then is,

\[
\sum_{k=1}^{17} M_{ik} (\{\tilde{\nu}\}, \{\tilde{\nu}\}; \{\tilde{x}\}, \{\tilde{z}\}) \tilde{\zeta}_k = b_i (\{\tilde{\nu}\}, \{\tilde{\nu}\}; \{\tilde{x}\}, \{\tilde{z}\}) \quad (i = 1 \ldots 56)
\]

lead, in standard fashion, to a linear system with the \(17 \times 17\) matrix \(M^T M\),

\[
\sum_{k=1}^{17} (M^T M)_{nk} \tilde{\zeta}_k = (M^T b)_n \quad (n = 1 \ldots 17).
\]

Although the structure of \(M\) is too complicated to be handled analytically, we have checked numerically that in the physically acceptable parameter range where all 2-and-3-point coefficients are real, the matrix \(M^T M\) is always invertible. (The calculations have been performed using the MAPLE V computer-algebra system.) As a measure of the deviation one may consider

\[
\chi = \sqrt{\frac{1}{56} \sum_{i=1}^{56} \left( \sum_k M_{ik} \tilde{\zeta}_k - b_i \right)^2}
\]

as compared to a typical r.h.s. or l.h.s. of eqs. (4.6). Also, the quantities \(\tilde{Z}_1, \tilde{Z}_2\) when recalculated from the quasi-solution according to eqs. (4.4/4.5) will be different from their input values from the lower-vertices system, and the differences may serve as rough indicators of the overall degree of
difficulty in satisfying zeroth-order self-consistency requirements from (ordinary) DS equations with the rather simple structure of the \( r = 1 \) set of approximants. If they are large, one may alternatively try to enforce conditions \( (4.4/4.5) \) exactly by assigning a large weight \( w \) (e.g. \( w = 1000 \)) to the \( i = 55 \) and \( i = 56 \) terms of eq. \( (4.7) \). The \( Z_{1,2} \) from the two systems will then match, but the quality of the 54-term remainder solution will in general deteriorate.

4.2 Typical solution for \( N_F = 2 \)

The entire system of course shares the effective one-parameter freedom from the “decoupled” lower-vertices system. In the presence of fermions, this was parametrized \( [2] \) by the coefficient \( \tilde{w}_1 \). We only consider here the physically most interesting parameter range where not only all vertex coefficients are real, but also the values of the self-energy coefficients \( u, w \) imply the presence of a complex-conjugate pole pair in both the gluon and the fermion propagator. Over this range, as noted earlier, most of the other coefficients of the system do not vary substantially.

Table 4.1 gives least-squares values of the rescaled coefficients \( \tilde{\zeta}_n \) corresponding to the “typical” solution of table 5.1 of \( [2] \), which at \( |w_1| = |w_2| = 0.6749 \) (the signs of \( w_1, w_2 \) do not affect the 4-point system) is in about the middle of this parameter range. The two solutions shown are obtained either without extra weighting \( (w = 1) \) or with exact enforcement \( (w = 1000) \) of the 55th and 56th conditions. The resulting coefficients are generally rather large in absolute value, given the fact that from their very context one would expect them to be numbers of order unity (give or take an order of magnitude). This may partly be attributed to the choice of basis – the factors of \( \frac{1}{4}, \frac{1}{6}, \frac{1}{12} \) in the tensors \( (2.13, 2.14) \) employed in the \( W_n \) building blocks – and to the rescaling \( (4.1) \) : it is conspicuous that the large coefficients mostly have large exponents \( n_i \) in \( (1.2) \). Although these effects may account for one to two orders of magnitude, several coefficients still remain implausibly large. We interpret this as the direct result of the considerable “pressure” generated by the overdetermination of the system.

The typical 2-and-3-point solution of \( [2] \) implies values of

\[
\tilde{Z}_1 = 157.9, \quad \tilde{Z}_2 = 156.2 \quad (N_F = 2)
\]

for the parameter combinations of eqs. \( (4.4, 4.5) \) respectively. When not enforced (i.e. at \( w = 1 \)), their values recalculated from the \( \tilde{\zeta}'s \) of table 1, \( -335.95 \) and \( -165.07 \), are strongly mismatched and
even of the opposite sign. It is then hardly surprising to find that this solution has $\chi \approx 317$ in the sense of (4.9) – of the same magnitude as, or even slightly larger than, a typical $|b_i|$ in (4.6), which is exemplified by (4.10) and of the order of a hundred. Enforcing the values (4.10) would then be expected to strongly alter the solution, which is indeed what happens – several of the coefficients even change signs, and $\chi$ deteriorates further to $\approx 349$. This is in marked contrast to the purely gluonic case discussed in the next subsection, and implies that in the presence of (massless) fermions the 4-point solution at the $r = 1$ level is probably a poor one. The presence of the massless-quark DS loops evidently makes the total system at low $r$ much harder to satisfy; in particular these loops seem to work in the direction of forcing a mismatch at the (2+3)-point-to-4-point interface that can be alleviated only gradually at higher $r$.

4.3 Typical solution for pure-gluon theory

For pure Yang-Mills theory ($N_F = 0$) the typical solution, now parametrized by the gluonic coefficient $\tilde{x}_3$ as discussed in [2] and taken at $\tilde{x}_3 = 1$, leads to the 4-point $\tilde{\zeta}$’s given in table 4.2.

| $n$          | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9   |
|--------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| $\tilde{\zeta}_n (w = 10^3)$ | 0.814 | 6.439 | -4.733 | -57.35 | 350.05 | -3.057 | 8.672 | -30.03 | 0.931 |
| $\tilde{\zeta}_n (w = 1)$     | -0.432 | 9.285 | -4.789 | -54.834 | 255.08 | -2.512 | 6.398 | -21.50 | 1.275 |

| $n$          | 10  | 11  | 12  | 13  | 14  | 15  | 16  | 17  |
|--------------|-----|-----|-----|-----|-----|-----|-----|-----|
| $\tilde{\zeta}_n (w = 10^3)$ | 96.02 | -328.14 | -0.060 | 3.354 | -4.212 | 13.74 | -121.67 | -9.060 |
| $\tilde{\zeta}_n (w = 1)$     | 56.75 | -110.07 | -0.518 | 2.595 | 0.461 | -19.15 | 124.0 | -8.744 |

Table 4.2. Coefficients $\tilde{\zeta}_n$ for pure-gluon theory at typical value $\tilde{x}_3 = 1.0$

Two features deserve comment. First, the coefficients overall are of a distinctly more plausible order of magnitude, entirely understandable from the above-discussed simple mechanisms; in particular, the three coefficients of sizes more than a hundred are precisely those with $n_i = 4$ in (4.2). Second, and more remarkably, the input $\tilde{Z}_{1,2}$ values from the lower-point system,

$$\tilde{Z}_1 = -2.92, \quad \tilde{Z}_2 = 16.04 \quad (N_F = 0)$$

(4.11)

are matched reasonably well by the four-point quasisolution even for $w = 1$, i.e. without being enforced exactly: when recalculated they come out as -3.60 and +15.80 respectively. Moreover, the $\chi$ value of $\approx 0.11$ is now only about ten percent of the typical $|b_i|$ of (4.6), which in this case is of order unity. Exact enforcement of the values (4.11) then leads to no appreciable deterioration in $\chi$. This gives one confidence that for the pure Yang-Mills system the least-squares, four-point quasisolution does work reasonably well even on the $r = 1$ level of approximation – better, in fact, than one would expect in view of the still very simple and rigid structure of approximants at this level.
5 Conclusion

We have verified that self-consistent determination of a generalized Feynman rule for the highest superficially divergent and kinematically most complex QCD vertex is possible in principle, provided the overdetermination resulting from lack of manifest Bose symmetry in the relevant DS equation is dealt with by a least-squares procedure. Within the well-defined and clearly visible limitations of our calculation, available indicators suggest that the least-squares solution at level $r = 1$ is good for the pure gluon theory but quantitatively poor in the presence of massless quarks.

Among the limitations, the one most obviously in need of improvement may be the use of an “ordinary” DS system: starting from BS-resummed dynamical equations for $N \geq 3$ would presumably shift more important physical effects into the lower loop orders, and would provide partial (though not complete) relief from the pressures of overdetermination. Similar effects can probably be expected from use of a tensor basis larger than our “dynamically minimal” one; this would moreover allow $d_{abc}$ color dependence in the three-gluon vertex to be treated consistently. Going beyond the $r = 1$ and $l = 1$ levels of approximation would have the algebraic complication rising steeply, as usual in iterative schemes for QFT, but is presumably the only consistent way of better satisfying perturbative limits and other desirable secondary conditions. The above results do, however, give one confidence that the method as a whole is viable, and produces enough nontrivial features to render these improvements worth pursuing.
Appendix

A Absence of non-compensating zeroth-order poles

Here we ask whether the four-gluon generalized Feynman rule $\Gamma^{[r,0]}_{4\nu}$ may contain, in addition to the "compensating" poles in its three crossed color-octet channels as identified in sect. 2.2 and made explicit in eq. (1.1), still other poles of zeroth perturbative order in its Mandelstam variables. Such poles would be absent in the perturbative limit $\Lambda \to 0$, so their residue factors would be proportional to at least one power of $\Lambda$. In e.g. the $s$ channel, such a pole would be of the form

$$\frac{\Lambda \Phi^T(p_1,p_2)\Lambda \Phi(p_3,p_4)}{P^2 + b\Lambda^2}$$

with a dimensionless residue function (or vector of functions) $\Phi$ carrying the color and Lorentz quantum numbers of the channel considered. This contrasts with the case of the compensating pole, where residue comparison in the $\Gamma_{3\nu}$ equation forces the residue factors to be proportional to $B_n$'s – quantities of mass dimension +1 which by themselves need not vanish as $\Lambda \to 0$ since in their defining equation (eq. (2.14) of ref. [2]) they are already accompanied by a $\Lambda^2$ factor.

The Bethe-Salpeter amplitudes $\Lambda \Phi$ must satisfy a well-known normalization condition [7], which in a condensed notation, and again in the most simplified form omitting ghost and fermion terms, reads

$$\left\{ \frac{g_0^2}{4} \int \Lambda \Phi(\frac{\partial}{\partial P^\mu}(DD))\Lambda \Phi \right\}_{P^2=-b\Lambda^2}
+\left\{ g_0^2 \int \int \Lambda \Phi(DD)(\frac{\partial}{\partial P^\mu}K_s)(DD)\Lambda \Phi \right\}_{P^2=-b\Lambda^2} = -2P^\mu. \quad (A.2)$$

This is depicted in Fig.11. Fulfillment of this condition by purely zeroth-order quantities is possible only if the loop integrals on the l.h.s. diverge and thereby trigger the divergence-related $1/g^2$ mechanism. With the $\Phi$ functions behaving at worst like constants at large loop momenta $q$, and with the easily checked behavior of

$$\frac{\partial}{\partial P^\mu}(DD) = O(q^{-5}) \quad , \quad \frac{\partial}{\partial P^\mu}K_s = O(q^{-1}) \quad (A.3)$$

(note that terms in $K_s$ behaving like constants at large $q$'s, such as the $\Gamma^{(0)\text{pert}}$ term, drop out after differentiation), it is however clear that the integrals are convergent, and do not provide the $\frac{1}{\epsilon}$ factors necessary for the mechanism to work. Thus poles of type (A.1) in $T^{[r,0]}_{4\nu}$ are ruled out.

Note that the "compensating" poles, by contrast, can satisfy (A.2) as zeroth-order quantities, since there $\Lambda \Phi$ is replaced by a $B_n$ (compare eq. (2.21) of [8]) which at large $q$ behaves like $q^1$, and therefore provides divergences on the l.h.s. of (A.2).

Note also that if one does not insist on the $\Phi$ being quantities of zeroth perturbative order, (A.2) may be satisfied, at suitable eigenvalues $-b\Lambda^2$ of $P^2$, by quantities which have no overall $\Lambda$ factor but are power series starting at least at first order in $g^2$. This, as emphasized in the introduction, is the case for ordinary bound-state poles, which arise from a Bethe-Salpeter partial resummation of the perturbation series for $\Gamma_{4\nu}$.
B Parametrizations of the reduced four-gluon vertex

B.1 Building blocks for the symmetric parametrization

To list the building blocks $W_n^{[1,0]}$ of the fully Bose-symmetric $V_4V$ representation (2.15), we use the following combinations of single-pole quantities (2.11):

$$G_{(1)}(p_1^2 \ldots p_4^2) = \Pi_1 + \Pi_2 + \Pi_3 + \Pi_4; \quad \text{(B.1)}$$

$$G_{(2s)}(p_1^2 \ldots p_4^2) = \Pi_1\Pi_2 + \Pi_3\Pi_4, \quad G_{(2u)}(p_1^2 \ldots p_4^2) = \Pi_1\Pi_3 + \Pi_4\Pi_2; \quad \text{(B.2)}$$

$$G_{(3)}(p_1^2 \ldots p_4^2) = \Pi_1\Pi_2\Pi_3 + \Pi_1\Pi_2\Pi_4 + \Pi_1\Pi_3\Pi_4 + \Pi_2\Pi_3\Pi_4; \quad \text{(B.3)}$$

$$G_{(4)}(p_1^2 \ldots p_4^2) = \Pi_1\Pi_2\Pi_3\Pi_4. \quad \text{(B.4)}$$

Here $G_{(1)}$, $G_{(3)}$, and $G_{(4)}$ are Bose-symmetric in themselves, while $G_{2s}$, $G_{2u}$, and $G_{2t}$ form a crossing triplet. In terms of these,

$$W_1^{[1,0]} : = \left\{ C^{(S)} \left[ L_3 - 2L_1 + L_2 \right] + ( \text{perms. } s \rightarrow u, s \rightarrow t ) \right\} G_{(1)}; \quad \text{(B.5)}$$

$$W_2^{[1,0]} : = \left\{ C^{(S)} \left[ L_3 - 2L_1 + L_2 \right] + ( \text{perms. } s \rightarrow u, s \rightarrow t ) \right\} \left( G_{(2s)} + G_{(2u)} + G_{(2t)} \right); \quad \text{(B.6)}$$

$$W_3^{[1,0]} : = \left\{ C^{(S)} \left[ L_3 - 2L_1 + L_2 \right] \times \left[ G_{(2t)} - 2G_{(2s)} + G_{(2u)} \right] \right\} + \left( \text{perms. } s \rightarrow u, s \rightarrow t \right); \quad \text{(B.7)}$$

$$W_4^{[1,0]} : = \left\{ C^{(S)} \left[ L_3 - 2L_1 + L_2 \right] + ( \text{perms. } s \rightarrow u, s \rightarrow t ) \right\} G_{(3)}; \quad \text{(B.8)}$$

$$W_5^{[1,0]} : = \left\{ C^{(S)} \left[ L_3 - 2L_1 + L_2 \right] + ( \text{perms. } s \rightarrow u, s \rightarrow t ) \right\} G_{(4)}; \quad \text{(B.9)}$$

$$W_6^{[1,0]} : = \left\{ \frac{1}{4} C^{(1)} \left[ L_1 + L_2 + L_3 \right] \times \left[ G_{(2t)} - 2G_{(2s)} + G_{(2u)} \right] \right\} + \left( \text{perms. } s \rightarrow u, s \rightarrow t \right); \quad \text{(B.10)}$$

$$W_7^{[1,0]} : = \left\{ \frac{1}{4} C^{(1)} \left[ L_3 - 2L_1 + L_2 \right] + ( \text{perms. } s \rightarrow u, s \rightarrow t ) \right\} G_{(1)}; \quad \text{(B.11)}$$

$$W_8^{[1,0]} : = \left\{ \frac{1}{4} C^{(1)} \left[ L_3 - 2L_1 + L_2 \right] + ( \text{perms. } s \rightarrow u, s \rightarrow t ) \right\} \left( G_{(2s)} + G_{(2u)} + G_{(2t)} \right); \quad \text{(B.12)}$$

$$W_9^{[1,0]} : = \left\{ \frac{1}{4} C^{(1)} \left[ L_3 - 2L_1 + L_2 \right] \times \left[ G_{(2t)} - 2G_{(2s)} + G_{(2u)} \right] \right\} + \left( \text{perms. } s \rightarrow u, s \rightarrow t \right); \quad \text{(B.13)}$$

18
\[ W_{10}^{[1,0]} : = \left\{ \frac{1}{4} C^{(1)} \left[ L_{(3)} - 2L_{(1)} + L_{(2)} \right] \right. \\
\left. + \left( \text{perms. } s \rightarrow u, s \rightarrow t \right) \right\} \ G_{(3)} ; \] (B.14)

\[ W_{11}^{[1,0]} : = \left\{ \frac{1}{4} C^{(1)} \left[ L_{(3)} - 2L_{(1)} + L_{(2)} \right] \right. \\
\left. + \left( \text{perms. } s \rightarrow u, s \rightarrow t \right) \right\} \ G_{(4)} ; \] (B.15)

\[ W_{12}^{[1,0]} : = \left\{ \frac{1}{4} C^{(1)} \left[ L_{(1)} + L_{(2)} + L_{(3)} \right] \right. \\
\left. \times \left[ G_{(2t)} - 2G_{(2s)} + G_{(2u)} \right] \right\} \ + \left( \text{perms. } s \rightarrow u, s \rightarrow t \right) ; \] (B.16)

\[ W_{13}^{[1,0]} : = \frac{1}{4} \left[ C^{(1)} + C^{(2)} + C^{(3)} \right] \left[ L_{(1)} + L_{(2)} + L_{(3)} \right] \ G_{(1)} ; \] (B.17)

\[ W_{14}^{[1,0]} : = \frac{1}{4} \left[ C^{(1)} + C^{(2)} + C^{(3)} \right] \left[ L_{(1)} + L_{(2)} + L_{(3)} \right] \right. \\
\left. \times \left[ G_{(2t)} + G_{(2s)} + G_{(2u)} \right] \right) ; \] (B.18)

\[ W_{15}^{[1,0]} : = \frac{1}{4} \left[ C^{(1)} + C^{(2)} + C^{(3)} \right] \left[ L_{(1)} + L_{(2)} + L_{(3)} \right] \ G_{(3)} ; \] (B.19)

\[ W_{16}^{[1,0]} : = \frac{1}{4} \left[ C^{(1)} + C^{(2)} + C^{(3)} \right] \left[ L_{(1)} + L_{(2)} + L_{(3)} \right] \ G_{(4)} ; \] (B.20)

\[ W_{17}^{[1,0]} : = \frac{1}{4} \left[ C^{(1)} + C^{(2)} + C^{(3)} \right] \left\{ \left[ L_{(3)} - 2L_{(1)} + L_{(2)} \right] \ G_{(2s)} \right. \\
\left. + \left( \text{perms. } s \rightarrow u, s \rightarrow t \right) \right\} . \] (B.21)

B.2 Relation between parametrizations

To obtain the expressions for the \( \eta \) parameters of (2.24) and (2.25) in terms of the 17 \( \zeta \) coefficients, one rewrites the \( W_{n}^{[1,0]} \) building blocks (as listed above) in eq. (2.15) in terms of the linearly independent color tensors (2.17)/(2.18) and the \( s \)-channel-adapted Lorentz tensors (2.19)/(2.20) and compares coefficients with eq. (2.23). The ensuing relations are,

\[ \eta_{A,0,1} = -\frac{3}{2} \zeta_7 + \frac{3}{2} \zeta_{13} \] (B.22)

\[ \eta_{A,0,2} = -\frac{3}{4} \zeta_3 - \frac{3}{2} \zeta_8 - \frac{3}{2} \zeta_9 + \frac{3}{2} \zeta_{12} + \frac{3}{2} \zeta_{14} + \frac{3}{4} \zeta_{17} \] (B.23)

\[ \eta_{A,0,4} = \frac{3}{2} \zeta_3 - \frac{3}{2} \zeta_8 + 3 \zeta_9 - 3 \zeta_{12} + \frac{3}{2} \zeta_{14} - \frac{3}{2} \zeta_{17} \] (B.24)

\[ \eta_{A,0,5} = -\frac{3}{2} \zeta_{10} + \frac{3}{2} \zeta_{15} \] (B.25)

\[ \eta_{A,0,6} = -\frac{3}{2} \zeta_{11} + \frac{3}{2} \zeta_{16} \] (B.26)

\[ \eta_{A,+1} = -\frac{1}{2} \zeta_7 + \frac{1}{2} \zeta_{13} \] (B.27)

\[ \eta_{A,+2} = \frac{1}{4} \zeta_3 + \frac{1}{2} \zeta_8 + \frac{1}{2} \zeta_9 + \frac{1}{2} \zeta_{12} + \frac{1}{2} \zeta_{14} - \frac{1}{4} \zeta_{17} \] (B.28)

\[ \eta_{A,+4} = -\frac{1}{2} \zeta_3 + \frac{1}{2} \zeta_8 - \zeta_9 - \zeta_{12} + \frac{1}{2} \zeta_{14} + \frac{1}{2} \zeta_{17} \] (B.29)

\[ \eta_{A,+5} = \frac{1}{2} \zeta_{10} + \frac{1}{2} \zeta_{15} \] (B.30)
\eta_{A,+6} = \frac{1}{2} \zeta_{11} + \frac{1}{2} \zeta_{16} \quad \text{(B.31)}

\eta_{A,,-3} = \frac{3}{4} \zeta_{3} - \frac{3}{4} \zeta_{17} \quad \text{(B.32)}

\eta_{B,0,1} = \frac{3}{4} \zeta_{7} + \frac{3}{2} \zeta_{13} \quad \text{(B.33)}

\eta_{B,0,2} = \frac{3}{4} \zeta_{3} + \frac{3}{4} \zeta_{8} - \frac{3}{8} \zeta_{9} - \frac{3}{4} \zeta_{12} + \frac{3}{2} \zeta_{14} + \frac{3}{4} \zeta_{17} \quad \text{(B.34)}

\eta_{B,0,4} = \frac{3}{2} \zeta_{3} + \frac{3}{4} \zeta_{8} + \frac{3}{4} \zeta_{9} + \frac{3}{2} \zeta_{12} + \frac{3}{2} \zeta_{14} - \frac{3}{2} \zeta_{17} \quad \text{(B.35)}

\eta_{B,0,5} = \frac{3}{4} \zeta_{10} + \frac{3}{2} \zeta_{15} \quad \text{(B.36)}

\eta_{B,0,6} = \frac{3}{4} \zeta_{11} + \frac{3}{2} \zeta_{16} \quad \text{(B.37)}

\eta_{B,+,1} = -\frac{1}{4} \zeta_{7} + \frac{1}{2} \zeta_{13} \quad \text{(B.38)}

\eta_{B,+,2} = \frac{1}{4} \zeta_{3} - \frac{1}{4} \zeta_{8} + \frac{1}{8} \zeta_{9} - \frac{1}{4} \zeta_{12} + \frac{1}{2} \zeta_{14} - \frac{1}{4} \zeta_{17} \quad \text{(B.39)}

\eta_{B,+,4} = -\frac{1}{2} \zeta_{3} - \frac{1}{4} \zeta_{8} - \frac{1}{4} \zeta_{9} + \frac{1}{2} \zeta_{12} + \frac{1}{2} \zeta_{14} + \frac{1}{2} \zeta_{17} \quad \text{(B.40)}

\eta_{B,+,5} = -\frac{1}{4} \zeta_{10} + \frac{1}{2} \zeta_{15} \quad \text{(B.41)}

\eta_{B,+,6} = -\frac{1}{4} \zeta_{11} + \frac{1}{2} \zeta_{16} \quad \text{(B.42)}

\eta_{C,0,3} = \frac{3}{4} \zeta_{3} + \frac{9}{8} \zeta_{9} - \frac{3}{4} \zeta_{17} \quad \text{(B.43)}

\eta_{C,+,3} = \frac{3}{8} \zeta_{9} - \frac{3}{4} \zeta_{12} \quad \text{(B.44)}

\eta_{C,+,1} = -\frac{3}{4} \zeta_{7} \quad \text{(B.45)}

\eta_{C,+,2} = -\frac{3}{4} \zeta_{8} + \frac{3}{8} \zeta_{9} \quad \text{(B.46)}

\eta_{D,0,3} = \frac{9}{4} \zeta_{3} + \frac{9}{2} \zeta_{6} \quad \text{(B.47)}

\eta_{D,+,3} = -\frac{3}{4} \zeta_{3} + \frac{3}{2} \zeta_{6} \quad \text{(B.48)}

\eta_{D,+,1} = \frac{3}{2} \zeta_{1} \quad \text{(B.49)}

\eta_{D,+,2} = \frac{3}{2} \zeta_{2} - \frac{3}{4} \zeta_{3} \quad \text{(B.50)}

\eta_{D,+,4} = \frac{3}{2} \zeta_{2} + \frac{3}{2} \zeta_{3} \quad \text{(B.51)}
\[ \eta_{D,-,5} = \frac{3}{2} \zeta_4 \]  
(B.56)

\[ \eta_{D,-,6} = \frac{3}{2} \zeta_5 \]  
(B.57)

\[ \eta_{E,0,1} = -\frac{3}{2} \zeta_1 \]  
(B.58)

\[ \eta_{E,0,2} = -\frac{3}{2} \zeta_2 - \frac{3}{4} \zeta_3 + \frac{3}{2} \zeta_6 \]  
(B.59)

\[ \eta_{E,0,4} = -\frac{3}{2} \zeta_2 + \frac{3}{2} \zeta_3 - 3 \zeta_6 \]  
(B.60)

\[ \eta_{E,0,5} = -\frac{3}{2} \zeta_4 \]  
(B.61)

\[ \eta_{E,0,6} = -\frac{3}{2} \zeta_5 \]  
(B.62)

\[ \eta_{E,+1} = \frac{1}{2} \zeta_1 \]  
(B.63)

\[ \eta_{E,+2} = \frac{1}{2} \zeta_2 + \frac{1}{4} \zeta_3 + \frac{1}{2} \zeta_6 \]  
(B.64)

\[ \eta_{E,+4} = \frac{1}{2} \zeta_2 - \frac{1}{2} \zeta_3 - \zeta_6 \]  
(B.65)

\[ \eta_{E,+5} = \frac{1}{2} \zeta_4 \]  
(B.66)

\[ \eta_{E,+6} = \frac{1}{2} \zeta_5 \]  
(B.67)

\[ \eta_{E,-3} = -\frac{3}{4} \zeta_3 \]  
(B.68)

## C Representations of the amplitude \( T_{5V}' \)

Here we sketch derivations for two different representations of the partially irreducible 5-gluon amplitude \( T_{5V}' \) needed in the argument of sect. 3.

(1) To establish the representation given in Fig.3, start from the full connected and amputated 5-gluon amplitude (off-shell 5-gluon T matrix), \( T_{5V} \). It has 25 one-gluon-reducible terms (dressed tree diagrams): one of structure \( \Gamma_3 V D \Gamma_4 V \), reducible along a single internal gluon line, for each of the 10 different 2+3 partitions (or \( 2V \leftrightarrow 3V \) channels) of the 5 legs, and one of structure \( \Gamma_3 V D \Gamma_3 V D \Gamma_3 V \), reducible along two different internal lines, for each of the 15 different 2+1+2 partitions of the 5 legs. In the condensed notation adopted for eq. (3.6), we have

\[
T_{5V} = \Gamma_{5V} + \sum_{i=1}^{10} \{ \Gamma_3 V D \Gamma_4 V \}_i \\
+ \sum_{k=1}^{15} \{ \Gamma_3 V D \Gamma_3 V D \Gamma_3 V \}_k .
\]

(C.1)

Of these one-gluon-reducible terms, 13 are reducible in at least one of the four channels (3.1/3.2), and therefore by definition are to be excluded from the \( T_{5V}' \) amplitude, leaving the latter to consist of the
fully one-gluon-irreducible piece ( proper vertex ) $\Gamma_5$, plus 12 dressed-tree diagrams still reducible in other channels – 6 from the second and 6 from the third line of (C.1).

The 6 one-gluon exchange terms from the second line of (C.1) are those in which one of the two legs no. 5 and 6 entering from the left in Fig.3 connects to the $\Gamma_3$, while the other connects to the $\Gamma_4$. The 3 terms in which leg no. 6 connects to a $\Gamma_3$ constitute the second line of Fig.3. The 3 terms in which leg no. 5 connects to the $\Gamma_3$ may each be taken together with a suitable pair from among the 6 terms retained of the third line of (C.1), in such a way as to replace their $\Gamma_4$’s with $T_4’s$ whose primes refer to the channels defined by their external-line pairs. ( Remember that, by definition, $T_4 = \Gamma_4$ plus 2 one-gluon exchange terms in the channels other than the distinguished channel to which the prime refers ). This establishes the third line of Fig.3.

Of course, in this regrouping the roles of legs 5 and 6 may be interchanged, leading to a representation equivalent to Fig.3 in which the $T_4’s$ and $\Gamma_4’s$ have their roles exchanged. This explains the apparent asymmetry of Fig.3. ( 2 ) The representation of $T_5$ given in Fig.5 is established by

(i) applying the decomposition of eq. (3.6) to the $\Gamma_5$ in the first line of Fig.3, (ii) inserting the decompositions of Fig.1(a) and Fig.1(b) into the $\Gamma_4$ and the $T_4$ terms of Fig.3 respectively, and (iii) performing decompositions of the remaining ordinary gluon lines into “softened” one-gluon exchanges and shadow-pole terms as indicated in Fig.6. ( As for Fig.6(b), it lumps together for simplicity two decompositions, corresponding to its first and second lines, that actually occur separately ). The six last terms of Fig.3 then give rise to:

(a) 6 softened one-gluon-exchange graphs of the type of term (B) of Fig.6, shown in the second line of Fig.5,

(b) 6 graphs with two softened one-gluon exchanges each, of the type of term (E) of Fig.6, shown in the third line of Fig.5,

(c) 6 one-shadow-line graphs as in term (C) of Fig.6, which cancel 6 of the 10 negative terms coming from the second line of the $\Gamma_5$ decomposition (3.6), leaving just those four of the 10 negative terms that possess a shadow line in one of the four channels (3.1-3.2).

(d) 12 graphs with two shadow lines each of the type of term (H) of Fig.6 – 9 from the $T_4$ terms – with minus signs, which cancel 12 of the 15 terms from the third line of eq. (3.6), leaving just those three of the 15 terms that have one shadow in the “horizontal” channel (3.1) and the other in one of the three “tilted” channels (3.2).

(e) 18 graphs with one softened-gluon exchange and one shadow line each: 12 with minus signs from both the $\Gamma_4$ and $T_4$ terms, and 6 with plus signs from the $T_4$ terms alone, and which actually cancel 6 of the minus-sign graphs, leaving a net count of 6 terms with one softened-gluon and one shadow line and with minus signs.

Now the 6 terms surviving from (e), the 3 two-shadows terms surviving from (d), and 3 of the 4 one-shadow terms from (c) may be lumped together in three groups by defining the auxiliary amplitudes $\Xi_n$ as in Fig.7; they then give the three graphs in the last two lines of Fig.5. The one remaining one-shadow graph with minus sign from (c) appears explicitly in the first line of Fig.5, which is therefore fully established.
D  Listing of $V_{4V}$ self-consistency equations

In the following, the 54 self-consistency conditions (4.6), multiplied by $\beta_0 u_3^2$ to rid them of ubiquitous factors from the self-consistency mechanism, are listed according to the $C(i) \otimes L(j)$ tensor combination ($i = A \ldots E, j = 0, +, -$) in whose invariant function they arise. For the quark-vertex coefficients $z_i$, the simplified numbering of eqs. (4.6) of [2] is employed.

D.1  $C_A - L_0$ equations:

\[
\begin{align*}
\frac{9}{4} u_3^2 x_3 \left( 5 \zeta_2 + \zeta_3 + 8 \zeta_6 - 6 \zeta_8 + 12 \zeta_9 - 12 \zeta_{12} + 6 \zeta_{14} - 6 \zeta_{17} \right) & - \frac{45}{4} u_3 x_4 \zeta_4 \\
+ \left( \frac{3}{2} \beta_0 u_3^2 + \frac{27}{2} u_3 x_4 \right) (\zeta_{10} - \zeta_{15}) & + \left( \frac{45}{4} u_3 x_1 - \frac{15}{8} u_3 x_3 - N_F u_3 z_3 \right) (\zeta_{11} - \zeta_{16}) \\
= & -27 u_3^2 x_3^3 + 54 u_3 x_3 x_4^2 - 27 x_3^2 x_5
\end{align*}
\]

(D.1)

\[
\begin{align*}
\frac{9}{2} u_3^2 x_3 \zeta_1 & + \left( \frac{27}{16} u_3^2 - \frac{9}{2} u_3 x_4 \right) \zeta_2 - \left( \frac{3}{2} \beta_0 u_3^2 - \frac{27}{16} u_3^2 + \frac{9}{4} u_3 x_4 \right) \zeta_3 + \frac{27}{4} u_3 x_1 \zeta_4 \\
+ \left( \frac{27}{8} u_3^2 + \frac{9}{4} u_3 x_4 \right) \zeta_6 & + \left( \frac{3}{2} \beta_0 u_3^2 - \frac{27}{8} u_3^2 - \frac{9}{4} u_3 x_4 \right) (\zeta_8 - 2 \zeta_9 + 2 \zeta_{12} - \zeta_{14} + \zeta_{17}) \\
+ \left( \frac{99}{4} u_3 x_1 - \frac{15}{8} u_3 x_3 - N_F u_3 z_3 \right) (\zeta_{10} - \zeta_{15}) & \\
= & -\frac{27}{2} u_3^2 x_3^2 + 36 u_3 x_1 x_3 x_4 + \frac{9}{2} u_3 x_4^2 - 9 x_2 x_4^2 - 18 x_1 x_4 x_5 \\
+ N_F \left( \frac{u_3}{w_3} \right)^2 \left( \frac{2}{3} w_3 z_1 z_3 z_4 - \frac{2}{3} w_3 z_4^2 + \frac{2}{3} z_1 z_4 z_5 - \frac{2}{3} z_2 z_4^2 \right)
\end{align*}
\]

(D.2)
\[
\frac{9}{2} u_3^2 x_3 \left( 2 \zeta_1 - 3 \zeta_7 + 3 \zeta_{13} \right) - 9 u_3 x_4 \zeta_2 + \left( \frac{3}{4} \beta_0 u_3^2 + \frac{9}{4} u_3 x_4 \right) \zeta_3 - \frac{9}{4} u_3 x_1 \zeta_4 \\
+ \left( \frac{27}{16} u_3^2 + \frac{63}{8} u_3 x_4 \right) \zeta_6 + \left( \frac{3}{4} \beta_0 u_3^2 + \frac{27}{4} u_3 x_4 \right) \left( 2 \zeta_8 + 2 \zeta_9 - 2 \zeta_{12} - 2 \zeta_{14} - \zeta_{17} \right) \\
+ \left( \frac{45}{4} u_3 x_1 - \frac{15}{8} u_3 x_3 - N_F u_3 z_3 \right) \left( \zeta_{10} - \zeta_{15} \right) \\
= - \frac{45}{2} u_3^2 x_3 + 36 u_3 x_1 x_3 x_4 + 27 u_3 x_4^2 - 9 x_2 x_4^2 - 18 x_1 x_4 x_5 \\

Figure 1:  (a) Decomposition of 4-gluon vertex into reduced vertex and negative-shadow (“compensating”) poles.  (b) Decomposition of partially irreducible 4-gluon amplitude $T'$ into reduced vertex, compensating pole, and softened 1-gluon exchanges.
Figure 2: DS equation for proper 4-gluon vertex in compact form, featuring partially irreducible $T$ matrices.
Figure 3: Representation of partially 1-gluon-irreducible 5-gluon $T$ matrix $T_{5V}$. $\Gamma_{5V}$ denotes the proper 5-gluon vertex. An equivalent representation has the roles of $\Gamma_{4V}$ and $T_{4V}'$ interchanged.
Figure 4: Decomposition of proper 5-gluon vertex into reduced (1-gluon- and 1-shadow-irreducible) vertex $V_{5V}$, negative one-shadow terms in the 10 channels, and positive two-shadows terms for the 15 (2+1+2) partitions of the external legs.
Figure 5: Another representation of the $T'_{5V}$ amplitude. The $\Xi$ amplitudes in the last two lines are defined by Fig.7.
Figure 6: Definition of (a) single and (b) double 1-shadow-irreducible (“softened”) gluon exchanges, marked by dots, through extraction of shadow terms from ordinary single and double gluon exchanges.
Figure 7: Definition of 3-gluon-1-shadow auxiliary amplitudes $\Xi$.

Figure 8: Decomposition of the $(C)_4$ term of Fig.2, obtained by use of Fig.1(b).
Figure 9: DS-like integral equation for partial amplitudes $B_n \ (n \geq 1)$ of 3-gluon vertex $\Gamma_{3V}$. The auxiliary amplitude $\Xi$ in the second line is defined in Fig.7.
Figure 10: DS equation for reduced 4-gluon vertex $V_{4V}$, obtained from Fig. 2 upon using Figs. 5, 8, and 9.
Figure 11: Diagrammatic representation of Bethe-Salpeter normalization condition. The partial differentiations with respect to $P_\mu$ act on the portions in dashed brackets.
