Abstract—In this paper, we introduce an emerging quantum machine learning (QML) framework to assist classical deep learning methods for biosignal processing applications. Specifically, we propose a hybrid quantum-classical neural network model that integrates a variational quantum circuit (VQC) into a deep neural network (DNN) for electroencephalogram (EEG), electromyogram (EMG), and electrocorticogram (ECoG) analysis. We demonstrate that the proposed quantum neural network (QNN) achieves state-of-the-art performance while the number of trainable parameters is kept small for VQC.

Index Terms—Quantum computing, deep neural network (DNN), quantum machine learning (QML), electroencephalogram (EEG), electromyogram (EMG), biosignal processing

I. INTRODUCTION

The great advancement of artificial intelligence (AI) techniques based on deep neural networks (DNN) has enabled practical development of human-machine interfaces (HMI) including brain-computer interfaces (BCI) through the analysis of the user’s physiological data [1], such as electroencephalogram (EEG) [2] and electromyogram (EMG) [3]. However, such biosignals are highly prone to variation depending on the biological states of each subject [4]. Hence, frequent calibration is often required in typical HMI systems. Toward resolving this issue, subject-invariant methods [5]–[11], employing domain generalization and transfer learning, have been proposed to reduce user calibration for HMI systems.

In this paper, we introduce an emerging framework “quantum machine learning (QML)” [12]–[31] into biosignal processing applications for the first time in the literature, envisioning future era of quantum supremacy [32], [33]. Quantum computers have the potential to realize computationally efficient signal processing compared to traditional digital computers by exploiting quantum mechanisms, e.g., superposition and entanglement, in terms of not only execution time but also energy consumption. In the past few years, several vendors have successfully manufactured commercial quantum processing units (QPUs). For instance, IBM released 127-qubit QPUs in 2021, and plans to produce 1121-qubit QPUs by 2023. It is thus no longer far future when QML will be widely used for real applications. Recently, hybrid quantum-classical algorithms based on the variational principle [34]–[37] were proposed to deal with quantum noise.

The main contributions of this paper are summarized below:

• We introduce the emerging QML framework for biosignal processing;
• We propose a hybrid quantum-classic DNN model called quEEGNet;
• We demonstrate the proof-of-concept study on QML for various physiological datasets.

To the best of our knowledge, this is the very first research on QML applied to HMI and BCI fields. Although there exist a few literature [38], [39] discussing the potential use of quantum computing for BCI, no practical demonstration on QML-assisted HMI systems is found to date. Note that our QNN is different from a recurrent QNN (RQNN) employing quantum stochastic filtering based on the Shr鰀inger equation [40]–[43], which is motivated by quantum physics but does not need real QPUs. In addition, our work is tangential to quantum sensing technologies such as superconducting quantum interference devices (SQUID) [44].

II. QUANTUM ARTIFICIAL INTELLIGENCE (QAI) FOR HMI

A. Quantum Bit (Qubit)

In quantum systems, a qubit is expressed as the following state superposing bases of |0⟩ and |1⟩: |φ⟩ = α₀|0⟩ + α₁|1⟩, where α₀ and α₁ are complex numbers subject to |α₀|² + |α₁|² = 1. When qubits are measured, the classical bit 0 or 1 is observed with a probability of |α₀|² or |α₁|², respectively. The above ket-notation corresponds to column-vector operations of the two basis states |0⟩ = [1, 0]T and |1⟩ = [0, 1]T, whereas the bra-notation is used for row-vector operations corresponds to its Hermitian transpose; i.e., ⟨φ| = |φ⟩† = [α₀*, α₁*]T. Here, [·]†, [·]* and [·]T denote Hermitian transpose, complex conjugate and transpose, respectively. Note that a multi-qubit state is represented by sum of Kronecker products of basis vectors such as |00⟩ = |0⟩⊗|0⟩.

B. Quantum Gates

The basic operations on a qubit is defined as a unitary matrix, which is called gate. Some of the most common gates are associated with Pauli matrices: I = [1 0; 0 1], X = [0 1; 1 0], Y = [0 −j; j 0], and Z = [1 0; 0 −1], where j is the imaginary unit satisfying j² = −1. The X gate is bit-flip (i.e., NOT operation), Z gate is phase-flip, and Y gate flips both bit and phase. The Hadamard (H) gate is used to generate a superposition state |+) = 1/√2|0⟩ + 1/√2|1⟩: H = 1/√2 [1 1; 1 −1]. A controlled-NOT (CNOT) (CNOT or CX) gate is a multi-qubit gate that flips the target qubit if and only if the control qubit is |1⟩.

C. Quantum Machine Learning (QML)

A number of modern DNN methods have already migrated into the quantum domain, e.g., convolutional layers [12], autoencoders [13], graph neural networks [17], and
there are $2(n-1)L$ variational parameters $\{\theta\}$ over an $L$-layer S2D ansatz.

To feed multi-dimensional data, an input layer based on batch normalization is used to initialize the quantum state through the use of an amplitude embedding, which enables encoding up to $2^n - 1$ values for $n$-qubit QPUs. The multi-label task prediction is provided by quantum measurements in the Hamiltonian observable of Pauli-Z operations, followed by a post-processing layer to align the dimension. The variational parameters as well as input/output layers are optimized by a gradient method to minimize the softmax cross entropy loss. While QNN is not necessarily better than DNN in prediction accuracy, it can be computationally efficient by manipulating exponentially many quantum states in parallel with a small number of quantum gates.

We integrate the QNN with EEGNet, where the QNN performs as feature extraction and EEGNet works as the post-processing layers. Note that various other different combinations are possible, e.g., two individual VQC layers for temporal and spatial convolutions; VQC in recurrent networks. We refer to all such hybrid QNN+DNN concepts (not specific architectures) suited for biological analysis as a quantum EEGNet (qEEGNet) by convention.

## III. Experimental Evaluation

### A. Datasets

We use publicly available physiological datasets, summarized in Table I. These cover a wide variety of data size, dimensionality, and subject scale as well as sensor modalities, including EEG, EMG, and electrocorticography (ECoG).

| Dataset | Modality | Dimension | Subjects | Classes | Samples |
|---------|----------|-----------|----------|---------|---------|
| Stress [48] | Temp. etc. | $\times 1$ | 20 | 4 | 24,000 |
| RSVP [49] | EEG | $16 \times 128$ | 10 | 4 | 41,400 |
| MI [50] | EEG | $64 \times 480$ | 106 | 4 | 9,540 |
| ErP [51] | EEG | $56 \times 250$ | 27 | 2 | 9,180 |
| Faces Basic [52] | ECoG | $31 \times 400$ | 14 | 2 | 4,100 |
| Faces Needy [53] | ECoG | $39 \times 400$ | 7 | 2 | 2,100 |
| ASL [54] | EMG | $16 \times 50$ | 5 | 33 | 9,900 |

### D. Quantum Neural Network (QNN) for HMI

Fig. 1 shows an HMI system employing quantum-classical neural network model for biosignal processing. The system feeds biological waveform arrays to predict a task label through a neural network, which integrates a QNN model with a classical DNN model such as EEGNet [2]. The variational parameters for QNN and other trainable parameters for DNN are jointly optimized by stochastic gradient methods to minimize a loss function in an iterative manner.

Fig. 2 depicts an exemplar QNN model based on VQC employing the S2D ansatz [19], which consists of Pauli-Y rotations and staggered controlled-Z entanglers, to evolve the quantum states. This ansatz is a simplified variant of a 2-design whose statistical properties are identical to ensemble random unitaries with respect to the Haar measure up to the first 2 moments. For an $n$-qubit variational quantum circuit, generative adversarial networks [15], [16]. Interestingly, the number of QML articles has been exponentially increasing at the same rate of DNN articles, doubling every year, but just 6 years behind [28]. It suggests that QML will be potentially used in numerous communities in a couple of years. In fact, real QPUs are readily accessible through a cloud quantum server such as IBM QX and Amazon braket.

In analogy with DNN, it was proved that QNN holds the universal approximation property [45]. Accordingly, increasing the number of qubits and quantum layers may enjoy state-of-the-art DNN performance. In addition, quantum circuits are analytically differentiable [46], enabling stochastic gradient optimization of QNN. Nevertheless, QNN often suffers from a vanishing gradient issue called the barren plateau [47]. To mitigate the issue, a simplified 2-design (S2D) ansatz [19] was proposed to realize shallow entanglers for arbitrary unitary approximation. It is highly expected that quantum computers would offer breakthroughs in a wide range of fields.
were displayed rapidly in random sequence for 400 ms. Excluding irregular timestamps, the dataset consists of 106 subjects’ EEG data. The subjects were instructed to perform cue-based motor execution/imagery tasks while 64 channels were recorded at a sampling rate of 160 Hz. We use the EEG data for three seconds of post-cue interval data \((T = 480\) time samples). The subject performed 4-class tasks: right hand motor imagery; left hand motor imagery; both hands motor imagery; or both feet motor imagery.

4) **ErrP:** An error-related potential (ErrP) EEG dataset [51]. The dataset consists of EEG data recorded from 16 healthy subjects in an offline P300 spelling task, where visual feedback of the inferred letter is provided at the end of each trial for 1.3 seconds to monitor evoked brain responses for erroneous decisions made by the system. EEG data were recorded from 56 channels for epoched 1.25 seconds at a sampling rate of 200 Hz \((T = 250)\). Across 5 recording sessions, each subject performed a total of 340 trials.

5) **Faces Basic:** An implanted ECoG array dataset for visual stimulus experiments [52], [53]. ECoG arrays were implanted on the subtemporal cortical surface of 14 epilepsy patients. 2 classes of grayscale images, either faces or houses, were displayed rapidly in random sequence for 400 ms. The ECoG potentials were measured with respect to a scalp reference and ground, at a sampling rate of 1000 Hz. Subjects performed a basic face-vs-house discrimination task. We use the first 31 channels to analyze for \(T = 400\).

6) **Faces Noisy:** The implanted ECoG arrays dataset for visual stimulus experiments [52], [53]. The experiment is similar to Faces Basic dataset, while pictures of faces and houses are randomly scrambled. There are 7 subjects with 39 channels. Refer ethics statement to reuse the dataset.

7) **ASL:** An EMG dataset for finger gesture identification for American Sign Language (ASL) [54]. 5 healthy, right-handed, subjects participated in experiments with surface EMG (Delsys Trigio) recorded at 2 kHz from 16 lower-arm muscles. Subjects shaped their right hand into an ASL posture presented on a video screen (33 postures, 3 trials per posture). Dynamic letters ‘J’ and ‘Z’ were omitted, along with the number ‘0’, which is confusing with the letter ‘O’. The participants were given 2 seconds to form the posture and 6 seconds to maintain. The signal is decimated to be \(T = 50\).

### B. Model Implementation

We use PennyLane and PyTorch libraries to train quEEGNet. The trainable parameters are optimized by the adaptive momentum (Adam) with a learning rate of 0.1 for 50 epochs with a batch size of 128.

### C. Performance Results

Table II shows the performance comparison between EEGNet and quEEGNet. It was verified that the hybrid quantum-classical model outperforms classical neural networks for all of the physiological datasets. Since we have not explored different variants of quantum ansatz yet, it is expected that the performance can be further improved via AutoQML [30].

---

### IV. Conclusions

We proposed an emerging QML framework for HMI/BCI systems, considering the recent rapid advancement of quantum technology. Our hybrid quantum-classical neural network was demonstrated to achieve the state-of-the-art performance for various physiological datasets. As the application of QML to HMI/BCI fields is still at a proof-of-concept phase, there remain many open problems to explore for future work.
