Article

Construction of Higher-Order Metric Fluctuation Terms in Spacetime Symmetry-Breaking Effective Field Theory

Quentin G. Bailey

Abstract: We examined the basic conservation laws for diffeomorphism symmetry in the context of spontaneous diffeomorphism and local Lorentz-symmetry breaking. The conservation laws were used as constraints on a generic series of terms in an expansion around a flat background. We found all such terms for a two-tensor coupling to cubic order in the metric and tensor field fluctuations. The results are presented in a form that can be used for phenomenological calculations. One key result is that if we preserve the underlying diffeomorphism symmetry in a spontaneous-symmetry breaking scenario, one cannot decouple the two-tensor fluctuations from the metric fluctuations at the level of the action, except in special cases of the quadratic actions.

Keywords: Lorentz violation; gravity; spontaneous-symmetry breaking

1. Introduction

The diffeomorphism, the operation of mapping points on a spacetime manifold, is a fundamental symmetry transformation in gravitational theories of physics. Together with local Lorentz transformations in the tangent space at each point, these comprise the gauge symmetry groups that allow general relativity (GR) to be formulated as a local gauge theory [1]. Since local gauge symmetries can be broken in quantum field theories, for instance, via spontaneous symmetry breaking, it is natural to question whether the same could occur for local Lorentz and diffeomorphism symmetries [2]. Much recent work has been devoted to the possibility of spacetime-symmetry breaking, and its possible detection in sensitive tests [3–7]. Among the theoretical mechanisms for this symmetry breaking is we have elegant spontaneous symmetry breaking, in which the underlying action maintains the local symmetries, but due to the presence of a potential energy function with a nonzero minimum for a tensor field, the solutions of the model break this symmetry.

A systematic approach to studying the theory and phenomenology of hypothetical diffeomorphism and local Lorentz violation is the use of effective field theory [8–10]. In this approach, generic symmetry breaking terms are added to the action of general relativity and the standard model [11]. These terms can generally be written using coordinate invariant contractions of background tensor fields and gravitational or matter field operators. The imposition of perfect symmetry occurs when these background tensor fields vanish, and any statistically significant nonzero value for their components would indicate a breaking of diffeomorphism and local Lorentz symmetry. The use of a standard Sun-centered coordinate system to express the experimental measurements of these background coefficients allows cross comparisons between a wide variety of tests [4]. For example, the results of time-delay VLBI measurements in the solar system already limited the coefficient \( s_{00} \) that describes the variation of the speed of gravity compared to light at parts in \( 10^5 \) [12], well beyond the initial constraints obtainable from the first gravitational wave observation. These measurements were subsequently improved from the simultaneous observations of electromagnetic waves and gravitational waves [13]. In both tests, the same set of coefficients \( s_{\mu\nu} \) controls the deviation from GR, at least in the lowest order description of the effective field theory framework [14–17].
To date, much of the development of effective field theory approaches to diffeomorphism and Lorentz breaking have focused on the weak-field regime, in which the spacetime metric can be expanded around a flat background [15,18,19]. For many measurements, it is appropriate to use this limit [20–25]. However, it is of importance to extend results beyond this level, and some work already exists in this regard [26–34]. A generic action quadratic in the metric fluctuations \( h_{\mu\nu} \) has already been constructed to describe any Lorentz violation that can be written in the form \( L \sim h\Delta \), where \( \Delta \) contains arbitrary coefficients and any number of partial derivatives [15,17,35]. This form assumes that the coefficients are constant and the fluctuation around their background values can be eliminated from the action by inserting their solutions from the field equations. The class of models in which this “decoupling” is possible has been studied in various toy models with vectors and tensors [36–38]. However, a full study remains incomplete at higher order in small fluctuations \( h_{\mu\nu} \) around a flat background.

We started the investigation in this work of higher-order terms in the weak-field expansion around a flat background. A general cubic action is constructed for the case of two-tensor couplings \( s_{\mu\nu} \) under the assumption of spontaneous-symmetry breaking. Using an expansion around the background or vacuum values, we show that when proceeding to cubic order in the action, terms that include the fluctuations \( \tilde{s}_{\mu\nu} \) are needed for proper adherence to the underlying diffeomorphism symmetry. Thus, one cannot generally decouple the fluctuations from the metric fluctuations at the level of the action to cubic and higher order, in contrast to past assumptions about the quadratic order terms [15]. We also show that these terms can be matched to a general covariant version of the effective field theory at the second and higher order in \( s_{\mu\nu} \) [31,39].

The paper is organized as follows. First, we consider the terms originally proposed in Reference [11], and argue for the inclusion of dynamical terms for the fluctuations in Section 2. In Section 3, we perform a general construction of all possible terms in the quadratic and cubic order Lagrange densities. Then, we discuss the match to “covariant” terms in Section 4. In Section 5, we display the field equations resulting from the general action. Finally, we summarize in Section 6, and comment on generalizations of this work. We adopt natural units in this work, and conventions in past articles [11,15].

2. Background on the Action

The observer covariant form of the action for the effective field theory framework in the gravity sector is:

\[
S = \frac{1}{16\pi G_N} \int d^4x \sqrt{-g} \left( (1-u)R + s_{\alpha\beta} R^{\alpha\beta} + t_{\alpha\beta\gamma\delta} R^{\alpha\beta\gamma\delta} \right) + S',
\]

(1)

where \( t_{\alpha\beta\gamma\delta}, s_{\alpha\beta} \), and \( u \) are the coefficient fields for Lorentz violation, controlling the size of the mass dimension 4 (\( M^4 \)) Lorentz-violating terms [11] (the gravitational constant \( G_N \) has the mass dimension \( M^{-2} \)). The term \( S' \) contains additional dynamical contributions to the coefficients, should the origin of the symmetry breaking be spontaneous.

In the spontaneous symmetry breaking scenario, the following expansions are used:

\[
\begin{align*}
\mathcal{g}_{\alpha\beta} &= \eta_{\alpha\beta} + h_{\alpha\beta}, \\
u &= \bar{u} + \bar{u}, \\
s_{\alpha\beta} &= \bar{s}_{\alpha\beta} + \bar{s}_{\alpha\beta}, \\
t_{\alpha\beta\gamma\delta} &= \bar{t}_{\alpha\beta\gamma\delta} + \bar{t}_{\alpha\beta\gamma\delta}.
\end{align*}
\]

(2)

The vacuum expectation value for the coefficients are denoted with bars, for example, for \( s_{\alpha\beta} \) it is \( \bar{s}_{\alpha\beta} \), and we assume the constancy of these coefficients (e.g., \( \partial_\mu \bar{s}_{\alpha\beta} = 0 \)). A flat background spacetime metric is assumed so that \( \eta_{\alpha\beta} \) is constant in Cartesian coordinates and we assume that the partial derivatives of \( \bar{s}_{\alpha\beta} \) vanish to avoid global energy–momentum conservation violation [15]. From here on, we use the flat metric \( \eta_{\alpha\beta} \) and its inverse \( \eta^{\alpha\beta} \) to raise and lower indices on quantities unless specified. Note that
converting expressions from covariant form to linear, quadratic, cubic or beyond, must include the appropriate use of (2) [40]. For example, for the metric inverse:

\[
S^{\alpha\beta} = \eta^{\alpha\beta} - \eta^{\alpha\gamma} \eta^{\delta\beta} h_{\gamma\delta} + \eta^{\alpha\gamma} \eta^{\delta\epsilon} \eta^{\beta\epsilon} h_{\gamma\delta} u_{\epsilon} + O(h^3),
\]

\[
= \eta^{\alpha\beta} - h^{\alpha\beta} + h^{\alpha\gamma} h^{\beta}_{\gamma} + O(h^3),
\]

(3)

where in the second line it is understood that the indices are raised and lowered with the Minkowski metric.

Much work has been done by assuming a quadratic order and “decoupled” version of (1). This implies that only the vacuum values of the coefficients \( t_{\alpha\beta\gamma\delta} \), \( s_{\alpha\beta} \), and \( \Pi \) contribute to the gravitational effects of Lorentz violation in the weak-field limit. The Lagrange density for the gravity sector in this limit, up to overall constant scalings, can be written as

\[
L = \frac{1}{32 \kappa} (-h_{\alpha\beta} \mathcal{G}^{\alpha\beta} + s_{\alpha\beta} h_{\gamma\delta} \mathcal{G}^{\alpha\gamma\beta\delta}),
\]

(4)

with \( \kappa = 8\pi G_N \) and where the Einstein curvature tensor \( \mathcal{G}^{\mu\nu} \) and the curvature double dual \( \mathcal{G}^{v p d} \) are linear order in \( h_{\mu\nu} \). Despite the lack of fluctuations \( \Pi, s, f \) in the second term, this remains invariant under linearized gauge transformations of \( h_{\mu\nu} \). Thus, the fluctuations of the coefficients \( \Pi, s_{\alpha\beta} \), and \( t_{\alpha\beta\gamma\delta} \) are assumed to have been decoupled via their field equations. The latter process involves assumptions on the dynamics in \( S' \) [15], which limits the class of possible models included [38]. On the other hand, (4) represents the simplest limit in which the focus is on the effects acting on only the known gravitational degrees of freedom in \( h_{\mu\nu} \), thereby invoking Occam’s razor for the already ambitious suggestion of Lorentz violation.

We note that the coefficients \( t_{\alpha\beta\gamma\delta} \) also do not appear in the quadratic action (4). The fact that this occurs can be viewed as a consequence of the assumptions on the dynamics of the coefficients that leads to the decoupled form of (4). Alternatively, (4) can be derived by considering all possible operators in a general quadratic action of the form \( h K + \ldots + h \) [17], and then truncating the expansion to only mass dimension 4 coefficients for Lorentz violation. Either way, a deeper understanding of why the \( t_{\alpha\beta\gamma\delta} \) coefficients vanish in this limit represents a statement of the “t-puzzle” [41]. While alternative covariant actions have been countenanced leading to physical effects of \( t_{\alpha\beta\gamma\delta} \) [28,30,34], so it remains unexplained why it does not occur in (4).

In this work, we include the fluctuation terms so that we relax the assumptions made in (4), and thus consider a more general version of \( S' \). To include the generality of possible \( s_{\mu\nu} \) dynamics, we posit all possible kinetic, potential, and coupling terms with the constraint that we only consider terms in the Lagrange density with no higher than second order terms in derivatives, and first-order terms in the vacuum coefficients \( s_{\mu\nu} \). We will attempt here the \( s_{\mu\nu} \) case, however, other coefficients can similarly be accommodated.

### 3. General Construction of Lagrange Density

First, we start with the quadratic action terms. These Lagrange density terms, discarding those equivalent by partial integration, are constructed from scalar density contractions of the following:

\[
\mathcal{L}^{(2)} \supset \text{All contractions of \{ } h_{\alpha\beta} \partial_{\gamma} \partial_{\delta} h_{\epsilon\zeta}, s_{\alpha\beta} h_{\gamma\delta} \partial_{\epsilon} \partial_{\zeta} h_{\eta\theta}, s_{\alpha\beta} \partial_{\gamma} \partial_{\delta} s_{\epsilon\zeta}, s_{\alpha\beta} \partial_{\gamma} \partial_{\epsilon} h_{\delta\zeta}, s_{\alpha\beta} \partial_{\delta} \partial_{\epsilon} h_{\gamma\zeta}, s_{\alpha\beta} s_{\gamma\delta} \partial_{\epsilon} \partial_{\zeta} h_{\eta\theta}, s_{\alpha\beta} \partial_{\gamma} \partial_{\delta} s_{\epsilon\zeta}, s_{\alpha\beta} \partial_{\gamma} \partial_{\epsilon} h_{\delta\zeta}, s_{\alpha\beta} \partial_{\delta} \partial_{\epsilon} h_{\gamma\zeta}, s_{\alpha\beta} \partial_{\delta} \partial_{\epsilon} \partial_{\zeta} h_{\eta\theta}, s_{\alpha\beta} \partial_{\gamma} \partial_{\delta} s_{\epsilon\zeta}, s_{\alpha\beta} \partial_{\gamma} \partial_{\epsilon} h_{\delta\zeta}, \}
\]

(5)

In addition, there are potential-type terms that are dealt with separately below. We note that the form of the terms considered in (5) includes, in the second set of terms \( \sim \tilde{h} \tilde{h} \partial \partial h \), the general structure of the Lorentz-violating terms considered in the quadratic Lagrangian construction of Ref. [17], and it will include the general relativity terms from \( \sim \tilde{h} \tilde{h} \partial \partial h \). We truncate the series in this work by considering terms of second order in derivatives, though the pattern could be generalized to accommodate higher derivative terms.
For the cubic terms in the action, the construction follows similarly by including all possible terms cubic in $h_{\alpha\beta}$, or quadratic in $h_{\alpha\beta}$ and linear in $\delta s_{\alpha\beta}$, etc. We truncate the expansion to leading order in the vacuum values $\delta s_{\alpha\beta}$, since these terms will be of primary interest for phenomenology. The structure of these terms, again discarding those equivalent by integration by parts, is:

$$L^{(3)} \supset \text{All Contractions of } \{ h_{\alpha\beta} h_{\gamma\delta} \partial_\mu \partial_\nu s_{\gamma\delta}, h_{\alpha\beta} \partial_\mu h_{\gamma\delta} \partial_\nu s_{\gamma\delta}, s_{\alpha\beta} h_{\gamma\delta} \partial_\mu \partial_\nu h_{\gamma\delta}, \delta s_{\alpha\beta} \partial_\mu \partial_\nu h_{\gamma\delta}, \delta s_{\alpha\beta} \partial_\mu \partial_\nu \partial_\kappa \delta s_{\kappa\lambda}, \delta s_{\alpha\beta} \partial_\kappa \delta s_{\gamma\delta}, \delta s_{\alpha\beta} h_{\gamma\delta} \partial_\kappa \delta s_{\kappa\lambda}, \delta s_{\alpha\beta} \partial_\kappa \partial_\lambda \delta s_{\kappa\lambda} \}.$$

Among all the terms considered in (5) and (6) are the would-be decoupled terms, i.e., those terms that do not have $\delta$ in them. If such terms are possible through cubic order, they will appear in this construction.

We then impose the requirement of diffeomorphism invariance of the action without assuming that the field equations are satisfied (this is an “off-shell” requirement). The quantity constructed by the series

$$L = L^{(2)} + L^{(3)} + ..., \quad (7)$$

is a scalar density of weight $-1$. In the spontaneous-symmetry breaking scenario, this function depends on the matter fields, the vacuum values of the coefficients for Lorentz violation $(\delta s_{\mu\nu})$, the metric fluctuations $h_{\mu\nu}$ and coefficient fluctuations $\delta s_{\mu\nu}$. To impose the symmetry requirement, we will need the infinitesimal diffeomorphism symmetry transformations, which are given by the Lie derivatives of the underlying fields $g_{\mu\nu}$ and $s_{\mu\nu}$ along an arbitrary vector field $\xi^\mu$. These transformations are:

$$\mathcal{L}_{\xi} g_{\mu\nu} = g_{\lambda\mu} \partial_\nu \xi^\lambda + g_{\lambda\nu} \partial_\mu \xi^\lambda + \xi^\lambda \partial_\lambda g_{\mu\nu},$$

$$\mathcal{L}_{\xi} s_{\mu\nu} = s_{\lambda\mu} \partial_\nu \xi^\lambda + s_{\lambda\nu} \partial_\mu \xi^\lambda + \xi^\lambda \partial_\lambda s_{\mu\nu}. \quad (8)$$

From this, we can derive the effective Lie derivatives, or diffeomorphism transformations for the field fluctuations:

$$\mathcal{L}_{\xi} h_{\mu\nu} = \partial_\mu \xi^\nu + \partial_\nu \xi^\mu + h_{\lambda\mu} \partial_\nu \xi^\lambda + h_{\lambda\nu} \partial_\mu \xi^\lambda + \xi^\lambda \partial_\lambda h_{\mu\nu},$$

$$\mathcal{L}_{\xi} \delta s_{\mu\nu} = (\delta s_{\lambda\mu} + \delta s_{\lambda\nu}) \partial_\nu \xi^\lambda + (\delta s_{\lambda\nu} + \delta s_{\lambda\mu}) \partial_\mu \xi^\lambda + \xi^\lambda \partial_\lambda \delta s_{\mu\nu}. \quad (9)$$

where we impose $\partial_\lambda \delta s_{\mu\nu} = 0$ in the chosen asymptotically flat Cartesian coordinates. In this treatment, it is necessary to keep all terms in linear order in $\xi_\alpha$ in order to result in the correct conservation laws. This includes terms typically discarded like $\sim \xi^\alpha h_{\alpha\beta}$ in the linearized limit.

The total action will take the form:

$$S = S_M + \int d^4x (L^{(2)} + L^{(3)} + ...), \quad (10)$$

where the first term is the matter sector, which we assume to be minimally coupled to gravity. The remaining terms are those that we seek to construct and are the focus in what follows. Under a diffeomorphism, one can show that total change in the action takes the form:

$$\delta S = \int d^4x \left( \frac{\delta L}{\delta h_{\alpha\beta}} \mathcal{L}_{\xi} h_{\alpha\beta} + \frac{\delta L}{\delta \delta s_{\alpha\beta}} \mathcal{L}_{\xi} \delta s_{\alpha\beta} \right). \quad (11)$$

At this stage, we make no assumption about whether the field equations are satisfied. The insertion of (9) and using integration by parts gives:
\[
\delta S = -\int d^4x \left\{ \partial_{\beta} \left( \frac{\delta L}{\delta h_{\gamma\beta}} \right) + \Gamma_{\alpha\beta}^\gamma \frac{\delta L}{\delta h_{\alpha\beta}} + g^{\rho\gamma} s_{\rho\alpha} \partial_{\beta} \left( \frac{\delta L}{\delta s_{\alpha\beta}} \right) + g^{\rho\gamma} \frac{1}{2} \left( \partial_{\alpha} s_{\beta\delta} + \partial_{\beta} s_{\alpha\delta} - \partial_{\delta} s_{\alpha\beta} \right) \frac{\delta L}{\delta h_{\alpha\beta}} \right\} \delta_{\gamma\epsilon} \epsilon^\epsilon.
\] (12)

The quantity in braces will vanish for “off-shell” diffeomorphism invariance of the action in the spontaneous-symmetry breaking scenario. For more details, the reader is referred to expositions on Noether identities in the context of Lorentz and diffeomorphism breaking presented in Refs. [11,42–47].

We take the general expansion in Equations (5) and (6) and insert an arbitrary parameter in front of each independent contraction. The starting Lagrange density for quadratic order takes the form:

\[
L^{(2)} = C_1 h^\rho\gamma s^\sigma h_{\rho\gamma} + C_2 h^\rho\gamma s^\sigma \gamma_{\rho\gamma} + C_3 h^\rho\gamma s^\sigma \gamma_{\rho\gamma} + \ldots,
\] (13)

with the remaining terms not displayed here for brevity. For the cubic terms, these take the form:

\[
L^{(3)} = A_1 h^\gamma h^\rho\gamma s^\sigma \gamma_{\rho\gamma} + A_2 h h^\rho\gamma s^\sigma \gamma_{\rho\gamma} + A_3 h^\gamma h^\rho\gamma s^\sigma \gamma_{\rho\gamma} + \ldots,
\] (14)

only displaying the first few terms. Note that because the Lagrange density has mass dimension 4, and \(s_{\mu\nu}\) is taken as dimensionless, the parameters \(C_n\) and \(A_n\) have mass dimension 2.

The idea is to insert the total Lagrange density into the vector combination of terms in brackets (12) above, and demand the result be zero. All tensorially independent terms must vanish and this imposes many relations among the arbitrary parameters \(\{C_n\}\) and \(\{A_n\}\). When one imposes these relations on the parameterized Lagrange densities (13) and (14), a vastly smaller subset of these terms remains, each obeying the off-shell conservation law expected from the underlying diffeomorphism symmetry. This entire calculation is carried out within the Mathematica set of packages in xAct, including in particular, the xTras package [48].

We now display the Lagrange density result in several pieces. Firstly, the entire process produces the quadratic and cubic Lagrange densities of general relativity, up to integration by parts. Secondly, scalings of GR by the trace \(\sigma^\alpha\) occur, which we leave out of our tables below because these are unobservable scalings, as expected. Neglected also are terms that satisfy the constraints (12), but do not contribute to the gravitational field equation for \(h_{\mu\nu}\), such as, for example, terms in equation (5) of the form \(\delta \delta \delta \delta\). We find the following quadratic terms organized in the generic form:

\[
L^{(2)} = L^{(2)}_{GR} + \sum_{n=1}^{10} a_n M^{(2)}_n,
\] (15)

where the \(M^{(2)}_n\) terms are listed in the Table 1. Where necessary for clarity, terms with the parentheses label of (1) are first order in the metric \(h_{\alpha\beta}\) and \(s_{\alpha\beta}\) fluctuations, while those with the label (2) are second order. All Christoffel symbols are taken to first order in \(h_{\alpha\beta}\) with indices raised and lowered with the flat metric. It is also useful to use a linearized Christoffel symbol \(\Gamma\) with the substitution \(h_{\alpha\beta} \rightarrow s_{\alpha\beta}\). Thus:

\[
\Gamma_{\alpha\rho\gamma} = \frac{1}{2} (\partial_{\rho} h_{\gamma\alpha} + \partial_{\gamma} h_{\rho\alpha} - \partial_{\alpha} h_{\rho\gamma}),
\]

\[
\tilde{\Gamma}_{\alpha\rho\gamma} = \frac{1}{2} (\partial_{\rho} s_{\gamma\alpha} + \partial_{\gamma} s_{\rho\alpha} - \partial_{\alpha} s_{\rho\gamma}).
\] (16)

Two different contractions of the Christoffel symbols with one free index are defined by
\( \Gamma_{\alpha \mu} = \Gamma^\alpha_{\alpha \mu} \)
\( \Gamma^\alpha_{\mu \nu} = \Gamma^\alpha_{\mu \nu} \),
(17)

with the same definitions holding for \( \bar{\Gamma} \). We employ some shorthands like \( \Gamma^2_{\alpha} = (\Gamma_A)^\alpha (\Gamma_A)_\alpha \), \( h = h_{\alpha \beta} \eta^\beta \), and \( \bar{s} = \bar{s}_{\alpha \beta} \eta^\beta \). Finally, we use shorthands for curvature-like quantities built from \( \bar{s}_{\alpha \beta \gamma} \), like, for example, \( \bar{\alpha}_{\mu \nu} = \partial_{\mu} \bar{\Gamma}^\alpha_{\nu \mu} - \partial_{\nu} \bar{\Gamma}^\alpha_{\mu \nu} - \frac{1}{2} \eta_{\mu \nu} (\partial^\alpha \bar{\Gamma}_{A \alpha} - \partial^\alpha \bar{\Gamma}_{A \alpha}) \).

Table 1. Quadratic order terms in (15).

| Term  | Expression |
|-------|------------|
| \( \mathcal{L}^{(2)}_{\text{GR}} \) | \( -\frac{1}{2} \eta_{\alpha \beta} \mathcal{C}^{(1)}_{\alpha \beta} \) |
| \( \mathcal{M}^{(2)}_{\text{GR}} \) | \( \bar{s}_{\alpha \beta} \eta^\beta \Gamma_{\alpha \beta} \) |
| \( \mathcal{M}^{(2)}_{\text{GR}} \left(R_{\gamma} - \frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} \right) \) | \( -\frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} - \bar{s}_{\alpha \beta} \eta^\beta \Gamma_{\alpha \beta} \) |
| \( \mathcal{M}^{(2)}_{\text{GR}} \left(R_{\gamma} - \frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} \right) \) | \( -\frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} - \bar{s}_{\alpha \beta} \eta^\beta \Gamma_{\alpha \beta} \) |
| \( \mathcal{M}^{(2)}_{\text{GR}} \left(R_{\gamma} - \frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} \right) \) | \( -\frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} - \bar{s}_{\alpha \beta} \eta^\beta \Gamma_{\alpha \beta} \) |
| \( \mathcal{M}^{(2)}_{\text{GR}} \left(R_{\gamma} - \frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} \right) \) | \( -\frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} - \bar{s}_{\alpha \beta} \eta^\beta \Gamma_{\alpha \beta} \) |
| \( \mathcal{M}^{(2)}_{\text{GR}} \left(R_{\gamma} - \frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} \right) \) | \( -\frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} - \bar{s}_{\alpha \beta} \eta^\beta \Gamma_{\alpha \beta} \) |
| \( \mathcal{M}^{(2)}_{\text{GR}} \left(R_{\gamma} - \frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} \right) \) | \( -\frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} - \bar{s}_{\alpha \beta} \eta^\beta \Gamma_{\alpha \beta} \) |
| \( \mathcal{M}^{(2)}_{\text{GR}} \left(R_{\gamma} - \frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} \right) \) | \( -\frac{1}{2} \eta_{\alpha \beta} \Gamma_{\alpha \beta} - \bar{s}_{\alpha \beta} \eta^\beta \Gamma_{\alpha \beta} \) |

Similarly, the cubic terms can be organized as

\[ \mathcal{L}^{(3)} = \mathcal{L}^{(3)}_{\text{GR}} + \sum_{n=1}^{10} a_n \mathcal{M}^{(3)}_n, \]
(18)

and they are listed in Table 2. We use parenthesis around indices to denote symmetrization with a factor of 1/2, and brackets denote antisymmetrization with a factor of 1/2.

One consequence of this construction is that there are no terms \( \mathcal{M}^{(2)}_{\text{GR}} + \mathcal{M}^{(3)}_{\text{GR}} \) that are devoid of the fluctuations \( \bar{s}_{\alpha \beta} \), save for the GR terms. In other words, in Equations (5) and (6), terms of the form \( \bar{h} \delta \bar{h} \) with cubic counterparts \( \bar{h} \delta \bar{h} \), \( \bar{h} \delta \bar{h} \) would be decoupled, however, such terms do not occur in the results in the Tables 1 and 2. Furthermore, no linear combination of these terms can be taken to eliminate the fluctuations. This shows it is not possible to construct terms in the action at the cubic order, and second order in derivatives, that arise from spontaneous symmetry breaking that also fully decouple the metric fluctuations and the coefficient fluctuations.

For the potential terms for the two-tensor \( \bar{s}_{\alpha \beta} \), these are functions of the four possible independent scalar traces of products of the tensor \( \bar{s}_{\alpha \beta} \eta^\beta \) [49]. Note that this includes the possibility of having "steep" potentials that vanish in the linearized or higher-order approximations. For example, one useful potential is a function of \( \bar{s}_{\alpha} \bar{s}^{\alpha} \) via

\[ V = \frac{1}{4} \lambda (\bar{s}_{\alpha} \bar{s}^{\alpha} - x)^4, \]
(19)

where \( x \) is a constant. When expanding around a flat background, it can be shown that the leading order effects in the field equations are of the cubic order in the fluctuations.
Table 2. Cubic order terms in (18). Each term, $\mathcal{M}_n^{(2)} + \mathcal{M}_n^{(3)}$, is invariant under the diffeomorphism transformations of the metric fluctuations $h_{\alpha\beta}$ and the fluctuations $s_{\alpha\beta}$ in Equations (8) and (9).
4. Covariant Construction of Lagrange Density

As an alternative method to Section 3, we can construct fully covariant Lagrangian for the gravitational sector including the $s_{a\beta}$ terms. We seek kinetic Lagrangian terms that would produce the ones in the expansion in the previous section. These terms were included as a second order in $s_{a\beta}$ expansion in Ref. [31]. These are labeled $\alpha_1$ and obtained by considering all possibilities of scalar contractions of $s_{a\beta}s_{\gamma\delta}R_{\mu\nu\kappa\lambda}$ and $\nabla_{s_{\gamma\delta}}s_{\mu\nu}$, and discarding surface terms:

$$\mathcal{L}_{\text{cov}} = \frac{\sqrt{-g}}{2\kappa} \left[ a_1 s^\Lambda_{\Lambda\Lambda} R + a_2 s_{\mu\nu} R^{\mu\nu} + a_3 \frac{1}{2} (\nabla_{\mu} s^\Lambda_{\Lambda}) (\nabla_{\nu} s_\Lambda^\Lambda) + a_4 \frac{1}{2} (\nabla_{\mu} s^\Lambda_{\Lambda}) (\nabla_{\nu} s^\Lambda_{\Lambda}) + a_5 \frac{1}{2} (\nabla_{\mu} s^\Lambda_{\Lambda}) (\nabla_{\nu} s^\Lambda_{\Lambda}) + a_6 \frac{1}{2} (\nabla_{\mu} s^\Lambda_{\Lambda}) (\nabla_{\nu} s^\Lambda_{\Lambda}) + a_7 s_{\mu\nu} s_{\kappa\lambda} R^{\mu\nu\kappa\lambda} + a_8 s_{\mu\nu} s^\Lambda_{\Lambda} R^{\mu\nu} + a_9 s_{\mu\nu} s_{\kappa\lambda} R^{\mu\nu} + a_{10} s_{\mu\nu} s_{\kappa\lambda} R^{\mu\nu} + a_{11} s_{\mu\nu} s_{\kappa\lambda} R^{\mu\nu} \right].$$

(20)

The covariant terms can be matched to the cubic and quadratic terms by expanding them to the relevant orders. The expansion, however, is cumbersome, hence the advantage of the earlier construction. We find the following matches at quadratic order in the expansion:

$$\mathcal{L}_{\alpha_1} = \frac{a_1}{2\kappa} M_4^{(2)} + O(3) + O(\bar{s}^2)$$
$$\mathcal{L}_{\alpha_2} = \frac{a_2}{2\kappa} M_5^{(2)} + O(3) + O(\bar{s}^2)$$
$$\mathcal{L}_{\alpha_3} = \frac{a_3}{2\kappa} (M_5^{(2)} - M_3^{(2)}) + O(3) + O(\bar{s}^2)$$
$$\mathcal{L}_{\alpha_4} = \frac{a_4}{2\kappa} (M_5^{(2)} + M_3^{(2)} + M_8^{(2)}) + O(3) + O(\bar{s}^2)$$
$$\mathcal{L}_{\alpha_5} = \frac{a_5}{2\kappa} (M_5^{(2)} + \frac{1}{2} M_8^{(2)}) + O(3) + O(\bar{s}^2)$$
$$\mathcal{L}_{\alpha_6} = \frac{a_6}{2\kappa} M_5^{(2)} + O(3) + O(\bar{s}^2)$$
$$\mathcal{L}_{\alpha_7} = -\frac{a_7}{2\kappa} (M_8^{(2)} + M_4^{(2)}) + O(3) + O(\bar{s}^2)$$
$$\mathcal{L}_{\alpha_8} = \frac{a_8}{2\kappa} (M_3^{(2)} + M_5^{(2)}) + O(3) + O(\bar{s}^2)$$
$$\mathcal{L}_{\alpha_9} = \frac{a_9}{2\kappa} (M_4^{(2)} + M_8^{(2)} - M_6^{(2)} + \frac{1}{2} M_{10}^{(2)}) + O(3) + O(\bar{s}^2)$$
$$\mathcal{L}_{\alpha_{10}} = \frac{a_{10}}{k} M_1^{(2)} + O(3) + O(\bar{s}^2)$$
$$\mathcal{L}_{\alpha_{11}} = \frac{a_{11}}{k} M_{10}^{(2)} + O(3) + O(\bar{s}^2)$$

Here, $O(3)$ denotes terms of cubic order in fluctuations $h^3, \bar{s}^3, h^2\bar{s}$, etc. while the $O(\bar{s}^2)$ includes terms of second order in the vacuum values $\bar{s}_{\mu\nu}$. We note that one could have started with the covariant expansion instead of going through the process of the earlier section in the work. However, the quadratic and cubic expansions are more useful for approximate solutions for weak fields, for which one has to expand, order by order, in any case. Furthermore, the conservation law construction can be used for more general tensor couplings, for which it may be challenging to construct the covariant terms. The terms in (20) are a subset of the recent construction in Ref. [39].

5. Field Equations

We turn to the field equations from the action above. Considering the large number of terms in the tables above, abbreviations will be used for different pieces of the field equations. Multiple partial derivatives will be abbreviated as $\partial_{a\beta}$, etc. The variation of the entire Lagrange density (through cubic order) with respect to the metric fluctuations yields the field equations in the form:
\[
\frac{\delta L}{\delta h_{\mu \nu}} = -\frac{1}{2\kappa} (G^{(1)})_{\mu \nu} + \frac{1}{2} \tau_{\mu \nu} + \frac{1}{2} \tau_{\nu \mu} + \delta L_{\mu \nu} + \alpha_1 \tilde{s}^\beta (\partial_{\mu \nu} - \eta_{\mu \nu} \Box) \tilde{s}_{\beta} + \\
\alpha_2 (3s^\mu \partial_{\mu} \partial_{\nu} - \frac{1}{2} \tau_{\mu \nu} \tilde{s}^\mu \tilde{s}_a \partial_{\nu} \tilde{s}_a 3) + \alpha_3 (\tau_{\mu \nu} \partial_{\rho} \partial_{\nu} \gamma - 3s^\mu \tilde{s}_a \partial_{\rho} \tilde{s}_a \gamma) + \\
\alpha_4 (\tau_{\mu \nu} \partial_{\rho} \partial_{\nu} \gamma - 3s^\mu \tilde{s}_a \partial_{\rho} \tilde{s}_a \gamma) + \alpha_5 (\tilde{s}^\mu \tilde{s}_a \partial_{\mu} \partial_{\nu} \gamma - 3s^\mu \tilde{s}_a \partial_{\mu} \partial_{\nu} \gamma) + \\
\alpha_6 (\tilde{s}^\mu \tilde{s}_a \partial_{\mu} \partial_{\nu} \gamma - 3s^\mu \tilde{s}_a \partial_{\mu} \partial_{\nu} \gamma) + \alpha_7 \tilde{s}^\mu \partial_{\rho} \partial_{\nu} \gamma + \alpha_8 \tilde{s}^\mu \Box \tilde{s} + \alpha_9 (2\tilde{\tilde{C}}^{(1)}_{\mu \nu} + 2\tilde{s}_{\mu \nu} \tilde{\tilde{C}}^{(1)}_{\mu \nu} ) + \\
\alpha_{10} (\tau_{\mu \nu} - \eta_{\mu \nu} \Box) (s - \tilde{s}^\mu \tilde{s}_a \partial_{\mu} \partial_{\nu} \gamma - \tilde{s}^\mu \tilde{s}_a \gamma) \]
\]

where \( \tau_{\mu \nu} \) contains the full variation of the cubic terms \( \tau_{\mu \nu} = 2\delta L^{(3)} / \delta h_{\mu \nu} \), and the factor of 2 was chosen so that it matches the GR pseudo tensor in the correct limit. Here, \( L_V \) is the portion of the Lagrange density with the potential energy function for \( \tilde{s}_{\mu \nu} \), and \( T_{\mu \nu} \) comes from the variation of the matter sector with respect to the metric fluctuations. Similarly, the variation of the Lagrange density with respect to the two-tensor fluctuations \( \tilde{s}_{\alpha \beta} \) is:

\[
\frac{\delta L}{\delta \tilde{s}_{\mu \nu}} = (\tau_\alpha)_{\mu \nu} + \delta L_{\mu \nu} + \alpha_1 \tilde{s}^\mu \tilde{\tilde{R}}^{(1)} + \alpha_2 (2\tilde{\tilde{C}}^{(1)}_{\mu \nu} + 2\tilde{s}_{\mu \nu} \tilde{\tilde{C}}^{(1)}_{\mu \nu} + \\
\alpha_3 (3s^\mu \partial_{\rho} \partial_{\nu} \gamma - 3s^\mu \tilde{s}_a \partial_{\rho} \tilde{s}_a \gamma) + \alpha_5 (\tilde{s}^\mu \tilde{s}_a \partial_{\rho} \partial_{\nu} \gamma - 3s^\mu \tilde{s}_a \partial_{\rho} \tilde{s}_a \gamma) + \\
\alpha_6 (\tilde{s}^\mu \tilde{s}_a \partial_{\rho} \partial_{\nu} \gamma - 3s^\mu \tilde{s}_a \partial_{\rho} \tilde{s}_a \gamma) + \alpha_7 \tilde{s}^\mu \partial_{\rho} \partial_{\nu} \gamma + \alpha_8 \tilde{s}^\mu \Box \tilde{s} + \alpha_9 (2\tilde{\tilde{C}}^{(1)}_{\mu \nu} + 2\tilde{s}_{\mu \nu} \tilde{\tilde{C}}^{(1)}_{\mu \nu} ) + \alpha_{10} (\tau_{\mu \nu} - \eta_{\mu \nu} \Box) \]
\]

where \( (\tau_\alpha)_{\mu \nu} = \delta L^{(3)} / \delta \tilde{s}_{\mu \nu} \). The matter sector will have its own field equations which depend on the system to be modeled. We note here that when the field equations hold, the stress-energy tensor for matter will be conserved, a fact that can be exploited in solving the post-Newtonian limit.

The generic case of Equations (22) and (23) with arbitrary parameters contains “ghost” kinetic terms for the fluctuations \( \tilde{s}_{\alpha \beta} \), when treated as a field theory on a flat background. For example, a kinetic term of the form \( L \sim \tilde{s}^\alpha \Box \tilde{s}_\alpha \) will contain non-positive definite contributions to the Hamiltonian density, and could thereby result in unstable solutions. It is of general interest to study this issue in detail, but we do not attempt it here.

We note that this effective field theory construction represents a test framework for Lorentz and diffeomorphism breaking. Rather than just the nine coefficients in (4), we now have up to 10 arbitrary parameters \( a_1 - a_{10} \) and nine coefficients \( \tau_{\mu \nu} \) for a total of 19 quantities describing Lorentz and diffeomorphism violation for gravity.

6. Summary and Outlook

In this work, we described the method to construct quadratic and cubic effective actions for weak-field gravity studies of spontaneous symmetry breaking. The main results are the Lagrange density terms in Equations (15) and (18) and the Tables 1 and 2. Furthermore, we showed that the complete decoupling of the fluctuations from the metric fluctuations cannot occur at the level of the action with only the second derivatives when going to the cubic order in the fluctuations.

The field equations for the metric fluctuations and the two-tensor fluctuations are given in Equations (22) and (23). Future work will solve these equations in the post-Newtonian limit, with near-field and radiation zone solutions for applications in astrophysics. Some preliminary analysis of the field equations in (22) and (23) shows that the near-field post-Newtonian metric contains many of the same fluid potential function terms that were found in Ref. [15]. We conjecture that including all of the extra terms
in the Lagrange density could potentially provide an interesting re-analysis of the match to the parametrized post-Newtonian metric [50,51]. The match of the action above the vector models of Lorentz violation should also be revisited [36,52,53]. Finally, the method adopted in this work for the two-tensor \( s_{\mu\nu} \) could be continued and applied to other gravity sector coefficients, such as the \( t_{\alpha\beta\gamma\delta} \) coefficients, or non-minimal coefficients.

Analysis could also proceed with the general covariant action (20), such as exploring black hole solutions or cosmology solutions. Progress has already been made studying strong-field gravity solutions with vector and tensor models of spontaneous Lorentz-symmetry breaking [54,55]. Complimentary analysis with (20) would be of interest.

**Funding:** This work was supported in part by the National Science Foundation under Grant No. 1806871.

**Acknowledgments:** K. O’Neal-Ault and M. Mewes provided valuable comments on the manuscript.

**Conflicts of Interest:** The author declares no conflict of interest.
