Demographic and Clinical Characteristics of Adult Acute Myeloid Leukemia - Tertiary Care Experience

Sadia Sultan1*, Hasan Abbas Zaheer2, Syed Mohammed Irfan1, Sana Ashar1

Abstract

Background: Acute myeloid leukemia (AML) is an acquired clonal frequent malignant disorder of myeloid progenitor cells. Our aim was to study demographical and clinicopathological features of adult Pakistani AML patients at presentation. Materials and Methods: In this single centre study extending from January 2010 to December 2014, data were retrieved from the patient records with a predetermined performa and analyzed with SPSS version 22. Results: Overall 125 patients were diagnosed at our institution with de novo AML during the study period. There were 76 males and 49 females (ratio 1.5:1), with an age range between 15 and 85 years and a mean age of 38.8±20.1 years. The major complaints were fever (72.8%), generalized weakness (60%), bleeding (37.6%) and dyspnea (12%). Physical examination revealed pallor in 56.8%, splenomegaly and hepatomegaly in 16% and 12.8%, respectively, and lymphadenopathy in 10.4%. The mean hemoglobin was 8.19±2.12g/dl with a mean MCV of 86.0±9.83 fl, a mean total leukocyte count of 43.1±68.5x10^9/l, an ANC of 3.09±6.66x10^9/l and a mean platelet count of 62.3±78.6x10^9/l. Conclusions: AML in Pakistani patients is seen in a relatively very young population with male preponderance, compared with the west. However, clinicopathological features appear comparable to published data.

Keywords: Acute myeloid leukemia - demographics - clinical characteristics - Pakistan.
myeloid leukemia, Myeloproliferative neoplasm and with prior history of chemotherapy/radiotherapy were excluded from the study. The patients who were known cases of relapse/refractory AML were also not included. Based on this, a total of 125 subjects with newly diagnosed untreated de novo AML were included in the study. The diagnosis of AML was ascertained according to the standard FAB criteria, and was based on bone marrow morphology and cytochemistry (Bennett et al., 1985).

Complete blood counts were done on Cell Dyné counter (Abbott, USA). Bone marrow aspiration was done from posterior iliac crest through Jamshidi needle and was stained by Leishman’s stain. Cytochemical stains were carried out on each bone marrow smears including Sudan Black B (SBB), Periodic acid-Schiff (PAS) and Alpha naphthyl acetate esterase by commercially provided kits from Merck Diagnostic according to manufacturer’s instructions. Immunophenotyping was done where it was deemed necessary, in patients with diagnostic uncertainty.

Approval from the institutional ethical and research review committee was obtained prior to the study.

Data analysis

Data was compiled and analyzed using the Statistical Package for the Social Sciences version 22.0 (SPSS Inc, Chicago, IL, USA). The results were expressed as mean±SD for quantitative variables and qualitative variables are presented as frequency & percentages.

Results

Out of 125 patients, 76 were males (60.8%) and 49 were females (39.2%) with male to female ratio of 1.5:1. Age ranged between 15 and 85 years with a mean age of 37.97±20.12 years and median age of 34.5 years. Overall 95 (76%) patients were under 50 years of age, and remaining only 24% (30 patients) were above 50 years. Age stratification is shown in Table-1.

The major complaints were fever in 91 (72.8%) patients; generalized weakness in 75 (60%) patients; bleeding in 47 (37.6%) patients and dyspnea in 15 (12%) patients. The most frequent sites of bleeding were skin, gums and nose. None of the patients had history of intracranial bleeding.

Physical examination revealed pallor as a predominant finding detected in 71 (56.8%) patients followed by splenomegaly and hepatomegaly in 20 (16%) and 16 (12.8%) patients respectively. Lymphadenopathy was noted in 13 (10.4%) patients.

The mean hemoglobin was 8.19±2.12 (range 3.7-13.6) g/dl with the mean MCV of 85.98±9.83 fl. The mean total leucocyte count of 43.08±68.45 (range 0.6-372) x10^9/l; Absolute neutrophilic count (ANC) of 3.09±6.66 (range 0.01-15.4) x10^9/l and mean platelets count were 62.32±78.61 (range 3.0-576) x10^9/l.

Anemia (Hb<10gm/dl) was noted in 102 (81.6%) patients. Hyperleukocytosis (TLC count >100x10^9/l) was seen in 19 (15.2%) patients. Thrombocytopenia (platelets count <100x10^9/l) was detected in 105 (84%) patients, while severe thrombocytopenia (platelets <20x10^9/l) was seen in 33 (26.4%) patients.

Discussion

Acute myeloid leukemia is an aggressive, clonal neoplasm, with maturation arrest in granulopoiesis, resulting in an accretion of immature myeloblasts in the bone marrow. It progresses rapidly and is fatal within weeks or months if left untreated. The present study has illustrated demographics, clinical features and hematological markers in Pakistani AML patients.

AML can occur in patients of any age, but in general the overall incidence increases with age. AML is a disease of the elder, with a median age of onset around ~70 years (Juliusson et al., 2009). According to the National comprehensive cancer network (NCCN), 54% of patients diagnosed at 65 years or older and approximately a third diagnosed at ≥75 years of age (Yin et al., 2012). Surprisingly, the median age of the patients in our study is 34.5 years. Previously published studies, about a decade back, from Pakistan also revealed comparable age at presentation; 32 and 38 years respectively (Kakepoto et al., 2002; Harani et al., 2005).

Similar to us a large regional study reported by Chauhan et al from neighbor India, revealed the mean age of AML patients as 32 years at disease presentation (Chauhan et al., 2013). One recent Malaysian study by Meng et al reported the median age of 39 years at diagnosis (Meng et al., 2013). When compared with earlier international reports, our results are in conflict with studies published from Sweden and Germany, where the median age were 71 and 60 years respectively. (Lazarevic, 2014; Pastore, 2014). Perhaps this disparity may be clarified by obvious difference based on geographical and genetic makeup between two populations and also accountable is the higher mean age in western countries compared to us.

AML is slightly more common in men, with a male to female ratio of ~2:1. In the present study male preponderance was observed and it was consistent with other studies (Harani et al., 2005; Chauhan et al., 2011).

In general, diminution in hematopoiesis owing to marrow proliferation of myeloblast cells, results in anemia, thrombocytopenia and leucopenia with the clinical symptoms of pallor, easy fatigue, bleeding manifestations and fever respectively.

Among our patients majority presented with fever and generalized weakness. Similar presenting symptoms were observed by prior Indian and Pakistani studies conducted by Preethi and Kakepoto et al (Kakepoto et al., 2002; CRP, 2014). Clinical features in our study somewhat correlated with the study conducted by Khalid et al. (1997) showing
59% of patients had febrile illness compared with us having prevalence of 72.8% (Khalid et al., 1997). Bleeding was also a common presenting feature in our patients. Comparable findings have been reported in other studies on AML. When compared with earlier reports, our results are in concurrence with a study which reported fever and bleeding diathesis in 80.4% and 44.5% respectively (Asif and Hassan, 2013).

Pallor was found as a presenting symptom in 56.8% of the patients. This correlates with the study conducted by Harakati et al from Saudi Arabia revealed pallor in 69% of their patient’s series (Harakati et al., 1998).

In Acute myeloid leukemia extramedullary infiltrates by leukemic cells may causes visceromegaly or lymphadenopathy. Though lymphadenopathy is not as common as seen in acute lymphoblastic leukemia. Rather hepatosplenomegaly is more frequent but massive visceromegaly is very rare. In our patients, hepatomegaly and splenomegaly were observed in 12.8% and 16% patients respectively. Majority had mild to moderate visceromegaly. Lymph node enlargement was noted in 10.4% of our patients. Our results are comparable with other study reported from Yemen which revealed 20% of patients had lymphadenopathy (Hamid and Nabi, 2015).

Anemia is a constant feature in all acute leukemias and in majority of cases is due to bone marrow infiltration. Evaluations of hematological parameters in our cases predominantly showed low mean hemoglobin levels. Our results are analogous with other studies (Ghosh et al., 2003; Naseem et al., 2013).

Among all adult patients with acute leukemias, approximate 5 to 30% may present with symptoms of leukostasis and hyperleukocytosis. Hyperleukocytosis are much more pronounced in AML than in ALL (Asif and Hassan, 2013). In our study 15.2% of patients showed hyperleukocytosis. Analogous to this finding one regional study from Islamabad revealed 11% prevalence of hyperleukocytosis in AML patients (Asif and Hassan, 2013).

Lastly thrombocytopenia is an important well known manifestation of acute leukemias. Thrombocytopenia was present in the majority (84%) of cases in the present study. In concurrence to our results regional study (86%) revealed more or less similar findings (Naseem et al., 2013).

So in conclusion, AML is predominantly seen in very younger age group in Pakistan. At disease presentation age is approximately half that is reported in international data. However clinico-epidemiological features are appearing comparable to published data.
