FLAT AFFINE OR PROJECTIVE GEOMETRIES ON LIE GROUPS

MEDINA A.*, SALDARRIAGA O.**, AND GIRALDO H.**

Abstract. This paper deals essentially with affine or projective transformations of Lie groups endowed with a flat left invariant affine or projective structure. These groups are called flat affine or flat projective Lie groups. Our main results determine Lie groups admitting flat bi-invariant affine or projective structures. These groups could play an essential role in the study of homogeneous spaces $M = G/H$ admitting flat affine or flat projective structures invariant under the natural action of $G$ on $M$. A. Medina asked several years ago if the group of affine transformations of a flat affine Lie group is a flat projective Lie group. In this work we provide a partial positive answer to this question.

Keywords: Flat affine Lie groups, Flat projective Lie groups, Affine transformations, Projective transformations, Affine étale representations, Projective étale representations.

0. Introduction

One of the aims of this paper is to give a positive answer to a question raised by the first author several years ago. More precisely, we prove, in several cases, that the group $\text{Aff}(G, \nabla^+)$ of affine transformations of a Lie group $G$ endowed with a flat left invariant affine structure $\nabla^+$, admits a flat left invariant projective (some times affine) structure.

Recall that a locally affine manifold is a smooth manifold $M$ endowed with a linear connection $\nabla$ (and consequently an affine connection). The pair $(M, \nabla)$ is called locally flat if its curvature and torsion tensors are null. This means that the corresponding affine connection is flat. In this case we say that $\nabla$ is a flat affine structure on $M$ (see Section 1). We will suppose manifolds to be real connected unless otherwise stated.

The set of diffeomorphisms $\text{Aff}(M, \nabla)$ of $M$ preserving $\nabla$ endowed with the open compact topology and composition is a Lie group (see [20] page 229). That $F \in \text{Aff}(M, \nabla)$ means that $F$ verifies the system of partial differential equations $F_*(\nabla_X Y) = \nabla_{F_*X} F_*Y$, where $F_*$ is the differential of $F$ and $X$ and $Y$ are smooth vector fields on $M$. In particular $F$ preserves...
geodesics, but in general the group of geodesic preserving diffeomorphisms of $M$ is larger than $\text{Aff}(M, \nabla)$.

The aim of flat affine geometry is the study of flat affine manifolds. The local model of the real flat affine geometry is the n-dimensional real affine space $\mathbb{A}^n$ endowed with the usual affine structure $\nabla^0$. This one is given in standard notation by

$$\nabla^0_X Y = \sum_{j=1}^{n} X(g_j)\partial_j, \quad \text{for} \quad Y = \sum_{j=1}^{n} g_j\partial_j$$

with $X$ and $Y$ smooth vector fields in $\mathbb{A}^n$.

In what follows we identify $\mathbb{A}^n$ with $\mathbb{R}^n$. We will often see $\mathbb{R}^n$ as the affine subspace $\{(x, 1) \mid x \in \mathbb{R}^n\}$ of $\mathbb{R}^{n+1}$. Hence the classical affine group $\text{Aff}(\mathbb{R}^n) = \mathbb{R}^n \rtimes \text{Id}_{\text{GL}(\mathbb{R}^n)} \text{GL}(\mathbb{R}^n)$ of affine transformations of $(\mathbb{R}^n, \nabla^0)$ will be identified with a closed subgroup of $\text{GL}(\mathbb{R}^n \oplus \mathbb{R})$.

Notice also that every invariant pseudo metric in $\mathbb{R}^n$ determines the same geodesics as $\nabla^0$.

**Definition 1.** A flat affine (respectively flat projective) Lie group is a Lie group endowed with a flat left invariant affine structure (respectively flat left invariant projective structure). The first one will be abbreviated as FLIAS. The corresponding infinitesimal object is called an affine Lie algebra (respectively a projective Lie algebra).

For the local model of flat projective geometry see Section [1]

An important and difficult open problem is to determine whether a manifold (respectively a Lie group) admits a flat (respectively left invariant) affine or projective structure. Obviously a manifold $H \backslash G$, where $H$ is a discrete co-compact subgroup of a flat affine Lie group $G$, inherits a flat affine structure. Having a FLIAS on a Lie group is equivalent to having a left symmetric product on its Lie algebra compatible with the bracket, i.e., $[x, y] = x \cdot y - y \cdot x$. It is also equivalent to having an affine étale representation of $G$, i.e., a representation with an open orbit and discrete isotropy (see [23] and [26]). The group $\text{Aff}(G, \nabla^+)$ has been studied in [6] in the case where $\nabla^+$ is bi-invariant. Sometimes the group $\text{Aff}(G, \nabla^+)$ is also a flat affine Lie group. In particular $\text{Aff}(\mathbb{R}^n, \nabla^0)$ is a flat affine group since its co-adjoint representation is étale ([1], [6], [31]). This fact and other observations led the first author of this paper to ask whether the group $\text{Aff}(G, \nabla^+)$ admits a FLIAS or by default a flat left invariant projective structure.

One of the main tools used in our work is the following well known result (see [13] and [23]).

Denote by $p : \hat{M} \rightarrow M$ the universal covering map of a real $n$-dimensional flat affine manifold $(M, \nabla)$. The pullback $\hat{\nabla}$ of $\nabla$ by $p$ is a flat affine structure on $\hat{M}$ and $p$ is an affine map. Moreover, the group $\pi_1(M)$ of deck transformations acts on $\hat{M}$ by affine transformations.

**Theorem 2. (Development Theorem)** There exists an affine immersion $D : \hat{M} \rightarrow \mathbb{R}^n$, called the developing map of $(M, \nabla)$, and a group homomorphism $A : \text{Aff}(\hat{M}, \hat{\nabla}) \rightarrow \mathbb{R}^n$. 
Aff \((\mathbb{R}^n, \nabla)\) so that the following diagram commutes

\[
\begin{array}{ccc}
\hat{M} & \xrightarrow{D} & \mathbb{R}^n \\
F & \downarrow & A(F) \\
\hat{M} & \xrightarrow{D} & \mathbb{R}^n.
\end{array}
\]

In particular for every \(\gamma \in \pi_1(M)\) we have \(D \circ \gamma = H(\gamma) \circ D\) where \(H(\gamma) := A(\gamma)\) and \(H\) being a group homomorphism. This last homomorphism is called the holonomy representation of \((M, \nabla)\).

This result seems to be due to Ehresman (see [12]).

Let us consider a homogeneous space \((S, T)\), i.e., a manifold \(S\) and a Lie group \(T\) acting transitively on \(S\). A manifold \(M\) is provided of an \((S, T)\)-geometry if it admits a smooth subatlas \(\{(U_i, \varphi_i)\}\) so that \(\varphi_i(U_i) \subseteq S\) with \(\varphi_i^{-1} \circ \varphi_j\) the restriction of an element of \(T\), whenever \(U_i \cap U_j \neq \emptyset\).

**Remark 3.** Suppose given an embedding \((\theta, \rho) : (S, T) \rightarrow (S', T')\) of homogeneous spaces, that is, embeddings \(\theta : S \rightarrow S'\) and \(\rho : T \rightarrow T'\) where \(\rho\) is a group homomorphism so that the following diagram commutes

\[
\begin{array}{ccc}
S & \xrightarrow{\theta} & S' \\
t & \downarrow & \rho(t) \\
S & \xrightarrow{\theta} & S'.
\end{array}
\]

for any \(t \in T\). Then it is is clear that an \((S, T)\)-geometry determines an \((S', T')\)-geometry. In particular an affine geometry determines a projective geometry. Consequently a flat affine Lie group is a flat projective Lie group.

**Remark 4.** Suppose that \(G\) and \(G'\) are locally isomorphic Lie groups, i.e., \(G\) and \(G'\) have isomorphic Lie algebras. If \(G\) has a flat left invariant (or bi-invariant) affine or projective structure then so does \(G'\). In the affine case, if the structure is left invariant, the Lie bracket is the commutator of a left symmetric product; if the structure is bi-invariant, the bracket is the commutator of an associative product (see [26] and [6]).

The main two problems of flat affine (or projective) geometry are to find conditions for the existence of a flat affine (or projective) structure on a manifold, and once such a structure exists on a particular manifold \(M\), to determine all the flat affine (or projective) structures on \(M\). Benzécri classified the flat affine structures on closed surfaces (see [3]). In general it seems hopeless to try to classify general geometric structures on noncompact manifolds (see [15]). There are not known sufficient and necessary conditions for the existence of a flat affine structure on a manifold (see [34], [35], [22] and [36]).

**Definition 5.** A Lie group endowed with a left invariant symplectic (respectively Kähler) structure is called a symplectic (respectively Kähler) Lie group.

A symplectic Lie group with a symplectic form \(\omega^+\) is always a flat affine Lie group. For instance, Equation (7) determines a flat affine structure on a symplectic Lie group (non geodesically complete). In particular, a Kähler Lie group is a flat affine Lie group.
Symplectic or Kähler Lie groups have been studied in [8], [16], [25], [28], [27], [9] and [24].

The paper is organized as follows. In Section 1 we recall some basic notions about affine and projective geometry to facilitate the reading of this paper. We also describe a method to construct pseudo-Kähler Lie groups from pseudo-Hessian Lie groups. Section 2 answers positively Medina’s question in some particular cases. Section 3 shows that there infinitely many non-isomorphic FLIAS on $G = \text{Aff}(\mathbb{R})$. In Section 4 we show that, for every FLIAS $\nabla^+$ on $G = \text{Aff}(\mathbb{R})$, the group of affine transformations $\text{Aff}(G, \nabla^+)$ is a symplectic Lie group and therefore a flat affine Lie group. The Appendix exhibits the affine étale representations and geodesics corresponding to each FLIAS on $G = \text{Aff}(\mathbb{R})$ and we explicit FLIAS on $G$ of special interest in geometry, such as flat Hessian structures, flat Lorentzian structures, affine symplectic structures, and Khălerian structures.

The reader can refer to [26] for elements on affine Lie groups and to [25], [28], [8] and [24] for elements on symplectic or Kähler Lie groups.

1. Preliminaries

Let $M$ be an $n$-dimensional real manifold. Two torsion free affine connections $\nabla$ and $\nabla'$ on $M$ are projectively equivalent if there exists a smooth 1-form $\phi$ on $M$ verifying $\nabla_XY - \nabla'_X Y = \phi(X)Y + \phi(Y)X$ for any smooth vector fields $X$ and $Y$ on $M$. The equivalence class $[\nabla]$ of $\nabla$ under this relation is called a projective structure on $M$. A projective isomorphism is a diffeomorphism $F: M \rightarrow M'$ so that $F^*([\nabla']) = [\nabla]$. A projective structure $[\nabla]$ on $M$ is called projectively flat if for each point $p \in M$ there exists a neighborhood $U$ of $p$ and a diffeomorphism $f: U \rightarrow f(U) \subseteq \mathbb{R}^n$, so that $f^*([\nabla^0]) = [\nabla]$. This means that the Cartan normal connection is flat (see [7] and [19]). In particular the Weyl tensor vanishes (see [40], [11] and [38]).

For what follows let us recall also the following basic facts. Let $A(M)$ (respectively $L(M)$) be the bundle of affine frames (respectively linear frames) on an $n$-dimensional manifold $M$. The split exact sequence of Lie groups

$$0 \rightarrow \mathbb{R}^n \rightarrow \text{Aff}(\mathbb{R}^n) \xrightarrow{\gamma} \text{GL}(\mathbb{R}^n) \rightarrow 1$$

determines morphisms of principal bundles $\hat{\beta}: A(M) \rightarrow L(M)$ and $\hat{\gamma}: L(M) \rightarrow A(M)$ such that $\hat{\beta} \circ \hat{\gamma} = \text{id}$. So, if $\hat{\omega}$ is a connection form on $A(M)$ (i.e., a generalized affine connection) we have that

$$\hat{\gamma}^*\hat{\omega} = \omega + \varphi,$$

where $\omega$ is a $gl(n, \mathbb{R})$-valued 1-form and $\varphi$ is an $\mathbb{R}^n$-valued 1-form on $L(M)$. In the case where $\varphi$ is the canonical form on $L(M)$, the 1-form $\hat{\omega}$ is called an affine connection on $M$. Hence, if $\Theta$ and $\Omega$ are respectively the torsion and the curvature forms of a linear connection on $M$, we will have that $\hat{\gamma}^*\hat{\Omega} = \Theta + \Omega$, where $\hat{\Omega}$ is the curvature form of an affine connection $\omega$. In summary, a flat and torsion free linear connection can be viewed as a flat affine connection on $M$ (see [20]).

E. Cartan already studied (and solved) the problem of determining when the $(0)$-Cartan connection is projectively flat (see [7] and [30]). Notice that the model space of the real projective geometry is the pair $(P_n(\mathbb{R}), SL(n+1, \mathbb{R})/\text{center})$ where $P_n(\mathbb{R})$ is the $n$-dimensional
real projective space and $SL(n+1, \mathbb{R})/\text{center}$ is the group of projective transformations of $P_n(\mathbb{R})$. Notice also that $SL(n+1, \mathbb{R})/\text{center}$ does not admit flat affine geometry. E. Vinberg in [39] developed a theory for projectively homogeneous bounded domains in $\mathbb{R}^n$ (see also [30]). The study of projective geometry can be done via Cartan connections (see [7], [19] and [1]) or using the theory of jets ([12], [19] and [37]).

**Remark 6.** It is well known that the Levi-Civita connection corresponding to a pseudo-Riemannian metric is projectively flat if and only if its scalar curvature is constant (see [11]).

Every left invariant (respectively bi-invariant) pseudo-Riemannian metric on a Lie group determines a left invariant (respectively bi-invariant) projective structure (non necessarily flat).

Next we give a sufficient and necessary condition for the existence of a flat left invariant projective structure on a Lie group.

**Proposition 7.** Let $G$ be an $n$-dimensional connected Lie group. The group $G$ admits a flat left invariant projective structure if and only if there exists a Lie group homomorphism $\rho : G \rightarrow Pr(P_n(\mathbb{K}))$, where $Pr(P_n(\mathbb{K}))$ is the group of projective transformations of $P_n(\mathbb{K})$ so that there exists an open orbit with discrete isotropy, that is, $\rho$ is a projective étale representation of $G$.

**Proof.** Let $\rho : G \rightarrow Pr(P_n(\mathbb{K}))$ be an étale projective representation of $G$. If $[v] \in P_n(\mathbb{K})$ is of open orbit and discrete isotropy, then $\text{Orb}([v])$ inherits a flat projective structure from those of $P_n(\mathbb{K})$. Moreover, the orbital map $\pi : G \rightarrow \text{Orb}([v])$ is a covering map equivariant by the action of $G$ on $G$ by left multiplications and the action of $\rho(G)$ on $\text{Orb}([v])$. We also have that the following diagram is commutative

$$
\begin{array}{ccc}
G & \xrightarrow{L_\sigma} & G \\
\downarrow{\pi} & & \downarrow{\pi} \\
\text{Orb}([v]) & \xrightarrow{\rho(L_\sigma)} & \text{Orb}([v])
\end{array}
$$

The pullback by $\pi$ of the projective structure on $\text{Orb}([v])$ is a flat projective structure on $G$ and, since the diagram is commutative, the structure is left invariant.

Let $p : \mathbb{R}^{n+1} \setminus \{0\} \rightarrow P_n(\mathbb{R})$ be the canonical projection. Since $\text{Orb}([v])$ is open in $P_n(\mathbb{R})$, then $p^{-1}(\text{Orb}([v]))$ is open in $\mathbb{R}^{n+1}$ saturated by the relation $\sim$ determined by $u \sim v$ if and only if $v = \lambda u$, with $\lambda \neq 0$. It follows from this and the fact that $\text{orb}([v])$ is open, that $\rho_{*,c} : \mathfrak{g} \rightarrow \text{sl}(n+1, \mathbb{R})$ is a Lie group homomorphism so that there exists $w \in \mathbb{R}^{n+1}$ verifying that $\rho_{*,c}(\mathfrak{g}) + Rw = \mathbb{R}^{n+1}$.

Conversely suppose that $G$ is endowed with a flat left invariant projective structure, let us suppose also that $G$ simply connected. Hence there exists a representation $\rho : G \rightarrow Pr(P_n(\mathbb{K}))$ so that for every $\sigma \in G$, the map $L_\sigma$, left multiplication by $\sigma$, preserves the structure. Hence the diagram (1) commutes. It follows that there exists at least a point $[p]$ whose orbit $\text{Orb}([p])$ is open with discrete isotropy. □
From the arguments used in the previous proof we can deduce the following.

**Remark 8.** Let $G$ be a Lie group of dimensión $n$ and $\mathfrak{g} = \text{Lie}(G)$, then the following statements are equivalent.

1. $G$ admits a flat left invariant projective structure.
2. there exists a representation $\Theta : G \rightarrow \text{Pr}(P_n(\mathbb{R}))$ and a point $[p] \in P_n(\mathbb{R})$ whose orbit is open and with discrete isotropy, i.e., $G$ admits a projective étale representation.
3. there exists a representation $\rho : \mathfrak{g} \rightarrow \text{sl}(n+1, \mathbb{R})$ and a point $w \in \mathbb{R}^{n+1}$ so that $\rho(\mathfrak{g}) + \mathbb{R}w = \mathbb{R}^{n+1}$.

**Remark 9.** It is well known that a semisimple Lie group $G$ of finite dimensión $m$ does not admit a FLIAS (see [17]). This follows from observing that such a structure on $G$ has to be radiant and this implies $m = 0$. In particular $SL(n + 1, \mathbb{R})$ does not admit a FLIAS, nevertheless it does admit a flat left invariant projective structure.

**Example 10.** Consider the group homomorphism $\rho : SL(2, \mathbb{R}) \rightarrow \text{Pr}(P_3(\mathbb{R}))$ $u \mapsto \begin{bmatrix} u & 0 \\ 0 & I_2 \end{bmatrix}$. It is easy to verify that $\rho_*(\mathfrak{sl}(2, \mathbb{R})) + \mathbb{R}e_3 = \mathbb{R}^4$, where $e_3 = (0, 0, 1, 0)$. Therefore $\rho$ is a projective étale representation of $SL(2, \mathbb{R})$.

This example easily generalizes to $SL(n, \mathbb{R})$ with $n \geq 3$.

In the rest of the section we give a tool to study the symplectic cotangent Lie group associated to each pseudo-Hessian structure given in Subsection 5.2.2 of the appendix.

**Definition 11.** Let $(G, \Omega^+) = (G, \delta, \Omega)$ be a symplectic Lie group. If $G$ is provided of a left invariant complex structure $j^+$ so that

$$g^+(a, b) := \omega(a, j^+(b))$$

defines a left invariant pseudo-Riemannian metric on $G$, then $(G, g^+, j^+)$ is called a pseudo-Kähler Lie group.

For the study of symplectic or pseudo-Kähler Lie groups see [29], [8], [9] and [24].

**Theorem 12.** Given a flat affine pseudo-Hessian Lie group $(G, \nabla^+, g^+)$ the cotangent bundle $T^*(G) = \mathfrak{g}^* \times_G G$, endowed with the product $(\alpha, \sigma)(\beta, \tau) = (\alpha + \rho(\sigma), \sigma \tau)$ where $\rho_*(a) = -L_a$, for $a \in \mathfrak{g}$, is a pseudo-Kähler Lie group.

**Proof.** Denote by $t^*\mathfrak{g}$ the Lie algebra of $T^*G$. The dual space $\mathfrak{g}^*$ of the left symmetric algebra $\mathfrak{g}$ is a $\mathfrak{g}$-bimodule by the actions $\alpha \cdot b = \alpha \circ R_b$ and $b \cdot \alpha = \text{Ad}^*(b)(\alpha)$. Then the vector space $t^*\mathfrak{g} = \mathfrak{g}^* \times \mathfrak{g}$ can be viewed as a left symmetric algebra, extension of the left symmetric algebra $\mathfrak{g}$ by the $\mathfrak{g}$-bimodule $\mathfrak{g}^*$ as described in [28]. The pair $(t^*\mathfrak{g}, \omega)$, with $\omega((\alpha, \sigma), (\beta, \tau)) = \alpha(\tau) - \beta(\sigma)$, is a symplectic Lie algebra. The restriction on $\mathfrak{g}$ of the
product determined by \( \{7\} \) agrees with the given product of \( \mathfrak{g} \). On the other hand, the form defined by
\[
j(x) = -g(x, \cdot), \quad \text{for} \quad x \in \mathfrak{g}\\n\]
j(\alpha) = x \quad \text{if} \quad \alpha = g(x, \cdot)
\]
is an integrable complex structure. Finally, \( \langle x, y \rangle := \omega(x, j(y)) \) is a non-degenerate bilinear form on \( t^* \mathfrak{g} \).

\[\square\]

2. Projective or affine geometries on transformation groups

Results on this section give a positive answer to Medina’s question in some particular cases.

**Theorem 13.** The flat bi-invariant affine structure on \( GL(n, \mathbb{R}) \) given by composition of linear isomorphisms can be lifted to a flat bi-invariant affine structure on \( T = Aff(\mathbb{R}^n) \) so that the induced structure on \( \mathbb{R}^n \) is \( \nabla^0 \). Moreover the sequence
\[
0 \rightarrow \mathbb{R}^n \rightarrow Aff(\mathbb{R}^n) \rightarrow GL(n, \mathbb{R}) \rightarrow Id
\]
is an exact sequence of flat affine Lie groups and consequently an exact sequence of flat projective Lie groups.

**Proof.** A direct calculation shows that the product
\[
(x, u) \cdot (y, v) = (u(y), u \circ v)
\]
defines an associative product on \( Lie(T) = \mathbb{R}^n \oplus Id gl(n, \mathbb{R}) \) compatible with the bracket. When \( u, v = 0 \) we obtain \( \nabla^0 \). Moreover, the set \( \{(x, 0) \mid x \in \mathbb{R}^n\} \) is a bilateral ideal of the left symmetric algebra \( (Lie(T), \cdot) \).

\[\square\]

**Remark 14.** Analogous results are obtained for the real Lie group \( GL(n, \mathbb{K}) \) where \( \mathbb{K} = \mathbb{C} \) or \( \mathbb{H} \), the field (non-commutative) of quaternions. Also notice that similar results to the previous theorem hold even if the connection on \( GL(n, \mathbb{R}) \) is assumed only left invariant.

**Proposition 15.** If \( (G, \nabla^+) \) is a complete flat affine Lie group then the group \( Aff(G, \nabla^+) \) admits a non-complete flat bi-invariant affine structure and a left invariant symplectic structure.

**Proof.** Using the covering map \( p : \tilde{G} \rightarrow G \) and the \( p \)-pullback of \( \nabla^+ \) we can suppose that \( G \) is simply connected. Denote by \( \theta : \mathfrak{g} \rightarrow aff(\mathfrak{g}) \) the affine representation of \( \mathfrak{g} = Lie(G) \) and by \( \rho : G \rightarrow Aff(\mathfrak{g}) \) the corresponding étale affine representation.

As \( Q : G \rightarrow \mathfrak{g} \) is the developing map of \( (G, \nabla^+) \), there exists a homomorphism of Lie groups \( A : Aff(G, \nabla^+) \rightarrow Aff(\mathfrak{g}, \nabla^0) \) such that the following diagram commutes
\[
\begin{array}{ccc}
G & \xrightarrow{Q} & \mathfrak{g} \\
\downarrow{F} & & \downarrow{A(F)} \\
G & \xrightarrow{Q} & \mathfrak{g}
\end{array}
\]
Moreover, since $\nabla^+$ is complete, the map $Q$ is an affine diffeomorphism. We need to prove
that $A$ is an isomorphism.

Let us suppose that $F \in \ker(A)$, i.e., $A(F) = \text{Id}_{\mathfrak{g}}$. As the diagram commutes we get that $F = \text{Id}_{\mathfrak{g}}$. On the other hand, as $\text{Aff}(G, \nabla^+)$ is complete, $\dim \text{Aff}(G, \nabla^+) = \dim \text{Aff}(\mathfrak{g}, \nabla^0)$. Consequently $A$ is an isomorphism of Lie groups.

Since $\text{Aff}(\mathfrak{g}, \nabla^0)$ has a flat bi-invariant affine structure (Theorem 13) and a left invariant symplectic structure (the co-adjoint representation of $\text{Aff}(\mathfrak{g}, \nabla^0)$ is étale, see [31] and [5]), by the pullback by $A$, we get the result.

\[ \square \]

Let $\nabla^+(g)$ denote the Levi-Civita connection associated to a flat left invariant pseudo-Riemannian metric $g^+$ on a Lie group $G$. Then we have the following.

**Corollary 16.** If $G$ is unimodular then $\text{Aff}(G, \nabla^+(g))$ admits a flat bi-invariant affine structure and a left invariant symplectic structure.

**Proof.** A flat left invariant and pseudo-Riemannian metric on a Lie group $G$ is complete if and only if $G$ is unimodular (see [2]). Then from Proposition 15 it admits a flat bi-invariant structure. The left invariant symplectic structure on $\text{Aff}(G, \nabla^+(g))$ follows from [5] and [31] and the fact that the structure on $G$ is complete. \[ \square \]

Consider the $\text{Int}(\mathfrak{g})$-structure $P$ on a Lie group $G$ with Lie algebra $\mathfrak{g}$ obtained by the natural right action of $\text{Int}(\mathfrak{g})$ on the left invariant parallelism $(e_1^+, \ldots, e_n^+)$ of $G$ (see [26]). It is clear that the product $\nabla_{xy} = \text{ad}_f(y)$, where $f \in \text{gl}(\mathfrak{g})$, determines a left invariant connection $\nabla_f^+$ on $G$ adapted to $P$. We have the following proposition.

**Corollary 17.** If $\nabla_f^+$ is flat and torsion free, then the group $\text{Aff}(G, \nabla_f^+)$ is a flat affine Lie group.

**Proof.** It is easy to verify that right multiplications $R_a$, $a \in \mathfrak{g}$, are nilpotent, hence $\nabla_f^+$ is geodesically complete (see [26]). \[ \square \]

**Theorem 18.** Let $G = \text{GL}(n, \mathbb{K})$ be the real Lie group, with $\mathbb{K} = \mathbb{R}$ or $\mathbb{H}$, and $\nabla^+$ the flat bi-invariant affine structure determined by composition of linear endomorphisms of $\mathbb{K}^n$. Then the group $\text{Aff}(G, \nabla^+)$ admits a flat bi-invariant projective structure.

**Proof.** For every $\sigma \in G$, let $L_\sigma$ and $R_\sigma$ denote the maps left and right multiplication by $\sigma$, respectively, and $I_\sigma = L_\sigma \circ R_{\sigma^{-1}}$. Since $\nabla^+$ is bi-invariant, we have that $L_\sigma, R_\sigma, I_\sigma \in \text{Aff}(G, \nabla^+)$. Let $Z$ be the center of $G$, $M = G \times G/Z$ and $\psi : M \rightarrow \text{Diff}(G)$ the map defined by $\psi(\tau, \overline{\sigma}) = L_\tau \circ I_\sigma$. An easy calculation shows that $\psi$ is an injective Lie group homomorphism, and therefore it is an immersion. Let us consider the group structure on $\psi(M)$ determined by composition and define the product on $M$ by

$$ (\tau_1, \overline{\sigma_1}) \cdot (\tau_2, \overline{\sigma_2}) = \psi^{-1} \left( \psi(\tau_1, \overline{\sigma_1}) \circ \psi(\tau_2, \overline{\sigma_2}) \right) . $$

It can be checked that, under this product, $M$ is a Lie group, $G$ is a normal subgroup of $M$ and $G/Z$ is a subgroup.
Let \( \theta : G/Z \rightarrow \text{Int}(G) \) be the map defined by \( \theta(\sigma) = I_\sigma \). It is easy to check that
\[
\psi(\tau_1, \overline{\sigma_1}) \circ \psi(\tau_2, \overline{\sigma_2}) = \psi(\tau_1 I_{\sigma_1}(\tau_2), \overline{\sigma_1 \sigma_2}) = \psi(\tau_1 \theta(\sigma_1)(\tau_2), \overline{\sigma_1 \sigma_2})
\]
therefore \( \psi^{-1}(M) = G \rtimes_{\theta} G/Z \). The Lie algebra of \( G \rtimes_{\theta} G/Z \) is \( gl(n, \mathbb{R}) \oplus_{ad} sl(n, \mathbb{R}) \), the semidirect product of the Lie algebras \( gl(n, \mathbb{R}) \) and \( sl(n, \mathbb{R}) \) where \( ad : sl(n, \mathbb{R}) \rightarrow \text{End}(gl(n, \mathbb{R})) \) is the restriction to \( sl(n, \mathbb{R}) \) of the adjoint map, hence \( \text{dim} M = 2n^2 - 1 \). Since \( \text{dim} \text{Aff}(G, \nabla^+) = 2n^2 - 1 \) (see [3]) we get that \( M \cong \psi(M) \) and \( \text{Aff}(G, \nabla^+) \) are locally isomorphic. Hence, by Remark [3], \( M \) admits a flat bi-invariant structure.

It can be verified that the product \((t_1, s_1) \cdot (t_2, s_2) = (t_1 \circ t_2 + t_1 \circ s_2 + s_1 \circ t_2, s_1 \circ t_1)\) in \( gl(n, \mathbb{R}) \oplus gl(n, \mathbb{R}) \) is associative and compatible with bracket in \( gl(n, \mathbb{R}) \oplus_{ad} gl(n, \mathbb{R}) \). The associative algebra \( (gl(n, \mathbb{R}) \oplus gl(n, \mathbb{R}), \cdot) \) is unitary with unit \((0, I)\), where \( I \) is the identity endomorphism of \( gl(n, \mathbb{R}) \). One can verify that
\[
\{ L_{(s,t)} \mid \text{tr}(L_{(s,t)}) = 0 \} = sl(n, \mathbb{R}) \oplus sl(n, \mathbb{R}) \oplus \mathbb{R}(2I, -I) \cong gl(n, \mathbb{R}) \oplus_{ad} sl(n, \mathbb{R}),
\]
where \( L_{(s,t)} \) is left multiplication by \((s,t)\). Hence by Theorem 2.2 in [33] (see also the converse to Theorem 2 in [30] stated after the proof of that theorem) the group \( \text{Aff}(G, \nabla^+) \) admits a flat bi-invariant projective structure.

Mutatis mutandis we prove for \( \mathbb{H} \).

Recall that an associative algebra \( A \) over a field \( \mathbb{F} \) is called central if its center \( C \) is given by \( C := \mathbb{F}1 = \{ d1 \mid d \in \mathbb{F} \} \) (see [18]). If \( A \) is a finite dimensional algebra over \( \mathbb{F} \) then \( A \cong M_r(\Delta) = \{ \text{ set of } r \times r \text{ matrices with entries in } \Delta \} \), where \( \Delta \) is a finite dimensional division algebra. In this case the center \( C \) of \( A \) is isomorphic to the center of \( \Delta \) and hence \( C \) is a field. So, \( A \) can be regarded as an algebra over \( C \). When this is done \( A \) becomes a finite dimensional simple central algebra over \( C \). The division algebras over \( \mathbb{F} = \mathbb{R} \) are the fields of real numbers \( \mathbb{R} \), complex numbers \( \mathbb{C} \) or quaternions \( \mathbb{H} \) (Theorem of Hurewitz).

In what follows \( G = U(A) \) is the real group of units of a finite dimensional real associative algebra \( A \). It is clear that \( G \) is endowed with a natural flat bi-invariant affine structure \( \nabla^+ \). The group \( \text{Aff}(G, \nabla^+) \) has been studied in [6]. We have

**Proposition 19.** If \( A = M_n(\mathbb{K}) \), with \( \mathbb{K} = \mathbb{R} \) or \( \mathbb{H} \) and \( G = U(A) \), then the natural structure \( \nabla^+ \) on \( G \) determines a natural flat left invariant projective structure on \( \text{Aff}(G, \nabla^+) \).

**Proof.** Every quaternion can be represented as a real \( 4 \times 4 \) matrix. Hence every element of \( A \) can be seen as a real matrix and \( A \) is a real associative algebra. It is obvious that \( G = U(A) \) admits a flat bi-invariant affine structure determined by the product on \( A \). This structure determines a flat bi-invariant projective structure on \( G \). In particular, this projective structure is invariant under \( \text{Int}(G) = GL(n, \mathbb{K})/C = SL(n, \mathbb{K}) \). The second assertion can be proved using an argument similar to that given in the proof of Theorem [18].

**Remark 20.** In fact \( SL(n, \mathbb{R}) \) (respectively \( SL(n, \mathbb{H}) \)) admits a flat bi-invariant projective structure. These are the only semisimple real Lie groups admitting such a structure (see [30]).

2.1. **Remarks on complex projective or affine geometry.** Using a similar argument in the proof of Theorem [13] we get the following result.
Proposition 21. The holomorphic flat bi-invariant affine structure on $GL(n, \mathbb{C})$ determined by composition of $\mathbb{C}$-linear endomorphisms can be lifted to a flat bi-invariant affine holomorphic structure on $T = Aff(\mathbb{C}^n)$ so that the induced structure on $\mathbb{C}^n$ is $\nabla^\circ$. Moreover the sequence $$0 \rightarrow \mathbb{C}^n \rightarrow Aff(\mathbb{C}^n) \rightarrow GL(n, \mathbb{C}) \rightarrow Id$$ is an exact sequence of complex flat affine Lie groups and consequently an exact sequence of flat projective Lie groups.

Let us consider $P_n(\mathbb{C})$ endowed with the Fubini-Study metric. Since the holomorphic sectional curvature is constant, the manifold $P_n(\mathbb{C})$ has a flat projective structure (see [14]). The group of projective transformations $GL(n+1, \mathbb{C})/C^* I_n$ of $P_n(\mathbb{C})$ can be identified to $SL(n+1, \mathbb{C})/center$. This group does not admit flat left invariant affine structures (see for instance [17]). Nevertheless, since $sl(n, \mathbb{C})$ can be realized as the subalgebra of $gl(n+1, \mathbb{C})$ formed by elements $a$ so that $\text{trace}(L_a) = 0$, where $L_a$ is left composition of $\mathbb{C}$-endomorphisms, it follows that $SL(n+1, \mathbb{C})/center$ admits a flat bi-invariant projective structure.

Proposition 22. The group $Aff(G, \nabla)$ admits a flat bi-invariant projective structure, where $G = GL(n+1, \mathbb{C})$.

Proof. The proof is similar to that given in Theorem [18] \hfill \Box

3. Flat left invariant affine structures on $Aff(\mathbb{R})$

In this section we show that there exists infinitely many non-isomorphic flat affine structures on $G = Aff(\mathbb{R})$. In Section 4 we prove that each group of affine transformations preserving these structures admits a left invariant symplectic structure, and therefore a flat left invariant affine structure.

A FLIAS on Lie group $G$ corresponds to a bilinear product on $\mathfrak{g} = T_i(G)$ verifying

$$(a, b, c) = (b, a, c), \quad (a, b, c) = (b, a, c),$$

$$a \cdot b - b \cdot a = [a, b]$$

where $(a, b, c)$ is the associator of $a, b$ and $c$ in $\mathfrak{g}$ and $[a, b]$ is the bracket given in $\mathfrak{g}$. Such a product is called a left symmetric product on $\mathfrak{g}$ compatible with the bracket. The pair $(\mathfrak{g}, \cdot)$ is called a left symmetric algebra (LSA).

The product on $Aff(\mathbb{R}) = \mathbb{R}^* \times \mathbb{R}$ is given by $(a, b)(c, d) = (ac, ad + b)$ with corresponding Lie algebra $\mathfrak{g} = \text{span}\{e_1^+, e_2^+\}$ where $e_{1,(x,y)}^+ = x \frac{\partial}{\partial x}$ and $e_{2,(x,y)}^+ = x \frac{\partial}{\partial y}$ are left invariant vector fields of $G$ with $[e_1^+, e_2^+] = e_2^+$.

Bilinear products on $\mathfrak{g}$ satisfying (3) can be written as

$$e_1 \cdot e_1 = \alpha e_1 + \beta e_2, \quad e_1 \cdot e_2 = \gamma e_1 + (\delta + 1)e_2,$$

$$e_2 \cdot e_1 = \gamma e_1 + \delta e_2 \quad e_2 \cdot e_2 = \epsilon e_1 + \lambda e_2$$

where $\alpha, \beta, \gamma, \delta, \epsilon$ and $\lambda$ are real numbers.
Such products verifying (2) produce the system of polynomial equations

\[ \begin{align*}
\beta \epsilon - \gamma \delta + \gamma &= 0 \\
\alpha \delta - \beta \gamma + \beta \lambda - \delta^2 &= 0 \\
\alpha \epsilon - \gamma^2 + \gamma \lambda - \delta \epsilon - 2 \epsilon &= 0 \\
\beta \epsilon - \gamma \delta - \lambda &= 0
\end{align*} \]

These equations determine an algebraic variety \( V \). Each point on \( V \) is a FLIAS on \( G_0 \), connected component of the unit of \( G = Aff(\mathbb{R}) \). The variety \( V \) is a closed algebraic submanifold of \( Hom(\mathfrak{g} \otimes \mathfrak{g}, \mathfrak{g}) \). By direct examination of the above equations one finds that \( V \) is the union of three irreducible components of dimension 2 which pairwise intersect along three non intersecting affine lines. These components are described as follows.

Component 1. \( \gamma = \delta = \epsilon = \lambda = 0 \) and we get the family of left symmetric products on \( \mathfrak{g} \)

\[ \begin{align*}
e_1 \cdot e_1 &= \alpha e_1 + \beta e_2, & e_1 \cdot e_2 &= e_2,
e_2 \cdot e_1 &= 0, & e_2 \cdot e_2 &= 0.
\end{align*} \]

We will refer to this family as \( \mathcal{F}_I(\alpha, \beta) \).

Component 2. \( \gamma = \epsilon = \lambda = 0 \) and \( \delta = \alpha \). In this case we obtain the family of left symmetric products

\[ \begin{align*}
e_1 \cdot e_1 &= \alpha e_1 + \beta e_2, & e_1 \cdot e_2 &= (\alpha + 1)e_2,
e_2 \cdot e_1 &= \alpha e_2, & e_2 \cdot e_2 &= 0.
\end{align*} \]

We will label this family as \( \mathcal{F}_{II}(\alpha, \beta) \) with \( \alpha \neq 0 \) to avoid repetition with \( \mathcal{F}_I(0, \beta) \).

Component 3. \( \epsilon \neq 0, \alpha = 2 + \frac{\gamma^2}{\epsilon}, \beta = -\frac{\gamma^3 - \gamma \epsilon}{\epsilon^2}, \delta = -\frac{\gamma^2}{\epsilon} \) and \( \lambda = -\gamma \). Consequently we get

\[ \begin{align*}
e_1 \cdot e_1 &= \left(2 + \frac{\gamma^2}{\epsilon}\right)e_1 - \left(\frac{\gamma^3 + \gamma \epsilon}{\epsilon^2}\right)e_2, & e_1 \cdot e_2 &= \gamma e_1 + \left(1 - \frac{\gamma^2}{\epsilon}\right)e_2,
e_2 \cdot e_1 &= \gamma e_1 - \frac{\gamma^2}{\epsilon}e_2, & e_2 \cdot e_2 &= \epsilon e_1 - \gamma e_2
\end{align*} \]

This family will be named as \( \mathcal{F}_{III}(\gamma, \epsilon) \) with \( \epsilon \neq 0 \).

The planes below are idealized pictures of the first two components.

The first plane represents the Component 1 of \( V \) given above. Each vertical line provides one isomorphism class of FLIAS on \( G_0 \) except for \( \alpha = 1 \). In this case there are two classes one of them is represented by the point \((1, 0)\).

Hence each point on the line \( \beta = \alpha \) (on blue) is an isomorphism class. There is other class at \( C:(1,0) \). In fact each point of any line transversal to the foliation determined by vertical lines, for instance \( \beta = c_1 + c_2 \alpha \) with \( c_1 \) and \( c_2 \neq 0 \) constants, is an isomorphism class.
The points on the dashed red lines ($\alpha = 0$ and $\alpha = 2$) are singular points of $\mathcal{V}$, the points $A:(-1,-1)$, $B:(0,0)$ and $C:(1,0)$ represent special structures on $G_0$. The first one is a Lorentzian connection which is also symplectic, the point $B$ corresponds to a complete connection (see Subsection 5.2) and the point $C$ is a bi-invariant structure (in fact the unique bi-invariant connection within this component) in this case the dimension of the group of affine transformations is at least 3 (see Theorem 18, [6], [26] and [5]). The points of this irreducible component, seen as groups of (classic) affine transformations of the plane, have a one-parameter subgroup of translations ($N(g) = \{ x \in g \mid L_x = 0 \}$ is a line, where $L_x \in \text{End}(g)$ is defined by $L_x(y) = xy$). Each left symmetric algebra within this family (with the exception of $(1,1)$) is isomorphic to the semidirect product of Lie algebras of the line $\mathbb{R}e_1$ with product $e_1 \cdot e_1 = \alpha e_1$, $\alpha \in \mathbb{R}$, by the bilateral ideal $N(g)$ with the action given by the identity ($e_1 \cdot e_2 = e_2$).

The points on the second plane correspond to the irreducible Component 2 of $\mathcal{V}$ described above. As before, each point on the blue line gives one isomorphism class of affine structures on $G_0$. There is an extra class at the point $(-1,0)$.

As above the dashed red lines ($\alpha = 0$ and $\alpha = 1$) are singular points of $\mathcal{V}$, the line $\alpha = 0$ is the intersecting line with the first component. The points $A:(-2,2)$, $B: (-1/2, 1/2)$ and $C:(-1,0)$ correspond to special structures on $G_0$. The first one is a Hessian connection, the point $B$ is a symplectic connection relative to the symplectic structure determined by an open orbit of the co-adjoint representation of $G_0$ (see Subsection 5.2), and the point $C$ is the affine bi-invariant structure determined by Equation (7) (the unique bi-invariant connection within this component) and the dimension of its group of affine transformations is at least 3. The structures on this component, seen as groups of affine transformations of the plane, contain no translations.

The irreducible Component 3 of $\mathcal{V}$ contains just two isomorphism classes of affine structures, given respectively by

$$
e_1 \cdot e_1 = 2e_1 \quad e_1 \cdot e_2 = e_2$$
$$e_2 \cdot e_1 = 0 \quad e_2 \cdot e_2 = \pm e_1$$

according to whether $\epsilon > 0$ or $\epsilon < 0$. These structures, seen as affine transformations of the plane, contain no translations and they determine, by complexification, the same affine structure over $\text{Aff}(\mathbb{C})$. Both of these structures are also Hessian structures (see Subsection 5.2.2).

The two families and the four extra products displayed below describe all (real) isomorphism classes of FLIAS on $G_0$. The products $A_1$ and $A_2$ are associative products and the complexifications $R_1$ and $R_2$ are isomorphic. Notice that these products ($R_1$ and $R_2$) are real
non-isomorphic products but the corresponding affine étale representations are isomorphic (see Subsection [5.1]).

\[ F_1(\alpha) = F_I(\alpha, \alpha) : \begin{cases} e_1 \cdot e_1 = \alpha e_1 + \alpha e_2, & e_1 \cdot e_2 = e_2, \\ e_2 \cdot e_1 = 0, & e_2 \cdot e_2 = 0, \end{cases} \quad \text{with } \alpha \in \mathbb{R}, \quad (4) \]

\[ F_2(\alpha) = F_{II}(\alpha, -\alpha) : \begin{cases} e_1 \cdot e_1 = \alpha e_1 - \alpha e_2, & e_1 \cdot e_2 = (\alpha + 1)e_2, \\ e_2 \cdot e_1 = \alpha e_2, & e_2 \cdot e_2 = 0, \end{cases} \quad \text{with } \alpha \in \mathbb{R} \setminus \{0\}, \quad (5) \]

4. The groups of affine transformations of the line as symplectic Lie groups

We start the section proving the following theorem.

**Theorem 23.** The Lie group \( Aff(G, \nabla^+) \) where \( \nabla^+ \) denotes any FLIAS on \( G = Aff(\mathbb{R}) \) is a flat affine Lie group. The structure \( \nabla^+ \) is not geodesically complete except in one case.

**Proof.** We use Theorem 2 to compute the group \( Aff(G, \nabla^+) \) case by case. We will make explicit a left symmetric product compatible with the bracket on the Lie algebra of \( Aff(G, \nabla^+) \) for each isomorphism class of \( \nabla^+ \).

From now on we will denote by \( \nabla_i(\alpha) \) the connection determined by the product \( F_i(\alpha) \) with \( i = 1, 2 \), by \( \nabla_i, i = 1, 2 \), the connections given by the products \( A_i \), and \( \nabla_i, i = 3, 4 \), the connections determined by the products \( R_{i-2} \).

Case 1. The Lie group \( Aff(G, \nabla_1(\alpha)) \), with \( \alpha \notin \{0, 1\} \), is given by

\[ Aff(G, \nabla_1(\alpha)) = \left\{ \phi : G \longrightarrow G \mid \phi(x, y) = \left( a^{\frac{1}{\alpha}} x, bx^{a} + \frac{a}{\alpha - 1} (a^\frac{1}{\alpha} - c) x + cy + d \right) \right\}. \]

It decomposes as the semidirect product \( Aff(G, \nabla_1(\alpha)) = N \rtimes_{\rho} H \) of the normal subgroup \( N = \{ \phi : G \longrightarrow G \mid \phi(x, y) = (a^{\frac{1}{\alpha}} x, \frac{a}{\alpha - 1} (a^\frac{1}{\alpha} - a) x + ay + b) \}, a > 0 \) \( \cong G \) and the subgroup \( H = \{ \phi : G \longrightarrow G \mid \phi(x, y) = (x, bx^a + \frac{a}{\alpha - 1} (1 - c) x + cy) \}, c \neq 0 \) \( \cong G \) where \( H \) acts on \( N \) by conjugation.

Its Lie algebra \( aff(G, \nabla_1(\alpha)) = \text{span}\{e_1, e_2, e_3, e_4\} \) has nonzero brackets \([e_1, e_2] = -e_2, [e_2, e_3] = -e_2, [e_3, e_4] = e_4\) (the rest are zero or obtained by anti-symmetry). It follows that
where $\cdot$ is the left symmetric on $n$ given by $[1]$ or $[5]$ and $\ast$ is any left symmetric product on $h$.

Case 2. The group $\operatorname{Aff}(G, \nabla_2(\alpha))$, with $\alpha \neq -1$, is given by

$$\operatorname{Aff}(G, \nabla_2(\alpha)) = \left\{ \phi : G \to G \mid \phi(x, y) = (a^\frac{1}{3}x, bx^{-\alpha} + \frac{a^\frac{1}{3}}{\alpha + 1}(a^\frac{1}{3} - c)x + cy + d) \quad \text{with} \quad a, c, b, d \in \mathbb{R}, \ a > 0 \text{ and } c \neq 0 \right\}.$$ 

It decomposes as the semidirect product $\operatorname{Aff}(G, \nabla_2(\alpha)) = N \rtimes_\rho H$ of the normal subgroup $N = \{ \phi : G \to G \mid \phi(x, y) = (a^\frac{1}{3}x, bx^{-\alpha} + \frac{a^\frac{1}{3}}{\alpha + 1}(a^\frac{1}{3} - 1)x + y), \ a > 0 \}$ $\cong G$ and the subgroup $H = \{ \phi : G \to G \mid \phi(x, y) = (x, (1 - c)x + cy + d), \ c \neq 0 \}$ $\cong G$ where $H$ acts on $N$ by conjugation.

The Lie algebra is given by $\operatorname{aff}(G, \nabla_2(\alpha)) = \text{span}\{e_1, e_2, e_3, e_4\}$ and has nonzero brackets $[e_1, e_2] = e_2$, $[e_2, e_3] = -e_2$, $[e_3, e_4] = e_4$. It follows that $\operatorname{aff}(G, \nabla_2(\alpha)) = n \rtimes_h h$ where $n = \text{span}\{e_1, e_2\}$, $h = \text{span}\{e_3, e_4\}$ are the Lie algebras of $N$ and $H$, respectively, and $h$ acts on $n$ by the adjoint action. Then $n \rtimes_h h$ is an LSA with the product given by $[1]$, where the left symmetric product on $n$ is given by $[1]$ or $[5]$ and any left symmetric product on $h$.

Case 3. For $i = 1, 2$, the elements of $\operatorname{Aff}(G, \nabla_i((-1)^{i+1}))$ are diffeomorphisms of $G$ given by $\phi(x, y) = (ax, (c-a)x \ln x + bx + cy + d)$ where $a, c, b, d \in \mathbb{R}$, $a > 0$ and $c \neq 0$. This group decomposes as the semidirect product $\operatorname{Aff}(G, \nabla_i((-1)^{i+1})) = N \rtimes_\rho H$ of the normal subgroup $N = \{ \phi : G \to G \mid \phi(x, y) = (ax, (1-a)x \ln x + bx + y), \ a > 0 \}$ $\cong G$ and the subgroup $H = \{ \phi : G \to G \mid \phi(x, y) = (x, (c-1)x \ln x + cy + d), \ c \neq 0 \}$ $\cong G$ where $H$ acts on $N$ by conjugation.

The Lie algebra $\operatorname{aff}(G, \nabla_i((-1)^{i+1})) = \text{span}\{e_1, e_2, e_3, e_4\}$ of $\operatorname{Aff}(G, \nabla_i)$ has nonzero brackets $[e_1, e_2] = -e_2$, $[e_1, e_3] = -e_2$, $[e_3, e_4] = e_4$. We also get that $\operatorname{aff}(G, \nabla_i((-1)^{i+1})) = n \rtimes_\rho h$ where $n = \text{span}\{e_1, e_2\}$, $h = \text{span}\{e_3, e_4\}$ are the Lie algebras of $N$ and $H$, respectively, and $h$ acts on $n$ by the adjoint action. Then $n \rtimes_\rho h$ is an LSA with the product given by $[1]$, where the left symmetric product on $n$ is given by $[1]$ with $\alpha = 1$ or by $[5]$ with $\alpha = -1$ and any left symmetric product on $h$.

Case 4. For $i = 1, 2$, the group $\operatorname{Aff}(G, \nabla_i) = \{ \phi : G \to G \mid \phi(x, y) = (ax, bx + cy + d), \ a > 0, \ c \neq 0 \}$.

It can be checked that $\operatorname{Aff}(G, \nabla_i) = N \rtimes_\rho H$ where $N = \{ \phi : G \to G \mid \phi(x, y) = (ax, bx + y), \ a > 0 \}$ $\cong G$, $H = \{ \phi : G \to G \mid \phi(x, y) = (x, cy + d), \ c \neq 0 \}$ $\cong G$ and $H$ acts on $N$ by conjugation.

Its Lie algebra is given by $\operatorname{aff}(G, \nabla_i) = \text{span}\{e_1, e_2, e_3, e_4\}$ with non-zero brackets given by $[e_1, e_2] = -e_2$, $[e_2, e_4] = -e_2$ and $[e_3, e_4] = e_4$. It is the semidirect product $n \rtimes_\rho h$ of the Lie subalgebras $n = \text{span}\{e_1, e_2\}$ and $h = \text{span}\{e_3, e_4\}$. These are, respectively, the Lie algebras of $N$ and $H$.

In all cases so far we get the exact sequence of Lie groups

$$\begin{array}{cccc}
\epsilon & \to & N \cong G & \to \operatorname{Aff}(G, \nabla) & \to & \operatorname{Aff}(G, \nabla)/N \cong H \cong G & \to & \epsilon \\
\sigma & \mapsto & \phi \in \operatorname{Aff}(G, \nabla) & \mapsto & \phi \mapsto \phi \circ \sigma & \mapsto & \phi \\
\end{array}$$

with $\phi = \sigma \circ \varphi$.
The sequence splits since \( \pi \circ i = \text{id}_\mathcal{H} \) where \( i : \mathcal{H} \rightarrow \text{Aff}(G, \nabla) \) is the inclusion map. In fact it is an exact sequence of flat affine Lie groups (compare with Example 3.6 of [28]).

Case 5. By Remark 25, the connection \( \nabla_1(0) \) is complete, hence \( \text{Aff}(G, \nabla_1(0)) \cong \text{Aff}(\mathbb{R}^2) \).

Therefore it admits an affine (symplectic) structure (see [5]).

Case 6. For \( j = 3, 4 \), the Lie group \( \text{Aff}(G, \nabla_j) \) is given by

\[
\text{Aff}(G, \nabla_j) = \{ \phi : G \rightarrow G \mid \phi(x, y) = (ax, ay + b) \text{ where } a, b \in \mathbb{R} \text{ and } a > 0 \} \cong G.
\]

Therefore it is an affine group. \( \square \)

We conclude the section with the following result.

**Theorem 24.** For any FLIAS on \( G = \text{Aff}(\mathbb{R}) \), the group \( \text{Aff}(G, \nabla^+) \) is a symplectic Lie group.

**Proof.** By the previous proof \( \text{Aff}(G, \nabla^+) \) has dimension 2, 4 or 6.

If \( \text{Aff}(G, \nabla^+) \) is 2-dimensional, it follows that \( \text{Aff}(G, \nabla^+) \cong \text{Aff}(\mathbb{R}, \nabla^0) \) is symplectic (see Section 5.2.5).

If \( \text{Aff}(G, \nabla^+) \) is 6-dimensional, it follows that \( \text{Aff}(G, \nabla^+) \cong \text{Aff}(\mathbb{R}^2, \nabla^0) \) is symplectic (see [5]).

If \( \text{Aff}(G, \nabla^+) \) is 4-dimensional, it follows from the proof of the previous theorem that \( \text{Aff}(G, \nabla^+) \cong \text{Aff}(\mathbb{R}, \nabla^0) \rtimes \text{Ad} \text{Aff}(\mathbb{R}, \nabla^0) \), where \( \text{Ad} \) is the adjoint action, is the double Lie group of \( \text{Aff}(\mathbb{R}, \nabla^0) \) and therefore it is symplectic (see [10]). These groups are also pseudo-Kähler Lie groups, see Theorem 12. \( \square \)

5. **Appendix**

5.1. **Étale Affine Representations of** \( \text{Aff}(\mathbb{R})_0 \). A bilinear product \( L_a(b) = ab \) on an arbitrary Lie algebra \( \mathfrak{g} \) is a left symmetric product compatible with the bracket in \( \mathfrak{g} \) if and only if the map \( \theta : x \mapsto (x, L_x) \) is a representation of the Lie algebra \( \mathfrak{g} \) by (classical) affine endomorphisms of \( \mathfrak{g} \). Let \( G \) be a connected Lie group and \( \mathfrak{g} = \text{Lie}(G) \) its Lie algebra. Using the exponential map \( \theta \) determines a unique Lie group homomorphism

\[
\Theta : \hat{G} \rightarrow \text{Aff}(\mathfrak{g}) = \mathfrak{g} \rtimes GL(\mathfrak{g}).
\]

This means that \( \sigma \mapsto Q(\sigma) \) is a 1-cocycle of \( \hat{G} \) relative to the linear representation \( \sigma \mapsto F_\sigma \). The orbital map \( \pi : \hat{G} \rightarrow \text{Orb}(0) \) is a local diffeomorphism equivariant by the actions of \( \hat{G} \) on itself by left multiplications and of the group \( \Theta(\hat{G}) \) on \( \mathfrak{g} \) by affine transformations. So the \( \pi \)-pullback \( \nabla^+ \) of \( \nabla^0 \) is a FLIAS. Moreover, this structure on \( \hat{G} = G \) is geodesically complete if and only if the action associated to \( \Theta \) is transitive (see [26]).

It is easy to see that \( Q(\sigma) : G \rightarrow \mathfrak{g} \) is a developing map of \( (G, \nabla^+) \).
Since the exponential map of $g = \text{aff}(\mathbb{R})$ is given by
\[
\exp : \ g \rightarrow \tilde{G} \quad (a, b) \mapsto \begin{cases} (e^a, b) (e^a - 1), & \text{for } a \neq 0 \\ (1, b) & \text{for } a = 0 \end{cases}
\]
the corresponding affine étale representations of $G_0 = \text{Aff}(\mathbb{R})_0$, for each of the FLIAS, are as follows

**Family $\mathcal{F}_1(\alpha)$**. For $\alpha \notin \{0, 1\}$

\[
\rho_1(\alpha) : G_0 \rightarrow \text{Aff}(g) \subseteq GL(g \oplus \mathbb{R}) \\
(x, y) \mapsto \begin{bmatrix}
\alpha x \\
\alpha x (x^\alpha - x) \\
x \\
\alpha x (x^\alpha - 1) \\
\end{bmatrix} x y + \frac{1}{\alpha}(x^\alpha - \alpha x) + 1
\]

when $\alpha = 1$

\[
\rho_1 : G_0 \rightarrow \text{Aff}(g) \\
(x, y) \mapsto \begin{bmatrix}
x & 0 & x - 1 \\
x \ln x & x & 1 + y + x (\ln x - 1) \\
0 & 0 & 1
\end{bmatrix}
\]

when $\alpha = 0$ we get the representation

\[
\rho_1(0) : G_0 \rightarrow \text{Aff}(g) \\
(x, y) \mapsto \begin{bmatrix}
1 & 0 & \ln x \\
0 & x & y \\
0 & 0 & 1
\end{bmatrix}
\]

**Family $\mathcal{F}_2(\alpha)$**. For $\alpha \notin \{0, -1\}$

\[
\rho_2(\alpha) : G_0 \rightarrow \text{Aff}(g) \\
(x, y) \mapsto \begin{bmatrix}
\alpha x \alpha (y - x + 1) & 0 & \frac{1}{\alpha}(x^\alpha - 1) \\
0 & x^{\alpha+1} & x^{\alpha} (y + 1) - \frac{1}{\alpha+1}(\alpha x^{\alpha+1} + 1)
\end{bmatrix}
\]

and when $\alpha = -1$, we get the representation

\[
\rho_2(-1) : G_0 \rightarrow \text{Aff}(g) \\
(x, y) \mapsto \begin{bmatrix}
\frac{1}{x} & 0 & 1 - 1/x \\
1 - y/x - 1/x & 1 & 1/x + y/x - 1 + \ln x \\
0 & 0 & 1
\end{bmatrix}
\]

\[
\mathcal{A}_1 \\
\rho_1 : G_0 \rightarrow \text{Aff}(g) \\
(x, y) \mapsto \begin{bmatrix}
x & 0 & x - 1 \\
0 & x & y \\
0 & 0 & 1
\end{bmatrix}
\]
\[ A_2 \]
\[
\begin{array}{c}
\rho_2 : G_0 \rightarrow Aff(\mathfrak{g}) \\
(x, y) \mapsto \begin{bmatrix} 1/x & 0 & 1-1/x \\
-y/x & 1 & y/x \\
0 & 0 & 1 \end{bmatrix}
\end{array}
\]

\[ \mathcal{R}_1 \]
\[
\begin{array}{c}
\rho_3 : G_0 \rightarrow Aff(\mathfrak{g}) \\
(x, y) \mapsto \begin{bmatrix} x^2 & xy & \frac{1}{2}(x^2 + y^2 - 1) \\
0 & x & y \\
0 & 0 & 1 \end{bmatrix}
\end{array}
\]

\[ \mathcal{R}_2 \]
\[
\begin{array}{c}
\rho_4 : G_0 \rightarrow Aff(\mathfrak{g}) \\
(x, y) \mapsto \begin{bmatrix} x^2 & -xy & \frac{1}{2}(x^2 - y^2 - 1) \\
0 & x & y \\
0 & 0 & 1 \end{bmatrix}
\end{array}
\]

Notice that the \((\mathfrak{g}, \mathcal{R}_1)\) and \((\mathfrak{g}, \mathcal{R}_2)\) are not isomorphic real LSA's. However their corresponding affine étale representations \(\rho_3\) and \(\rho_4\) are isomorphic.

5.2. Special flat left invariant affine structures on \(Aff(\mathbb{R})\). Among the FLIAS on \(Aff(\mathbb{R})\) we identify those of special interest in geometry. More specifically we identify affine pseudo-Riemannian structures, affine symplectic structures, affine Kähler structures, and affine Hessian structures.

5.2.1. Complete Structures. It is known that a FLIAS on a Lie group \(G\) determined by a left symmetric product \(\cdot\) in \(\mathfrak{g} = Lie(G)\), is geodesically complete if and only if \(tr(R_b) = 0\) for all \(b \in \mathfrak{g}\), where \(R_b\) is the matrix of the transformation defined by \(R_b(a) = a \cdot b\) (see [17] and [26]). A direct calculation shows that \(\nabla_1(0)\) is the unique structure on \(Aff(\mathbb{R})\) with this property (anyone can check using the equations of the geodesics as well).

Remark 25. Let \(G\) be the Lie group of affine transformations of the line. There exists a unique geodesically complete FLIAS \(\nabla\) on \(G\). This connection is given by

\[
\nabla_{e_1^+} e_1^+ = 0, \quad \nabla_{e_1^+} e_2^+ = e_2^+, \quad \nabla_{e_2^+} e_1^+ = 0 \quad \text{and} \quad \nabla_{e_2^+} e_2^+ = 0.
\]

Geodesics for this connection are given by (8) and (9).

5.2.2. Hessian structures. Recall that an affine manifold is pseudo-Hessian if there exists a pseudo-Riemannian metric which in local affine coordinates is the Hessian of a function (see [28] and [32]). For an affine Lie group \((G, \nabla^+)\) this means that there is a left invariant pseudo-Riemannian metric on \(G\) verifying the identity

\[
\langle \nabla^+_{X^+}, Y^+, Z^+ \rangle = \langle X^+, \nabla^+_{Y^+}, Z^+ \rangle = \langle \nabla^+_{Y^+}, X^+, Z^+ \rangle + \langle Y^+, \nabla^+_{X^+}, Z^+ \rangle
\]

The affine structures on \(Aff(\mathbb{R})\) determined by \(\nabla_1(-1)\), \(\nabla_2(-2)\), \(\nabla_3\) and \(\nabla_4\) are Hessian relative to the metrics \(\langle , \rangle\) given by the matrices \(A_i = M(\langle , \rangle, \{e_1, e_2\})\), respectively, where

\[
A_1 = \begin{bmatrix} 0 & 1 \\
1 & 0 \end{bmatrix}, \quad A_2 = \begin{bmatrix} 1 & -1/4 \\
-1/4 & 1/8 \end{bmatrix}, \quad A_3 = \begin{bmatrix} 2 & 0 \\
0 & 1 \end{bmatrix} \quad \text{and} \quad A_4 = \begin{bmatrix} 2 & 0 \\
0 & -1 \end{bmatrix}.
\]

The structures \(\nabla_2(-2)\) and \(\nabla_3\) are both Riemannian while the structures \(\nabla_1(-1)\) and \(\nabla_4\) are pseudo-Riemannian.
**Lemma 26.** The symplectic cotangent Lie group $T^*G$ of $(G, \nabla^+, g^+)$, where $\nabla^+$ is one of $\nabla_1(-1)$, $\nabla_2(-2)$, $\nabla_3$ and $\nabla_4$ and $g^+$ the corresponding metric given above, is a pseudo-Kähler Lie group.

**Proof.** The proof follows from Theorem 12. □

5.2.3. **Lorentzian structures.** Let $(\langle , \rangle)$ be the left invariant Lorentzian metric on $Aff(\mathbb{R})$ given by the matrix $M(\langle , \rangle, \{e_1, e_2\}) = \begin{bmatrix} 1 & -1 \\ -1 & 0 \end{bmatrix}$. The corresponding Levi-Civita connexion $\nabla_L = \nabla_1(-1)$ is flat.

The group $Aff(G, \nabla_1(-1))$, where $G = Aff(\mathbb{R})$, is a 4-dimensional flat affine Lie group (see Section 1). The group of diffeomorphisms of $Aff(\mathbb{R})$ preserving both the affine and the Lorentzian structures of $(Aff(\mathbb{R}), \nabla_L)$ is the 2-dimensional group given by

$$\{ \phi : Aff(\mathbb{R}) \rightarrow Aff(\mathbb{R}) | \phi(x, y) = (ax, ay + b) \text{ with } a, b \in \mathbb{R} \text{ and } a \neq 0 \} \cong Aff(\mathbb{R})$$

5.2.4. **Flat left invariant affine symplectic structures.** The co-adjoint action of the group $Aff(\mathbb{R})$ on $aff(\mathbb{R})^*$, the dual space of $aff(\mathbb{R})$, is given by $\sigma \cdot (ae_1^* + \beta e_2^*) = Ad^*(\sigma)(ae_1^* + \beta e_2^*) = (\alpha + \beta) e_1^* + \frac{\beta}{\alpha} e_2^*$, where $\sigma = (a, b)$. This action has two open orbits and a line of fixed points. Since every open orbit of the co-adjoint representation is a symplectic manifold, the pullback by the orbital map on the $Orb(e)$ defines a left invariant symplectic form on $Aff(\mathbb{R})$ given by $w^+(e_1^*, e_2^*) = 1$. The formula

$$\omega^+((a \cdot b)^+, c^+) = -\omega^+(b^+, [a^+, c^+]). \quad (7)$$

determines the affine structure $\nabla_2$. Notice that $(Aff(\mathbb{R})_0, \nabla_2)$ is a symplectic Lie group in the sense of Lichnerowicz-Medina (see 25).

5.2.5. **Symplectic Structures.** Recall that a symplectic connection on a symplectic manifold $(M, \Omega)$ is a linear connection $\nabla$ satisfying the condition

$$\Omega(\nabla_X Y, Z) + \Omega(Y, \nabla_X Z) = X \cdot \Omega(Y, Z) \quad \text{for all } X, Y, Z \in \mathfrak{X}(M).$$

Let $(G, \omega^+)$ be a symplectic Lie group. That $\nabla$ is a symplectic flat left invariant linear connection, means that there exists a bilinear product on $\mathfrak{g}$ verifying $\omega(xy, z) + \omega(y, xz) = 0$ for all $x, y, z \in \mathfrak{g}$. A direct calculation shows that $\nabla_1(-1)$ and $\nabla_2(-1/2)$ on $(Aff(\mathbb{R}), \omega^+)$ are symplectic flat affine connections.

It can also be verified that $(Aff(G), g^+, j^+)$ is a Kähler Lie group by taking the left invariant Riemannian metric $g^+$ with matrix $M(\langle , \rangle, \{e_1, e_2\}) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$ and the left invariant complex structure determined by $j^+(e_1) = -e_2$ and $j^+(e_2) = e_1$. This structure is holomorphic non-Ricci Flat (see 25 and 24).

5.3. **Geodesics in $Aff(\mathbb{R})_0$.** In terms of global coordinates $x$ and $y$, geodesics $\gamma(t) = (x(t), y(t))$ are solutions to the system of differential equations

$$\begin{cases}
\begin{aligned}
x''(t) + \Gamma^1_{1,1}[x'(t)]^2 + (\Gamma^1_{1,2} + \Gamma^1_{2,1})x'(t)y'(t) + \Gamma^1_{2,2}[y'(t)]^2 &= 0 \\
y''(t) + \Gamma^2_{1,1}[x'(t)]^2 + (\Gamma^2_{1,2} + \Gamma^2_{2,1})x'(t)y'(t) + \Gamma^2_{2,2}[y'(t)]^2 &= 0
\end{aligned}
\end{cases}$$
where $\Gamma^k_{ij}$ denote the Christoffel symbols of the connection

$$(e_i \cdot e_j)^+ = \nabla^+_{e_i} e_j^+ = \sum_{k=1}^2 \Gamma^k_{ij} e_k^+.$$

Since we are considering only left invariant connections, it is enough to know geodesics through the group identity $\epsilon = (1, 0)$, i.e., verifying the initial conditions $(x(0), y(0)) = (1, 0)$ and $(x'(0), y'(0)) = (a, b)$.

Below we display, for each affine structure in $A f f(\mathbb{R})_0$, the geodesics through $\epsilon$.

**Geodesics for $\nabla_1(\alpha)$**. For $a \neq 0$

$$
\begin{align*}
  x(t) &= 1 + \frac{1}{a} \ln |aat + 1| \\
  y(t) &= \frac{b(a+1)-aa}{a(a-1)} \left[(aat + 1)^{\frac{a-1}{a}} - 1\right] + \frac{1}{a-1} \ln |aat + 1|

eq\begin{cases}
  &\text{if } \alpha \notin \{0, 1\}.
\end{cases}
\end{align*}
$$

and for $a = 0$ we get

$$x(t) = 1 \quad \text{and} \quad y(t) = bt \quad \text{for any } \alpha$$

**Geodesics for $\nabla_2(\alpha)$**. For $a \neq 0$

$$
\begin{align*}
  x(t) &= 1 + \ln |at + 1| \\
  y(t) &= \frac{1}{2a} \ln |at + 1| [2b - a \ln |at + 1|]
\end{align*}
$$

and for $a = 0$ we get

$$x(t) = at + 1 \quad \text{and} \quad y(t) = \frac{b}{a} (1 - e^{-at}), \quad \text{if } \alpha = 0. \tag{8}$$

**Geodesics for $\nabla_1$.** For $a \neq 0$

$$x(t) = 1 + \ln |at + 1| \quad \text{and} \quad y(t) = \frac{b}{a} \ln |at + 1|.$$  
vara e a = 0

and for $a = 0$ we get

$$x(t) = 1 \quad \text{and} \quad y(t) = bt.$$  

**Geodesics for $\nabla_2$.** For $a \neq 0$

$$x(t) = 1 - \ln |1 - at| \quad \text{and} \quad y(t) = \frac{-b}{a} \ln |1 - at|$$
and for $a = 0$ we get
\[ x(t) = 1 \quad \text{and} \quad y(t) = bt. \]

**Geodesics for $\nabla_3$.** For $a$ and $b$ no both zero
\[ x(t) = \frac{1}{2} \ln |b^2t^2 + 2at + 1| + 1 \]
\[ y(t) = \arcsin \left( \frac{b^2t - a}{\sqrt{a^2 + b^2}} \right) + \arcsin \left( \frac{a}{\sqrt{a^2 + b^2}} \right). \]

**Geodesics for $\nabla_4$.** For $a \geq |b|
\[ x(t) = \frac{1}{2} \ln |b^2t^2 + 2at + 1| + 1 \]
\[ y(t) = \ln |b^2t + a| - \ln |a + b| \]
and for $|b| > a$ we have
\[ x(t) = \frac{1}{2} \ln |b^2t^2 + 2at + 1| + 1 \]
\[ y(t) = \frac{1}{2} \ln \left| \frac{b \sqrt{b^2t^2 + 2at + 1} + b^2t + a}{b \sqrt{b^2t^2 + 2at + 1} - b^2t - a} \right| - \frac{1}{2} \ln \left| \frac{b + a}{|b| - a} \right| \]
