Choroid plexus (CP) forms an anatomically functional barrier between the blood and cerebrospinal fluid (CSF) that dictates the cellular and humoral composition of the CSF. The immunological response of CP to inflammatory stimuli, such as cancer, remains unclear. Here, we find that CP expresses immune-related proteins even when CP is not at inflammatory states as well as in the presence of metastatic cancer. We show that the circulation-derived leptomeningeal monocyte/macrophages entering the CP through CP presents the growth of leptomeningeal metastasis (LMD) by perturbing the environment with a form of chronic pro- and anti-inflammatory cytokines. Functional manipulation of Type II Interferon pathway particularly within inflamed leptomeninges revealed that IFN-γ can serve as a dominant signal, further recruiting peripheral myeloid cells and activating their protective anti-tumor response. This preclinical strategy was sufficient to control the growth of syngeneic LM cancer cells and delay the onset of lethal LM.

LMD-19. ANATOMIC AND SURGICAL FACTORS PREDICT DEVELOPMENT OF LEPTOMENINGEAL DISEASE IN PATIENTS WITH METASTATIC MELANOMA

Stephen Lowet1, Christopher P. Wang2, Amanda Briscoe2, Kamran Ahmed1, Michael A. Vogelbaum3, James K. C. Liu4; 1HLee Moffitt Cancer Center, Tampa, FL, USA, 2University of South Florida College of Medicine, Tampa, FL, USA

BACKGROUND: Leptomeningeal disease (LMD) is a devastating complication of systemic malignant, portending a poor prognosis with an estimated median survival of 4-6 weeks if left untreated. Several reports have suggested surgical intervention, particularly craniotomy resection, as potential causative factor. Herein, we explore if surgical and anatomical factors are correlated with development of LMD in patients with melanoma brain metastases. METHODS: Patients treated at our institution between 1999–2019 for primary melanoma with brain metastases were compiled into an institutional database based on CD9/10 coding. 1,079 patients with melanoma brain metastases and appropriate imaging were identified, and 834 patients with a minimum of 3 months’ follow-up were included. Patients were dichotomized by development of LMD or lack thereof. General demographic information, surgical and anatomical data, and ventricular access during surgery were investigated as possible correlative factors for the development of LMD. RESULTS: On univariate analysis, female gender (p=0.033), presence of dural metastasis (p=0.018), presence of ventriculitis lesions (p<0.001), presence of intraventricular lesions (p<0.001), and ventricular access during surgery (p<0.001) were significantly associated with LMD. Patients undergoing surgery, or those undergoing surgery without ventricular access, were not at higher risk of LMD. Administration of immunotherapy, either as first-line or salvage therapy, did not impact rates of LMD. On multivariate analysis, female gender (p=0.03), presence of ventriculitis lesions (p<0.001), presence of intraventricular lesions (p<0.002), and presence of dural metastasis (p=0.032) were significantly associated with development of LMD. In patients who had surgery, iatrogenic ventricular access (p<0.001) was significantly correlated with LMD. CONCLUSIONS: In a retrospective cohort of patients with melanoma metastatic to the brain, those patients with pre-existing lesions in contact with the CSF space are more likely to develop LMD than those who do not. In addition, iatrogenic access to the CSF space during surgery is highly correlated with LMD development.

LMD-18. DETECTION AND SERIAL MONITORING OF CSF ctDNA IN BREAST CANCER LEPTOMENINGEAL DISEASE (BCLM)

Amanda Fitzpatrick1, Marjan Iravani1, Alicia Okines2, Adam Mills3, Mark Harries4, Andrew Tutt1, Clare Isacke1; 1Institute of Cancer Research, London, UK, 2Royal Marsden Hospital, London, UK, 3Guy’s Cancer Centre, London, UK

BACKGROUND: CSF cytology is the gold standard diagnostic test for BCLM, but is hampered by a low sensitivity, often necessitating repeated lumbar punctures to confirm or refute the diagnosis. Furthermore, during the treatment of BCLM, there is no robust quantitative response tool to guide treatment decisions. Material and METHODS: ctDNA was obtained from CSF and plasma in patients with breast cancer undergoing investigation for BCLM (n=28) and during subsequent intrathecal treatment (n=13). Using low pass whole genome sequencing (dupWGS) and estimation of the ctDNA fraction was performed. Results were validated by mutation-specific droplet PCR (dupPCR). RESULTS: 22/28 cases had confirmed BCLM by positive MRI and/or CSF cytology. The remaining 6/28 had suspected but non-conclusive findings. At median 20 months follow-up, these n馻tation cases remained BCLM-free. CSF ctDNA fraction was significantly elevated (median 57.5 IQR 38.3 - 84.9%) in confirmed BCLM compared to 6 non-confirmed BCLM (median 5.0, IQR 0.0 - 6.7%) (p <0.001). ctDNA fraction was detected in BCLM confirmed cases regardless of negative cytology or MRI. Plasma ctDNA fraction was only detected in extra-cranial disease progression. ctDNA fraction was concordant with mutant allele fraction measured by ddPCR (n = 118 samples). Serial CSF ctDNA fraction during intrathecal treatment showed dynamic changes, while CSF cytology and MRI were often unchanged or equivocal. Early reduction in CSF ctDNA fraction was associated with longer responses to intrathecal therapy. Further, rising ctDNA fraction during intrathecal chemotherapy could be detected up to 6 weeks before relapse in neurological symptoms, cytology or MRI. CONCLUSION: Measuring CSF ctDNA fraction during intrathecal treatment could be a useful tool to guide clinical management in the difficult treatment scenario.
of LMD is largely devoid of CD3+ T cells, but is enriched for immune suppression and innate immunity.

LMD-23. HEADACHE IMPROVEMENT PREDICTS SURVIVAL AFTER CSF DIVERSION IN LEPTOMENINGEAL DISEASE

Adam Robin1, Sameah Hadier1, Natalie Dostefano4, Anne Reiner2, Viviane Talwar2, Jacob Pawloski2, 1Henry Ford Health System, Detroit, MI, USA, 2Memorial Sloan Kettering Cancer Center, New York, NY, USA, 3Henry Ford Health Center, Detroit, MI, USA

BACKGROUND: Leptomeningeal carcinomatosis (LMD) is a seeding of the leptomeninges by malignant cells. Clinical, treatment and patient-related factors have been described in patients with LMD. Current data are limited by small sample size, particularly in patients undergoing ventriculoperitoneal shunting (VPS) as part of the treatment regimen.

OBJECTIVE: This study presents the largest cohort of LMD patients in the literature undergoing cerebrospinal fluid (CSF) diversion and seeks to identify prognostic factors related to survival. METHODS: A retrospective review of patients diagnosed with LMD between 2010 and 2016 at a quaternary referral center was performed. Cox proportional hazards modeling was utilized to identify variables associated with improved overall survival from LMD diagnosis. Overall survival was depicted using Kaplan-Meier methodology. Competing risk methodology was used to identify variables associated with VPS, considering death as a competing event. RESULTS: Of the 314 patients identified, 112 underwent VPS placement. The median overall survival from LMD diagnosis was 3.9 months (95% CI: 3.2-4.4). The presence of headaches, increased opening pressure, and gait difficulty increased the likelihood of VPS placement (all p<0.05). VPS was more common in older patients (Karnofsky Performance Status (KPS), higher opening pressure and CSF nucleated cell count (NCC) increased the risk of death (all p<0.05). Patients reporting headache improvement after VPS had better survival (p=0.05). CONCLUSIONS: Headache, increased opening pressure and gait instability were associated with higher rate of VPS placement and may portend more aggressive disease. Headache improvement following VPS is a favorable prognostic sign, suggesting survival advantage for patients with hydrocephalus undergoing VPS. Age, KPS, VPS, opening pressure, CSF NCC, concomitant visceral metastases and histology-specific molecular profile impact survival.

LMD-22. CLINICOPATHOLOGICAL SPECTRUM OF LEPTOMENINGEAL METASTASES: A 3 YEAR RETROSPECTIVE STUDY

Saloni Pahwa, Anila Sharma, Meenakshi Kamboj, Anurag Mehta; RGCI&RC, Delhi, India

OBJECTIVES: Cytological examination of cerebrospinal fluid is a widely used cost effective, simple procedure and a reliable routine diagnostic test. CSF cytology helps in detection of inflammatory diseases of the CNS, diagnosis of subarachnoid haemorrhage and the identification of malignant cells in metastatic or rarely primary CNS malignancies. Leptomeningeal metastases (LM) is estimated to occur in 5% of all patients with cancer. It has a higher propensity to occur in solid tumours compared to haematological malignancies. In view of poor prognosis, early diagnosis may aid in appropriate staging and aggressive therapeutic intervention. METHODS: All the samples of CSF received in the Department of Laboratory for cytological examination and reported as ‘positive for malignant cells during the year January 2018 to December 2020 were included in the study. All the cases were routinely evaluated on Neubauer’s chamber, direct smear and a cytospin preparation stained using MGG stain. The clinical records and any further ancillary testing performed were retrospectively analysed. RESULTS: 87 cases with LM were identified over 3 year duration. Mean age of presentation was 43 years. Metastatic solid malignancies (56%) had a higher incidence of leptomeningeal metastases compared to haematological malignancies (40%) and CNS medulloblastomas (2%). Most common solid tumour with involvement of CSF was adenocarcinoma lung (51%) followed by breast CNS metastasis (37%). Of all the cases of adenocarcinoma lung with LM, EGFR mutant NSCLC were 40% while 8% showed ALK gene rearrangement. Amongst the haematological malignancies, acute leukaemia’s constituted 67% of cases while systemic NHLs were 34%. Most of the cases (96%) presented with neurological symptoms during the course of treatment while 3 cases (3%) showed LM at the time of first presentation. CONCLUSIONS: With appropriate clinicoradiological correlation, CSF cytology remains the gold standard for identification of malignant cells in cases with already known primary tumour (leptomeningeal dissemination of the disease). In this study, clinical features of both solid and haematolymphoid malignancies were evaluated. The group of solid malignancies included adenocarcinomas lung, breast, gastrointestinal tract and renal cell carcinoma. With the availability of EGFR TKIs and ALK inhibitors, overall survival of the patients may be prolonged with therapeutic interventions despite limited CSF and CNS penetration of these drugs.

MEDICAL THERAPY (CHEMOTHERAPY AND IMMUNOTHERAPY)

THER-01. TARGETED THERAPY AND INTRACRANIAL METASTATIC DISEASE: A POPULATION-BASED RETROSPECTIVE COHORT STUDY

Anders Erickson1, Steven Halcomb4, Frances Wright3, Ansha Lotter3, Katrina Jerzak1, Sunit Das1, 1Institute of Medical Research, Faculty of Medicine, University of Toronto, Toronto, ON, Canada, 2Ontario Health Cancer Care Ontario (Cancer Care Toronto), Toronto, ON, Canada, 3Division of General Surgery, Department of Surgery, Sunnybrook Hospital, University of Toronto, Toronto, ON, Canada, 4Department of Family and Community Medicine, University of Toronto, Women’s College Hospital, Toronto, ON, Canada, 5Department of Medicine, Sunnybrook Odette Cancer Centre, University of Toronto, Toronto, ON, Canada, 6Division of Neurosurgery, Department of Surgery, St. Michael’s Hospital, University of Toronto, Toronto, ON, Canada

BACKGROUND: Targeted therapies have been hypothesized to prolong survival in the management of patients with intracranial metastatic disease (IMD), but, paradoxically, to increase IMD incidence by improving systemic disease control and prolonging survival from the primary tumor. The real-world benefits of targeted therapy in management of patients with IMD are unclear, as clinical trials have excluded patients with IMD and lacked endpoints reporting intracranial outcomes. METHODS: This retrospective cohort study included all patients in Ontario, Canada, diagnosed with IMD from 2003 to 2018 with primary diagnoses of breast cancer, lung or gastrointestinal tract and matched control patients by primary disease without IMD. Kaplan-Meier and multivariable regression analyses were performed to compare overall survival (OS) between patient subcohorts divided by primary disease and stratified by targeted therapy receipt or IMD status. RESULTS: Post-IMD targeted therapy was associated with prolonged OS in patients with HER2-positive breast cancer (HR 0.41; 95% CI, 0.33–0.5), EGFR-positive lung cancer (HR 0.28; 95% CI, 0.23–0.34), and BRAF-positive melanoma (HR 0.2; 95% CI, 0.14–0.29), compared to those who did not receive post-IMD targeted therapy. Presence of IMD was associated with shorter OS in patients with metastatic breast cancer (HR 1.8; 95% CI, 1.56–2.08) and metastatic EGFR-positive lung cancer (HR 1.22; 95% CI, 1.08–1.39) but not metastatic BRAF-positive melanoma (HR 1.1; 95% CI, 0.77–1.61), compared to those without IMD. CONCLUSIONS: Our findings show that real-world use of targeted therapies was associated with prolonged OS in patients with IMD in the setting of HER2-positive breast cancer, EGFR-positive lung cancer, and BRAF-positive melanoma. Inclusion of patients with IMD in clinical trials and use of endpoints that interrogate IMD will be critical to determine the role of targeted therapies in the management of patients with IMD.

THER-02. PARP INHIBITOR TOLERABILITY AND IMPACT ON PROGRESSION-FREE SURVIVAL IN PATIENTS WITH HIGH-GRADE OVARIAN CARCINOMA WITH BRAIN METASTASIS: A CASE-SERIES

Alexander Mohler1, Belkys Salama2, Karissa Nazur2, Yazzmin Oda2, Nicholas Lambrou2, 1Miami Cancer Institute, Miami, FL, USA, 2Miami Cancer Institute, Miami, FL, USA

Brain metastases secondary to ovarian carcinoma is an uncommon but increasing phenomenon. PARP inhibitors (PARPi) are increasingly used as an adjunctive treatment in patients with central nervous system metastases (CNS). Historically brain metastases have a historically poor prognosis. Five women with a mean age of 60.4 ± 7.6 years were included. All had stage IIIC/IV ovarian cancer and diagnosed with brain metastases at recurrence. Three underwent resection for oligometastatic disease followed by post-operative stereotactic radiosurgery (SRS). One patient with metastatic HER2-positive breast cancer and one patient underwent whole brain radiotherapy for multiple metastases. Pathology was confirmed in those who were resected. Two patients had evidence of systemic disease in addition to CNS spread. Three women were BRCA1/2 Positive. Following initial radiotherapy, one patient received adjuvant chemotherapy followed by olaparib maintenance, one received 13 cycles of bevacizumab/olaparib, followed by olaparib maintenance. A third patient was treated with olaparib/bevacizumab and two patients received olaparib monotherapy, both of whom continued on therapy. All received olaparib therapy during their treatment and all had minor dose modifications due to side effects. Mean survival from initial cancer diagnosis was 62.4 ± 20.4 months. Mean duration of PARPi therapy was 27.6 ± 16.8 months. Mean survival following CNS recurrence was 22.8 ± 12 months. One patient is disease-free, two patients are alive with stable disease, one patient is alive but off treatment secondary to progression, and one patient is deceased secondary to progression of her brain metastases after being on PARP therapy for 18 months. The cohort remained highly functional across the trajectory of their disease with ECOG scores of 1 (n=4) or 0 (n=1). The results of this single institution retro-
