ABSTRACT: We present the device properties of a nickel (Ni)–gallium oxide (Ga$_2$O$_3$) Schottky junction with an interfacial hexagonal boron nitride (hBN) layer. A vertical Schottky junction with the configuration Ni/hBN/Ga$_2$O$_3$/In was created using a chemical vapor-deposited hBN film on a Ga$_2$O$_3$ substrate. The current–voltage characteristics of the Schottky junction were investigated with and without the hBN interfacial layer. We observed that the turn-on voltage for the forward current of the Schottky junction was significantly enhanced with the hBN interfacial film. Furthermore, the Schottky junction was analyzed under the illumination of deep ultraviolet light (254 nm), obtaining a photoresponsivity of 95.11 mA/W under an applied bias voltage (−7.2 V). The hBN interfacial layer for the Ga$_2$O$_3$-based Schottky junction can serve as a barrier layer to control the turn-on voltage and optimize the device properties for deep-UV photosensor applications. Furthermore, the demonstrated vertical heterojunction with an hBN layer has the potential to be significant for temperature management at the junction interface to develop reliable Ga$_2$O$_3$-based Schottky junction devices.

INTRODUCTION

Gallium oxide (Ga$_2$O$_3$) with an ultrawide band gap (UWBG) has piqued the interest of researchers working on deep ultraviolet (UV) photonics and next-generation power electronic devices.\textsuperscript{1–5} Semiconductors based on UWBG Ga$_2$O$_3$ materials can withstand much higher critical electric fields (6–8 MV/cm) before avalanche breakdown than silicon-(Si), silicon carbide- (SiC), and gallium nitride (GaN)-based devices.\textsuperscript{6,7} Furthermore, Baliga’s figure of merit presents the advantage of Ga$_2$O$_3$ for power switching applications over the Si (3000X), SiC (10X), and GaN (4X).\textsuperscript{8,9} It has been demonstrated that high-quality single-crystal Ga$_2$O$_3$ can be synthesized using melt growth techniques such as Czochralski, floating zone, and edge-defined film-fed growth (EFG).\textsuperscript{10–13} In addition, halide vapor phase epitaxy (HVPE), molecular beam epitaxy (MBE), and chemical vapor deposition (CVD) methods for growing high-quality Ga$_2$O$_3$ have been developed.\textsuperscript{14–25} Johnson’s figure of merit (JFOM/power–frequency product) of Ga$_2$O$_3$ (3X of GaN)\textsuperscript{16,22} illustrates the potential benefit of using Ga$_2$O$_3$ in radio frequency (RF) devices. Chabak et al. have reported on the fabrication of the Ga$_2$O$_3$ MOSFET device using a thin and highly doped channel and achieving a drain-source current of 275 mA/mm at a drain to source bias of 10 V for that exhibited record-high $f_t/f_{max} = 5.1/17.1$ GHz.\textsuperscript{26} However, it is expected that Ga$_2$O$_3$ devices will suffer from self-heating due to the poor thermal conductivity of the material. The device model demonstrates that a homoepitaxial device suffers from an unacceptable junction temperature increase to 1500 °C at a power density of 10 W/mm, highlighting the importance of applying device-level thermal managements to individual Ga$_2$O$_3$ devices.\textsuperscript{29,30} In this case, the integration of thermal conducting materials with Ga$_2$O$_3$-based devices may be critical for achieving dependable device performance.

The heterojunction and Schottky junction-based β-Ga$_2$O$_3$ devices are of great interest for the development of high-voltage devices and solar-blind UV photodetectors, considering the intrinsic n-type conductivity of β-Ga$_2$O$_3$ in the presence of unintentional dopants.\textsuperscript{25–31} The conventional Ga$_2$O$_3$ Schottky junction devices were studied with metal electrodes such as Au, Pt, and Ni, taking into account the metals’ appropriate work function.\textsuperscript{32,33} Again, studies on metal–insulator–semiconductor (MIS)-based SBD devices have been conducted, owing to the benefit of lowering the reverse saturation current.\textsuperscript{34–36} The MIS-based SBD devices have been fabricated using insulating dielectric materials, such as SiO$_2$, Si$_3$N$_4$, Al$_2$O$_3$, and so forth.\textsuperscript{35–37,40} The thermal stability of Ga$_2$O$_3$ Schottky contacts
is also an important aspect, for which materials with high melting temperatures and low reactivity with $\text{Ga}_2\text{O}_3$ are of significant interest. Furthermore, controlling near-surface ion damage during sputtering deposition of a barrier layer/insulating dielectric is required. In this case, the CVD-synthesized chemically inert insulating hBN layer will be significant with much higher in-plane thermal conductivity for use in $\text{Ga}_2\text{O}_3$-based Schottky junctions.

Previously, we have demonstrated the integration of highly conducting graphene and copper iodide ($\gamma$-CuI) films with the $\beta$-$\text{Ga}_2\text{O}_3$ substrate for the fabrication of deep-UV photo-responsive devices. The fabrication of quasi-two-dimensional metal–insulator–semiconductor field-effect transistors was demonstrated by the mechanical transfer process of hBN and nanotin flakes of $\beta$-$\text{Ga}_2\text{O}_3$. In contrast to previous reports, we show how to make a vertical Ni/$\beta$-$\text{Ga}_2\text{O}_3$ Schottky junction with and without the hBN interfacial layer. The UWBG heterostructure of hBN and $\beta$-$\text{Ga}_2\text{O}_3$ can be significant due to the complementing electronic, chemical, and thermal properties of the materials. The following sections go over the specifics of hBN integration with the free-standing $\beta$-$\text{Ga}_2\text{O}_3$ substrate and the fabrication of a vertical Schottky junction. We discovered that the hBN interfacial film can be used to control the device’s turn-on voltage and current density.

### EXPERIMENTAL SECTION

The hBN film was synthesized on recrystallized Cu (111) foil by the atmospheric pressure CVD (APCVD) as reported previously by the research group. For this experiment, ammonia borane (10 mg) is used as a precursor and placed atop a magnetic boat, which was placed inside the tube about 20 cm away from the furnace to avoid precursor loss before the deposition step. The furnace was set at a high temperature of 1050 °C for the growth of the hBN film on the Cu surface. During the deposition step, the gas flow into the chamber was changed by the addition of argon gas with a flow rate of 98 sccm, and the flow rate of hydrogen gas was reduced to 2 sccm, and the mixed gas flow was 98:2 of Ar/H$_2$. To achieve vaporization of ammonia borane, the precursor is brought close to the furnace using a magnet at 3 cm away from the furnace, as shown in the schematic diagram.
formation of an hBN layer on a Cu (111) substrate. Finally, the cooling step was completed by simultaneously switching the H\textsubscript{2} gas flow, partially opening the furnace, and moving the precursor approximately 20 cm away from the furnace to avoid a secondary deposition. After the reaction chamber was cooled to room temperature, the hBN-grown Cu foil was removed and subjected to a wet transfer process described in the previous reports.

An hBN/\textbeta-Ga\textsubscript{2}O\textsubscript{3} stack was obtained by transferring the CVD-synthesized hBN film on the Ga\textsubscript{2}O\textsubscript{3} substrate. The fabricated hBN/\textbeta-Ga\textsubscript{2}O\textsubscript{3} stack was used to fabricate an MIS-based Schottky junction device by depositing Ni and In metal electrodes, as shown in the schematic diagram (Figure 1b).

The fabricated Schottky junction with a configuration of Ni/ hBN/\textbeta-Ga\textsubscript{2}O\textsubscript{3}/In was characterized, and the effect of the interfacial hBN layer was analyzed. The as-received \textbeta-Ga\textsubscript{2}O\textsubscript{3} sample was characterized using X-ray diffraction (XRD), UV–vis absorption spectroscopy, and Raman spectroscopy. The XRD studies were carried out using a Rigaku Smart Lab SE with Cu K\textalpha radiation as the X-ray source (\(\lambda_{\text{Cu}} = 1.5406 \text{ Å}\)). A JEOL JSM 5600 scanning electron microscope at a voltage of 20 kV was used to examine the hBN-transfered \textbeta-Ga\textsubscript{2}O\textsubscript{3} sample. An NRS 3300 laser Raman spectrometer was used to analyze the \textbeta-Ga\textsubscript{2}O\textsubscript{3} sample at a laser excitation wavelength of 532.08 nm. Vertical Schottky junction

Figure 3. XPS spectra for the fabricated hBN/\textbeta-Ga\textsubscript{2}O\textsubscript{3} heterostructure sample. (a) B 1s spectra with a peak center at around 192.8 eV, (b) N 1s spectra with a peak center at 400.1 eV, (c) Ga 3d spectra with a peak center at 22.3 eV, and (d) Ga 2p\textsubscript{3/2} and Ga 2p\textsubscript{1/2} peaks with peak centers at 1119.4 and 1146.0 eV, respectively.

Figure 2a shows the cross-sectional image of the hBN and β-Ga2O3 heterostructure with the Schottky junction. The metal electrodes were created by depositing Ni and In metal electrodes with the help of a metal mask. A metal mask with round-shaped holes (electrode area ~0.003 cm²) was used to deposit the top Ni electrode, whereas the In electrode was deposited on the backside of the β-Ga2O3 substrate almost covering the entire surface. The metal electrodes were deposited using the ULVAC VPC-260F thermal evaporator under high vacuum. The mid- and high-frequency Raman peaks are at 61.01 cm⁻¹ corresponding to the (020) reflection phase of β-Ga2O3, was observed for the sample. The XRD spectra are shown in the JCPD card number 06-0246. The XPS peak for the β-Ga2O3 sample, presenting the elemental composition. Figure 3a shows the B 1s XPS spectrum for the hBN/β-Ga2O3 heterostructure and stable on the substrate surface. The current−voltage properties of the hBN/β-Ga2O3 heterostructure were confirmed by XPS analysis, with the transferred CVD-synthesized hBN film remaining intact and stable on the β-Ga2O3 substrate surface. The current−voltage characteristics indicate that a suitable Schottky junction formation for the Ni/β-Ga2O3 heterostructure was studied. Figure 4a shows the J−V characteristics for the device with a voltage range of −2 to 2 V. The inset of Figure 4a shows the schematic diagram for the fabricated Ni/β-Ga2O3 heterostructure with a peak center at 192 eV. Similarly, Figure 4b shows the N 1s XPS spectra for the hBN film on a β-Ga2O3 substrate with a peak center at 400.1 eV. Again, Figure 4c shows the Ga 3d peak with a peak center at around 22.3 eV for the β-Ga2O3 sample. The XPS peak for the β-Ga2O3 was obtained considering the thin hBN film for the fabricated hBN/β-Ga2O3 heterostructure. Figure 3d shows the split Ga 2p peaks, where Ga 2p₁/₂ and Ga 2p₃/₂ peaks are obtained at 1119 and 1144.8 eV, respectively. The chemical structures of the hBN/β-Ga2O3 heterostructure were further studied by X-ray photoelectron spectroscopy (XPS) analysis. Figure 3 shows the XPS analysis for the hBN/β-Ga2O3 sample, presenting the elemental composition. Figure 3a shows the B 1s XPS spectrum for the hBN/β-Ga2O3 heterostructure with a peak center at 192 eV. Similarly, Figure 4b shows the N 1s XPS spectra for the hBN film on a β-Ga2O3 substrate with a peak center at 400.1 eV. Again, Figure 4c shows the Ga 3d peak with a peak center at around 22.3 eV for the β-Ga2O3 sample. The XPS peak for the β-Ga2O3 was obtained considering the thin hBN film for the fabricated hBN/β-Ga2O3 heterostructure. Figure 3d shows the split Ga 2p peaks, where Ga 2p₁/₂ and Ga 2p₃/₂ peaks are obtained at 1119 and 1144.8 eV, respectively. The chemical structures of the hBN/β-Ga2O3 heterostructure were confirmed by XPS analysis, with the transferred CVD-synthesized hBN film remaining intact and stable on the β-Ga2O3 substrate surface. The current−voltage properties of the hBN/β-Ga2O3 heterostructure were studied. Figure 4a shows the J−V characteristics for the device with a voltage range of −2 to 2 V. The inset of Figure 4a shows the schematic diagram for the fabricated Ni/β-Ga2O3 heterostructure with a peak center at 192 eV. Similarly, Figure 4b shows the N 1s XPS spectra for the hBN film on a β-Ga2O3 substrate with a peak center at 400.1 eV. Again, Figure 4c shows the Ga 3d peak with a peak center at around 22.3 eV for the β-Ga2O3 sample. The XPS peak for the β-Ga2O3 was obtained considering the thin hBN film for the fabricated hBN/β-Ga2O3 heterostructure. Figure 3d shows the split Ga 2p peaks, where Ga 2p₁/₂ and Ga 2p₃/₂ peaks are obtained at 1119 and 1144.8 eV, respectively. The chemical structures of the hBN/β-Ga2O3 heterostructure were confirmed by XPS analysis, with the transferred CVD-synthesized hBN film remaining intact and stable on the β-Ga2O3 substrate surface. The current−voltage properties of the hBN/β-Ga2O3 heterostructure were studied.

### RESULTS AND DISCUSSION

Figure 2a shows the cross-sectional image of the hBN and β-Ga2O3 heterostructure with the Schottky junction. A barrier layer for the β-Ga2O3 Schottky junction can be formed by an hBN layer with a high band gap (6.0 eV) and a suitable dielectric constant. The XRD spectra of the free-standing β-Ga2O3 substrate are shown in Figure 2b. A strong diffraction peak at 61.01 cm⁻¹ corresponding to the (020) reflection phase of β-Ga2O3 was observed for the sample. The XRD spectra are shown in the JCPD card number 06-0246. Figure 2c shows a scanning electron microscopy (SEM) image for the transferred hBN film on the β-Ga2O3 substrate. The transferred hBN film on the β-Ga2O3 substrate remains intact due to van der Waals interaction; however, SEM analysis revealed the formation of a wrinkle in the hBN thin film and surface impurities. Generally, such a type of wrinkle formation is observed for the large-area-transferred hBN film synthesized by a CVD process. The Raman spectra of the β-Ga2O3 sample are shown in Figure 2d, with a high-intensity Raman peak at 200 cm⁻¹ for the Ag Raman mode, indicating the high-quality crystalline nature of the β-Ga2O3 sample used for device fabrication. The mid- and high-frequency Raman peaks are at around 354, 424, 486, 640, and 657 cm⁻¹, corresponding to distortion of Ga2O3 octahedra and the stretching/bending of the GaO3 tetrahedra, respectively, as also discussed in previous reports. These analyses show a successful transfer of the CVD-synthesized hBN film on the bulk β-Ga2O3 substrate.

The hBN/β-Ga2O3 sample was further studied by X-ray photoelectron spectroscopy (XPS) analysis. Figure 3 shows the XPS analysis for the hBN/β-Ga2O3 sample, presenting the elemental composition. Figure 3a shows the B 1s XPS spectrum for the hBN/β-Ga2O3 heterostructure with a peak center at 192 eV. Similarly, Figure 4b shows the N 1s XPS spectra for the hBN film on a β-Ga2O3 substrate with a peak center at 400.1 eV. Again, Figure 4c shows the Ga 3d peak with a peak center at around 22.3 eV for the β-Ga2O3 sample. The XPS peak for the β-Ga2O3 was obtained considering the thin hBN film for the fabricated hBN/β-Ga2O3 heterostructure. Figure 3d shows the split Ga 2p peaks, where Ga 2p₁/₂ and Ga 2p₃/₂ peaks are obtained at 1119 and 1144.8 eV, respectively. The chemical structures of the hBN/β-Ga2O3 heterostructure were confirmed by XPS analysis, with the transferred CVD-synthesized hBN film remaining intact and stable on the β-Ga2O3 substrate surface. The current−voltage properties of the hBN/β-Ga2O3 heterostructure were studied. Figure 4a shows the J−V characteristics for the device with a voltage range of −2 to 2 V. The inset of Figure 4a shows the schematic diagram for the fabricated Ni/β-Ga2O3 heterostructure with a peak center at 192 eV. Similarly, Figure 4b shows the N 1s XPS spectra for the hBN film on a β-Ga2O3 substrate with a peak center at 400.1 eV. Again, Figure 4c shows the Ga 3d peak with a peak center at around 22.3 eV for the β-Ga2O3 sample. The XPS peak for the β-Ga2O3 was obtained considering the thin hBN film for the fabricated hBN/β-Ga2O3 heterostructure. Figure 3d shows the split Ga 2p peaks, where Ga 2p₁/₂ and Ga 2p₃/₂ peaks are obtained at 1119 and 1144.8 eV, respectively. The chemical structures of the hBN/β-Ga2O3 heterostructure were confirmed by XPS analysis, with the transferred CVD-synthesized hBN film remaining intact and stable on the β-Ga2O3 substrate surface. The current−voltage properties of the hBN/β-Ga2O3 heterostructure were studied. Figure 4a shows the J−V characteristics for the device with a voltage range of −2 to 2 V. The inset of Figure 4a shows the schematic diagram for the fabricated Ni/β-Ga2O3 heterostructure with a peak center at 192 eV. Similarly, Figure 4b shows the N 1s XPS spectra for the hBN film on a β-Ga2O3 substrate with a peak center at 400.1 eV. Again, Figure 4c shows the Ga 3d peak with a peak center at around 22.3 eV for the β-Ga2O3 sample. The XPS peak for the β-Ga2O3 was obtained considering the thin hBN film for the fabricated hBN/β-Ga2O3 heterostructure. Figure 3d shows the split Ga 2p peaks, where Ga 2p₁/₂ and Ga 2p₃/₂ peaks are obtained at 1119 and 1144.8 eV, respectively. The chemical structures of the hBN/β-Ga2O3 heterostructure were confirmed by XPS analysis, with the transferred CVD-synthesized hBN film remaining intact and stable on the β-Ga2O3 substrate surface. The current−voltage properties of the hBN/β-Ga2O3 heterostructure were studied.
Figure 5 shows the $J-V$ characteristics of the fabricated device with and without UV light illumination under $-8$ to $8$ V. The forward turn-on voltage for the Ni/$\beta$-Ga$_2$O$_3$/In Schottky junction was obtained to be around 3.8 V. Figure 5a,b shows the $J-V$ characteristic in the dark and the corresponding logarithmic plot for bias voltages ranging from $-8$ to $8$ V. The $J-V$ characteristics of the Ni/$\beta$-Ga$_2$O$_3$ Schottky junction, Figure 5c, depict a schematic of the fabricated device with a device structure of Ni/$\beta$-Ga$_2$O$_3$/In, the forward and reverse sweeps at bias voltages ranging from $-8$ to $8$ V. For the forward bias voltage, the measured $J-V$ curve revealed no hysteresis effect. Figure 5d depicts the $J-V$ characteristics of an applied bias voltage ranging from $-8$ to $8$ V under deep UV illumination (254 nm). Similarly, a dark current of 0.00208 mA/cm$^2$ was enhanced to 0.0643 mA/cm$^2$ at a reverse bias voltage of 7.2 V, under the illumination of 254 nm wavelength and a power density of 614 $\mu$W/cm$^2$. The photoresponsivity is calculated to be 101.33 mA/W at 7.2 V reverse bias voltage for the constructed Ni/$\beta$-Ga$_2$O$_3$/In Schottky junction device.

Figure 6a shows a schematic diagram of the fabricated Ni/hBN/$\beta$-Ga$_2$O$_3$/In Schottky junction device. The CVD-synthesized hBN film was transferred on $\beta$-Ga$_2$O$_3$ by wet-etching the Cu foil with a support layer of PMMA. The Ni top electrode on the hBN/$\beta$-Ga$_2$O$_3$ heterojunction was deposited by thermal evaporation to configure a Schottky junction device. Figure 6b depicts the $J-V$ characteristics of the fabricated device with and without deep-UV light illumination for a bias voltage range of $-2$ to $2$ V (wavelength 254 nm). In contrast to the device fabricated without the hBN layer, the forward current did not increase as the bias voltage was increased up to 2 V. The hBN film with an ultrawide band gap can act as a barrier layer at the interface of Ni and $\beta$-Ga$_2$O$_3$. However, at the reverse bias voltage, photoresponsivity was measured, indicating the heterojunction device’s sensitivity to deep-UV light.

Figure 7a shows the $J-V$ characteristics of the Ni/hBN/$\beta$-Ga$_2$O$_3$/In Schottky junction device for the voltage range of $-8$ to 8 V. The forward turn voltage for the Ni/hBN/$\beta$-Ga$_2$O$_3$/In Schottky junction was obtained to be around 4.8 V, which is higher than that of the device with the hBN layer. It was also observed that the device’s forward current was significantly low up to an applied voltage of 2 V. Figure 7b shows the corresponding logarithmic plot for the corresponding $J-V$ curve. (a) $J-V$ characteristics with and without deep-UV illumination (254 nm) for bias voltage in the range of $-8$ to 8 V and (d) photoresponsivity at the reverse bias voltage (photoresponsivity of 95.11 mA/W at 7.2 V).
curve. Similarly, Figure 7c shows the $J-V$ characteristics for the device with and without light illumination. Under the illumination of deep-UV light with a wavelength of 254 nm, a significant photoresponsivity can be observed in the reverse bias voltage. Figure 7d depicts the $J-V$ curve in the reverse bias voltage range (0 to −8 V) used to measure photoresponsivity at a bias voltage. At 7.2 V bias, the photoresponsivity was 95.11 mA/W. The photoresponsivity is nearly identical to that of the device without the hBN layer; however, the forward turn-on voltage is higher, and the current density is lower. Turn-on voltage and forward current density differ significantly with and without the hBN layer on the $\beta$-Ga$_2$O$_3$, whereas photoresponsive reverse current density was nearly identical at an applied bias voltage of −7.2 V. Thus, a high photoresponsivity can be obtained in a Ni/hBN/$\beta$-Ga$_2$O$_3$/In-based heterojunction Schottky diode with high forward current turn-on voltage and low current density.

Figure 8a shows the energy band diagram for the Ni/$\beta$-Ga$_2$O$_3$ Schottky junction. The Ni metal contact with a higher work function (5.15 eV) forms a suitable Schottky potential with the n-type $\beta$-Ga$_2$O$_3$. A photoresponsivity was obtained at a reverse bias voltage for the illuminated deep-UV light considering the Schottky junction interface of Ni and Ga$_2$O$_3$. Similarly, Figure 8b shows the energy band diagram for the Ni/$\beta$-Ga$_2$O$_3$ Schottky junction, where the hBN layer acts as a barrier layer at the Ni and $\beta$-Ga$_2$O$_3$ interface. The $J-V$ curve shows that the diode turn-on voltage increased, but no reduction in reverse saturation current was observed. The photoresponsivity of the Ni/hBN/$\beta$-Ga$_2$O$_3$/Schottky junction to the illuminated deep-UV light of wavelength 254 nm was 95.11 mA/W. Thus, the Ni/hBN/$\beta$-Ga$_2$O$_3$/In Schottky junction demonstrated that a significant photoresponsivity can be obtained with a tunable turn-on voltage and forward current. Our study showed that the interfacial hBN layer can be used as an insulating barrier layer for the fabrication of ultrawide band gap Schottky junction devices.

# CONCLUSIONS

In conclusion, we have demonstrated the fabrication of a Ni/$\beta$-Ga$_2$O$_3$ Schottky junction device with an hBN interface layer. The hBN film was synthesized by CVD process and transferred on a free-standing $\beta$-Ga$_2$O$_3$ substrate by the wet chemical transfer method. XRD, Raman spectroscopy, and SEM analysis confirmed the hBN/$\beta$-Ga$_2$O$_3$ heterostructure of the Ga$_2$O$_3$ substrate and transferred hBN film. The $J-V$ characteristics of a fabricated Schottky junction with and without the hBN interfacial layer were investigated. It was discovered that the hBN interfacial film significantly increases the turn-on voltage for the forward current of the Ni/hBN/Ga$_2$O$_3$/In Schottky junction. Furthermore, the created Ni/hBN/Ga$_2$O$_3$/In Schottky junction showed a photoresponsivity of 95.11 mA/W for the illuminated deep-UV light of wavelength 254 nm. The hBN layer acts as a suitable barrier layer as demonstrated, where the turn-on voltage, forward current density, and photoresponsivity can be optimized for the Ni/$\beta$-Ga$_2$O$_3$ Schottky junction.
