Amplitude analysis and branching-fraction measurement of $D_s^+ \rightarrow K_S^0 \pi^+ \pi^0$

The BESIII collaboration

E-mail: besiii-publications@ihep.ac.cn

ABSTRACT: By using 6.32 fb$^{-1}$ of data collected with the BESIII detector at center-of-mass energies between 4.178 and 4.226 GeV, we perform an amplitude analysis of the decay $D_s^+ \rightarrow K_S^0 \pi^+ \pi^0$ and determine the relative fractions and phase differences of different intermediate processes, which include $K_S^0 \rho(770)^+$, $K_S^0 \rho(1450)^+$, $K^*(892)^0 \pi^+$, $K^*(892)^+ \pi^0$, and $K^*(1410)^0 \pi^+$. With the detection efficiency based on the amplitude analysis results, the absolute branching fraction is measured to be $B(D_s^+ \rightarrow K_S^0 \pi^+ \pi^0) = (5.43 \pm 0.30_{\text{stat}} \pm 0.15_{\text{syst}}) \times 10^{-3}$.

1 Introduction

Knowledge of $D_s^\pm$ decay properties are vital input for studies of the $B_s^0$ hadron, whose decay channels are dominated by the final states involving $D_s^\pm$ mesons [1]. Furthermore, hadronic $D_s^\pm$ decays probe the interplay of short-distance weak-decay matrix elements and long-distance QCD interactions, and the measured branching fractions (BFs) provide valuable information concerning the amplitudes and phases that the strong force induces in the decay process [2–4]. The singly Cabibbo-suppressed (SCS) decay $D_s^+ \to K_S^0 \pi^+ \pi^0$ has a large BF of the order of $10^{-2}$ [1]. This decay, therefore, is often used as a reference channel for the other decays of $D_s^\pm$ mesons. Accurate knowledge of its substructure is essential to reduce the systematic uncertainties in those analyses using this channel. To date, there have been few measurements of charge-parity asymmetries $A_{CP}$ in SCS $D_s^\pm$ decay modes in general [5, 6] and none for the mode discussed here.

An amplitude analysis of the $D_s^+$ decay to a three-body pseudoscalar meson final state is a powerful tool for studying the vector-pseudoscalar channels of the SCS $D_s^+$ decay. Table 1 shows the current measured values and theoretical predictions, in various models, for the BFs of $D_s^+ \to K_S^0 \rho^+, K^*(892)^0 \pi^+$, and $K^*(892)^+ \pi^0$ ($\rho^+$ denotes $\rho(770)^+$ throughout this paper). References [7] and [8] took into account quark flavor SU(3) symmetry and its

breaking effects. Reference [4] used a generalized factorization method considering the resonance effects in the pole model for the annihilation contributions and introducing large strong phases between different topological diagrams. More precise experimental results are required to validate or falsify these theoretical predictions.

The CLEO collaboration has reported a measurement of $B(D_s^+ \to K^0\pi^+\pi^0) = (1.00 \pm 0.18)\%$ [9], using 600 pb$^{-1}$ of $e^+e^-$ collisions recorded at a center-of-mass energy ($\sqrt{s}$) of 4.17 GeV. In this paper, by using 6.32 fb$^{-1}$ of data collected with the BESIII detector at $\sqrt{s} = 4.178$–4.226 GeV, we perform the first amplitude analysis of $D_s^+ \to K^0_{S}\pi^+\pi^0$ and improve the measurement of its absolute BF.

2 Detector and data sets

The BESIII detector is a magnetic spectrometer [10, 11] located at the Beijing Electron Positron Collider (BEPCII) [12]. The cylindrical core of the BESIII detector consists of a helium-based multilayer drift chamber (MDC), a plastic scintillator time-of-flight system (TOF), and a CsI(Tl) electromagnetic calorimeter (EMC), which are all enclosed in a superconducting solenoidal magnet providing a 1.0 T magnetic field. The solenoid is supported by an octagonal flux-return yoke with resistive plate counter muon identifier modules interleaved with steel. The acceptance of charged particles and photons is 93% over a 4$\pi$ solid angle. The charged-particle momenta resolution at 1.0 GeV/$c$ is 0.5%, and the specific energy loss ($dE/dx$) resolution is 6% for the electrons from Bhabha scattering. The EMC measures photon energies with a resolution of 2.5% (5%) at 1 GeV in the barrel (end-cap) region. The time resolution of the TOF barrel part is 68 ps, while that of the end-cap part is 110 ps. The end-cap TOF was upgraded in 2015 with multi-gap resistive plate chamber technology, providing a time resolution of 60 ps [13–15].

The data samples used in this analysis are listed in table 2. For some aspects of the analysis, these samples are organized into three sample groups, 4.178 GeV, 4.189–4.219 GeV, and 4.226 GeV, that were acquired during the same year under consistent running conditions. Since the cross section of $D^+_sD^-_s$ production in $e^+e^-$ annihilation is about a factor of twenty larger than that of $D^+_sD^-_s$ [16], and the $D^{\pm}$ mesons decays to $\gamma D^{\pm}_s$ with a dominant BF of $(93.5 \pm 0.7)\%$ [1], the signal events discussed in this paper are selected from the process $e^+e^- \to D^{\pm}_sD^{\mp}_s \to \gamma D^{\pm}_sD^{\mp}_s$.

Simulated samples are produced with the geant4-based [17] Monte Carlo (MC) package, which includes the geometric description of the BESIII detector and the detector

Table 2. The integrated luminosities ($\mathcal{L}_{\text{int}}$) and the requirements on $M_{\text{rec}}$ for various collision energies. The definition of $M_{\text{rec}}$ is given in eq. (3.1). The first and second uncertainties are statistical and systematic, respectively.

response. These samples are used to determine the detection efficiency and to estimate the background. The simulation includes the beam-energy spread and initial-state radiation (ISR) in $e^+e^-$ annihilations modeled with the generator KKMC [18]. The generic MC samples consist of the production of $D\bar{D}$ pairs with consideration of quantum coherence for all neutral $D$ modes, the non-$D\bar{D}$ decays of the $\psi(3770)$, the ISR production of the $J/\psi$ and $\psi(3686)$ states, and the continuum processes. The known decay modes are modeled with EVTGEN [19, 20] using the BFs taken from the Particle Data Group (PDG) [1], and the remaining unknown decays from the charmonium states with LUNDCHARM [21, 22]. Final-state radiation from charged particles is incorporated with the PHOTOS [23] package.

3 Event selection

The data samples were collected just above the $D_s^{*\pm}D_s^{\mp}$ threshold. The tag method allows clean signal samples to be selected, which provide an opportunity to perform amplitude analyses and to measure the absolute BFs of the hadronic $D_s^{\pm}$ meson decays. In the tag method, a single-tag (ST) candidate requires only one of the $D_s^{\pm}$ mesons to be reconstructed via a hadronic decay; a double-tag (DT) candidate has both $D_s^+D_s^-$ mesons reconstructed via hadronic decays. The DT candidates are required to have the $D_s^+$ meson decaying to the signal mode $D_s^+ \rightarrow K_S^0\pi^+\pi^0$ and the $D_s^-$ meson decaying to a tag mode. (Charge conjugation is implied throughout this paper.) Nine tag modes are reconstructed and the corresponding mass windows on the tagging $D_s^-$ mass ($M_{\text{tag}}$) are listed in table 3. The $D_s^{\pm}$ candidates are constructed from individual $\pi^\pm$, $K^\pm$, $\eta$, $\eta'$, $K_S^0$ and $\pi^0$ particles.

Charged track candidates from the MDC must satisfy $|\cos\theta| < 0.93$, where $\theta$ is the polar angle with respect to the direction of the positron beam. The closest approach to the interaction point is required to be less than 10 cm along the beam direction and less than 1 cm in the plane perpendicular to the beam. Particle identification (PID) of charged particles is implemented by combining the dE/dx information in the MDC and the time-of-flight information from the TOF system. For charged kaon (pion) candidates, the probability for the kaon (pion) hypothesis is required to be larger than that for the pion (kaon) hypothesis.
Tag mode Mass window (GeV/c²)

| Tag mode                  | Mass window (GeV/c²) |

Table 3. Requirements on $M_{\text{tag}}$ for various tag modes, where the $\eta$ and $\eta'$ subscripts denote the decay modes used to reconstruct these particles.

The $K^0_S$ mesons are reconstructed with pairs of two oppositely charged tracks, which satisfy $|\cos \theta| < 0.93$ and the distances of closest approach along the beam direction must be less than 20 cm. The decay length of the reconstructed $K^0_S$ in the signal side decay is required to be more than twice that of the vertex resolution away from the interaction point. The invariant masses of these charged track pairs are required to be in the range $[0.487, 0.511]$ GeV/c², which is about three times the resolution of the detector.

Photons are reconstructed from the clusters of deposited energy in the EMC. The shower time is required to be within $[0, 700]$ ns of the event start time in order to suppress electronics noise or $e^+e^-$ beam background. Photon candidates within $|\cos \theta| < 0.80$ (barrel) are required to have an energy deposition larger than 25 MeV and those with $0.86 < |\cos \theta| < 0.92$ (end-cap) must have an energy deposition larger than 50 MeV. To suppress the noise from hadronic shower splitoffs, the calorimeter positions of photon candidates must lie outside a cone of $10^\circ$ from all charged tracks. The $\pi^0$ ($\eta$) candidates are reconstructed through $\pi^0 \to \gamma\gamma$ ($\eta \to \gamma\gamma$) decays, with at least one barrel photon. The invariant mass of the photon pair for $\pi^0$ and $\eta$ candidates must be in the ranges $[0.115, 0.150]$ GeV/c² and $[0.490, 0.580]$ GeV/c², respectively, which are about three times the resolution of the detector. A kinematic fit that constrains the $\gamma\gamma$ invariant mass to the $\pi^0$ or $\eta$ nominal mass [1] is performed to improve the mass resolution. The $\chi^2$ of the kinematic fit is required to be less than 30. The $\eta'$ candidates are formed from the $\pi^+\pi^-\eta$ combinations with an invariant mass within a range of $[0.946, 0.970]$ GeV/c².

$D_s^\pm$ candidates with $M_{\text{rec}}$ lying with the mass windows listed in table 2 are retained for further study. The quantity $M_{\text{rec}}$ is defined as

$$M_{\text{rec}} = \sqrt{(E_{\text{cm}} - \sqrt{p_{D_s}^2 + m_{D_s}^2})^2 - p_{D_s}^2}, \quad (3.1)$$

where $E_{\text{cm}}$ is the initial energy of the $e^+e^-$ center-of-mass system, $p_{D_s}$ is the three-momentum of the $D_s^\pm$ candidate in the $e^+e^-$ center-of-mass frame, and $m_{D_s}$ is the $D_s^\pm$ nominal mass [1].
A “$K_S^0K$” veto and a “$D^0$” veto are applied on the signal $D_s^+$ candidates. The Cabibbo-favored $D_s^+ \to K_S^0K^+$ decay contributes to the background when the $K^+$ is misidentified as a $\pi^+$. This background is reduced by a veto on the signal $D_s^+$ with $M_{K_S^0K^+} - m_{D_s} < -20\text{ MeV}/c^2$, where $M_{K_S^0K^+}$ is the invariant mass of the $K_S^0$ and reconstructed $\pi^+$ track but assumed to be a kaon. There is also swap background where $D^0 \to K_S^0K^+\pi^0$ versus $D^0 \to K^+\pi^-\pi^0$ fake $D_s^+ \to K_S^0\pi^+\pi^0$ versus $D_s^- \to K^+K^-\pi^-$ events through the exchange of $K_S^0$ and $K^+$, or $\pi^0$ and $K^-$. Events which simultaneously satisfy $|M_{K_S^0K^+} - m_{D^0}| < 30\text{ MeV}/c^2$ and $|M_{K^+\pi^-\pi^0} - m_{D^0}| < 30\text{ MeV}/c^2$ are rejected, where $M_{K_S^0K^+}$ ($M_{K^+\pi^-\pi^0}$) is the invariant mass of the $K_S^0K^+ (K^+\pi^-\pi^0)$ combination and $m_{D^0}$ is the $D^0$ nominal mass [1].

4 Amplitude analysis of $D_s^+ \to K_S^0\pi^+\pi^0$

4.1 Event selection

The following selection criteria are further applied in order to obtain data samples with high purities for the amplitude analysis. The selection criteria discussed in this section are not used in the BF measurement.

An eight-constraint kinematic fit is performed assuming the process $e^+e^- \to D_s^{\pm}\bar{D}_s^\mp \to \gamma D_s^+ D_s^-$, with $D_s^-$ decaying to one of the tag modes and $D_s^+$ decaying to the signal mode. The combination with the minimum $\chi^2$ is chosen, assuming that a $D_s^{\pm}$ meson decays to $D_s^+\gamma$ or a $D_s^{\mp}$ meson decays to $D_s^-\gamma$. In addition to the constraints of four-momentum conservation in the $e^+e^-$ center-of-mass system, the invariant masses of $(\gamma\nu)_\pi$, $(\pi^+\pi^-)_K$, tag $D_s^-$, and $D_s^{\pm}$ candidates are constrained to the corresponding nominal masses [1]. In order to ensure that all candidates fall within the phase-space boundary, the constraint of the signal $D_s^+$ mass is added to the kinematic fit and the updated four-momenta are used for the amplitude analysis.

Moreover, it is required that the energy of the transition photon from $D_s^{\pm}\to \gamma D_s^\pm$ is smaller than 0.18 GeV and the mass recoiling against this photon and the signal $D_s^+$ candidate lies within the range [1.952, 1.995] GeV/$c^2$. Figure 1 shows the fits to the invariant-mass distributions of the accepted signal $D_s^+$ candidates, $M_{\text{sig}}$, for various data samples. The signal is described by an MC-simulated shape convolved with a Gaussian resolution function, and the background is described by a second-order Chebyshev function. Finally, a mass window, [1.930, 1.990] GeV/$c^2$, is applied on the signal $D_s^+$ candidates. There are 352, 193, and 64 events retained for the amplitude analysis with purities, $w_{\text{sig}}$, of $(88.9 \pm 6.8)\%$, $(84.6 \pm 8.3)\%$, and $(75.9 \pm 14.3)\%$ for the data samples at $\sqrt{s} = 4.178$ GeV, 4.189–4.219 GeV, and 4.226 GeV, respectively.

4.2 Fit method

The intermediate-resonance composition in the decay $D_s^+ \to K_S^0\pi^+\pi^0$ is determined by an unbinned maximum-likelihood fit to data. The likelihood function is constructed with a probability density function (PDF), which depends on the momenta of the three daughter particles. The amplitude of the $n$th intermediate state ($A_n$) is

$$A_n = P_nS_nF_n^TF_n^D,$$

(4.1)
Figure 1. Fits to the $M_{\text{sig}}$ distributions of the data samples at $\sqrt{s}$ = (a) 4.178 GeV, (b) 4.189–4.219 GeV, and (c) 4.226 GeV. The black points with error bars are data. The blue solid lines are the total fits. The red dotted and the black dashed lines are the fitted signal and background, respectively. The pairs of red arrows indicate the signal regions.

where $S_n$ and $F_n^{(D)}$ are the spin factor and the Blatt-Weisskopf barriers of the intermediate state (the $D_\pm$ meson), respectively, and $P_n$ is the propagator of the intermediate resonance.

The total amplitude $M$ is then the coherent sum of the amplitudes of intermediate processes, $M = \sum c_n A_n$, where $c_n = \rho_n e^{i\phi_n}$ is the corresponding complex coefficient. The magnitude $\rho_n$ and phase $\phi_n$ are free parameters in the fit, and are defined relative to those of a reference mode, for which they are fixed. The signal PDF $f_S(p_j)$ is given by

$$f_S(p_j) = \frac{\epsilon(p_j) |M(p_j)|^2 R_3(p_j)}{\int \epsilon(p_j) |M(p_j)|^2 R_3(p_j) dp_j},$$

where $\epsilon(p_j)$ is the detection efficiency parameterized in terms of the final four-momenta $p_j$. The index $j$ refers to the different particles in the final states, and $R_3(p_j)$ is the standard element of three-body phase space. The normalization integral is determined by an MC integration,

$$\int \epsilon(p_j) |M(p_j)|^2 R_3(p_j) dp_j \approx \frac{1}{N_M} \sum_{k=1}^{N_M} \left| \frac{M(p_{j,k}^p)}{M^g(p_{j,k}^p)} \right|^2,$$

where $k$ is the index of the $k$th event and $N_M$ is the number of the selected MC events. Here $M^g(p_j)$ is the PDF used to generate the MC samples in MC integration. To account for any bias caused by differences in PID and tracking efficiency between data and MC simulation, each signal MC event is weighted with a ratio, $\gamma_\epsilon(p_j)$, of the efficiency of data to that of MC simulation and the MC integration then becomes

$$\int \epsilon(p_j) |M(p_j)|^2 R_3(p_j) dp_j \approx \frac{1}{N_M} \sum_{k=1}^{N_M} \left| \frac{M(p_{j,k}^p)}{M^g(p_{j,k}^p)} \right|^2 \gamma_\epsilon(p_{j,k}^p).$$

A signal-background combined PDF is introduced to account for the approximate 15% of background in this analysis. The background PDF is given by

$$f_B(p_j) = \frac{B(p_j)R_3(p_j)}{\int B(p_j)R_3(p_j) dp_j}.$$
The background events in the signal region from the generic MC sample are used to model the corresponding background in data. The \(M_{K^0\pi^+}\), \(M_{K^0\pi^0}\), and \(M_{\pi^+\pi^0}\) distributions of events outside the \(M_{\text{sig}}\) signal region between the data and the generic MC samples are compared to check validity of the background from the generic MC samples. The distributions of background events from the generic MC samples within and outside the \(M_{\text{sig}}\) signal region are also examined. They are found to be compatible within statistical uncertainties.

The background shape \(B(p_j)\) is derived using RooNDKeysPdf \([24]\). RooNDKeysPdf is a kernel estimation method \([25]\) implemented in RooFit \([24]\) which models the distribution of an input dataset as a superposition of Gaussian kernels. This background PDF is then added to the signal PDF incoherently and the combined PDF is written as

\[
W_{\text{sig}} f_S(p_j) + (1 - W_{\text{sig}}) f_B(p_j) = W_{\text{sig}} \frac{\epsilon(p_j) |M(p_j)|^2 R_3(p_j)}{\int \epsilon(p_j) |M(p_j)|^2 R_3(p_j) \, dp_j} + (1 - W_{\text{sig}}) \frac{B(p_j) R_3(p_j)}{B(p_j) R_3(p_j) \, dp_j}. \tag{4.6}
\]

A efficiency-corrected background shape, \(B(p_j) = \epsilon(p_j)/\epsilon(p_j)\) is introduced in order to factorize the \(\epsilon(p_j)\) term out from the combined PDF. In this way, the \(\epsilon(p_j)\) term, which is independent of the fitted variables, is regarded as a constant and can be dropped during the log-likelihood fit. As a consequence, the combined PDF becomes

\[
W_{\text{sig}} f_S(p_j) + (1 - W_{\text{sig}}) f_B(p_j) = \epsilon(p_j) R_3(p_j) \left[ \frac{W_{\text{sig}} |M(p_j)|^2}{\int \epsilon(p_j) |M(p_j)|^2 R_3(p_j) \, dp_j} \right. \\
\left. + \frac{(1 - W_{\text{sig}}) B_3(p_j)}{\int \epsilon(p_j) B_3(p_j) R_3(p_j) \, dp_j} \right]. \tag{4.7}
\]

Next, the integration in the denominator of the background term can also be handled by the MC integration method in the same way as for the signal only sample:

\[
\int \epsilon(p_j) B_3(p_j) R_3(p_j) \, dp_j \approx \frac{1}{N_M} \sum_{k=1}^{N_M} B_3(p_j^k)/M_3(p_j^k)^2. \tag{4.8}
\]

Eventually, the log-likelihood is written as

\[
\ln L = \sum_{i=1}^{3} \sum_{D=1}^{N_{D,i}} \ln \left[ W_{\text{sig}} f_S(p_j^k) + (1 - W_{\text{sig}}) f_B(p_j^k) \right], \tag{4.9}
\]

where \(i\) indicate the data sample and \(N_D\) is the number of candidate events in data.

### 4.2.1 Blatt-Weisskopf barrier factors

For the process \(a \rightarrow bc\), the Blatt-Weisskopf barrier \(F_L(p_j)\) is parameterized as a function of the angular momenta \(L\) and the momenta \(q\) of the daughter \(b\) or \(c\) in the rest system of \(a\),

\[
F_{L=0}(q) = 1, \\
F_{L=1}(q) = \sqrt{\frac{z_0^2 + 1}{z_0^2 + 1}}, \\
F_{L=2}(q) = \sqrt{\frac{z_0^2 + 3z_0^2 + 9}{z_0^4 + 3z_0^2 + 9}}, \tag{4.10}
\]

- 7 -
where \( z = qR \) and \( z_0 = q_0R \). The effective radius of the barrier \( R \) is fixed to 3.0 GeV\(^{-1}\) for the intermediate resonances and 5.0 GeV\(^{-1}\) for the \( D^+_s \) meson.

### 4.2.2 Propagator

The intermediate resonances \( K^*(892)^{0,+} \) and \( K^*(1410)^0 \) are parameterized as relativistic Breit-Wigner functions,

\[
P = \frac{1}{(m_0^2 - s_a) - i m_0 \Gamma(m)},
\]

\[
\Gamma(m) = \Gamma_0 \left( \frac{q}{q_0} \right)^{2L+1} \left( \frac{m_0}{m} \right) \left( \frac{F_L(q)}{F_L(q_0)} \right)^2,
\]

where \( s_a \) denotes the invariant-mass squared of the parent particle; \( m_0 \) and \( \Gamma_0 \) are the rest masses and the widths of the intermediate resonances, respectively, and are fixed to the PDG values [1].

We parameterize the \( \rho^+ \) and \( \rho(1450)^+ \) resonances by the Gounaris-Sakurai line-shape [26], which is given by

\[
P_{GS}(m) = \frac{1 + d \Gamma_0}{(m_0^2 - m^2) + f(m) - i m_0 \Gamma(m)}.
\]

The function \( f(m) \) is given by

\[
f(m) = \Gamma_0 \frac{m_0^2}{q_0^2} \left[ q^2 (h(m) - h(m_0)) + (m_0^2 - m^2) q_0^2 \frac{dh}{d(m^2)} \right]_{m_0^2},
\]

where

\[
h(m) = \frac{2q}{\pi m} \ln \left( \frac{m + 2q}{2m_\pi} \right),
\]

and

\[
\frac{dh}{d(m^2)} \bigg|_{m_0^2} = h(m_0) \left[ (8q_0^2)^{-1} - (2m_0^2)^{-1} \right] + (2\pi m_0^2)^{-1}.
\]

The normalization condition at \( P_{GS}(0) \) fixes the parameter \( d = f(0)/(\Gamma_0 m_0) \). It is found to be

\[
d = \frac{3m_\pi^2}{\pi q_0^2} \ln \left( \frac{m_0 + 2q_0}{2m_\pi} \right) + \frac{m_0}{2\pi q_0} - \frac{m_\pi^2 m_0}{\pi q_0^3}.
\]

### 4.2.3 Spin factors

The spin-projection operators are defined as [27]

\[
P_{\mu\nu}^{(1)}(a) = -g_{\mu\nu} + \frac{p_a \cdot \vec{P}_{a'} \cdot \vec{p}_{a'}}{p_a^2},
\]

\[
P_{\mu\nu;\mu'}^{(2)}(a) = \frac{1}{2} \left( P_{\mu\nu}^{(1)}(a) P_{\nu\mu'}^{(1)}(a) + P_{\mu\nu'}^{(1)}(a) P_{\nu\mu}^{(1)}(a) \right) - \frac{1}{3} P_{\mu\nu}^{(1)}(a) P_{\mu'\nu'}^{(1)}(a).
\]

The quantities \( p_a, p_b, \) and \( p_c \) are the momenta of particles \( a, b, \) and \( c \), respectively, and \( r_a = p_b - p_c \). The covariant tensors are given by

\[
\tilde{t}_\mu^{(1)}(a) = -P_{\mu\nu}^{(1)}(a) r_a^\nu, \quad \tilde{t}_\mu^{(2)}(a) = P_{\mu\nu;\mu'}^{(2)}(a) r_{a'}^\nu.
\]
The spin factors for $S$, $P$, and $D$ wave decays are

$$S = 1,$$  
$$S = \tilde{T}^{(1)\mu}(D_s^\pm)\tilde{t}^{(1)}(a),$$  
$$S = \tilde{T}^{(2)\mu\nu}(D_s^\pm)\tilde{t}^{(2)}(a),$$

(4.19)

where the $\tilde{T}^{(l)}$ factors have the same definition as $\tilde{t}^{(l)}$. The tensor describing the $D_s^+$ decay is denoted by $\tilde{T}$ and that of the $a$ decay is denoted by $\tilde{t}$.

### 4.3 Fit results

The Dalitz plot of $M_{K_S}^2$ versus $M_{K_S}^2$ summed over all the data samples is shown in figure 2. One can see an anti-diagonal band corresponding to $K^0_S\rho^+$. In the fit, the magnitude and phase of the reference amplitude $D_s^+ \rightarrow K^0_S\rho^+$ are fixed to 1.0 and 0.0, respectively, while that of other amplitudes are floated. The masses and widths of all resonances are fixed to the corresponding PDG averages [1], and $w_{\text{sig}}$ are fixed to the purities discussed in section 4.1. The systematic uncertainties associated with these fixed parameters will be considered by repeating the fit after variation of the tested ones. In addition to the dominating amplitude $D_s^+ \rightarrow K^0_S\rho^+$, we have tested for the contribution of all possible intermediate resonances including $K^*(892)^0$, $K^*(892)^+$, $K^*(1410)$, $K_0^*(1430)$, $K_2^*(1430)$, $\rho(1450)$, $K^*(1680)$, $\rho(1700)$, etc. We find that $D_s^+ \rightarrow K_0^0\rho(1450)^+$, $D_s^+ \rightarrow K^{*+}(892)\pi^0$, and $K^*(1410)^0\pi^+$ have a statistical significance greater than three standard deviations and retain these amplitudes in the final model.

The calculation of the fit fractions (FFs) for individual amplitudes, involves the phase-space MC truth information without detector acceptance or resolution effects. The FF for
The uncertainties are statistical only. The systematic uncertainties for the amplitude analysis are summarized in table 6, with their assignment described below. The interference between amplitudes is listed in table 5. The Dalitz plot projections are shown in figure 3. The assignment of systematic uncertainties is discussed in next section.

### 4.4 Systematic uncertainties for amplitude analysis

The systematic uncertainties for the amplitude analysis are summarized in table 6, with their assignment described below.

- i Resonance parameters. The masses and the widths of $\rho^+$, $\rho(1450)^+$, $K^*(892)^0(+)$, and $K^*(1410)^0$ are shifted by their corresponding uncertainties [1].

| Amplitude | Magnitude ($\rho_n$) | Phase ($\phi_n$) | FF (%) | Significance ($\sigma$) |
|-----------|---------------------|----------------|--------|------------------------|
| $D_s^+ \to K_S^0 \rho^+$ | 1.0 (fixed) | 0.0 (fixed) | 50.2 $\pm$ 7.2 $\pm$ 3.9 | $>10$ |
| $D_s^+ \to K_S^0 \rho(1450)^+$ | 2.7 $\pm$ 0.5 | 2.2 $\pm$ 0.2 $\pm$ 0.1 | 20.4 $\pm$ 4.3 $\pm$ 4.4 | $>10$ |
| $D_s^+ \to K^*(892)^0 \pi^+$ | 0.4 $\pm$ 0.1 | 3.2 $\pm$ 0.2 $\pm$ 0.1 | 8.4 $\pm$ 2.2 $\pm$ 0.9 | 5.0 |
| $D_s^+ \to K^*(892)^+ \pi^0$ | 0.3 $\pm$ 0.1 | 0.2 $\pm$ 0.2 $\pm$ 0.2 | 4.6 $\pm$ 1.4 $\pm$ 0.4 | 4.0 |
| $D_s^+ \to K^*(1410)^0 \pi^+$ | 0.8 $\pm$ 0.2 | 0.2 $\pm$ 0.3 $\pm$ 0.1 | 3.3 $\pm$ 1.6 $\pm$ 0.5 | 3.7 |

**Table 4.** Magnitudes, phases, FFs, and significances for the amplitudes. The uncertainties in the magnitudes are statistical only. The first and the second uncertainties in the phases and FFs are statistical and systematic, respectively. The total FF is 86.9%.

| B | C | D | E |
|---|---|---|---|
| A | 20.3 $\pm$ 5.3 | $-4.1 \pm 1.0$ | $-2.6 \pm 0.9$ | 5.1 $\pm$ 1.6 |
| B | $-4.5 \pm 0.9$ | $-3.2 \pm 0.7$ | 0.8 $\pm$ 1.7 |
| C | $-0.5 \pm 0.1$ | 0.4 $\pm$ 1.0 |
| D | 0.5 $\pm$ 0.4 |

**Table 5.** Interference between amplitudes, in % of the total amplitude. A denotes $D_s^+ \to K_S^0 \rho^+$, B $D_s^+ \to K_S^0 \rho(1450)^+$, C $D_s^+ \to K^*(892)^0 \pi^+$, D $D_s^+ \to K^*(892)^+ \pi^0$, and E $D_s^+ \to K^*(1410)^0 \pi^+$. The uncertainties are statistical only.

The magnitudes, phases, FFs, and significances for the amplitudes are listed in table 4. The interference between amplitudes is listed in table 5. The Dalitz plot projections are shown in figure 3. The assignment of systematic uncertainties is discussed in next section.
Figure 3. The projections of (a) $M_{K^0\pi^0}$, (b) $M_{K^0\pi^+}$, and (c) $M_{\pi^+\pi^0}$ from the nominal fit. The data samples at $\sqrt{s} = 4.178-4.226$ GeV are represented by points with error bars, the fit results by the solid blue lines, and the background estimated from generic MC samples by the black dashed lines. Colored curves show the components of the fit model. Due to interference effects, the total is not necessarily equal to the sum of the components. Pull projections are shown beneath each distribution, for which if there are less than 10 events in a certain bin, this bin is merged to the next bin until the number of events is larger than or equal to 10.

ii R values. The radii of the nonresonant state and $D_s^\pm$ mesons are varied within the range $[2.0, 4.0]$ GeV$^{-1}$ for intermediate resonances and $[3.0, 7.0]$ GeV$^{-1}$ for $D_s^\pm$ mesons.

iii Background estimation. The uncertainties associated with background are studied by varying the fractions of signal (equivalent to the fractions of background), i.e. $w_{\text{sig}}$ in eq. (4.9). The fractions of signal for the three sample groups are varied by one corresponding statistical uncertainty. The largest differences from the nominal results are assigned as the uncertainties.

The other source of potential bias arisen from the knowledge of the background
Table 6. Systematic uncertainties on the $\phi$ and FFs for each amplitude in units of the corresponding statistical uncertainties. The sources are: (i) Fixed parameters in the amplitudes, (ii) The $R$ values, (iii) Background, (iv) Experimental effects, (v) Fit bias.

We follow an alternative procedure by determining the background shape with another two variables, $M_{K_S^0\pi^+}^2$ versus $M_{\pi^+\pi^0}^2$, and change the smooth parameters in RooNDKeysPdf [24]. This resulting change in results is small enough to be ignored and so we assign no uncertainty from this source.

iv Experimental effects. To estimate the systematic uncertainty related to the difference in acceptance between MC and data associated with the PID and tracking efficiencies, that is $\gamma_\epsilon$ in eq. (4.4), the amplitude fit is performed varying the PID and tracking efficiencies according to their uncertainties.

v Fit bias. The amplitude analysis is performed on three-hundred data-sized signal MC samples and the pulls, which are the normalized-residual distributions of the fit, are inspected to look for biases or significant excursions from a normal distribution. These studies indicate that the FFs of $D_s^+ \rightarrow K^*(892)^0\pi^+$ and $D_s^+ \rightarrow K^*(1410)^0\pi^+$ are slightly biased. Therefore, we correct the biased FFs by the mean values of the pull distributions (from 8.9% to 8.4% for $D_s^+ \rightarrow K^*(892)^0\pi^+$ and from 3.5% to 3.3% for $D_s^+ \rightarrow K^*(1410)^0\pi^+$). In addition, the statistical uncertainties of the FF and phase of $D_s^+ \rightarrow K^*(892)^0\pi^+$ are overestimated. We scale the uncertainties by the widths of the pulls (a factor of 0.84 for the FF and 0.85 for the phase). The systematic uncertainty of fit bias is assigned as the statistical uncertainty of the mean value. An additional systematic uncertainty due to the scale is taken into account by $\sqrt{2f\Delta f}$, where $f$ is the fitted width and $\Delta f$ is its uncertainty [28, 29].
the case of more than one tag modes and sample groups, and $\epsilon_{\text{tag}}$ and $\epsilon_{\text{signal}}$ modes, respectively; $N_{\text{ST}}$ is the ST yield for the tag mode; $N$ closest to the case of multiple candidates, the DT candidate with the average mass, these two peaking background sources are added to the background polynomial functions. $D_0$ background in any tag mode, except for a second-order Chebyshev function. MC studies show that there is no significant peaking to take into account the data-MC resolution difference. The background is described by fits, the signal is modeled by an MC-simulated shape convolved with a Gaussian function as an example, the fits to the data sample at $\sqrt{s} = 4.178$ GeV are shown in figure 4. In the fits, the signal is modeled by an MC-simulated shape convolved with a Gaussian function to take into account the data-MC resolution difference. The background is described by a second-order Chebyshev function. MC studies show that there is no significant peaking background in any tag mode, except for $D^- \rightarrow K_S^0 \pi^-$ and $D^- \rightarrow \eta \pi^+ \pi^- \pi^-$ faking the $D^- \rightarrow K_S^0 K^-$ and $D^- \rightarrow \pi^- \eta'$ tags, respectively. Therefore, the MC-simulated shapes of these two peaking background sources are added to the background polynomial functions. Once a tag mode is identified, we search for the signal decay $D^+_s \rightarrow K_S^0 \pi^+ \pi^0$. In the case of multiple candidates, the DT candidate with the average mass, $(M_{\text{signal}} + M_{\text{tag}})/2$, closest to the $D^+_s$ nominal mass is retained.

To measure the BF, we start from the following equations for a single tag mode:

$$N_{\text{tag}}^{\text{ST}} = 2N_{D^+_s D^-_s} B_{\text{tag}}^{\epsilon_{\text{tag}}}$$
$$N_{\text{tag,sig}}^{\text{DT}} = 2N_{D^+_s D^-_s} B_{\text{tag}}^{\epsilon_{\text{tag}}} B_{\text{sig}}^{\epsilon_{\text{tag,sig}}},$$

where $N_{D^+_s D^-_s}$ is the total number of $D_s^{\pm} D_s^{\mp}$ pairs produced from the $e^+ e^-$ collisions; $N_{\text{tag}}^{\text{ST}}$ is the ST yield for the tag mode; $N_{\text{tag,sig}}^{\text{DT}}$ is the DT yield; $B_{\text{tag}}$ and $B_{\text{sig}}$ are the BFs of the tag and signal modes, respectively; $\epsilon_{\text{tag}}^{\text{ST}}$ is the ST efficiency to reconstruct the tag mode; and $\epsilon_{\text{tag,sig}}^{\text{DT}}$ is the DT efficiency to reconstruct both the tag and the signal decay modes. In the case of more than one tag modes and sample groups,

$$N_{\text{total}}^{\text{DT}} = \Sigma_{\alpha,i} N_{\alpha,sig,i}^{\text{DT}} = B_{\text{sig}}^{\epsilon_{\alpha}} \Sigma_{\alpha,i} 2N_{D^+_s D^-_s} B_{\alpha}^{\epsilon_{\alpha,sig,i}},$$

Table 7: The ST yields for the samples collected at $\sqrt{s} = (I) 4.178$ GeV, (II) 4.199–4.219 GeV, and (III) 4.226 GeV. The uncertainties are statistical.

| Tag mode | (I) $N_{\text{ST}}$ | (II) $N_{\text{ST}}$ | (III) $N_{\text{ST}}$ |
|----------|---------------------|---------------------|---------------------|
| $D^+_s \rightarrow K_S^0 K^-$ | 31668 ± 315 | 18340 ± 260 | 6550 ± 158 |
| $D^-_s \rightarrow K^+ K^- \pi^-$ | 135867 ± 610 | 80417 ± 507 | 28289 ± 328 |
| $D^-_s \rightarrow K_S^0 K^- \pi^0$ | 11284 ± 512 | 6729 ± 462 | 2144 ± 218 |
| $D^-_s \rightarrow K^+ K^- \pi^- \pi^0$ | 38421 ± 767 | 22894 ± 645 | 7855 ± 439 |
| $D^-_s \rightarrow K_S^0 K^+ \pi^- \pi^-$ | 15644 ± 289 | 8922 ± 229 | 3241 ± 169 |
| $D^-_s \rightarrow \pi^- \pi^- \pi^+$ | 37702 ± 853 | 21675 ± 772 | 7506 ± 392 |
| $D^-_s \rightarrow \pi^- \eta_{\gamma \gamma}$ | 18070 ± 560 | 10033 ± 355 | 3699 ± 244 |
| $D^-_s \rightarrow \pi^- \pi^0 \eta_{\gamma \gamma}$ | 40862 ± 1313 | 25877 ± 1823 | 10659 ± 1060 |
| $D^-_s \rightarrow \pi^- \eta_{\pi \pi \eta \gamma}$ | 7773 ± 143 | 4464 ± 111 | 1676 ± 74 |
Figure 4. Fits to the $M_{\text{tag}}$ distributions of the ST candidates from the data sample at $\sqrt{s} = 4.178 \text{ GeV}$. The points with error bars are data, the blue solid lines are the total fits, and the black dashed lines are background. The pairs of red arrows denote the signal regions.

where $\alpha$ represents tag modes in the $i$th sample group. By isolating $B_{\text{sig}}$, we find

$$B_{\text{sig}} = \sum_{\alpha,i} \frac{N_{ST}^{DT}}{B_{K_S^0 \rightarrow \pi^+\pi^-} B_{\pi^0 \rightarrow \gamma\gamma} \epsilon^{ST}_{\alpha,i}} N_{ST}^{DT} \epsilon^{DT}_{\alpha,i},$$ (5.4)

where $N_{ST}^{DT}$ and $\epsilon^{ST}_{\alpha,i}$ are obtained from the data and generic MC samples, respectively, while $\epsilon^{DT}_{\alpha,i}$ is determined with signal MC samples, where $D_s^+ \rightarrow K_S^0 \pi^+\pi^-\pi^0$ events are generated according to the results of the amplitude analysis. The two branching ratios $B_{K_S^0 \rightarrow \pi^+\pi^-}$ and $B_{\pi^0 \rightarrow \gamma\gamma}$ have been introduced to account for the fact that the signal is reconstructed through these decays.

The DT yield $N_{\text{total}}^{DT}$ is found to be $666 \pm 37$ from the fit to the $M_{\text{sig}}$ distribution of the selected $D_s^+ \rightarrow K_S^0\pi^+\pi^0$ candidates. The fit result is shown in figure 5. The signal shape is described by an MC-simulated shape convolved with a Gaussian function to take into account the data-MC resolution difference. The background shape is described by an MC-simulated shape, which includes the small peaking background (2.1%) that is mainly from $D_s^+ \rightarrow \pi^+\pi^+\pi^-\pi^0$ decays. The width of the Gaussian function is fixed to be $1.9 \pm 1.1 \text{ MeV}/c^2$, which is extracted from the control sample of $D_s^+ \rightarrow K_S^0K^+\pi^0$ decays. Note that the DT yield is larger than the fit yields of figure 1 since the kinematic fit and selections discussed in section 4.1 is not applied in the BF measurement.
Figure 5. Fit to the $M_{\text{sig}}$ distribution of the DT candidates from the data samples at $\sqrt{s} = 4.178$-4.226 GeV. The data are represented by points with error bars, the total fit by the blue solid line, and the fitted signal and the fitted background by the red dotted and the black dashed lines, respectively.

We take the differences in pion tracking efficiency between data and MC simulation into account, and apply a correction to the MC signal efficiency of $+0.3\%$. The differences in PID efficiency are negligible. The BF is determined to be $B(D_s^+ \to K_S^0\pi^+\pi^0) = (5.43 \pm 0.30_{\text{stat}} \pm 0.15_{\text{syst}}) \times 10^{-3}$.

In order to test $CP$ conservation in the decay, the BFs are measured separately for the charge-conjugated modes. The BFs of $D_s^+ \to K_S^0\pi^+\pi^0$ and $D_s^- \to K_S^0\pi^-\pi^0$ are measured to be $(5.33 \pm 0.41_{\text{stat}} \pm 0.15_{\text{syst}}) \times 10^{-3}$ and $(5.63 \pm 0.44_{\text{stat}} \pm 0.16_{\text{syst}}) \times 10^{-3}$, respectively. The asymmetry of the BFs is determined to be $(2.7 \pm 5.5_{\text{stat}} \pm 0.9_{\text{syst}})\%$ by $A_{CP} = \frac{B(D_s^+)-B(D_s^-)}{B(D_s^+)+B(D_s^-)}$, where $B(D_s^{+(-)})$ is the BF of the decay $D_s^{+(-)} \to K_S^0\pi^{+(-)}\pi^0$. Hence, no $CP$ violation is observed. Note that the systematic uncertainties related to $K_S$ and $\pi^0$ reconstructions cancel in the $A_{CP}$ calculation.

The following sources of the systematic uncertainties are taken into account for the BF measurement.

- Signal shape. The systematic uncertainty due to the signal shape is studied by repeating the fit with an alternative width of the convolved Gaussian. This width is varied according to the uncertainty of the control sample.

- Background shape. Since $q\bar{q}$ or non-$D_s^{\pm}\bar{D}_s^\mp$ open charm are the major background sources, we alter the MC shapes by varying the relative fractions of the background from $q\bar{q}$ or non-$D_s^{\pm}\bar{D}_s^\mp$ open charm by $\pm 30\%$. This $30\%$ is the statistical uncertainties of the cross section of $q\bar{q}$ and non-$D_s^{\pm}\bar{D}_s^\mp$ open charm in the data sample. The largest change is taken as the corresponding systematic uncertainty.

- $\pi^+$ tracking/PID efficiency. The $\pi^+$ tracking and PID efficiencies are studied with $e^+e^- \to K^+K^-\pi^+\pi^-$ events. The data-MC efficiency ratios of the $\pi^+$ tracking and
The PID efficiencies are 1.003 ± 0.002 and 1.000 ± 0.002, respectively. After multiplying the signal efficiencies by the factor 1.003, we assign 0.2% and 0.2% as the systematic uncertainties arising from π+ PID and tracking, respectively.

- \( K_S^0 \) reconstruction. The systematic uncertainty related to the \( K_S^0 \) reconstruction efficiency is estimated with the control samples of \( J/\psi \rightarrow K^*(892)^+ K^- \) and \( J/\psi \rightarrow \phi K_S^0 K^+ \pi^- \). Selection criteria mentioned in section 3 are used to reconstruct all the particles in the event except \( K_S^0 \). The number of \( K_S^0 \)s is determined by fitting the distribution of missing mass squared. By applying \( K_S^0 \) selection, the number of reconstructed \( K_S^0 \) is determined. The associated systematic uncertainty is assigned as 1.5% per \( K_S^0 \) according to the efficiency difference of data and MC samples.

- \( \pi^0 \) reconstruction. The systematic uncertainty of the \( \pi^0 \) reconstruction efficiency is investigated by using a control sample of the process \( e^+ e^- \rightarrow K^+ K^- \pi^+ \pi^- \pi^0 \). Selection criteria mentioned in section 3 are used to reconstruct the two kaons and the two pions. The recoiling mass distribution of \( K^+ K^- \pi^+ \pi^- \) is fitted to obtain the total number of \( \pi^0 \)s and the \( \pi^0 \) selection is applied to determined the number of reconstructed \( \pi^0 \)s. The efficiency difference of data and MC samples is then determined to be 2.0% per \( \pi^0 \).

- MC statistics. The uncertainty due to the limited MC statistics is obtained by \( \sqrt{\sum_i (f_i \delta \epsilon_i \epsilon_i)^2} \), where \( f_i \) is the tag yield fraction, and \( \epsilon_i \) and \( \delta \epsilon_i \) are the signal efficiency and the corresponding uncertainty of tag mode \( i \), respectively.

- Dalitz model. The uncertainty from the Dalitz model is estimated by varying the Dalitz model parameters based on their error matrix. The distribution of 600 efficiencies resulting from this variation is fitted by a Gaussian function and the fitted width divided by the mean value is taken as an uncertainty.

- Peaking background. A sample of \( D_s^+ \rightarrow \pi^+ \pi^+ \pi^- \pi^0 \) is reconstructed with the same tag modes and selection criteria as the nominal analysis except the \( K_S^0 \) selection is replaced by a \( K_S^0 \) veto on the \( \pi^+ \pi^- \) invariant mass to remove events from \( D_s^+ \rightarrow K_S^0 \pi^+ \pi^- \). The background contributed by the decay \( D_s^+ \rightarrow \pi^+ \pi^+ \pi^- \pi^0 \) is then estimated to be 2.1% of the \( D_s^+ \rightarrow K_S^0 \pi^+ \pi^- \pi^0 \) signal events. The relative uncertainty of this background is conservatively estimated to be 8% and corresponds to about one event in the \( D_s^+ \rightarrow K_S^0 \pi^+ \pi^- \pi^0 \) decay. Therefore, the associated uncertainty in the BF measurement is 0.2%.

All of the systematic uncertainties are summarized in table 8. Adding them in quadrature gives a total systematic uncertainty in the BF measurement of 2.8%.

6 Summary

An amplitude analysis has been performed for the decay \( D_s^+ \rightarrow K_S^0 \pi^+ \pi^0 \). The results for the FFs and phases among the different intermediate processes are listed in table 4. After
Table 8. Systematic uncertainties in the BF measurement.

| Source           | Sys. Uncertainty (%) |
|------------------|----------------------|
| Signal shape     | 0.8                  |
| Background shape | 0.5                  |
| $\pi^+$ PID efficiency | 0.2                |
| $\pi^+$ tracking efficiency | 0.2               |
| $K_S^0$ reconstruction | 1.5               |
| $\pi^0$ reconstruction | 2.0                |
| MC statistics    | 0.3                  |
| Dalitz model     | 0.8                  |
| Peaking Background | 0.2                |
| Total            | 2.8                  |

calculating a detection efficiency that accounts for the variation of decays over phase space found in the amplitude analysis, the BF for the decay $D^+_s \rightarrow K_S^0 \pi^+ \pi^0$ is measured to be $(5.43 \pm 0.30_{\text{stat}} \pm 0.15_{\text{syst}}) \times 10^{-3}$ with an improved precision by about a factor of 3 compared to the PDG value [1]. The BFs for the intermediate processes are calculated with $B_i = FF_i \times B(D_s^+ \rightarrow K_S^0 \pi^+ \pi^0)$ and listed in table 9. Assuming $B(K^0 \rightarrow K_S^0) = 0.5$, we determine $B(D_s^+ \rightarrow K^0 \rho^+) = (5.46 \pm 0.84_{\text{stat}} \pm 0.44_{\text{syst}}) \times 10^{-3}$, $B(D_s^+ \rightarrow K^+(892)^0 \pi^+) = (2.71 \pm 0.72_{\text{stat}} \pm 0.30_{\text{syst}}) \times 10^{-3}$, and $B(D_s^+ \rightarrow K^+(892)^0 \pi^0) = (0.75 \pm 0.24_{\text{stat}} \pm 0.06_{\text{syst}}) \times 10^{-3}$. Our results are valuable for a deeper understanding of quark flavor SU(3) symmetry, SU(3) breaking effects, and other related theoretical issues.

These results can be compared to the current theoretical predictions [4, 7, 8]. The predictions in ref. [7] are consistent with our results, but their large uncertainties make the comparisons less conclusive. The calculations in ref. [8] have small uncertainties, while the predicted $B(D_s^+ \rightarrow K^0 \rho^+)$ is over five standard deviations off the measured one. The predictions in ref. [4] have moderate uncertainties and match our measurements in principle, but the predicted $B(D_s^+ \rightarrow K^+(892)^+ \pi^0)$ is only marginally consistent with our measurement. Based on the current experimental and theoretical precisions, it is difficult to draw a definite conclusion to discriminate between models yet.

The asymmetry for the BFs of the decays $D_s^+ \rightarrow K_S^0 \pi^+ \pi^0$ and $D_s^- \rightarrow K_S^0 \pi^- \pi^0$ is determined to be $(2.7 \pm 5.5_{\text{stat}} \pm 0.9_{\text{syst}})\%$. No evidence for CP violation is found.
