Department of Pharmacology and Toxicology, Faculty of Pharmacy, University of Uyo, Uyo, Nigeria; Malaria Research Laboratory, International Centre for Genetic Engineering and Biotechnology, New Delhi, India; Department of Chemistry, University of Uyo, Uyo, Nigeria

**ABSTRACT**

**Context:** *Zea mays* L. (Poaceae) husk decoctions are traditionally used in the treatment of malaria by various tribes in Nigeria.

**Objective:** To assess the antimalarial and antiplasmodial potentials of the husk extract and fractions on malaria parasites using *in vivo* and *in vitro* models.

**Materials and methods:** The ethanol husk extract and fractions (187–748 mg/kg, p.o.) of *Zea mays* were investigated for antimalarial activity against *Plasmodium berghei* using rodent (mice) malaria models and *in vitro* activity against chloroquine sensitive (PF 3D7) and resistant (PF INDO) strains of *Plasmodium falciparum* using the SRBR green assay method. Median lethal dose and cytotoxic activities against HeLa and HEKS cells were also carried out. The GCMS analysis of the most active fraction was carried out.

**Results:** The husk extract (187–748 mg/kg, p.o.) with LD50 of 1874.83 mg/kg was found to exert significant (*p < 0.05–0.001*) antimalarial activity against *P. berghei* infection in suppressive, prophylactic and curative tests. The crude extract and fractions also exerted prominent activity against both chloroquine sensitive (PF 3D7) and resistant (PF INDO) strains of *P. falciparum* with the ethyl acetate fraction exerting the highest activity with IC50 values of 9.31 ± 0.46 µg/mL (PF 3D7) and 3.69 ± 0.66 µg/mL (PF INDO). The crude extract and fractions were not cytotoxic to the two cell lines tested with IC50 values of >100 µg/mL against both HeLa and HEKS cell lines.

**Discussion and conclusion:** These results suggest that the husk extract/fractions of *Zea mays* possesses antimalarial and antiplasmodial activities and these justify its use in ethnomedicine to treat malaria infections.

**Introduction**

*Zea mays* L. (Poaceae), known as maize or corn, is an annual grass plant cultivated for human consumption and as animal feed. It was introduced to Nigeria in the sixteenth century (Osagie & Eka 1998). It is tall with strong erect stalks and a fibrous root system. The plant has long narrow leaves that are spaced alternately on opposite side of the stem and bears ears that are enclosed in modified leaves known as husks (Simmonds 1979). Besides its nutritive values, maize grains, leaves, cornsilks, stalk, and inflorescence are also used in ethnomedicine for the treatment of several ailments. The corn silk is used as an antidiabetic or diuretic, and decoction of the silk is consumed for the treatment of urinary troubles and gallstones (Foster & Duke 1990; Gill 1992; Abo et al. 2008). The ash of the cob is used for the treatment of cough (Gill 1992) and inflammatory diseases. The husks are used for the treatment of pains and arthritis (Owoyel et al. 2010). Warm tea of the husks is used for the treatment of malaria and diabetes in Ibibio traditional medicine. Biological activities reported on the husk extract include; analgesic, anti-inflammatory (Owoyel et al. 2010), and antioxidant (Dong et al. 2014) activities. Arabininoxylan, which has immunological effects, has been isolated from the husk extract (Ogawa et al. 2005), while eight phenolic compounds (gallic acid, protocatechuic acid, chlorogenic acid, caffeic acid, ferulic acid, rutin, resveratrol, and kaempferol) have also been detected in ethanol husk extract of *Zea mays* (Dong et al. 2014). Information on the biological activities of the husk extract is scarce. We report in this study the antimalarial and antiplasmodial activity of the husk extract and fractions to confirm its use as malarial remedy in Ibibio ethnomedicine.

**Materials and methods**

**Collection of plant materials**

Fresh husks of *Zea mays* were collected in August, 2015 from Farmland in Uyo LGA, Akwa Ibom State, Nigeria. The husks were identified and authenticated as *Zea mays* by Dr. Margaret Bassey, a taxonomist in the Department of Botany and Ecological studies, University of Uyo, Uyo, Nigeria. Herbarium specimen (FPH, 614) was deposited at the Faculty of Pharmacy Herbarium, University of Uyo, Uyo.

**Extraction**

The plant parts (husks) were washed, cut into smaller pieces and air-dried for 2 weeks. The dried husks were pulverized using a pestle and mortar. The powdered husk was macerated in 50% ethanol for 72 h. The liquid ethanol extract obtained by filtration was evaporated to dryness in a rotary evaporator 40 °C. The crude
ethanol husk extract (20 g) was dissolved in 200 mL of distilled water and further partitioned successively into each of petroleum ether, chloroform, ethyl acetate and n-butanol to give the corresponding fractions of these solvents, while the residue was taken as aqueous fraction. The extract (yield 2.83%) and fractions were stored in a refrigerator at −4°C until they were used for the experiments reported in this study.

**Phytochemical screening**

Phytochemical screening of the crude husk extract was carried out employing standard procedures and tests (Trece & Evans 1989; Sofowora 1993), to reveal the presence of chemical constituents such as alkaloids, flavonoids, tannins, terpenes, saponins, anthraquinones, reducing sugars and cardiac glycosides.

**Animals**

Thirty Swiss albino mice (18–25 g) of either sex divided into five groups of 6 mice each per model were used for these experiments. The animals were housed in standard cages and were maintained on a standard pelleted feed (Guinea feed) and water ad libitum. Permission and approval for animal studies were obtained from the College of Health Sciences Animal Ethics Committee, University of Uyo.

**Parasites**

A chloroquine sensitive strain of *Plasmodium berghei* (ANKA) was obtained from the National Institute of Medical Research (NIMER), Yaba Lagos, Nigeria and was maintained by sub-passage in mice. While *Plasmodium falciparum* strains *Pf* 3D7 and *Pf* INDO were obtained from the International Center for Genetic Engineering and Biotechnology, New Delhi, India.

**Determination of acute toxicity of crude husk extract**

The median lethal dose (LD<sub>50</sub>) was determined for estimating acute toxicity of the crude husk extract in Swiss albino mice model using the method of Lorke (1983). This involved intraperitoneal administration of different doses of the extract (1000–5000 mg/kg) to groups of three mice each. The animals were observed for manifestation of physical signs of toxicity such as writhing, decreased motor activity, decreased body/limb tone, decreased respiration and death. The number of deaths in each group within 24 h was recorded.

**Parasite inoculation**

Each mouse used in the experiment was inoculated intraperitoneally with 0.2 mL of infected blood containing about 1 × 10<sup>7</sup> *P. berghei berghei* parasitized erythrocytes. The inoculum consisted of 5 × 10<sup>5</sup> *P. berghei berghiei* erythrocytes per mL. This was prepared by determining both the percentage parasitaemia and the erythrocytes count of the donor mouse and diluting the blood with isotonic saline in proportions indicated by both determinations (Odetola & Basir 1980).

**Drug administration**

The drug (artesunate) and extract used in the *in vivo* antiplasmodial study were orally administered with the aid of a stainless metallic feeding cannula.

**Evaluation of in vivo anti-malarial activity of ethanol crude extract**

This test was used to evaluate the schizontocidal activity of the extract and artesunate against early *P. berghei berghei* infection in mice. This was done as described by Knight and Peters (1980). Thirty mice were randomly divided into five groups of six mice each. On the first day (D<sub>0</sub>), the 30 mice were infected with the parasite and randomly divided into various groups. These were orally administered with the extract and artesunate. The mice in group 1 were administered 187 mg/kg, group 2, 374 mg/kg and group 3, 748 mg/kg of crude husk extract, while group 4 was administered 5 mg/kg of artesunate (positive control), and 10 mL/kg of distilled water was administered to group 5 (negative control) for four consecutive days (D<sub>0</sub>–D<sub>3</sub>) between 8 am and 9 am. On the fifth day (D<sub>4</sub>), thin blood film was made from tail blood of each mouse. The film was then stained with Giemsa stain to reveal parasitized erythrocytes out of 500 in a random field of the microscope. The average percentage suppression of parasitaemia was calculated in comparison with the controls as follows:

\[
\frac{\text{Average } \% \text{ parasitaemia in negative control} - \text{Average } \% \text{ parasitaemia in Positive groups}}{\text{Average } \% \text{ parasitaemia in negative control}} \times 100
\]

**Evaluation of suppressive activity of the extract (4-day test)**

This test was used to evaluate the schizontocidal activity of the extract and artesunate against early *P. berghei berghei* infection in mice. This was done as described by Ryley and Peters (1970). *Plasmodium berghei berghei* was injected intraperitoneally into another 30 mice on the first day (D<sub>0</sub>). Seventy-two hours later (D<sub>3</sub>), the mice were divided randomly into five groups of six mice each. Different doses of the extract, 187, 374 and 748 mg/kg were orally administered, respectively, to mice in groups 1–3, 5 mg/kg/day of artesunate (positive control) and 10 mL/kg of distilled water (negative control). Administration of the extract/drug continued for three consecutive days (D<sub>0</sub>–D<sub>2</sub>). On the fourth day (D<sub>4</sub>), the mice were inoculated with *P. berghie berghie*. The parasitaemia level of each mouse was assessed by blood smear 72 h later.

**Evaluation of prophylactic or repository activities of extract**

The repository activity of the extract and artesunate was assessed by using the method described by Peters (1965). The mice were randomly divided into five groups of six mice each. Groups 1–3 were orally administered 187, 374 and 748 mg/kg/day of the husk extract respectively, Groups 4 and 5 were respectively administered 5 mg/kg/day of artesunate (positive control) and 10 mL/kg of distilled water (negative control). Administration of the extract/drug continued for four consecutive days (D<sub>0</sub>–D<sub>3</sub>) between 8 am and 9 am. On the fifth day (D<sub>4</sub>), thin blood film was made from tail blood of each mouse. The film was then stained with Giemsa stain to reveal parasitized erythrocytes out of 500 in a random field of the microscope. The average percentage suppression of parasitaemia was calculated in comparison with the controls as follows:

\[
\frac{\text{Average } \% \text{ parasitaemia in negative control} - \text{Average } \% \text{ parasitaemia in Positive groups}}{\text{Average } \% \text{ parasitaemia in negative control}} \times 100
\]

**Evaluation of curative activities of extract (Rane's test)**

This was used to evaluate the schizontocidal activity of the extract, and artesunate in established infection. This was done as described by Ryley and Peters (1970). *Plasmodium berghei berghei* was injected intraperitoneally into another 30 mice on the first day (D<sub>0</sub>). Seventy-two hours later (D<sub>3</sub>), the mice were divided randomly into five groups of six mice each. Different doses of the extract, 187, 374 and 748 mg/kg were orally administered, respectively, to mice in groups 1–3, 5 mg/kg/day of artesunate was administered to the group 4 (positive control) and group 5 was given 10 mL/kg of distilled water (negative control). The extract and drugs were administered once daily for 5 days. Giemsa stained thin smears were prepared from tail blood samples collected on each day of treatment to monitor parasitaemia level. The mean survival time (MST) of the mice in each treatment group was determined over a period of 29 days (D<sub>0</sub>–D<sub>28</sub>).

\[
\frac{\text{No of days survived}}{\text{Total No. of days (29)}} \times 100 = \text{MST}
\]
Evaluation of in vitro antimalarial activity

In vitro cultivation of Plasmodium falciparum

CQ-sensitive strain 3D7 and CQ-resistant strain INDO of P. falciparum were used in this study to assess the antimalarial activity of the crude husk extract and fractions on erythrocytic stages in vitro. The culture was maintained at the Malaria Research Laboratory, International Centre for Genetic Engineering and Biotechnology, New Delhi, India. Plasmodium falciparum culture was maintained according to the method described by Trager and Jensen (1976) with minor modifications. Plasmodium falciparum (3D7) cultures were maintained in fresh O +ve human erythrocytes suspended at 4% hematocrit in RPMI 1640 (Sigma) containing 0.2% sodium bicarbonate, 0.5% albumax, 45 μg/L hypoxanthine, and 50 μg/L gentamicin and incubated at 37 °C under a gas mixture of 5% O₂, 5% CO₂, and 90% N₂. Every day, infected erythrocytes were transferred into fresh complete medium to propagate the culture. For Plasmodium falciparum (INDO strain) in culture medium, albumax was replaced by 10% pooled human serum.

Drug dilutions

Dimethyl sulfoxide (DMSO) was used to prepare the stock solutions of husk extract, fractions and artemisinin, while water (Milli-Q grade) was used in the case of CQ stock solution. Culture medium was used to dilute the stock solutions to their required concentrations exception of CQ. The final solution of each stock was constituted to contain nontoxic concentration of DMSO (0.4%), which was found to be harmless to the parasite. Drugs, husk extract and fractions were then placed in 96-well flat bottom tissue culture grade plates.

In vitro antimalarial assays

The crude husk extract and fractions of this plant were evaluated for their antimalarial activity against 3D7 and INDO strains of Plasmodium falciparum. For drug screening, SYBR green I-based fluorescence assay was set up as described previously (Smillie et al. 2004). Sorbitol synchronized parasites were incubated under normal culture conditions at 2% hematocrit and 1% parasitemia in the absence or presence of increasing concentrations of husk extract and fractions. CQ and artemisinin were used as positive controls, while 0.4% DMSO was used as the negative control. After 48 h of incubation, 100 μL of SYBR Green I solution (0.2 μL of 10,000 × SYBR Green I (Invitrogen)/mL) in lysis buffer (Tris (20 mM; pH 7.5), EDTA (5 mM), saponin (0.008%, w/v), and Triton X-100 (0.08%, v/v)) was added to each well and mixed twice gently with multi-channel pipette and incubated in dark at 37 °C for 48 h of incubation. 100 μL (20 mM; pH 7.5), EDTA (5 mM), saponin (0.008%, w/v), and Triton X-100 (0.08%, v/v)) was added to each well and mixed twice gently with multi-channel pipette and incubated in dark at 37 °C for 48 h of incubation. Formation of formazon was read on a microtiter plate reader. The fluorescence counts were plotted against the drug concentration and the 50% inhibitory concentration (IC₅₀) was determined by analysis of dose–response curves and IC₅₀ estimator. The identification of compounds present in the active fraction of the plants’ extract was based on direct comparison of the retention times and mass spectral data with those for standard compounds, and by computer matching with the Wiley and Nist Libraries (Adams 2001; Setzer et al. 2007).

Cytotoxic activity on HeLa and HEKs cells using MTT assay

The cytotoxic effects of extract and fractions on host cells were assessed by functional assay as described previously (Mosmann 1983) using HeLa cells cultured in RPMI containing 10% foetal bovine serum, 0.21% sodium bicarbonate (Sigma) and 50 μg/mL gentamicin (complete medium) and human embryonic kidney 293 cells cultured in DMEM and supplemented with 10% foetal bovine albumin. Briefly, cells (10⁴ cells/200 μL/well) were seeded into 96-well flat-bottom tissue culture plates in complete medium. Drug solutions were added after 24 h of seeding and incubated for 48 h in a humidified atmosphere at 37 °C and 5% CO₂. DMSO (as positive inhibitor) was added at 10%. A stock solution (20 μL) of MTT (5 mg/mL in 1 × phosphate buffered saline) was added to each well, gently mixed and incubated for another 4 h. After spinning the plate at 1500 rpm for 5 min, supernatant was removed and 100 μL of DMSO (stop agent) was added. Formation of formazon was read on a microtiter plate reader (Versa max tunable multi-well plate reader) at 570 nm. The 50% cytotoxic concentration (TC₅₀) of drug was determined by analysis of dose–response curves and IC₅₀ estimator.

Statistical analysis and data evaluation

Data obtained from this work were analyzed statistically using Student’s t-test and ANOVA (One-way) followed by a post test (Turkey–Kramer multiple comparison test). Differences between means was considered significant at 1% and 5% level of significance, that is p ≤ 0.01 and 0.05.

Results

Phytochemical screening

Results of phytochemical screening of the crude ethanol husk extract revealed the presence of chemical constituents such as...
alkaloids, flavonoids, tannins, terpenes, saponins, cardiac glycosides and sugars.

**Determination of acute toxicity of crude husk extract**

The median lethal dose (LD<sub>50</sub>) of the crude husk extract was calculated to be 1874.83 mg/kg. The physical signs of toxicity observed included excitation, paw licking, increased respiratory rate, decreased motor activity, gasping and coma, followed by death.

**Effect on suppressive activity of ethanol husk extract of Zea mays**

The extract showed a dose-dependent chemosuppressive effect on the parasitaemia. These effects were statistically significant relative to the control (p < 0.05–0.001). The chemoinhibitory percentages ranged from 34.58 to 69.18 (Table 1). However, the effect of the extract was weak compared to that of the standard drug, artemisinin, with a chemosuppression of 98.82% (Table 1).

**Effect on repository activity of ethanol husk extract of Zea mays**

The ethanol husk extract of Zea mays showed a dose-dependent chemosuppressive effect (65.89–81.85%) on the parasitaemia during prophylactic studies. These effects were statistically significant relative to the control (p < 0.001), but weak compared to that of the standard drug, artemisinin, with chemosuppression of 90.92% (Table 2).

**Antiplasmodial effect of ethanol husk extract of Zea mays on established infection**

The extract showed a dose-dependent schizonticidal effect on the parasitaemia. There were reductions in the percentage parasitaemia of the extract/artemisinin-treated groups compared to that of the control in which prominent increases were recorded. These reductions were statistically significant relative to the control (p < 0.05–0.001) (Figure 1). Though the extract showed a significant (p < 0.05–0.001) dose-dependent mean survival time on established infection, the effect of the extract (187–748 mg/kg) was weak compared to that of the standard drug, artemisinin (Table 3).

**In vitro antiplasmodial and cytotoxic activities**

The results of the in vitro studies showed that the plant extract and fractions displayed antiplasmodial activity against chloroquine sensitive Pf 3D7 and resistant Pf INDO strains of...
*P. falciparum* (Table 4). The ethyl acetate fraction was found to exhibit promising activity against both strains of *P. falciparum* with IC\(_{50}\) values of 9.31 ± 0.46 µg/mL (Pf 3D7) and 3.69 ± 0.66 µg/mL (Pf INDO). The potency order was ethyl acetate > chloroform > butanol > crude extract > petroleum ether. The crude extract and fractions were not cytotoxic to the two cell lines tested with TC\(_{50}\) of >100 µg/mL against both HeLa and HEKS cell lines.

**Discussion**

The husk extract of *Zea mays* used as malarial remedy by the Ibibio tribe of Nigeria was investigated for *in vivo* and *in vitro* antimalarial activities using standard models. Acute toxicity and cytotoxicity studies as well as phytochemical studies of the husk extract and fractions were carried out.

The median lethal dose (LD\(_{50}\)) which was determined to be 1874.83 mg/kg was found to be relatively safe with insignificant toxicity (Homburger 1989). The results of the *in vivo* study revealed that the crude extract significantly reduced parasitaemia in prophylactic, suppressive and curative models in a dose-dependent fashion confirming the antimalarial potential of this extract. These findings are further supported by the results of *in vitro* antiplasmodial activities of crude husk extract and fractions of *Z. mays*.

**GCMS analysis**

The GCMS analysis of the ethyl acetate fraction of *Zea mays* revealed the presence of bioactive compounds with major and minor ones as represented in Table 5.

the mean survival time of the extract-treated mice which was significantly prolonged compared to those of the control group demonstrating a significant protection potential of the extract. The results of in vitro study revealed that the husk extract and fractions had antiplasmodial activity against both chloroquine sensitive (3D7) and resistant (INDO) strains of Plasmodium falciparum with ethyl acetate fraction as the most active fraction. This suggests the localization of the active molecules in the ethyl acetate fraction. The results of the in vitro activity corroborated that of the in vivo study and confirm the antimalarial and antiplasmodial potentials of the husk extract. These findings further lay credence to the use of the husk of Zea mays in the treatment of malaria traditionally. Besides, the fact that the extract and fractions were active against the chloroquine-resistant strain (INDO) of P. falciparum implies that the husk extract can be an effective agent against chloroquine resistant malaria. The activities of the crude husk extract and fractions are predicated on the chemical constituents of the extract and fractions as revealed by the results of phytochemical screening of the crude husk extract and GCMS analysis of the active fraction.

The husk extract of Zea mays was found in this study to contain alkaloids, saponins, tannins, phlabatannins, flavonoids and cardiac glycosides. Some secondary metabolites of plants such as alkaloids, flavonoids and triterpenoids have been reported to possess antiplasmodial activity (Kirby et al. 1989; Philipsson & Wright 1991; Christensen & Kharazmi 2001). These chemical compounds which are present in this extract and fractions may in part be responsible for the observed antimalarial and antiplasmodial activities. Also, the GCMS analysis of the active ethyl acetate fraction revealed the presence of some pharmacologically active compounds such as phenolics and polyunsaturated fatty acids (PUFA) especially C-18 fatty acids among others. Polyunsaturated fatty acids such as p-hydroxyxynamic acid ethyl ester, stigmasterol, docosanoic acid ethyl ester, octadecanoic acid methyl ester, 9-octadecenoic acid (Z)-ethyl ester and hexadecanoic acid ethyl ester have been implicated in antiplasmodial activity and this activity has been reported to increase with the degree of unsaturation (Kumaratilake et al. 1992; Kruglik et al. 1995; Suksamrarn et al. 2005; Attioua et al. 2007; Melariri et al. 2011, 2012; Zofou et al. 2011, 2012; Zhai et al. 2014). Similarly, Dong et al. (2014) had reported the presence of polyphenolics such as gallic acid, protocatechuic acid, chlorogenic acid, caffeic acid, fucose acid, rutin, resveratrol, and kaempferol in the husk extract Zea mays. Gallic acid and kaempferol are implicated in the antimalarial activities of plants (Horgen et al. 1997; Teffo et al. 2010; Barliana et al. 2014). Rutin has been shown to possess significant antiplasmodial activity against chloroquine sensitive and resistant strains of P. falciparum with IC_{50} of 3.53 ± 13.34 μM against 3D7 and 15.00 μM against K1 (Attoua et al. 2011). These compounds present in this fraction are likely to be responsible for the observed antiplasmodial activity. Besides, antioxidant potentials of some plant and natural products especially flavonoids have been found to promote schizonticidal activity by modulating the cellular signalling pathway (Al-Adhroey et al. 2011) and this has been suggested to be responsible for antiplasmodial activity of compounds such as quercetin (Cimanga et al. 2009; Ganesh et al. 2012), as elevated free radicals levels which are common features of malaria disease are implicated in severe malaria complications. This could be one of the modes of action of this extract as it contains phenolics and flavonoids with antioxidant activity (Dong et al. 2014).

Flavonoids are known to exert antiplasmodial activity by chelating with nucleic base pairing of the parasite (Lui et al. 1992), while the plasmodicidal activities of terpenes and their derivatives such as monoterpenes and sesquiterpenes have been linked to endoperoxidation (Hatzakis et al. 2007). These compounds (flavonoids and terpenes) present in this plant extract may have contributed to the plasmodicidal activity of this extract and therefore explained the mechanism of antiplasmodial effect of the extract.

Conclusion

The results of this study indicate that the husk of Zea mays plant possesses significant in vivo antimalarial activity against P. berghei infection in mice and in vitro antiplasmodial activity against chloroquine sensitive and resistant strains of P. falciparum. These findings justify and confirm the ethno botanical usage of this plant in the treatment of malaria. Therefore, further research on ethanol husk extract and fractions of Zea mays could be carried out in order to isolate, identify and characterize the active principle from this plant.
