Abstract

We characterize Gaussian estimates for transition probability of a discrete time Markov chain in terms of geometric properties of the underlying state space. In particular, we show that the following are equivalent:

1. Two sided Gaussian bounds on heat kernel
2. A scale invariant Parabolic Harnack inequality
3. Volume doubling property and a scale invariant Poincaré inequality.

The underlying state space is a metric measure space, a setting that includes both manifolds and graphs as special cases. An important feature of our work is that our techniques are robust to small perturbations of the underlying space and the Markov kernel. In particular, we show the stability of the above properties under quasi-isometries. We discuss various applications and examples.
CHAPTER 1

Introduction

The goal of this work is to characterize Gaussian estimates for Markov chains and parabolic Harnack inequality for a corresponding discrete time version of heat equation by two geometric properties on the state space

1. Large scale volume doubling property
2. Poincaré inequality.

A precise statement of this characterization is given in Theorem 1.4. The Gaussian estimates mentioned are upper and lower bounds for the iterated transition probability kernel. The parabolic Harnack inequality is a regularity estimate for non-negative solutions of the discrete time heat equation given by $u(k+1, x) = [Pu(k, \cdot)](x)$, where $P$ is the Markov operator corresponding to the given Markov chain.

The hardest and most useful implication in the characterization is that the conjunction of the volume doubling property and Poincaré inequality implies the two sided Gaussian estimates and parabolic Harnack inequality. The volume doubling property and Poincaré inequality are concrete properties the validity of which can be verified given the geometric data on the space. Also, an important consequence of this characterization is the stability of Gaussian estimates and parabolic Harnack inequality under quasi-isometric transformation of the underlying space.

An analogous characterization is well-known for diffusions on Riemannian manifolds [32, 69](or more generally local Dirichlet spaces [76]) and for discrete time Markov chains on graphs [27]. We extend the characterization of Gaussian estimates for Markov chain to a large family of state spaces that includes both graphs and Riemannian manifolds. Various applications of Gaussian estimates and Harnack inequalities are discussed.

Another motivation comes from the work of Hebisch and Saloff-Coste [44] on random walks on groups. By the main results of [44], we know that many natural translation-invariant Markov chains on groups (discrete and continuous groups) of polynomial volume growth satisfy two-sided Gaussian estimates. However the arguments in [44] for proving Gaussian lower bounds are specific to the case of translation-invariant Markov chains as the authors of [44] note “We want to emphasize that a number of key points of the argument presented below are specific to the case of translation invariant Markov chains”. To this end they conjecture “We have no doubt that, if $G$ has polynomial volume growth a corresponding Gaussian lower bound holds for (non translation-invariant) Markov chains as well. However, we have not been able to prove this result. We hope to come back to this question in the future.” [44, Remark 2]. Our work validates their conjecture.
A remarkable feature of our work is that the arguments we develop are robust under small perturbations of the Markov kernel and the geometry of the underlying state space. In particular, we show that parabolic Harnack inequality and Gaussian estimates for heat kernel for symmetric Markov chains is stable under quasi-isometric change of the state space and small changes in the Markov kernel. We do not rely on symmetries of the space (like group structure or transitivity) or on algebraic properties of the kernel (like translation invariance). As a consequence, the main results are new even when the state space is $\mathbb{R}^n$.

Heat kernel estimates and Harnack inequalities have been subjects of extensive research for more than fifty years. To place our results in a historical context, we will describe precisely the characterization of Gaussian estimates of heat kernel and parabolic Harnack inequality in the context of diffusions over manifolds developed in [32, 69]. We will also mention several related works, applications and other historical remarks.

1.1. Diffusions on Riemannian manifolds

For the purpose of the introduction, we describe our results in the restricted setting of weighted Riemannian manifolds. Let $(M,g)$ be a complete Riemannian manifold equipped with the Riemannian measure $\nu(dy)$. A weighted Riemannian manifold $(M,g,\mu)$ is a Riemannian manifold $(M,g)$ equipped with a measure $\mu(dy) = \sigma(y)\nu(dy)$, where $0 < \sigma \in C^\infty(M)$ is the weight, and the associated weighted Laplacian is given by $\Delta = -\sigma^{-1}\text{div}(\sigma\text{grad})^1$. We might sometimes consider a Riemannian manifold $(M,g)$ as a weighted Riemannian manifold equipped with Riemannian measure and Laplace-Beltrami operator. We denote the balls centered at $x$ and radius $r$ by $B(x,r) := \{y : d(x,y) \leq r\}$ and the volume of the balls by $V(x,r) := \mu(B(x,r))$. We denote the open balls by $B(x,r)^o := \{y : d(x,y) < r\}$.

The heat kernel of the weighted Riemannian manifold $(M,g,\mu)$ is the fundamental solution of a parabolic partial differential equation, the heat diffusion equation

$$\left(\frac{\partial}{\partial t} + \Delta\right) u = 0.$$  

That is heat kernel is a function $(t,x,y) \mapsto p(t,x,y)$ defined on $(0,\infty) \times M \times M$ such that for each $y \in M$, $(t,x) \mapsto p(t,x,y)$ is a solution of (1.1) and for any $\phi \in C_c^\infty(M)$, $u(t,x) = \int_M p(t,x,y)\phi(y)\mu(dy)$ tends to $\phi(x)$ as $t$ tends to 0. In other words, the heat kernel allows us to solve the Cauchy initial value problem for (1.1). Equivalently, we may view $p(t,x,y)\mu(dy)$ as the distribution at time $t$ of a stochastic process $(X_t)_{t \geq 0}$ started at $x$ (the diffusion driven by $\Delta$ on $M$). These two viewpoints are related by the formula

$$u(t,x) = \int_M p(t,x,y)\mu(dy) = \mathbb{E}_x(u_0(X_t))$$

where $u$ is the solution of Cauchy initial value problem for (1.1) with initial value condition $u_0$.

---

1The negative sign is to ensure that $\Delta$ has non-negative spectrum. Note that $\Delta$ depends on the Riemannian metric $g$ and the weight $\sigma$. 

1.1. DIFFUSIONS ON RIEMANNIAN MANIFOLDS

The most classical example of heat kernel is the Gauss-Weierstrass kernel on \( \mathbb{R}^n \) equipped with the Lebesgue measure, the Laplacian \( \Delta = -\sum_{i=1}^{n} \frac{\partial^2}{\partial x_i^2} \) and the heat kernel is given by

\[
p(t, x, y) = \left( \frac{1}{4\pi t} \right)^{n/2} \exp\left( -\frac{d(x, y)^2}{4t} \right), \quad t > 0, \quad x, y \in \mathbb{R}^n.
\]

We will present a well-known geometric characterization of those weighted Riemannian manifolds on which the heat kernel satisfies two-sided Gaussian bounds, that is having the property that there exists positive reals \( c_1, c_2, C_1, C_2 \) such that

\[
\frac{c_1}{V(x, \sqrt{t})} \exp\left( -\frac{d(x, y)^2}{c_2 t} \right) \leq p(t, x, y) \leq \frac{c_1}{V(x, \sqrt{t})} \exp\left( -\frac{d(x, y)^2}{c_2 t} \right)
\]

for all \( t > 0 \) and for all \( x, y \in M \).

Next, we describe Harnack inequalities for \((M, g, \mu)\) equipped with the weighted Laplacian \( \Delta \). We say that \((M, g, \mu)\) satisfies elliptic Harnack inequality if there exists \( C > 0 \) such that any non-negative harmonic function \( u \) in a ball \( B(x, r) \) (that is \( u \) satisfies \( \Delta u \equiv 0 \) in \( B(x, r) \)) satisfies the inequality

\[
\sup_{B(x, r/2)} u \leq C \inf_{B(x, r/2)} u.
\]

The constant \( C \in (0, \infty) \) is independent \( x, r \) and \( u \). An important consequence of the elliptic Harnack inequality in \( \mathbb{R}^n \) for the Laplacian \( \Delta = -\sum_{i=1}^{n} \frac{\partial^2}{\partial x_i^2} \) is that global positive harmonic functions must be constant (Liouville property).

J. Moser [61] proved elliptic Harnack inequality (1.3) for divergence form operators of the type

\[
\mathcal{L} = -\sum_{i,j=1}^{n} \frac{\partial}{\partial x_i} a_{i,j} \frac{\partial}{\partial x_j}
\]

where \( a_{i,j} \) are bounded measurable real functions on \( \mathbb{R}^n \) satisfying \( a_{i,j} = a_{j,i} \) and the uniform ellipticity condition:

\[
\forall x \in \mathbb{R}^n, \quad \forall \xi \in \mathbb{R}^n, \quad \lambda \|\xi\|^2 \leq \sum_{i,j} a_{i,j}(x) \xi_i \xi_j \leq \Lambda \|\xi\|^2
\]

for two constants \( 0 < \lambda \leq \Lambda < \infty \). This elliptic Harnack inequality implies the crucial Hölder continuity for solutions\(^2\) of the associated elliptic equation \( \mathcal{L} u \equiv 0 \), a result proved earlier by E. de Giorgi [24] and J. Nash [64] (See also [60]).

An important motivation behind the Hölder continuity of solutions obtained by de Giorgi, Nash and Moser [24, 64, 60] was to solve one of the famous Hilbert problems. Hilbert’s nineteenth problem asks whether the minimizers of Dirichlet integrals

\[
E(u) = \int_{\Omega} F(\nabla u(x)) \, dx
\]

are always smooth, if \( F \) is smooth and strictly convex, where \( \Omega \subset \mathbb{R}^n \) is bounded. E. de Giorgi and J. Nash independently answered Hilbert’s question in the affirmative.

We refer the interested reader to [49, Theorem 14.4.1] for a detailed exposition of the smoothness of the minimizers of Dirichlet integrals using Hölder regularity estimates of de Giorgi and Nash.

\(^2\)by solutions we mean weak solutions.
It is a long standing open problem to characterize (in geometric terms) those weighted manifolds that satisfy elliptic Harnack inequality. A related open question is to determine whether or not elliptic Harnack inequality is preserved under quasi-isometries. However several examples of Riemannian manifolds that satisfy elliptic Harnack inequality are known. For instance, Cheng and Yau \[16\] proved that there exists a constant depending only on \(\dim(M)\) such that for any positive solution \(u\) of \(\Delta u = 0\) in \(B(x,r)\) on a Riemannian manifold \((M,g)\) with Ricci curvature bounded from below by \(-K\) for some \(K \geq 0\) satisfies
\[
|\nabla \ln(u)| \leq C(r^{-1} + K) \quad \text{in} \quad B(x,r/2).
\]
When \(K = 0\), integrating the gradient estimate along minimal paths we immediately obtain the elliptic Harnack inequality \((1.3)\) for Riemannian manifolds with non-negative Ricci curvature.

We now describe the parabolic version of \((1.3)\). For any \(x \in M\), \(s \in \mathbb{R}\), \(r > 0\), let \(Q = Q(x,s,r)\) be the cylinder
\[
Q(x,s,r) = (s - r^2, s) \times B(x,r)^0.
\]
Let \(Q_+\) and \(Q_-\) be respectively the upper and lower sub-cylinders
\[
Q_+ = (s - (1/4)r^2, s) \times B(x,r/2)^0, \quad Q_- = (s - (3/4)r^2, s - (1/2)r^2) \times B(x,r/2)^0.
\]
We say that \((M,g,\mu)\) satisfies parabolic Harnack inequality if there exists a constant \(C\) such that for all \(x \in M\), \(s \in \mathbb{R}\), \(r > 0\) and for all positive solutions of \(\left(\frac{\partial}{\partial t} - \Delta\right) u = 0\) in \(Q = Q(x,s,r)\), we have
\[
\sup_{Q_-} u \leq C \inf_{Q_+} u.
\]
The constants \(1/4, 3/4, 1/2\) appearing in the definition of \(Q_+, Q_-\) are essentially arbitrary choices. The main difference between elliptic and parabolic Harnack inequalities is that the cylinders \(Q_+\) and \(Q_-\) are disjoint in \((1.6)\) whereas in the elliptic case \((1.3)\) the infimum and supremum are taken over the same ball.

J. Moser attributes the first parabolic Harnack inequality to Hadamard and Pini for operators with constant coefficients on \(\mathbb{R}^n\). In \[62\], J. Moser proved the parabolic Harnack inequality for uniformly elliptic operators in divergence form as given by \((1.4)\). As in the elliptic case, the parabolic Harnack inequality \((1.6)\) implies Hölder continuity of the corresponding solutions. This Hölder continuity was first obtained by J. Nash \[64\] in the parabolic setting and Moser’s parabolic Harnack inequality gives an alternative proof of Hölder continuity. For a proof of Harnack inequality using the ideas of Nash, we refer the reader to the work of Fabes and Stroock \[31\].

The gradient estimates \((1.5)\) of Cheng and Yau was generalized to the parabolic case by P. Li and S.T. Yau in \[58\]. The parabolic gradient estimates in \[58\] implies that complete Riemannian manifolds with non-negative Ricci curvature satisfy parabolic Harnack inequality \((1.6)\).

In contrast to elliptic Harnack inequality, there is a satisfactory description of weighted Riemannian manifolds that satisfy the parabolic Harnack inequality as described below.

**Theorem 1.1.** ([32, 69]) Let \((M,g,\mu)\) be a weighted, non-compact, complete Riemannian manifold equipped with the weighted Laplacian \(\Delta\) and let \(p(t,x,y)\) denote the corresponding heat kernel. The following three properties are equivalent:
(a) The parabolic Harnack inequality: there exists a constant $C_H > 0$ such that, for any ball $B = B(x, r)$, $x \in M$, $r > 0$ and for any smooth positive solution $u$ of $(\frac{\partial}{\partial t} + \Delta) u = 0$ in the cylinder $(s - r^2, s) \times B(x, r)^c$, we have

$$\sup_{Q} u \leq C_H \inf_{Q^c} u$$

with

$$Q_+ = (s - (1/4)r^2, s) \times B(x, r/2)^c, \quad Q_- = (s - (3/4)r^2, s - (1/2)r^2) \times B(x, r/2)^c.$$ 

(b) Two sided Gaussian estimates of the heat kernel: there exists positive reals $c_1, c_2, C_1, C_2$ such that

$$\frac{c_1}{V(x, \sqrt{t})} \exp\left(\frac{-d(x, y)^2}{c_2 t}\right) \leq p(t, x, y) \leq \frac{c_1}{V(x, \sqrt{t})} \exp\left(\frac{-d(x, y)^2}{c_2 t}\right)$$

for all $t > 0$ and for all $x, y \in M$.

(c) The conjunction of

- The volume doubling property: there exists $C_D > 0$ such that for all $x \in M$, for all $r > 0$ we have

$$V(x, 2r) \leq C_D V(x, r).$$

- The Poincaré inequality: there exists $C_P > 0, \kappa \geq 1$ such that for any ball $B = B(x, r)$, $x \in M$, $r > 0$ and for all $f \in C^\infty(M)$, we have

$$\int_B |f - f_B|^2 \, d\mu \leq C_P r^2 \int_{\kappa B} |\nabla f|^2 \, d\mu,$$

where $\kappa B = B(x, \kappa r)$ and $f_B = \frac{1}{\mu(B)} \int_B f \, d\mu$.

Example 1.2. We present examples of complete, non-compact, weighted Riemannian manifolds satisfying parabolic Harnack inequality and Gaussian bounds on the heat kernel. We refer the reader to [73, Section 3.3] for a more extensive list of examples.

- Complete Riemannian manifolds with non-negative Ricci curvature. The parabolic Harnack inequality was first obtained in this case by Li and Yau using a gradient estimate [58]. The volume doubling property follows from Bishop-Gromov inequality [15, Theorem III.4.5] and the Poincaré inequality follows from the work of P. Buser [14] (See [72, Theorem 5.6.5] for a different proof).

- Convex domains and complement of convex domains in Euclidean space. We refer the reader to the monograph [41] for this and other examples in this spirit.

- Connected Lie groups with polynomial volume growth. By a theorem of Y. Guiv'arch, we know that Lie groups with polynomial volume growth satisfies volume doubling property. Moreover, Lie groups with polynomial volume growth satisfy Poincaré inequality [72, Theorem 5.6.1]. Examples include nilpotent Lie groups like Euclidean spaces and Heisenberg group. See also [78, Theorem VIII.2.9]. Moreover volume doubling property and Poincaré inequality holds for subelliptic ‘sum of squares’ operators satisfying the Hörmander condition [78, Chapter V and VIII] under the Carnot-Carathéodory metric. See also [72, Section 5.6.1].
1. INTRODUCTION

- The Euclidean space $\mathbb{R}^n$, with $n \geq 2$ and weight $(1+|x|^2)^{\alpha/2}$, $\alpha \in (-\infty, \infty)$ satisfies parabolic Harnack inequality if and only if $\alpha > -n$. It satisfies the elliptic Harnack inequality for all $\alpha \in \mathbb{R}$. These examples are from [35].

- Any complete, weighted Riemannian manifold with bounded geometry that is quasi-isometric to a complete, weighted Riemannian manifold satisfying parabolic Harnack inequality. We say a weighted Riemannian manifold $(M,g,\mu)$ has bounded geometry if (a) There exists $K \geq 0$ such that $\text{Ric} \geq -Kg$ (b) There exists $C_1 > 1$ such that $\sigma(x)/\sigma(y) \in (C_1^{-1}, C_1)$ for all $x, y \in M$ with $d(x, y) \leq 1$ (c) There exists $C_2 > 1$ such that $C_2^{-1} \leq V(x, 1) \leq C_2$ for all $x \in M$. This illustrates the stability of parabolic Harnack inequality and two-sided Gaussian estimates under quasi-isometry [22, 50].

The primary goal of our work is to extend Theorem 1.1 in the context of discrete time Markov chains on a large class of spaces that include both weighted Riemannian manifolds and graphs. As mentioned before the hardest and most useful part of the Theorem 1.1 is (c) implies (a) and (b). The implication (c) implies (a) was proved independently by Grigor’yan [32] and Saloff-Coste [69]. Both [32] and [69] observed that volume doubling is necessary to obtain (a). In [69], Saloff-Coste proved that Poincaré inequality is also a necessary condition to prove (a) using an argument due to Kusuoka and Stroock [55].

The proof of (c) implies (a) in [69] is an adaptation of Moser’s iteration method. Moser’s iteration method relies on Poincaré inequality and a Sobolev inequality. The main contribution of [69] is to obtain a Sobolev inequality using volume doubling and Poincaré inequality (See also [72, Chapter 5], [70]). A. Grigor’yan [32] carried out a different iteration argument that relied on an equivalent Faber-Krahn inequality instead of a Sobolev inequality to prove (c) implies (a). Using the methods of [69], K.T. Sturm [76] generalized the above equivalence to diffusions on strongly local Dirichlet spaces. More recently in [45], Hebsich and Saloff-Coste developed an alternate approach to prove Gaussian bounds and parabolic Harnack inequality using (a). This approach relies on an elliptic Hölder regularity estimate and Gaussian upper bounds to prove parabolic Harnack inequality. We will use the approach outlined in [45] in our work.

Aronson [3] was the first to use parabolic Harnack inequality to obtain Gaussian bounds on the heat kernel in the context of divergence form uniformly elliptic operators in $\mathbb{R}^n$ as given in (1.4). Although in Aronson’s work, the parabolic Harnack inequality was used only to obtain Gaussian lower bounds, both Gaussian upper and lower bounds can be easily obtained using parabolic Harnack inequality. Conversely Nash’s approach aimed at deriving Harnack inequality from two-sided Gaussian bounds on the heat kernel was further developed by Krylov and Safonov [54] and by Fabes and Stroock [31].

1.2. Random walks on graphs

T. Delmotte extended Theorem 1.1 for discrete time Markov chains on graphs, which we now describe. To precisely describe the result, we will introduce some notions concerning symmetric Markov chains. Let $(M,d,\mu)$ be a metric measure space by which we mean a metric space $(M,d)$ equipped with a Borel measure
1.2. RANDOM WALKS ON GRAPHS

Recall that we denote closed ball by \( B(x, r) \) and their measure by \( V(x, r) = \mu(B(x, r)) \). We require \( V(x, r) \in (0, \infty) \) for all \( x \in M \) and for all \( r \in (0, \infty) \).

Let \( (X_n)_{n \in \mathbb{N}} \) be a Markov chain with state space \( M \) and let \( P \) be the corresponding Markov operator. Further, we assume that \( P \) has a kernel \( p_1 : M \times M \to \mathbb{R} \) with respect to the measure \( \mu \), that is for each \( x \in M \), we have \( p_1(x, \cdot) \in L^1(M, \mu) \) satisfying

\[
P f(x) = \mathbb{E}_x f(X_1) = \int_M p_1(x, y) f(y) \mu(dy)
\]

for all \( f \in L^\infty(M) \). Here \( \mathbb{E}_x \) denotes that the Markov chain starts at \( X_0 = x \). The equation (1.8) represents the basic relation between the Markov chain \( (X_n)_{n \in \mathbb{N}} \), corresponding Markov operator \( P \) and its kernel \( p_1 \) with respect to \( \mu \). We will assume that our Markov chain is stochastically complete that is \( P1 = 1 \) or equivalently \( \int_M p_1(x, y) \mu(dy) = 1 \) for all \( x \in M \).

We further assume that the kernel \( p_1 \) satisfies \( p_1(x, \cdot) \in L^\infty(M, \mu) \) for all \( x \in M \) and that \( p_1 \) is symmetric

\[
p_1(x, y) = p_1(y, x)
\]

for \( \mu \times \mu \)-almost every \( (x, y) \in M \times M \). Under the symmetry assumption (1.9) and the assumption \( p_1(x, \cdot) \in L^\infty(M, \mu) \) for all \( x \in M \), we define the iterated Markov kernel as for the Markov chain as

\[
p_{k+1}(x, y) := \int_M p_k(x, z)p_1(y, z) \mu(dz)
\]

for all \( x, y \in M \) and for all \( k \in \mathbb{N}^* \). It is easy to check that \( p_k(x, y)\mu(dy) \) is the distribution of \( X_k \) given that the random walk starts at \( X_0 = x \) (See Lemma 4.2). The function \( (k, x, y) \mapsto p_k(x, y) \) is called the ‘heat kernel’ for the symmetric Markov chain \( (X_n)_{n \in \mathbb{N}} \) driven by \( P \) on \((M, d, \mu)\).

Next, we introduce the Laplacian and heat equation for discrete time Markov chains. The Laplace operator \( \Delta_P \) corresponding to the random walk driven by \( P \) is

\[
\Delta_P = I - P.
\]

The corresponding discrete time heat equation is

\[
\partial_k u + \Delta_P u_k = 0
\]

for all \( k \in \mathbb{N} \), where \( \partial_k u(\cdot) = u(k + 1, \cdot) - u(k, \cdot) \) denotes the difference operator and \( u_k(\cdot) = u(k, \cdot) \). Note that (1.10) can be rewritten as \( u_{k+1} = Pu_k \). Therefore the ‘solution’ to the heat equation (1.10) can be written as

\[
u(x, k) = P^k u_0(x) = \int_M p_k(x, y)u_0(y) \mu(dy) = \mathbb{E}_x u_0(X_k)
\]

for all \( x \in M \) and for all \( k \in \mathbb{N}^* \) where \( u_0 \) is the initial value. Note that the above equation is analogous to its continuous time counterpart (1.2).

To describe the work of T. Delmotte, we consider a given graph as a metric measure space \((M, d, \mu)\) where \( M \) is the vertex set of the graph, \( d \) is the graph distance metric and \( \mu \) is a measure on the set of vertices such that each vertex has positive measure. In this context \( p_1(x, y) = p_1(y, x) \) for all \( x, y \in M \) is sometimes called the conductance. We denote integer intervals by \([a, b]\) = \( \{ k \in \mathbb{Z} : a \leq k \leq b \} \) for any \( a, b \in \mathbb{Z} \). The following theorem of T. Delmotte is the analogue of Theorem 1.1 for Markov chains on graphs.
1. Introduction

Theorem 1.3. ([27]) Let $(M, d, \mu)$ be an infinite graph equipped with a measure \( \mu \) on the set of vertices \( M \). Consider a Markov chain on \( M \) with a symmetric kernel \( p_k \) with respect to \( \mu \). Further we assume that there exists \( \alpha > 0 \) such that

\[
(1.11) \quad \alpha \frac{1_{B(x,1)}(y)}{V(x,1)} \leq p_1(x,y) \leq \alpha^{-1} \frac{1_{B(x,1)}(y)}{V(x,1)}
\]

for all \( x, y \in M \). Then the following properties are equivalent:

(a) The parabolic Harnack inequality: there exists \( \eta \in (0,1), C_H > 1, R_H > 0 \) such that for all balls \( B(x,r) \), \( x \in M, r > R_H \) and for all non-negative functions \( u : \mathbb{N} \times M \to \mathbb{R} \) that satisfies \( \partial_t u + \Delta u_k \equiv 0 \) in \([0, [4\eta^2 r^2]] \times B(x,r)\), we have

\[
\sup_{Q_0} u \leq C_H \inf_{Q_0} u
\]

where

\[
Q_0 = \left([\lfloor \eta^2 / 2 \rfloor^2, \lfloor 2\eta^2 r^2 \rfloor] \times B(x,(\eta / 2)r),
\right)
\]

Further there exists \( c_1, c_2, c_3 > 0 \) such that for all \( x, y \in M \) satisfying \( d(x,y) \leq c_3 n \) and for all \( n \in \mathbb{N} \) satisfying \( n \geq 2 \), we have

\[
(1.12) \quad p_n(x,y) \leq \frac{C_1}{V(x,\sqrt{n})} \exp \left( -\frac{d(x,y)^2}{C_2 n} \right)
\]

(b) Two sided Gaussian bounds on the heat kernel: there exists \( C_1, C_2 > 0 \) such that for all \( x, y \in M \) and for all \( n \in \mathbb{N}^* \) satisfying \( n \geq 2 \), we have

\[
(1.13) \quad p_n(x,y) \geq \frac{c_1}{V(x,\sqrt{n})} \exp \left( -\frac{d(x,y)^2}{c_2 n} \right)
\]

(c) The conjunction of

- The volume doubling property: there exists \( C_D > 0 \) such that for all \( x \in M, \) for all \( r > 0 \) we have

\[
V(x,2r) \leq C_D V(x,r)
\]

- The Poincaré inequality: there exists \( C_P > 0, \kappa \geq 1 \) such that for any ball \( B = B(x,r) \) that satisfies \( x \in M, r > 1 \) and for all \( f \in L^2(M, \mu) \), we have

\[
\int_B |f - f_B|^2 d\mu \leq C_P r^2 \int_{\kappa B} \left( \frac{1}{V(y,1)} \right) \int_{B(y,1)} |f(z) - f(y)|^2 \mu(dz) \mu(dy),
\]

where \( \kappa B = B(x,\kappa r), f_B = \frac{1}{\mu(B)} \int_B f d\mu \).

Delmotte’s strategy to prove Theorem 1.3 is to use Moser’s iteration method as developed in [69, 70] to prove a continuous time parabolic Harnack inequality. The next step is to prove estimates on the corresponding continuous time kernel obtained using parabolic Harnack inequality. Then a comparison between discrete and continuous time kernels provides Gaussian bounds on \( p_k \) which in turn yields parabolic Harnack inequality for the discrete time heat equation (1.10). The comparison argument is tricky because the continuous time heat kernel has non-Gaussian behavior as discovered by Pang [65] and E.B. Davies [23]. The discrete

\[3\] The upper bound in (1.11) was not explicitly stated in [27]. However the upper bound must hold due to the volume doubling property. Moreover the statement of Poincaré inequality and parabolic Harnack inequality is slightly different but equivalent to the ones presented in [27].
nature of space and time causes numerous other difficulties during Moser iteration that were overcome successfully by Delmotte.

1.3. Main results

Next, we state a version of our main result in a restricted setting. Recall that a weighted Riemannian manifold \((M, g, \mu)\) is a Riemannian manifold \((M, g)\) equipped with a measure \(\mu\) such that \(\mu(dy) = \sigma(y)\nu(dy)\), where \(\nu\) is the Riemannian measure and \(\sigma \in C^\infty(M)\) is the weight function.

**Theorem 1.4.** Let \((M, g, \mu)\) be a complete non-compact, weighted Riemannian manifold such that there exists \(K \geq 0\) such that \(\text{Ric} \geq -Kg\). Furthermore there exists \(C_1 \geq 1\) such that the weight function \(\sigma\) satisfies \(C_1^{-1} \leq \sigma(x)/\sigma(y) \leq C_1\) for all \(x, y \in M\) with \(d(x, y) \leq 1\). Consider a Markov chain on \(M\) with a symmetric kernel \(p_k\) with respect to \(\mu\). Further we assume that there exists \(C_0 > 1, h > 0, h' \geq h\) such that

\[
C_0^{-1} \frac{1_{B(x, h)}(y)}{V(x, h)} \leq p_1(x, y) \leq C_0 \frac{1_{B(x, h')}(y)}{V(x, h')}
\]

for all \(x \in M\) and for \(\mu\)-almost every \(y \in M\). Then the following properties are equivalent:

(a) The parabolic Harnack inequality: there exists \(\eta \in (0, 1), C_H > 1, R_H > 0\) such that for all balls \(B(x, r), x \in M, r > R_H\) and for all non-negative functions \(u : \mathbb{N} \times M \to \mathbb{R}\) that satisfies \(\partial_t u + \Delta u = 0\) in \([0, [4\eta^2r^2]] \times B(x, r)\), we have

\[
\sup_{Q_{\otimes}} u \leq C_H \inf_{Q_{\odot}} u
\]

where

\[
Q_{\otimes} = [([\eta^2/2]^2, [\eta^2r^2]) \times B(x, (\eta/2)r),
Q_{\odot} = [[2\eta^2r^2], [4\eta^2r^2]] \times B(x, (\eta/2)r)
\]

(b) Two sided Gaussian bounds on the heat kernel: there exists \(C_1, C_2 > 0\) such that for all \(x, y \in M\) and for all \(n \in \mathbb{N}^*\) satisfying \(n \geq 2\), we have

\[
p_n(x, y) \leq \frac{C_1}{V(x, \sqrt{n})} \exp \left( -\frac{d(x, y)^2}{C_2n} \right)
\]

Further there exists \(c_1, c_2, c_3 > 0\) such that for all \(x, y \in M\) satisfying \(d(x, y) \leq c_3\) and for all \(n \in \mathbb{N}^*\) satisfying \(n \geq 2\)

\[
p_n(x, y) \geq \frac{c_1}{V(x, \sqrt{n})} \exp \left( -\frac{d(x, y)^2}{c_2n} \right)
\]

(c) The conjunction of

- The volume doubling property: there exists \(C_D > 0\) such that for all \(x \in M, \) for all \(r > 0\) we have

\[
V(x, 2r) \leq C_D V(x, r)
\]

- The Poincaré inequality: there exists \(C_P > 0, \kappa \geq 1\) such that for any ball \(B = B(x, r), x \in M, r > 1\) and for all \(f \in L^2(M, \mu)\), we have

\[
\int_B |f - f_B|^2 d\mu \leq C_P r^2 \int_{\kappa B} \left( \frac{1}{V(y, 1)} \int_{B(y, 1)} |f(z) - f(y)|^2 \mu(dz) \right) \mu(dy),
\]
where $\kappa B = B(x, \kappa r)$, $f_B = \frac{1}{\mu(B)} \int_B f \, d\mu$.

The Poincaré inequalities presented in Theorem 1.1 and Theorem 1.4 are related. We will show that the Poincaré inequality (1.7) implies (1.17) (See Proposition 3.20). A partial converse of the previous statement hold as well.

Example 1.5. Consider a complete, non-compact Riemannian manifold $(M, g)$ with non-negative Ricci curvature whose unit balls have a uniform positive volume lower bound. Define a Markov kernel $p(x, y) = \frac{V(x, y)}{V(x, 1)}$ for all $x, y \in M$. Although $p$ is a Markov kernel with respect to the Riemannian measure $\nu$, $p(x, y) \neq p(y, x)$ in general. However $q_1(x, y) = \frac{\rho(x, y)}{V(x, 1)}$ is a symmetric Markov kernel with respect to $\mu(dx) = V(x, 1)\nu(dx)$ where $V$ denotes the volume with respect to $\nu$. By the remark preceding this example, $(M, g, \mu)$ satisfy the Poincaré inequalities (1.17) and (1.7). Moreover $(M, g, \mu)$ satisfies volume doubling property. Hence the iterated kernel $q_n$ satisfies two-sided Gaussian bounds and the corresponding Laplacian satisfies the parabolic Harnack inequality. Similarly many other examples known in the diffusion case can be extended to the discrete-Markov chain case due to Proposition 3.20.

The role of Theorem 1.4 is only to illustrate our main result without introducing additional definitions. We provide an unified approach to study random walks on both discrete and continuous spaces. We prove Theorem 1.4 as a corollary of a general result that also gives an alternate proof of Theorem 1.3.

Given the previous works on characterization of parabolic Harnack inequality and Gaussian bounds [32, 69, 76, 27, 45] our results should not be surprising. However we encounter new difficulties that had to be resolved here and which were not present in previous works. Recall that Moser’s iteration method for Harnack inequalities relies on repeated application of a Sobolev inequality [69, 76, 27]. Grigor’yan’s iteration method in [32] uses an equivalent Faber-Krahn inequality that is equivalent to the Sobolev inequality [4].

The Sobolev inequalities in the previous settings are of the form

$$\|f\|_2^{2\delta/(\delta-2)} \leq \frac{C r^2}{V_\mu(x, r)^{2/\delta}} \left( \mathcal{E}(f, f) + r^{-2} \|f\|_2^2 \right)$$

for all ‘nice’ functions $f$ supported in $B(x, r)$. However for discrete time Markov chains, the Dirichlet form satisfies the inequality $\mathcal{E}(f, f) = \langle (I-P)f, f \rangle \leq 2 \|f\|_2^2$. This along with (1.18) implies that $L^2(B(x, r)) \subseteq L^{2\delta/(\delta-2)}(B(x, r))$ for all balls $B(x, r)$ which can happen only if the space is discrete. Hence for discrete time Markov chains on Riemannian manifolds the Sobolev inequality (1.18) cannot possibly be true. We prove and rely on a weaker form of the Sobolev inequality (1.18) which seems to be too weak to run Moser’s iteration directly to prove parabolic Harnack inequality (See Theorem 5.1). Instead we use Moser’s iteration to prove a version of the mean value inequality which in turn gives Gaussian upper bounds. We adapt a method of [45] which uses elliptic Harnack inequality and Gaussian upper bounds to prove Gaussian lower bounds (See Chapter 8). Another difficulty that is new to our setting is explained in the beginning of Section 7.3.

In the context of diffusions on complete Riemannian manifolds the Sobolev inequality (1.18) is equivalent to the conjunction of volume doubling property and Gaussian upper bounds on the heat kernel [72, Theorem 5.5.6]. In the previous statement, we may replace Sobolev inequalities with a similar but equivalent set of
functional inequalities called Faber-Krahn inequalities both in the context of diffusions on Riemannian manifolds [33] and for random walks on graphs [19, Theorem 1.1]. We extend the above equivalences for random walks on a large class of metric measure spaces (Theorem 7.18).

1.4. Guide for the monograph

This monograph is organized as follows. In Chapter 2, we present the setting of quasi-geodesic spaces satisfying certain doubling hypotheses, study its basic properties and develop techniques that would let us compare discrete and continuous spaces.

In Chapter 3, we introduce Poincaré inequalities and discuss various examples and non-examples of spaces satisfying Poincaré inequality. We study how these new Poincaré inequalities on metric measure spaces compare with the previously studied Poincaré inequalities on graphs and Riemannian manifolds. Then we show that Poincaré inequality is stable under quasi-isometric transformation of quasi-geodesic spaces.

In Chapter 4, we introduce various hypotheses on the Markov chain, Dirichlet forms and study their basic properties. In Chapter 5, we introduce and prove a Sobolev inequality under the assumptions of large scale volume doubling and Poincaré inequality. In Chapter 6, we use Sobolev inequality and Poincaré inequality to run the Moser iteration argument to prove elliptic Harnack inequality.

Chapter 7 is devoted to the proof of Gaussian upper bounds using Sobolev inequality. In addition, we show that Sobolev inequality is equivalent to the conjunction of Gaussian upper bounds on the heat kernel and large scale volume doubling property. In Chapter 8 we prove Gaussian lower bounds using elliptic Harnack inequality and Gaussian upper bounds. This completes the proof that large scale volume doubling property and Poincaré inequality implies two sided Gaussian bound on the heat kernel.

In Chapter 9, we prove parabolic Harnack inequality using Gaussian bounds. Moreover, we prove large scale volume doubling property and Poincaré inequality using parabolic Harnack inequality, and thereby completing the proof of the characterization parabolic Harnack inequality and Gaussian bounds. In Chapter 10, we mention various applications of Gaussian estimates and Harnack inequalities. In Appendix B, we collect various examples and supplement them with figures and discussions.
CHAPTER 2

Metric Geometry

Let \((M, d, \mu)\) be a locally compact metric measure space where \(\mu\) is a Radon measure with full support. Let \(\mathcal{B}(M)\) denote the Borel \(\sigma\)-algebra on \((M, d)\). Let \(B(x, r) := \{y \in M : d(x, y) \leq r\}\) denote the closed ball in \(M\) for metric \(d\) with center \(x\) and radius \(r > 0\). Let \(V(x, r) := \mu(B(x, r))\) denote the volume of the closed ball centered at \(x\) of radius \(r\). Since \(M\) is a Radon measure with full support, we have that \(V(x, r)\) is finite and positive for all \(x \in M\) and for all \(r > 0\). In this section, we introduce some assumptions on the metric \(d\) and measure \(\mu\) and study some consequences of those assumptions.

2.1. Quasi-geodesic spaces

The main assumption on the metric \(d\) of the metric measure space \((M, d, \mu)\) is that of quasi-geodesicity. In Riemannian geometry, the distance between two points of a manifold is defined as the infimum of lengths of curves joining them. Such a relation between distance and length of curves is observed more generally in length spaces.

**Definition 2.1.** Let \((M, d)\) be a metric space. For \(x, y \in M\), a path from \(x\) to \(y\) is a continuous map \(\gamma : [0, 1] \to M\) such that \(\gamma(0) = x\) and \(\gamma(1) = y\). We define the length \(L(\gamma) \in [0, \infty]\) of a path \(\gamma\) is the supremum

\[
L(\gamma) = \sup_{P_{[0,1]}} \sum_{i} d(\gamma(t_{i-1}), \gamma(t_{i})).
\]

taken over all partition \(0 = t_{0} < t_{1} < \ldots < t_{k} = 1\) of \([0, 1]\).

The length of a path is a non-negative real number or \(+\infty\).

**Definition 2.2.** The inner metric or length metric associated with metric space \((M, d)\) is the function \(d_{i} : M \times M \to [0, \infty]\) defined by

\[
d_{i}(x, y) = \inf_{\gamma} L(\gamma)
\]

where the infimum is taken over all paths \(\gamma\) from \(x\) to \(y\). \((M, d)\) is called a length space if \(d_{i} = d\). A metric for which \(d = d_{i}\) is called an intrinsic metric.

**Remark 2.3.** All Riemannian manifolds equipped with Riemannian distance are length spaces. Since infimum of an empty set is \(+\infty\), for points \(x, y\) in different connected components of a metric space \((M, d)\), we have \(d_{i}(x, y) = +\infty\). Hence graphs with natural combinatorial metric are not length spaces because distinct vertices belong to different connected components under the metric topology. See [40, Chapter 1] or [13, Chapter 2] for a comprehensive introduction of length spaces.
One of the goals of this work is to provide an unified approach to the study of random walks in continuous spaces like Riemannian manifolds and discrete spaces like graphs. In view of Remark 2.3, we would like to consider spaces more general than length spaces to include disconnected metric spaces like graphs. Quasi-geodesic spaces provides a natural setting to include both length spaces and graphs as special cases. Quasi-geodesic spaces are equipped with a weak notion of geodesicity as presented by Tessera in [77].

**Definition 2.4.** Consider a metric space \((M,d)\) and \(b > 0\). For \(x,y \in M\), a \(b\)-chain between from \(x\) to \(y\), is a sequence \(\gamma : x = x_0, x_2, \ldots, x_m = y\) in \(M\) such that for every \(0 \leq i < m\), \(d(x_i, x_{i+1}) \leq b\). We define the length \(l(\gamma)\) of a \(b\)-chain \(\gamma : x_0, x_1, \ldots, x_m\) by setting

\[
l(\gamma) = \sum_{i=0}^{m-1} d(x_i, x_{i+1}).
\]

Define a new distance function \(d_b : M \times M \to [0, \infty]\) as

\[
d_b(x, y) = \inf_{\gamma} l(\gamma)
\]

where \(\gamma\) runs over every \(b\)-chain from \(x\) to \(y\). We say a metric space \((M,d)\) is

- \(b\)-geodesic if \(d(x,y) = d_b(x,y)\) for all \(x,y \in M\).
- quasi-\(b\)-geodesic if there exists \(C > 0\) such that \(d_b(x,y) \leq Cd(x,y)\) for all \(x,y \in M\).
- quasi-geodesic if there exists \(b > 0\) such that \((M,d)\) is quasi-\(b\)-geodesic.

**Remark 2.5.** We collect some simple consequences of the definitions.

- Any \(b\)-geodesic space is quasi-\(b\)-geodesic. Moreover \(b\)-quasi-geodesic space is \(b_1\)-quasi-geodesic for all \(b_1 \geq b\).
- Any length space is \(b\)-geodesic for all \(b > 0\).
- Graphs with natural combinatorial metric are \(b\)-geodesic if and only if \(b \geq 1\). If \(b < 1\), then \(d_b(x,y) = +\infty\) for distinct vertices \(x\) and \(y\).

The following lemma guarantees that quasi-geodesic spaces are endowed with sufficiently short chains at many length scales.

**Lemma 2.6 (Chain lemma).** Let \((M,d)\) be a quasi-\(b\)-geodesic space for some \(b > 0\). Then there exists \(C_1 \geq 1\) such that for all \(b_1 \geq b\) and for all \(x,y \in M\), there exists a \(b_1\)-chain \(x = x_0, x_1, \ldots, x_m = y\) with \(m \leq \frac{C_1 d(x,y)}{b_1}\).

**Proof.** Since \((M,d)\) is quasi-\(b\)-geodesic, there exists \(C > 0\) such that for all \(x,y \in M\), there exists a \(b\)-chain \(x = y_0, y_1, \ldots, y_n = y\) satisfying \(\sum_{i=0}^{n-1} d(y_i,y_{i+1}) \leq C d(x,y)\). We define a smaller \(b_1\)-chain \(x_0, x_1, \ldots, x_m\) where \(x_k = y_{i_k}\). We choose \(i_0 = 0\) and define \(i_k\) successively by

\[
i_k = \max\{1 \leq j \leq n : d(y_{i_{k-1}}, y_j) \leq b_1\}
\]

for \(k \geq 1\). Define \(m = \min\{j : y_j = y\}\). By the definition of \(i_k\) we have that

\[
d(x_i, x_{i+1}) + d(x_{i+1}, x_{i+2}) \geq d(x_i, x_{i+2}) > b_1
\]
2.2. Doubling Hypothesis

for all $i = 0, 1, \ldots, m - 2$. Therefore we have
\[
\sum_{i=0}^{m-1} d(x_i, x_{i+1}) > \frac{b_1}{2} (m - 1).
\]
By triangle inequality, we have
\[
\sum_{i=0}^{m-1} d(x_i, x_{i+1}) \leq \sum_{i=0}^{n-1} d(y_i, y_{i+1}) \leq Cd(x, y).
\]
Therefore
\[
m \leq 1 + \frac{2C}{b_1} d(x, y).
\]
Hence the choice $C_1 = 2C + 1$ satisfies the desired conclusion. \qed

2.2. Doubling hypothesis

The main assumption that we recall below on the Radon measure $\mu$ is the doubling property. For a metric measure space $(M, d, \mu)$, we denote volume of balls by $V(x, r) = \mu(B(x, r))$.

**Definition 2.7.** We define the following doubling hypothesis:

$(VD)_\text{loc}$ We say a space $(M, d, \mu)$ satisfies the local volume doubling property $(VD)_\text{loc}$, if for all $r > 0$, there exists $C_r$ such that
\[
V(x, 2r) \leq C_r V(x, r)
\]
for all $x \in M$.

$(VD)_\infty$ We say a space $(M, d, \mu)$ satisfies the large scale doubling property $(VD)_\infty$, if there exists positive reals $C_{r_0}, r_0$ such that
\[
V(x, 2r) \leq C_{r_0} V(x, r)
\]
for all $x \in M$ and $r \geq r_0$.

$(VD)$ We say a space $(M, d, \mu)$ satisfies the global volume doubling property $(VD)$, if there exists a constant $C_D > 0$ such that
\[
V(x, 2r) \leq C_D V(x, r)
\]
for all $x \in M$ and $r > 0$.

**Remark 2.8.** The property $(VD)$ implies $(VD)_\infty$ and $(VD)_\text{loc}$. The property $(VD)_\text{loc}$ is a condition local in $r$ but uniform in $x \in M$ while $(VD)_\infty$ and $(VD)$ are uniform in both $x$ and $r$. The property $(VD)_\text{loc}$ is a very weak property of bounded geometry introduced in [22]. Since $C_r$ depends on $r$, the local volume doubling property does impose too much constraint on volume growth as $r \to \infty$. However, we will see in Lemma 2.11 that large scale doubling can be used to control volume of large balls.

**Example 2.9.** We describe some examples satisfying the above hypothesis on volume growth. Every connected graph with bounded degree and equipped with the counting measure satisfies $(VD)_\text{loc}$. By Bishop-Gromov inequality [15, Theorem III.4.5.], Riemannian manifolds with Ricci curvature bounded from below satisfy $(VD)_\text{loc}$ and Riemannian manifolds with non-negative Ricci curvature satisfy $(VD)$.

We collect some basic properties of spaces satisfying the above doubling hypothesis $(VD)_\text{loc}$ and $(VD)_\infty$. 
2. METRIC GEOMETRY

Lemma 2.10. ([22, Lemma 2.1]) If \((M,d,\mu)\) satisfies \((VD)_{\text{loc}}\), then for all \(r_1, r_2 > 0\), there exists \(C_{r_1,r_2}\) such that
\[
V(x, r_2) \leq C_{r_1,r_2} V(x, r_1)
\]
for all \(x \in M\). In particular, for all \(x,y \in M\), such that \(d(x,y) \leq R\), we have
\[
V(x, r) \leq C_{r,R+r} V(y, r)
\]

Proof. Let \(k\) be the smallest integer such that \(2^k r_1 \geq r_2\). By repeated application of \((VD)_{\text{loc}}\), the choice
\[
C_{r_1,r_2} = \prod_{i=0}^{k-1} C_{2^i r_1}
\]
satisfies (2.2) where the constant \(C_{2^i r_1}\) is from \((VD)_{\text{loc}}\). The second part follows from \(B(x, r) \subseteq B(y, R + r)\) and (2.2).

The large scale doubling property \((VD)_{\infty}\) along with \((VD)_{\text{loc}}\) implies a polynomial volume growth upper bound.

Lemma 2.11. Let \((M,d,\mu)\) be a metric measure space satisfying \((VD)_{\text{loc}}\) and \((VD)_{\infty}\). Then for all \(b > 0\), there exists \(C_b > 0\) such that
\[
V(x, 2r) \leq C_b V(x, r)
\]
for all \(x \in M\) and \(r \geq b\). Moreover this \(C_b\) satisfies
\[
\frac{V(x,r)}{V(x,s)} \leq C_b \left(\frac{r}{s}\right)^{\delta}
\]
for all \(x \in M\), for all \(b \leq s < r\) and for all \(\delta \geq \log_2 C_b\). Furthermore
\[
\frac{V(x,r)}{V(y,s)} \leq C_b^2 \left(\frac{r}{s}\right)^{\delta}
\]
holds for all \(b \leq s \leq r\), for all \(x \in M\), for all \(y \in B(x, r)\) and for all \(\delta \geq \log_2 C_b\).

Proof. Let \(r_0, C_{r_0}\) be constants from \((VD)_{\infty}\). There is nothing to prove if \(r_0 \leq b\). Assume \(r_0 > b\) and let \(r\) be such that \(b \leq r < r_0\). Then by Lemma 2.10 and \((VD)_{\infty}\)
\[
V(x, 2r) \leq V(x, 2r_0) \leq C_{r_0} V(x, r_0) \leq C_{r_0} C_b r_0 V(x, b) \leq C_{r_0} C_b r_0 V(x, r).
\]
The case \(r \geq r_0\) follows from \((VD)_{\infty}\) which concludes the proof of (2.3).
Let \(b \leq s < r\), \(k = \log_2 (r/s)\) and \(\delta \geq \log_2 C_D\). Then from (2.3), we get (2.4),
\[
\frac{V(x,r)}{V(x,s)} \leq \frac{V(x,2^k s)}{V(x,s)} \leq C_b^{2^k + 1} \leq C_b \left(\frac{r}{s}\right)^{\delta}.
\]
To obtain (2.5) from (2.4), note that
\[
\frac{V(x,r)}{V(y,s)} \leq \frac{V(y,2r)}{V(y,s)} \leq C_b \frac{V(y,r)}{V(y,s)} \leq C_b^2 \left(\frac{r}{s}\right)^{\delta}.
\]
\[\square\]
2.3. QUASI-ISOMETRY

The equation (2.4) implies a polynomial upper bound on the volume growth. In quasi-geodesic spaces, we can reverse the inequality (2.4) and obtain a polynomial lower bound for all radii small enough compared to the diameter. The property stated in the following lemma is often called the reverse volume doubling property. It was known for graphs and Riemannian manifolds and our proof follows similar ideas.

**Lemma 2.12.** Let \((M,d,\mu)\) be a quasi-b-geodesic space with the measure \(\mu\) satisfying \((VD)_{loc}\) and \((VD)_{\infty}\). Then there exists \(c,\gamma > 0\) such that

\[
V(x,r) \geq c \left( \frac{r}{s} \right)^{\gamma}
\]

for all \(x \in M\) and for all \(b \leq s \leq r \leq \text{diam}(M)\), where \(\text{diam}(M) = \sup\{d(x,y) : x,y \in M\}\) denotes the diameter of \((M,d,\mu)\).

**Proof.** We first consider the case \(b \leq s \leq r \leq \text{diam}(M)/5\). Let \(x \in M\) and let \(z \in M\) be chosen such that \(d(x,z) \geq (3/7) \text{diam}(M)\). Let \(x = x_0, x_1, \ldots, x_m = z\) be a \(s\)-chain with minimal number of points \(m\). Therefore there exists \(3 \leq k \leq m\) such that \(2s < d(x_k, x) \leq 3s\). Since \(d(x_k, s) > 2s\), we have \(B(x_k, s) \cap B(x, s) = \emptyset\). By Lemma 2.11, there exists \(\epsilon > 0\) such that

\[
V(x, 3s) \leq V(x_k, 6s) \leq \epsilon^{-1} V(x_k, s)
\]

Therefore we obtain

\[
V(x, 4s) \geq V(x, s) + V(x_k, s) \geq (1 + \epsilon) V(x, s)
\]

for all \(x \in M\) and \(b \leq s \leq \text{diam}(M)/5\). Define \(k = \log_4(r/s)\) and \(\gamma = \log_4(1 + \epsilon)\). Then by (2.7)

\[
\frac{V(x, r)}{V(x, s)} \geq \frac{V(x, 4k/s)}{V(x, s)} \geq (1 + \epsilon)^{k-1} = (1 + \epsilon)^{-1} \left( \frac{r}{s} \right)^{\gamma}
\]

for all \(x \in M\) and \(b \leq s < r \leq \text{diam}(M)/5\).

The other cases follow from Lemma 2.10 and by choosing

\[
c = \min((1 + \epsilon)^{-1}s^{-\gamma}, C_{\text{diam}(M)/5, \text{diam}(M)}).
\]

\( \square \)

2.3. Quasi-isometry

One of the goals of this work is to develop arguments which are robust to small perturbations in the geometry of the underlying space; for example addition of few edges in a graph or small changes in the metric of a Riemannian manifold. We study properties that depend mainly on the large scale geometry of the underlying space. In this spirit, the concept of quasi-isometry was introduced by Kanai in [50] and in the more restricted setting of groups by Gromov in [39]. Informally, two metric spaces are quasi-isometric if they have the same large scale geometry. Here is a precise definition:

**Definition 2.13.** A map \(\phi : (M_1,d_1) \to (M_2,d_2)\), between metric spaces is called a quasi-isometry if the following conditions are satisfied:
We say metric spaces \((M_1, d_1)\) and \((M_2, d_2)\) are quasi-isometric if there exists a quasi-isometry \(\phi : (M_1, d_1) \to (M_2, d_2)\).

Remark 2.14. Quasi-isometry is an equivalence relation among metric spaces. Quasi-isometry is also called as \textit{rough-isometry} or \textit{coarse quasi-isometry}. Property (i) of Definition 2.13 above is called \textit{roughly bi-Lipschitz} and (ii) is called \textit{roughly surjective}.

We remark that a quasi-isometry is not necessarily a continuous map. Moreover, quasi-isometry is not necessarily injective and not necessarily surjective. However, we can construct a \textit{quasi-inverse} \(\phi^- : (M_2, d_2) \to (M_1, d_1)\) as \(\phi^- (y) = x\) where \(x \in M_1\) is chosen so that \(d_2(\phi(x), y) < \epsilon\) where \(\epsilon\) is given by the above definition.

We now describe some well-known examples of quasi-isometry. The space \(\mathbb{R}^d\) with Euclidean metric and \(\mathbb{Z}^d\) with standard graph metric (same as \(L^1\) metric) are quasi-isometric. Consider a finitely generated group \(\Gamma\) with a finite system of generator \(A\). For an element \(\gamma \neq 1\), let \(|\gamma|_A\) denote the smallest positive integer \(k\) such that a product of \(k\) elements of \(A \cup A^{-1}\), and put \(|1|_A = 0\). This \(|\cdot|_A\) is called the \textit{word norm} of \(\Gamma\) and defines a \textit{word metric} \(d_A(\gamma_1, \gamma_2) = |\gamma_1^{-1}\gamma_2|_A\). In other words, \(d_A\) is the graph metric in the Cayley graph of \(\Gamma\) corresponding to the symmetric generating set \(A \cup A^{-1}\). Assume two finite generating sets \(A\) and \(B\) of a group \(\Gamma\) which induces metric \(d_A\) and \(d_B\) respectively. Then \((\Gamma, d_A)\) and \((\Gamma, d_B)\) are quasi-isometric (See [67, Proposition 1.15]). Therefore every finitely generated group defines a unique word metric space up to quasi-isometry and we may often view a finitely generated group up as a metric space without explicitly specifying the generating set. A large class of examples of quasi-isometry is given by the Švarc-Milnor theorem. We refer the reader to [67, Theorem 1.18] for a proof and original references.

Theorem 2.15. (Švarc-Milnor theorem) Suppose that \((M, d)\) is a length space and \(\Gamma\) is a finitely generated group equipped with a word metric acting properly and cocompactly by isometries on \(M\). Then \(\Gamma\) is quasi-isometric to \((M, d)\). The map \(\gamma \mapsto \gamma \cdot x_0\) is a quasi-isometry for each fixed base point \(x_0 \in M\).

Note that the quasi-isometry between \(\mathbb{Z}^d\) and \(\mathbb{R}^d\) is a special case of Theorem 2.15. We will give a general construction of \textit{net} which approximates a quasi-geodesic space using a graph with combinatorial metric in next subsection.

The notion of quasi-isometry was extended to metric measure spaces by Coulhon and Saloff-Coste in [22] which they called “isometry at infinity”. Let \((M_i, d_i, \mu_i)\), \(i = 1, 2\) be two metric measure spaces. Define

\[ V_i(y, r) = \mu_i \left\{ z \in M_i : d_i(y, z) \leq r \right\} . \]

Definition 2.16. A map \(\phi : (M_1, d_1, \mu_1) \to (M_2, d_2, \mu_2)\), between metric measure spaces is called a \textit{quasi-isometry} if the following conditions are satisfied:

(i) \(\phi : (M_1, d_1) \to (M_2, d_2)\) is a quasi-isometry between metric spaces;
(ii) There exists a constant $C > 0$ such that
\[ C^{-1}V_1(x, 1) \leq V_2(\phi(x), 1) \leq CV_1(x, 1) \]
for all $x \in M_1$.

We say metric measure spaces $(M_1, d_1, \mu_1)$ and $(M_2, d_2, \mu_2)$ are quasi-isometric if there exists a quasi-isometry $\phi : (M_1, d_1, \mu_1) \to (M_2, d_2, \mu_2)$.

**Remark 2.17.** Quasi-isometry is an equivalence relation for metric measure spaces satisfying local volume doubling property $(VD)_{\text{loc}}$. The notion of large scale equivalence defined in Definition 5.5 of [77] is more general. That is every quasi-isometry is a large scale equivalence. However a map between quasi-geodesic metric measure spaces satisfying $(VD)_{\text{loc}}$ is a quasi-isometry if and only if it is large scale equivalence. See [77, Remark 5.7].

The arguments in this work implies that the long term behavior of natural random walks depends mainly on the large scale geometry of the quasi-geodesic space. Other important examples of properties invariant under quasi-isometries are large scale doubling and Poincaré inequality. (See Proposition 2.20 and Proposition 3.16).

We conclude this subsection by proving that the large scale doubling property is preserved by quasi-isometries for metric measure spaces satisfying $(VD)_{\text{loc}}$. It is due to Coulhon and Saloff-Coste in [22]. We need the following definition:

**Definition 2.18.** Let $(M, d)$ be a metric space with $X \subseteq M$ and let $R > 0$. Then a subset $Y$ of $X$ is $R$-separated if $d(y_1, y_2) > R$ whenever $y_1$ and $y_2$ are distinct points of $Y$, and a $R$-separated subset $Y$ of $X$ is called maximal if it is maximal among all $R$-separated subsets of $X$ with respect to the partial order of inclusion.

The existence of maximal $R$-separated subsets follows from Zorn’s lemma.

The following lemma compares volume of balls between quasi-isometric metric measure spaces.

**Lemma 2.19.** ([22, Proposition 2.2]) Let $\Phi : (M_1, d_1, \mu_1)$ and $(M_2, d_2, \mu_2)$ be a quasi-isometry between metric measure spaces satisfying $(VD)_{\text{loc}}$. Then for all $h > 0$, there exists $C_h > 0$ such that
\[ C_h^{-1}V_1(x, C_h^{-1}r) \leq V_2(\Phi(x), r) \leq C_h V_1(x, C_h r) \]
for all $x \in M_1$ and for all $r \geq h$.

**Proof.** We denote balls and volumes by $B_i$ and $V_i$ respectively for $i = 1, 2$. Let $R \geq h$ such that $aR - b = R' > 0$ where $a, b$ is from Definition 2.13. Let $Y$ be a maximal $R$-separated subset of $B(x, r)$. Thus $B(x, r) \subseteq \bigcup_{y \in Y} B(y, R)$. Hence
\begin{equation}
V_1(x, r) \leq \sum_{y \in Y} V_1(y, R)
\end{equation}
By Lemma 2.10 and Definition 2.16, we have
\begin{equation}
V_1(y, R) \leq C_{1,R}V_1(y, 1) \leq C_{1,R}CV_2(\Phi(y), 1).
\end{equation}
for all $y \in Y$. The balls $\{B(y, R/2)\}_{y \in Y}$ are pairwise disjoint and hence the balls $B(\Phi(x_i), R'/2)$ are pairwise disjoint. By Lemma 2.10
\begin{equation}
V_2(\Phi(x_i), h) \leq C_{h,R'}V_2(\Phi(x_i), R'/2)
\end{equation}
Combining 2.8, 2.9 and 2.10

\[ V_1(x, r) \leq \sum_{y \in Y} C_1, R CC_1, R V_2(\Phi(y), R'/2) \leq C_1, R CC_1, R V_2(\Phi(x), ar + b + R'/2) \]  

(2.11)

The last step follows from the definition of quasi-isometry, triangle inequality and that \( B(\Phi(x_i), R'/2) \) are pairwise disjoint. We can choose \( C_2 \) large enough so that, \( ar + b + R'/2 \leq C_2 r \) for all \( r \in [h, \infty) \). Hence by Lemma 2.11, we have the desired lower bound on \( V_2 \) for all \( r \geq R \) and by Lemma 2.10 for all \( r \geq h \). Similar argument applied to quasi-inverse \( \Phi^{-1} \) yields

\[ V_2(\Phi(x), r) \leq CV_1(\Phi^{-1} \circ \Phi(x), Cr). \]

The conclusion follows from the fact that \( d_1(\Phi^{-1} \circ \Phi(x), x) \) is bounded uniformly for all \( x \in M_1 \). \( \square \)

For metric measure spaces satisfying \((V D)_{loc}\), the condition \((V D)_\infty\) is preserved by quasi-isometries. This is the content of the following lemma.

**Proposition 2.20.** ([22, Proposition 2.3]) Let \((M_1, d_1, \mu_1)\) and \((M_2, d_2, \mu_2)\) be quasi-isometric spaces satisfying \((V D)_{loc}\). Then \((M_1, d_1, \mu_1)\) satisfies \((V D)_\infty\) if and only if \((M_2, d_2, \mu_2)\) satisfies \((V D)_\infty\).

**Proof.** Let \( \Phi : M_2 \to M_1 \) be a quasi-isometry. Using Lemma 2.19, there exists \( C > 0 \) such that

\[ C^{-1} V_2(x, C^{-1} r) \leq V_1(\Phi(x), r) \leq CV_2(x, Cr) \]

for all \( x \in M_2 \) and \( r \geq 1 \). Hence by (2.4), we have

\[ \frac{V_2(x, 2r)}{V_2(x, r)} \leq C^2 \frac{V_1(\Phi(x), 2Cr)}{V_1(\Phi(x), C^{-1} r)} \leq C^2 C_D (2C^2)^s \]

for all \( r \geq \max(C, 1) \). \( \square \)

### 2.4. Approximating quasi-geodesic spaces by graphs

One might think of \( \mathbb{Z}^d \) as a graph approximation or discretization of \( \mathbb{R}^d \). More generally, we can approximate quasi-geodesic spaces by graphs. By [77, Proposition 6.2], a metric space is quasi-isometric to a graph if and only if it is quasi-geodesic. Therefore quasi-geodesic spaces form a natural class of metric spaces that can be roughly approximated by graphs.

We begin by recalling some standard definitions and notation from graph theory. We restrict ourselves to simple graphs. A graph \( G \) is a pair \( G = (V, E) \) where \( V \) is a set (finite or infinite) called the vertices of \( G \) and \( E \) is a subset of \( \mathcal{P}_2(V) \) (i.e., two-element subsets of \( V \)) called the edges of \( G \). A graph \( (V, E) \) is countable (resp. infinite) if \( V \) is a countable (resp. infinite) set. We say that \( p \) is a neighbor of \( q \) (or in short \( p \sim q \) if \( \{x, y\} \in E \). The degree of \( p \) is the number of neighbors of \( p \), that is \( \deg(p) = |\{q \in V : p \sim q\}| \). A graph \( (V, E) \) is said to have bounded degree if \( \sup_{v \in V} \deg(v) < \infty \).

A finite sequence \((p_0, p_1, \ldots, p_l)\) of points in \( V \) is called a path from \( p_0 \) to \( p_l \) of length \( l \), if each \( p_k \) is a neighbor of \( p_{k-1} \). A graph \( G = (V, E) \) is said to be connected if for all \( p, q \in V \), there exists a path from \( p \) to \( q \). For points \( p, q \in V \) of a graph \( G = (V, E) \), let \( d_G(p, q) \) denote the minimum of the lengths of paths from \( p \) to \( q \) with \( d_G(p, q) = +\infty \) if there exists no path from \( p \) to \( q \). This makes \((V, d_G)\)
an extended metric space. The graph \((V, E)\) is connected if and only if \((V, d_G)\) is a metric space. The extended metric \(d_G\) is called \textit{graph metric} or \textit{combinatorial metric} of \(G\). Notice that we can recover a graph \((V, E)\) from its (extended) metric space structure \((V, d_G)\) and vice-versa.

Using the above identification, we view a connected graph as a metric space. We would like to view a connected graph as a metric measure space. This motivates the definition of weighted graph. A \textit{weight} \(m : V \to (0, \infty)\) on a graph \((V, E)\) is a positive function on \(V\). With a slight abuse of notation, \(m\) induces a measure on \(V\) (also denoted by \(m\)) as

\[
m(A) = \sum_{v \in A} m(v)
\]

for each \(A \subseteq V\). A \textit{weighted graph} is a graph \((V, E)\) endowed with a weight \(m\). By the above, we will identify a weighted graph \(G = (V, E)\) with weight \(m\) as a (possibly extended) metric measure space \((V, d_G, m)\).

The definition of \(\epsilon\)-net is due to Kanai in the setting of Riemannian manifolds (See [50]) and was extended in [22] for weighted Riemannian manifolds.

**Definition 2.21.** A \(\epsilon\)-net of a metric measure space \((M, d, \mu)\) is a weighted graph \(G = (V, E)\) with weight \(m\) described as follows: The vertices \(V\) is a maximal \(\epsilon\)-separated subset of \(M\). The edges \(E\) are defined by \(\{x, y\} \in E\) if and only if \(0 < d(x, y) \leq 3\epsilon\). The weight \(m\) is defined as \(m(x) = \mu(B(x, \epsilon))\). Let \(d_G\) denote the graph metric of \(G\). We often alternatively view the \(\epsilon\)-net as (extended) metric measure space \((V, d_G, m)\) defined by the corresponding weighted graph.

The above definition does not guarantee \(\epsilon\)-net to be a connected graph. However it is connected and countable in many situations as described in the lemma below. We collect the basic properties of nets in Proposition 2.22 which builds on the ideas of [50], [52] and [22].

**Proposition 2.22.** Let \((M, d, \mu)\) be a quasi-b-geodesic metric measure space satisfying \((VD)_{loc}\) and let \(\epsilon \geq b\). Let \(G = (X, E)\) be an \(\epsilon\)-net of \((M, d, \mu)\) with weight \(m\) and let \((X, d_G, m)\) denote the corresponding extended metric measure space. Then we have the following:

(a) The collection of balls \(I = \{B(x, \epsilon/2) : x \in X\}\) is pairwise disjoint and the collection \(J = \{B(x, \epsilon) : x \in X\}\) covers \(M\) where \(B(., .)\) denotes closed metric ball in \((M, d)\).

(b) Bounded degree property: The graph \((X, E)\) is of bounded degree, that is \(\sup_{x \in X} \deg(p) < \infty\).

(c) \((X, d_G, m)\) satisfies \((VD)_{loc}\).

(d) There exists \(A > 0\) such that

\[
\frac{1}{3\epsilon} d(x, y) \leq d_G(x, y) \leq Ad(x, y) + A
\]

for all \(x, y \in X\). Therefore \(G\) is a connected graph and \((X, d_G, m)\) is a metric measure space.

(e) The metric measure spaces \((M, d, \mu)\) and \((X, d_G, m)\) are quasi-isometric.

(f) \(X\) is a countable set. Moreover if diameter\((M, d)\) = \(\infty\), then \(X\) is an infinite set.

(g) If \((M, d, \mu)\) satisfies \((VD)_{\infty}\), then so does \((X, d_G, m)\).
(h) Finite overlap property: Define
\[ N_p(\delta) = |\{ x \in X : d(x, p) \leq \delta \}|. \]
for each \( \delta > 0 \) and \( p \in M \). Then \( \sup_{p \in M} N_p(\delta) < \infty \).

**Proof.** We denote the volume of balls in \((M, d, \mu)\) and \((X, d_G, m)\) by \(V_M\) and \(V_G\) respectively.
(a) The collection \( I \) is pairwise disjoint because \( X \) is \( \epsilon \)-separated. The collection \( J \) covers \( M \) due to the maximality of \( X \).
(b) Let \( d(p) \) denote the degree of a vertex \( p \). Since \( I \) is a disjoint collection, using Lemma 2.10
\[ V_M(p, 4\epsilon) \geq \sum_{q \in V_M(p) \sim p} V_M(q, \epsilon/2) \]
\[ \geq C_{\epsilon/2, 7\epsilon}^{-1} \sum_{q \in V_M(p) \sim p} V_M(q, 7\epsilon) \geq d(p)V_M(p, 4\epsilon)C_{\epsilon/2, 7\epsilon}^{-1}. \]
This yields \( d(p) \leq C_{\epsilon/2, 7\epsilon} \) for all \( p \in X \).
(c) Let \( x, y \in X \) with \( x \sim y \). By Lemma 2.10, we obtain
\[ \frac{m(y)}{m(x)} \leq \frac{V(x, 4\epsilon)}{V(x, \epsilon)} \leq C_{\epsilon, 4\epsilon}. \]
Hence we have the uniform estimate
\[ C_m = \sup_{x, y \in X, x \sim y} \frac{m(y)}{m(x)} < \infty. \]
(2.13)
By the above inequality and (b), we have
\[ m(x) \leq V_G(x, r) \leq m(x)C_m^r \left( \sup_{x \in X} \deg(x) \right)^r \]
for all \( x \in X \) and \( r > 0 \). This along with (b) yields \((VD)_{loc}\).
(d) Let \( x, y \in X \). By triangle inequality we have \( d(x, y) \leq 3d_G(x, y) \). By Lemma 2.6, there exists \( C_1 \geq 1 \) and an \( \epsilon \)-chain \( x = x_0, x_1, \ldots, x_k = y \) in \((M, d)\) such that \( k \leq \lfloor C_1d_G(x, y)/\epsilon \rfloor \). Since \( J \) covers \( M \), for each \( x_i \in M \) we can choose \( y_i \in X \) such that \( d(x_i, y_i) \leq \epsilon \) for \( i = 0, 1, \ldots, k \). Note that \( x_0 = y_0 \) and \( x_k = y_k \). By triangle inequality \( d(y_i, y_{i+1}) \leq 3\epsilon \) or equivalently \( y_i \sim y_{i+1} \) or \( y_i = y_{i+1} \) for all \( i = 0, 1, \ldots, k - 1 \). Therefore
\[ d_G(x, y) = d_G(y_0, y_k) \leq k \leq C_1 \left( \frac{d_G(x, y)}{\epsilon} + 1 \right). \]
This implies \((2.12)\) which implies the remaining conclusions.
(e) It follows from (d) that the inclusion map \( \Phi : (X, d_G) \to (M, d) \) is a quasi-isometry of metric spaces. Substituting \( m(x) = V_M(x, \epsilon) \) and \( r = 1 \) in \((2.14)\) and using (b), \((2.13)\) and Lemma 2.10, there exists \( C > 0 \) such that
\[ C^{-1}V_G(x, 1) \leq V_M(x, 1) \leq CV_G(x, 1). \]
This proves that \( \Phi \) is a quasi-isometry between the metric measure spaces \((M, d, \mu)\) and \((X, d_G, m)\).
(f) It follows from (b) and (d) that \( G \) is a connected graph with bounded degree. Hence \( X \) is countable. By \((2.12)\), we have \( \text{diameter}(X, d_G) \geq \text{diameter}(M, d)/3\epsilon \). Therefore if \( \text{diameter}(M, d) = \infty \), we have that \( G = (X, E) \) is a connected graph with infinite diameter. Hence \( X \) is infinite.
(g) It follows from (c), (e) and Proposition 2.20.
(h) The proof is similar to (b). Using (a) and Lemma 2.10, we have
\[ V(p, \delta + \epsilon) \geq \sum_{x \in X : d(x, p) < \delta} V(x, \epsilon/2) \]
\[ \geq C_{\epsilon/2, 2\delta + \epsilon}^{-1} \sum_{x \in X : d(x, p) < \delta} V(x, 2\delta + \epsilon) \]
\[ \geq N_p(\delta) C_{\epsilon/2, 2\delta + \epsilon}^{-1} V(p, \delta + \epsilon). \]
This yields the uniform bound \( N_p(\delta) \leq C_{\epsilon/2, 2\delta + \epsilon} \).

The bounded degree property and the estimate (2.13) are true for all weighted graphs \((X, d, m)\) satisfying \((VD)_{\text{loc}}\) as shown below.

**Lemma 2.23.** Let \((X, d, m)\) be a metric measure space satisfying \((VD)_{\text{loc}}\) that corresponds to a weighted graph \(G = (X, E)\) with weight \(m\). Then \(G\) is of bounded degree and

\[ \sup_{x, y \in X : x \sim y} \frac{m(y)}{m(x)} = C_m < \infty \]

**Proof.** By \((VD)_{\text{loc}}\), there exists \(C > 0\) such that
\[ m(y) \leq V(x, 1) \leq CV(x, 1/2) = Cm(x) \]
for all \(x, y \in X\) with \(x \sim y\). The above inequality shows that \(C_m \leq C\) and \(\sup_{x \in X} \deg(x) \leq C^2\). \(\square\)
CHAPTER 3

Poincaré inequalities

Poincaré inequalities and its many variants are functional inequalities that have been extensively studied. Many results in classical theory of Sobolev spaces, Hölder regularity estimates for solutions of elliptic and parabolic partial differential equations, properties of harmonic functions, Harnack inequalities can be generalized to spaces satisfying volume doubling and a Poincaré inequality. See the introduction in [42] for a survey and references.

Roughly speaking Poincaré inequalities control the variance of a function on a smaller ball by its Dirichlet energy (integral of the square of gradient) on a larger ball. We start by reviewing Poincaré inequalities on weighted Riemannian manifolds. Recall that a weighted Riemannian manifold \((M,g,\mu)\) is a Riemannian manifold \((M,g)\) equipped with a measure \(\mu\) having a smooth positive density \(w\) with respect to the Riemannian measure induced by the metric \(g\). The above function \(w\) with \(0 < w \in \mathcal{C}_\infty(M)\) is called a weight. Recall that the gradient \(\text{grad} f\) of a function \(f \in \mathcal{C}_\infty(M)\) is defined as the vector field satisfying \(g(\text{grad} f, Y) = Yf\) for all vector fields \(Y\). The length of the gradient is denoted by \(|\text{grad} f| = \sqrt{g(\text{grad} f, \text{grad} f)}\). We denote the Riemannian distance function by \(d\), which makes \((M,d,\mu)\) a length space. In a context when distance function is important, we will denote the weighted Riemannian manifold \((M,g,\mu)\) as a metric measure space \((M,d,\mu)\). As before for \((M,d,\mu)\), we denote closed ball and their volumes by \(B(x,r)\) and \(V(x,r)\) respectively.

**Definition 3.1.** We say that a complete weighted Riemannian manifold \((M,g)\) with measure \(\mu\) satisfies a Poincaré inequality \((P)_{Rm}\) if there exists \(C_1 > 0, C_2 \geq 1\) such that for all \(f \in \mathcal{C}_\infty(M)\), for all \(x \in M\) and for all \(r > 0\),

\[
(P)_{Rm} \int_{B(x,r)} |f(y) - f_{B(x,r)}|^2 \mu(dy) \leq C_1 r^2 \int_{B(x,C_2 r)} |\text{grad} f(y)|^2 \mu(dy)
\]

where \(f_{B(x,r)}\) denote the \(\mu\)-average of \(f\) in \(B(x,r)\)

\[
f_B = \frac{1}{V(x,r)} \int_{B(x,r)} f(y) \mu(dy).
\]

The above inequality is sometimes called a weak, local, scale-invariant or \(L^2\) Poincaré inequality but we will refrain from using such adjectives. The word local means that we are interested in average and integrals around some point \(x\). This is in contrast with global Poincaré inequality in which average and integrals are over the whole space \(M\). The Poincaré inequality is scale-invariant or uniform to emphasize the fact the the constants \(C_1\) and \(C_2\) is independent of \(x\) or \(r\). For \(1 \leq p < \infty\), we might replace \((P)_{Rm}\) with the \(L^p\) Poincaré inequality

\[
\int_{B(x,r)} |f(y) - f_{B(x,r)}|^p \mu(dy) \leq C_1 r^p \int_{B(x,C_2 r)} |\text{grad} f(y)|^p \mu(dy).
\]
instead of $L^2$ version presented above. For spaces satisfying global doubling property, one can always take $C_2 = 1$ in $(P)_{R^n}$. This is due to D. Jerison by a Whitney decomposition argument [47] (see also [72, Section 5.3.2]). The Poincaré inequality with $C_2 = 1$ is called strong Poincaré inequality as opposed to the weak inequality $(P)_{R^n}$.

3.1. Gradient and Poincaré inequality at a given scale

To generalize the Poincaré inequality $(P)_{R^n}$ to metric measure spaces, we must find a suitable definition for “length of gradient”. We will consider a class of random walks that spreads over different distances. Therefore we define length of gradient over different scales for a metric measure space. We use the following definition due to [77] for length of gradient at a scale $h$ for a function $f : M \rightarrow \mathbb{R}$ with $f \in L^\infty(M, \mu)$ (denoted by $|\nabla f|_h$).

**Definition 3.2.** Let $(M, d, \mu)$ be a metric measure space. For any function $f \in L^\infty_{loc}(M, \mu)$, the length of gradient at a scale $h$ for $f$ is defined as the function

$$|\nabla f|_h(x) = \left( \frac{1}{V(x, h)} \int_{B(x, h)} |f(y) - f(x)|^2 \mu(dy) \right)^{1/2}.$$  

for all $x \in M$.

**Remark 3.3.** Our definition of $|\nabla f|_h$ coincides with $|\nabla f|_{h,2}$ in the notation of Tessera [77].

Now that we are armed with length of gradient, we define the corresponding Poincaré inequality.

**Definition 3.4.** We say that a metric measure space $(M, d, \mu)$ satisfies a Poincaré inequality at scale $h$, if there exists $C_1 > 0$, $C_2 \geq 1$, $r_0 > 0$ such that for all $f \in L^\infty_{loc}(M, \mu)$, for all $x \in M$ and for all $r \geq r_0$.

$$(P)_h \quad \int_{B(x, r)} |f(y) - f_B(x, r)|^2 \mu(dy) \leq C_1 r^2 \int_{B(x, C_2 r)} (|\nabla f|_h(y))^2 \mu(dy)$$

where $f_B(x, r)$ denote the $\mu$-average of $f$ in $B(x, r)$

$$f_B = \frac{1}{V(x, r)} \int_{B(x, r)} f(y) \mu(dy).$$

We will denote the above inequality by $P_h(r_0, C_1, C_2)$ or simply $(P_h)$.

The rest of the chapter is devoted to the study of various properties and examples of the above Poincaré inequality $(P)_h$. In particular, we will show that for a weighted Riemannian manifold the Poincaré inequality at scale $h$ $(P)_h$, generalizes the Poincaré inequality $(P)_{R^n}$ under some mild hypothesis. One of the main results that we will see in this chapter is that Poincaré inequality $(P)_h$ is preserved under quasi-isometries.

The following simple fact will be frequently used in rest of this chapter. Let $(M, d, \mu)$ be a metric measure space and let $A \subset M$ with $0 < \mu(A) < \infty$. Then for every function $f \in L^\infty(A)$

$$\inf_{\alpha \in \mathbb{R}} \int_A |f(y) - \alpha|^2 \mu(dy) = \int_A |f(y) - f_A|^2 \mu(dy)$$
where \( f_A \) is the \( \mu \)-average of \( f \) in \( A \),
\[
    f_A = \frac{1}{\mu(A)} \int_A f \, d\mu.
\]
In other words, mean minimizes squared error.

A Poincaré inequality at scale \( h \) implies a Poincaré inequality at all larger scales \( h' \) with \( h' \geq h \).

**Lemma 3.5.** Let \((M, d, \mu)\) be a metric measure space satisfying \((VD)_{\text{loc}}\) and Poincaré inequality \((P)_h\) at scale \( h \). Then for all \( h' \geq h \), \((M, d, \mu)\) satisfies \((P)_{h'}\).

**Proof.** Assume \( P_h(r_0, C_1, C_2) \). Then for all functions \( f \in L^\infty_{\text{loc}} \) and for all balls \( B(x, r) \) with \( r \geq r_0 \) and \( x \in M \), we have
\[
    \int_{B(x, r)} |f - f_{B(x, r)}|^2 \, d\mu 
\]
\[
    \leq C_1 r^2 \int_{B(x, C_2 r)} |\nabla f|^2 \, d\mu
\]
\[
    = C_1 r^2 \int_{B(x, C_2 r)} \int_{B(x, C_2 r + h')} |f(y) - f(z)|^2 \frac{1_{d(x, y) \leq h}}{V(y, h)} \, dz \, dy
\]
\[
    \leq C_{h, h'} C_1 r^2 \int_{B(x, C_2 r)} \int_{B(x, C_2 r + h')} |f(y) - f(z)|^2 \frac{1_{d(x, y) \leq h'}}{V(y, h')} \, dz \, dy
\]
which is \( P_{h'}(r_0, C_1 C_{h, h'}, C_2) \). In the last line above, we used Lemma 2.10. \( \square \)

**Remark 3.6.** A question now arises: At what scales \( h \) does a Poincaré inequality \((P)_h\) hold? We have a satisfactory answer for length spaces and graphs. If a graph satisfies Poincaré inequality at some scale, it satisfies Poincaré inequality at all scales \( h \geq 1 \) (See Corollary 3.15). Moreover, a graph does not satisfy Poincaré inequality for scales smaller than 1 because the gradient at scales smaller than 1 is identically zero. If a length space satisfies Poincaré inequality at some scale, then it satisfies Poincaré inequality at all positive scales (See Corollary 3.17). We will see in Proposition 9.9 that if \((P)_h\) is satisfied at for some \( h > 0 \) then \((P)_h\) is true for all \( h > b \). We analyze an example which is neither a graph nor a length space (See Example 3.22) to show that \( h > b \) is the best possible bound.

We now show that the constant \( r_0 \) in \( P_h(r_0, C_1, C_2) \) is flexible.

**Lemma 3.7.** Assume the Poincaré inequality \( P_h(r_0, C_1, C_2) \) holds for a metric measure space \((M, d, \mu)\). Then for every \( r_1 > 0 \) and there exists constants \( C'_1, C'_2 \) such that the Poincaré inequality \( P_h(r_1, C'_1, C'_2) \) holds.

**Proof.** The non-trivial case to check is \( r_1 < r_0 \). Assume \( B(x, r) \) with \( r \leq r_1 \leq r_0 \). Then for all functions \( f \in L^\infty_{\text{loc}}(M) \), by (3.2) we have
\[
    \int_{B(x, r)} |f - f_{B(x, r)}|^2 \, d\mu 
\]
\[
    \leq \int_{B(x, r_0)} |f - f_{B(x, r_0)}|^2 \, d\mu
\]
\[
    \leq \int_{B(x, r_0)} |f - f_{B(x, r_0)}|^2 \, d\mu.
\]
Combining the above inequality with \( P_h(r_0, C_1, C_2) \) yields
\[
    \int_{B(x, r)} |f(y) - f_{B(x, r)}|^2 \, dy 
\]
\[
    \leq C_1 r_0^2 \int_{B(x, C_2 r_0)} |\nabla f|^2 \, d\mu.
\]
Hence we can choose $C'_1 = C_1(r_0/r_1)^2$ and $C'_2 = C_2(r_0/r_1)$. □

3.2. Robustness under quasi-isometry

Since quasi-isometry between metric measure spaces satisfying $(VD)_{loc}$ is an equivalence relation, we may expect that a quasi-isometry preserves certain invariants of such spaces. For instance, we saw in Proposition 2.20 that quasi-isometry preserves the large scale doubling property. In this section, we shall see that quasi-isometry preserves Poincaré inequality $(P)_h$. The approach for proving robustness of functional inequalities can traced back to the seminal works of Kanai [50, 51, 52] and further developments by Couhlon and Saloff-Coste [22].

The idea is to show that a functional inequality on the metric measure space is equivalent to a similar functional inequality on its net. Since quasi-isometry is an equivalence relation, it suffices to show that the functional inequality on graphs is preserved under quasi-isometries. To compare functional inequalities back and forth between a metric measure space and its net, we need to be able to transfer functions on metric measure space to functions on its net and vice-versa. We start by developing those tools.

As before, let $(M, d, \mu)$ be a quasi-b-geodesic metric measure space satisfying $(VD)_{loc}$ and let $(X, d_G, m)$ be its $\epsilon$-net for some fixed $\epsilon \geq b$. By Proposition 2.22, we have that $(X, d_G, m)$ is a metric measure space satisfying $(VD)_{loc}$. Moreover the graph corresponding to $(X, d_G, m)$ is connected, countable with bounded degree. Let $D_X = \sup_{x \in X} \deg(x) < \infty$ be the maximum degree. We will denote closed balls in $(M, d, \mu)$ and $(X, d_G, \mu)$ by $B$ and $B_G$ respectively. Similarly, we denote their corresponding volumes by $V$ and $V_G$ respectively.

Given a function $g \in L^\infty_{loc}(M, \mu)$, we define a function $\tilde{g} : X \to \mathbb{R}$ on its net as

$$
(3.3) \quad \tilde{g}(x) = \frac{1}{V(x, \epsilon)} \int_{B(x, \epsilon)} g \, d\mu.
$$

for all $x \in M$. Conversely, given a function $f : X \to \mathbb{R}$ on the net, we define $\hat{f} : M \to \mathbb{R}$ as

$$
(3.4) \quad \hat{f} = \sum_{x \in X} f(x) \theta_x
$$

where $\theta_x : M \to \mathbb{R}$ is defined by

$$
(3.5) \quad \theta_x(p) = \frac{1_{B(x, \epsilon)}(p)}{\sum_{y \in X} 1_{B(y, \epsilon)}(p)}.
$$

The sum in (3.4) and denominator of (3.5) is a finite sum due to the finite overlap property of Proposition 2.22(h). Moreover, there exists a constant $c_X > 0$ such that $\{\theta_x\}_{x \in X}$ is a partition of unity $(\sum_{x \in X} \theta_x = 1)$ satisfying

$$
(3.6) \quad c_X 1_{B(x, \epsilon)} \leq \theta_x \leq 1_{B(x, \epsilon)}
$$

for all $x \in X$. The above properties of the partition of unity $\theta_x$ can be verified using Proposition 2.22.

We will now compare norms and gradients for the transfer of functions between metric measure space and its net. For a metric measure space $(M, d, \mu)$ and for all
3.2. ROBUSTNESS UNDER QUASI-ISOMETRY

If $f \in L^\infty_{loc}(A)$ where $A \subset M$, we denote by

$$\|f\|_{p,A} = \left(\int_A |f|^p \, d\mu\right)^{1/p}.$$  

We adapt the same notation for its net by considering it as a metric measure space.

**Definition 3.8.** For a function $f : X \to \mathbb{R}$ on a graph $(X,E)$, we define the discrete gradient of $f$ at $x$ as

$$\delta f(x) = \left(\sum_{y \sim x} |f(y) - f(x)|^2\right)^{1/2}.$$  

This definition of discrete gradient was used to define Poincaré inequality for graphs in [22]. We now show that our definition of $|\nabla f|_1$ is comparable to $\delta f$.

**Lemma 3.9.** Let $(X,d_G,m)$ be a weighted graph satisfying $(VD)_{loc}$. Then there exists $C > 0$ such that

$$C^{-1}|\nabla f|_1(x) \leq \delta f(x) \leq C|\nabla f|_1(x)$$

for all functions $f : X \to \mathbb{R}$ and for all $x \in X$.

**Proof.** We write the gradient as

$$|\nabla f|_1(x)^2 = \frac{1}{m(x) + \sum_{y \in X : y \sim x} m(y)} \sum_{y \in X : y \sim x} |f(y) - f(x)|^2 m(y).$$

The conclusion immediately follows from Lemma 2.23.  

**Remark 3.10.** Therefore our Poincaré inequality $(P)_1$ generalizes the Poincaré inequality for graphs considered by Delmotte [25, 27]. Using the above lemma, our definition of $(P)_1$ for graphs is equivalent to the $L^2$ version of $(P)$ for graphs in [22].

The next lemma compares gradient of a function on net and with its metric measure space version.

**Lemma 3.11.** Let $(M,d,M)$ be a quasi-$b$-geodesic metric measure space satisfying $(VD)_{loc}$ and let $(X,d,m)$ be its $\epsilon$-net for some $\epsilon \geq b$. For all $h > 0$, there exists positive reals $C,C'$ such that for all $x \in M$, for all $r \geq 1$, and for all functions $f : X \to \mathbb{R}$, we have

$$\left\|\nabla \hat{f}\right\|_{2,B(x,r)}^2 \leq C \left\|\delta f\right\|_{2,B_G(\bar{x},C'r)}^2$$

where $\bar{x} \in X$ is such that $d(x,\bar{x}) \leq \epsilon$ and $\hat{f} : M \to \mathbb{R}$ is defined as in (3.4).

**Proof.** Using Lemma 2.10, Proposition 2.22 (a) and (2.12), there exists $C_1 > 0$ such that

$$\int_{B(x,r)} \int_M |\hat{f}(y) - \hat{f}(z)|^2 \frac{1_{d(y,z) \leq h}}{V(y,h)} \, dz \, dy$$

$$\leq \sum_{s \in B_G(\bar{x},C_1r)} \int_{B(s,r)} \int_M |\hat{f}(y) - \hat{f}(z)|^2 \frac{1_{d(y,z) \leq h}}{V(y,h)} \, dz \, dy$$

and

$$\int_{B(x,r)} \int_M |\hat{f}(y) - \hat{f}(z)|^2 \frac{1_{d(y,z) > h}}{V(y,h)} \, dz \, dy$$

$$\leq \sum_{s \in B_G(\bar{x},C_1r)} \int_{B(s,r)} \int_M |\hat{f}(y) - \hat{f}(z)|^2 \frac{1_{d(y,z) > h}}{V(y,h)} \, dz \, dy$$

and

$$\int_{B(x,r)} \int_M |\hat{f}(y) - \hat{f}(z)|^2 \frac{1_{d(y,z) \leq h}}{V(y,h)} \, dz \, dy$$

$$\leq \sum_{s \in B_G(\bar{x},C_1r)} \int_{B(s,r)} \int_M |\hat{f}(y) - \hat{f}(z)|^2 \frac{1_{d(y,z) \leq h}}{V(y,h)} \, dz \, dy$$
for all \( x \in M \) and \( r \geq 1 \). For all \( s \in X, \, y \in B(s, \epsilon) \) and \( z \in B(y, h) \), we have
\[
\hat{f}(y) - \hat{f}(z) = \sum_{t \in X} f(t)(\theta_t(y) - \theta_t(z)) = \sum_{t \in X} (f(t) - f(s))(\theta_t(y) - \theta_t(z))
\]

For the last line, if \( d(s, t) > 2\epsilon + h \), then by triangle inequality \( d(t, y) > h + \epsilon \), \( d(t, z) > \epsilon \) and therefore \( \theta_t(y) = \theta_t(z) = 0 \) whenever \( d(s, t) > 2\epsilon + h \). Let \( D_X < \infty \) be the maximum degree of the net from Proposition 2.22(b) and \( n_0 = A(h + 2\epsilon) + A + h \) where \( A \) is from (2.12). Since \( |B_G(s,n_0)| \leq 2N^{n_0} \), we have
\[
(3.8) \quad |\hat{f}(p_1) - \hat{f}(p_2)| \leq 2 \sum_{t \in B_G(s,n_0)} |f(t) - f(s)| \leq 4D_X^{n_0} \sup_{t \in B_G(s,n_0)} |f(t) - f(s)|
\]
Let \( p_0, p_1, \ldots, p_{d_G(s,t)} \) be a path from \( s \) to \( t \). For all \( t \in B_G(s,n_0) \), by Cauchy-Schwarz inequality we have
\[
(3.9) \quad |f(t) - f(s)|^2 \leq \left( \sum_{i=0}^{d_G(t,s)-1} (f(p_i) - f(p_{i+1})) \right)^2 \leq n_0 \sum_{p \in B_G(s,n_0)} |\delta f(p)|^2.
\]
Combining (3.7), (3.8) and (3.9)
\[
\left\| \nabla f_h \right\|_{2,B(x,r)}^2 \leq \sum_{s \in B_G(\bar{x},C r)} 4N^{2n_0}n_0 \sum_{t \in B_G(s,n_0)} |\delta f(t)|^2 m(s) \leq \sum_{s \in B_G(\bar{x},C r)} C_m^0 4N^{2n_0}n_0 \sum_{t \in B_G(s,n_0)} |\delta f(t)|^2 m(t) \leq 8C_m^0 D_X^{2n_0}n_0 \sum_{s \in B_G(\bar{x},C r)} |\delta f(t)|^2 m(t)
\]
for all \( x \in M \) and all \( r \geq 1 \). The second line follows from (2.13) and the last line from \( |B(t,n_0)| \leq 2D_X^{n_0} \).

The following proposition shows that Poincaré inequalities can be transferred between a metric measure space and its net.

**Proposition 3.12.** Let \( (M, d, \mu) \) be a \( b \)-quasi-geodesic space satisfying \((VD)_{loc}\) and let \((X,d,m)\) be its \( \epsilon \)-net for some \( \epsilon \geq b \). Then for all \( h \geq 5\epsilon \), \((X,d_G,m)\) satisfies \((P)_1\) if and only if \((M, d, \mu)\) satisfies \((P)_h\).

**Remark 3.13.** In general, we do not know if the inequality \( h \geq 5\epsilon \) in the above statement is required. We believe that \( h > b \) is sufficient but we are unable to prove this.

**Proof of Proposition 3.12.** Suppose \((X,d_G,m)\) satisfies \( P_1(r_0,C'_1,C'_2) \).
Let \( g \in L_{loc}^\infty \) and let \( \bar{g} : X \to \mathbb{R} \) be defined as (3.3). Let \( x \in M \) and \( r \geq r_0 \) be arbitrary. Let \( \bar{x} \in X \) be such that \( d(x, \bar{x}) \leq \epsilon \). There exists \( C_1 > 0 \) such that, we
have
\[
\int_{B(x,r)} |g(y) - g_{B(x,r)}|^2 \, dy \\
\leq \int_{B(x,r)} |g(y) - \alpha|^2 \, dy \leq \sum_{p \in B_G(\tilde{x},C_1\epsilon)} \int_{B(p,\epsilon)} |g(y) - \alpha|^2 \, dy \\
\leq 2 \sum_{p \in B_G(\tilde{x},C_1\epsilon)} \left( \int_{B(p,\epsilon)} |g(y) - \tilde{g}(p)|^2 \, dy + m(p)|\tilde{g}(p) - \alpha|^2 \right)
\]
for all \( \alpha \in \mathbb{R} \) and all functions \( g \). The second line above follows from (3.2), Proposition 2.22 (a) and (2.12). The last line follows from \((a + b)^2 \leq 2(a^2 + b^2)\). The first term above is bounded using Jensen’s inequality as
\[
\int_{B(p,\epsilon)} |g(y) - \tilde{g}(p)|^2 \, dy \leq \frac{1}{V(p,\epsilon)} \int_{B(p,\epsilon)} \int_{B(p,\epsilon)} |g(y) - g(z)|^2 \, dz \, dy
\]
Hence by Lemma 2.10, we have
\[
I_1 = \sum_{p \in B_G(\tilde{x},C_1\epsilon)} \int_{B(p,\epsilon)} |g(y) - \tilde{g}(p)|^2 \, dy \\
\leq C_\epsilon,6\epsilon \sum_{p \in B_G(\tilde{x},C_1\epsilon)} \int_{B(p,\epsilon)} \int_{B(p,\epsilon)} |g(y) - g(z)|^2 \frac{1}{V(y,5\epsilon)} \, dz \, dy \\
\leq C_2 \|\nabla g\|_{1,2, B(\tilde{x},C_3\epsilon)}^2
\]
for some \( C_2, C_3 \) large enough. We used Lemma 2.10 and triangle inequality in second line above and Proposition 2.22(h) and (2.12) in the last line. Choose \( \alpha = \tilde{g}_{B_G(\tilde{x},C_1\epsilon)} \) in (3.10), so as to apply \( P_1(r_0, C_1', C_2') \) on \((X,d,m)\) to bound the second term in (3.10) as
\[
I_2 = \sum_{p \in B_G(\tilde{x},C_1\epsilon)} m(p)|\tilde{g}(p) - \alpha|^2 \leq C_4\epsilon r^2 \|\delta \tilde{g}\|_{1,2, B_G(\tilde{x},C_5\epsilon)}^2
\]
For all \( p, q \in X \) satisfying \( p \sim q \), by Jensen’s inequality and triangle inequality we have
\[
|\tilde{g}(p) - \tilde{g}(q)|^2 \leq \frac{1}{m(p)m(q)} \int_{B(p,\epsilon)} \int_{B(q,\epsilon)} |g(y) - g(z)|^2 \, dz \, dy \\
\leq \frac{1}{m(p)m(q)} \int_{B(p,\epsilon)} \int_{B(q,\epsilon)} |g(y) - g(z)|^2 1_{d(y,z) \leq 5\epsilon} \, dz \, dy
\]
Hence for all \( p \in X \),
\[
|\tilde{g}(p)|^2 m(p) \\
\leq \sum_{q \in X, q \sim p} \frac{1}{V(q,\epsilon)} \int_{B(p,4\epsilon)} \int_{B(p,4\epsilon)} |g(y) - g(z)|^2 1_{d(y,z) \leq 5\epsilon} \, dz \, dy \\
\leq C_\epsilon,9\epsilon \sum_{q \in X, q \sim p} \int_{B(p,4\epsilon)} \int_{B(q,4\epsilon)} |g(y) - g(z)|^2 \frac{1}{V(y,5\epsilon)} 1_{d(y,z) \leq 5\epsilon} \, dz \, dy \\
\leq C_\epsilon,9\epsilon DX \int_{B(p,4\epsilon)} \int_{B(p,4\epsilon)} |g(y) - g(z)|^2 \frac{1}{V(y,5\epsilon)} 1_{d(y,z) \leq 5\epsilon} \, dz \, dy
\]
The third line follows from Lemma 2.10 and the last line from bounded degree property of Proposition 2.22(b). Combining (3.12), (3.13) along with (2.12) and Proposition 2.22(h) gives

\[ I_2 \leq C_6 r^2 \| \nabla g |_{5\epsilon} \|^2_{2,B(x,C_\gamma r)} \cdot \]

Combining (3.10), (3.11) and (3.14) yields Poincaré inequality \((P)_{5\epsilon}\) for \((M, d, \mu)\). By Lemma 3.5, we get \((P)_h\) for all \(h \geq 5\epsilon\).

Conversely, suppose that \((M, d, \mu)\) satisfies \(P_h(r_1, C_1', C_1')\) for some \(h \geq 5\epsilon\). Let \(f : X \to \mathbb{R}\) be an arbitrary function and define \(\hat{f} : M \to \mathbb{R}\) as in (3.4). Denote \(B_G(p, r)\) be an arbitrary ball in \((X, d, m)\) where \(r \geq r_1\). Then using (3.2), \((V D)_{loc}\) and the inequality \((a + b)^2 \leq 2(a^2 + b^2)\) we have

\[ \sum_{q \in B_G(p, r)} |f(q) - \hat{f}(q)|^2 m(q) \leq 2C_{1/2} \sum_{q \in B_G(x, r)} \int_{B(q, \epsilon/2)} |f(q) - \alpha|^2 d\mu \]

for all \(\alpha \in \mathbb{R}\). Using Proposition 2.22(a) and (2.12), there exists positive reals \(C_8, C_{11}, C_{12}\) such that for all \(r \geq \min(1, r_1/C_8)\) and all functions \(f\), we have

\[ J_2 = \sum_{q \in B_G(p, r)} \int_{B(q, \epsilon/2)} |\hat{f}(y) - \alpha|^2 dy \leq \int_{B(p, C_\gamma r)} |\hat{f}(y) - \alpha|^2 dy \]

\[ \leq C_9 r^2 \| \nabla \hat{f} \|^2_{2,B(p,C_\gamma r)} \leq C_{11} r^2 \|\delta f\|^2_{2,B_G(p,C_{12} r)} \cdot \]

In the second step above, we fix \(\alpha = \hat{f}_{B(p,C_\gamma r)}\) and apply Poincaré inequality \((P)_h\) and in the last line we apply Lemma 3.11. Let \(q \in X\) and \(y \in B(q, \epsilon/2)\). Since \(\hat{f}(y) = \sum_{t \in X : t \in d_G(t,q) \leq 1} \theta_t(y) f(t)\), we have

\[ |f(q) - \hat{f}(y)| = \sum_{t \in X : d(t,q) \leq 1} \theta_t(y) (f(q) - f(t)) \leq \sum_{t \in X : d(t,q) \leq 1} |f(q) - f(t)| \]

\[ \leq \delta f(q) \sqrt{D_X}. \]

The last line follows from Cauchy-Schwarz inequality and maximum degree \(D_X\) from Proposition 2.22(b). Using this estimate, we have

\[ J_1 = \sum_{q \in B_G(p, r)} \int_{B(q, \epsilon/2)} |f(y) - \hat{f}(y)|^2 dy \leq D_X C_{1/2} \sum_{y \in B_G(p, r)} |\delta f(y)|^2 m(q) \]

\[ \leq D_X C_{1/2} \|\delta f\|^2_{2,B_G(p,r)} \cdot \]

Thus \((P)_1\) for \((X, d, m)\) follows from (3.15), (3.16) and (3.17) along with Lemma 3.9.

We now show that Poincaré inequality \((P)_1\) is preserved under quasi-isometry for graphs.

Let \((X, d, m)\) be a weighted graph. Then for the closed balls in the graph, we have \(B(x,r) = B(x, |r|)\). Hence by Lemmas 3.7 and 3.9, we have the following...
equivalent definition of \((P)_1\): A weighted graph \((X, d, m)\) satisfies \((P)_1\), if there exists \(C_1 > 0, C_2 \geq 1\) such that for all \(f : X \to \mathbb{R}\), for all \(x \in X\) and for all \(n \in \mathbb{N}^*\).

\[
\sum_{y \in B(x, n)} |f(y) - f_{B(x, n)}|^2 \mu(dy) \leq C_1 n^2 \sum_{B(x, C_2 n)} |\delta f(y)|^2 m(y)
\]

where \(f_{B(x, n)}\) is the average of \(f\) in \(B(x, n)\) with respect to measure \(m\). We will use the alternate definition for the proposition below.

**Proposition 3.14** ([22], Proposition 4.2). Let \((X_1, d_1, m_1)\) and \((X_2, d_2, m_2)\) be quasi-isometric weighted graphs that satisfy \((V D)_{loc}\). Then \((X_1, d_1, m_1)\) satisfies \((P)_1\) if and only if \((X_2, d_2, m_2)\) satisfies \((P)_1\).

**Proof.** We denote the balls, volume of balls and gradient of \((X_i, d_i, m_i)\) by \(B_i, V_i, \delta_i\) respectively for \(i = 1, 2\).

Assume that \((X_1, d_1, m_1)\) satisfies \((P)_1\). Let \(\Phi : X_1 \to X_2\) be a quasi-isometry with \(\bigcup_{x \in X_1} B_2(\Phi(x), k) = X_2\) for some \(k \in \mathbb{N}^*\). Let \(f : X_2 \to \mathbb{R}\) and let \(f_k(x)\) denote the average of \(f\) in \(B_2(x, k)\) with respect to measure \(m_2\). Applying \((P)_1\) to the function \(f_k \circ \Phi : X_1 \to \mathbb{R}\), we have

\[
\|f_k \circ \Phi - (f_k \circ \Phi)_{B_1(x, n)}\|_{2, B_1(x, n)}^2 \leq C_1 n^2 \|\delta_1(f_k \circ \Phi)\|_{2, B_1(x, C_1 n)}^2
\]

For all \(y \in X_1\), we have

\[
\delta_1(f_k \circ \Phi)(y)^2 m_1(y) \leq C_2 \delta_1(f_k \circ \Phi)(y)^2 m_2(\Phi(y))
\]

\[
\leq C_2 D_{X_1} \sup_{w_1 \in X_1 : w_1 \sim y} |f_k(\Phi(w_1)) - f_k(\Phi(y))|^2 m_2(\Phi(y))
\]

The first line follows from the quasi-isometry condition \(m_1(y) \leq C'm_2(\Phi(y))\) and the second line from bounded degree property of Lemma 2.23. Since \(\Phi\) is a quasi-isometry, there exists \(l > 0\) such that \(B_2(\Phi(y), l) \subseteq \Phi(B_1(y, 1))\) for all \(y \in X_1\). An application of Cauchy-Schwarz inequality along the minimal path \(\Phi(w_1) = p_0, p_1, \ldots, p_s = \Phi(y)\) gives

\[
|f_k(\Phi(w_1)) - f_k(\Phi(y))|^2 \leq l \sum_{i=0}^{s-1} |f_k(\Phi(p_i)) - f_k(\Phi(p_{i+1}))|^2
\]

\[
\leq l \sum_{z \in B_2(\Phi(y), l)} \delta_2 f_k(z)^2
\]

for all \(y, w_1 \in X_1\) such that \(y \sim w_1\). Combining (3.20), (3.21) and (2.15) of Lemma 2.23, we obtain

\[
\delta_1(f_k \circ \Phi)(y)^2 m_1(y) \leq C_2 D_{X_1} l C_{m} \sum_{z \in B_2(\Phi(y), l)} \delta_2 f_k(z)^2 m_2(z)
\]

Since \(\Phi\) is a quasi-isometry, there exists \(C_2' > 0\) such that

\[
\bigcup_{x \in B_1(x, C_1 n)} B_2(z, l) \subseteq B_2(\Phi(x), C_2' n)
\]

for all \(x \in X_1\) and \(n \in \mathbb{N}^*\). Combining this with (3.22) and Lemma 2.23 gives

\[
\|\delta_1(f_k \circ \Phi)\|_{2, B_1(x, C_1 n)}^2 \leq C_3 \|\delta_2 f_k\|_{2, B_2(\Phi(x), C_2' n)}^2
\]
for all \( n \in \mathbb{N}^* \), for all \( x \in M \) and for all functions \( f \). We write,
\[
|\delta_2 f_k(z)|^2 = \sum_{y \in X_2:y \sim z} |f_k(z) - f_k(y)|^2
\]
\[
\leq 2 \sum_{y \sim z} \left( \frac{1}{V_2(z,k)} \sum_{t \in B_2(z,k)} |f(t) - f(z)|^2 m_2(t) + \frac{1}{V_2(y,k)} \sum_{s \in B_2(y,k)} |f(s) - f(z)|^2 m_2(s) \right)
\]
\[
\leq \frac{2Dx_2}{V_2(z,k)} \sum_{t \in B_2(z,k)} |f(t) - f(z)|^2 m_2(t) + \frac{C_4}{V_2(z,k)} \sum_{s \in B_2(z,k+1)} |f(s) - f(z)|^2 m_2(s).
\]

The second and third lines above follow from \((a + b)^2 \leq 2(a^2 + b^2)\) along with Jensen’s inequality. The last two lines follow from Lemmas 2.23 and 2.10 to compare \(V_2(z,k)\) \(\leq V_2(y,k+1)\) \(\leq C_4 V_2(y,k)\). By Lemma 2.23, we have \(m_2(t) \leq C_4 V_2(z,k)\) for all \(z \in X_2\) and for all \(t \in B_2(z,k+1)\). It follows that
\[
|\delta_2 f_k(z)|^2 \leq C_5 \sum_{t \in B_2(z,k+1)} |f(t) - f(z)|^2.
\]

An application of Cauchy-Schwarz inequality similar to (3.21) yields
\[
|\delta_2 f_k(z)|^2 \leq C_5 (k + 1) Dx_2^k \sum_{y \in B_2(z,k+1)} |\delta_2 f(y)|^2.
\]

Finally by Lemma 2.23,
\[
(3.24) \quad \|\delta_2 f_k(z)\|_{2,B_2(\Phi(z),C'_n)}^2 \leq C_6 \|\delta_2 f\|_{2,B_2(\Phi(z),C'_n)}^2
\]

Combining (3.19), (3.23) and (3.24), we have
\[
(3.25) \quad \|f_k \circ \Phi - (f_k \circ \Phi)_{B_1(x,n)}\|_{2,B_1(x,n)}^2 \leq C_6 h^2 \|\delta_2 f\|_{2,B_2(\Phi(z),C'_n)}^2
\]

Suppose we prove that
\[
(3.26) \quad \|f - f_{B_2(\Phi(x),n)}\|_{2,B_2(\Phi(x),n)}^2 \leq C_8 \|\delta_2 f\|_{2,B_2(\Phi(x),C'_n)}^2 + C_9 \left( \|f_k \circ \Phi - (f_k \circ \Phi)_{B_1(x,C'_n)}\|_{2,B_1(x,C'_n)}^2 \right).
\]

Then (3.25) and (3.26) gives
\[
(3.27) \quad \|f - f_{B_2(\Phi(x),n)}\|_{2,B_2(\Phi(x),n)}^2 \leq C_{10} n^2 \|\delta_2 f(z)\|_{2,B_2(\Phi(x),C'_n)}^2.
\]

for all \( x \in M_1 \) and for all \( n \in \mathbb{N}^* \). Thus we obtain Poincaré inequality for all balls centered in the image of \( \Phi \). Let \( y \in M_2 \). Then there exists \( \bar{y} \in M_1 \) such that \( y \in B_2(\Phi(\bar{y}),k) \). It follows from (3.2) that
\[
\|f - f_{B_2(y,n)}\|_{2,B_2(y,n)}^2 \leq \|f - f_{B_2(\Phi(\bar{y}),n+k)}\|_{2,B_2(y,n)}^2 \\
\leq \|f - f_{B_2(\Phi(\bar{y}),n+k)}\|_{2,B_2(\Phi(\bar{y}),n+k)}^2.
\]
Hence by (3.27), we have \((P)_1\) for \((X_2,d_2,m_2)\).

It remains to show (3.26). Let \(\Phi^{-1} : M_2 \to M_1\) denote the quasi-inverse such that \(\Phi^{-1}(m_2) \in M_1\) is such that \(d_2(m_2,(\Phi \circ \Phi^{-1})(m_2)) \leq k\). We have by (3.2) and \((a+b)^2 \leq 2(a^2+b^2)\) that

\[
\|f - f_{B_2(\Phi(x),n)}\|_{L^2(B_2(\Phi(x),n))}^2 \leq \|f - \alpha\|_{L^2(B_2(\Phi(x),n))}^2 \leq 2S_1 + 2S_2
\]

where

\[
S_1 = \|f - f_k \circ \Phi \circ \Phi^{-1}\|_{L^2(B_2(\Phi(x),n))}^2
\]

and

\[
S_2 = \|f_k \circ \Phi \circ \Phi^{-1} - \alpha\|_{L^2(B_2(\Phi(x),n))}^2
\]

for all \(\alpha \in \mathbb{R}\). Let \(\tilde{z} = \Phi \circ \Phi^{-1}(z)\), then \(d_2(z,\tilde{z}) \leq k\). We bound \(S_1\) as

\[
S_1 = \sum_{z \in B_2(\Phi(x),n)} |f(z) - f_k(\tilde{z})|^2 m_2(z)
\]

\[
\leq \sum_{z \in B_2(\Phi(x),n)} \left( \frac{1}{V_2(\tilde{z},k)} \sum_{t \in B_2(\tilde{z},k)} |f(z) - f(t)|^2 m_2(t) \right) m_2(z)
\]

\[
\leq C_{11} \sum_{z \in B_2(\Phi(x),n)} \sum_{t \in B_2(z;2k)} |\delta_2 f(t)|^2 m_2(z)
\]

\[
\leq C_{12} \|\delta_2 f\|_{L^2(B_2(\Phi(x),C_1^n))}^2.
\]

The second line follows from Jensen’s inequality. The third line follows from \(d_2(z,\tilde{z}) \leq k\) and an application of Cauchy-Schwarz inequality similar to (3.21).

The last two lines follows from bounded degree property and (2.15) of Lemma 2.23.

For the second term \(S_2\), we have

\[
S_2 \leq C_{13} \sum_{z \in B_2(\Phi(x),n)} |f_k \circ \Phi \circ \Phi^{-1}(z) - \alpha|^2 m_1(\Phi^{-1}(z))
\]

\[
\leq C_{14} \|f_k \circ \Phi - \alpha\|_{L^2(B_1(x,C_1^n))}^2.
\]

We use the fact that \(\Phi\) and \(\Phi^{-1}\) are quasi-isometries. Indeed, for \(C_{10}'\) big enough \(\Phi^{-1}(B_2(\Phi(x),n)) \subset B_1(x,C_{10}'n)\), since \(\Phi^{-1}\) is a quasi-isometry with \(d_2(x,\Phi \circ \Phi^{-1}(x)) \leq k\).

Moreover \(|\{z \in X_2 : \Phi^{-1}(z) = w\}|\) is uniformly bounded over all \(w \in X_1\). Choose \(C_{10}' = \max(C_7,C_{10}')\). The bounds on \(S_1\) and \(S_2\) along with the choice \(\alpha = (f_k \circ \Phi)_{B_1(x,C_1^n)}\) concludes the proof of (3.26).

**Corollary 3.15.** Let \((X,d,m)\) be a weighted graph satisfying \((VD)_{loc}\) and let \(h \geq 1\). Then \((X,d,m)\) satisfies \((P)_1\) if and only if \((X,d,m)\) satisfies \((P)_h\).

**Proof.** By Lemma 3.5, \((P)_1\) implies \((P)_h\).

Conversely, assume \((X,d,m)\) satisfies \((P)_h\). Fix \(k = |h|\). Since \(|\nabla f|_h = |\nabla f|_k\) for all functions \(f : X \to \mathbb{R}\), \((X,d,m)\) satisfies \((P)_k\). \(k\)-fuzz of a weighted graph is defined as the weighted graph \((X,d_k,m)\) where the edges are defined by \(d_k(x,y) = 1\) if and only if \(1 \leq d(x,y) \leq k\) for \(x,y \in X\). It is straightforward to verify that the \(k\)-fuzz \((X,d_k,m)\) satisfies \((VD)_{loc}\) and is quasi-isometric to \((X,d,m)\). Since \((X,d,m)\) satisfies \((P)_k\), the \(k\)-fuzz \((X,d_k,m)\) satisfies \((P)_1\). Hence by Proposition 3.14, \((X,d,m)\) satisfies \((P)_1\). \(\square\)
As outlined at the start, the robustness of Poincaré inequality on graphs in Proposition 3.14 can be transferred to arbitrary quasi-geodesic spaces using Proposition 3.12.

**Proposition 3.16.** For \( i = 1, 2 \), let \((M_i, d_i, \mu_i)\) be quasi-\( b_i\)-geodesic spaces satisfying \((V D)_{\text{loc}}\). Assume \((M_1, d_1, \mu_1)\) and \((M_2, d_2, \mu_2)\) are quasi-isometric. Let \( h_1 \geq 5b_1 \) and for all \( h_2 \geq 5b_2 \). Then \((M_1, d_1, \mu_1)\) satisfies \((P)_{h_1}\) if and only if \((M_2, d_2, \mu_2)\) satisfies \((P)_{h_2}\).

**Proof.** It is a direct consequence of Propositions 3.12 and 3.14.

The above Proposition along with the fact that length space is \( b\)-geodesic for all \( b > 0 \) gives the following.

**Corollary 3.17.** Let \((M, d, \mu)\) be a length space satisfying \((V D)_{\text{loc}}\). Then for every \( h_1, h_2 > 0 \), \((M, d, \mu)\) satisfies \((P)_{h_1}\) if and only if \((M, d, \mu)\) satisfies \((P)_{h_2}\).

### 3.3. Poincaré inequalities in Riemannian manifolds

In this section, we see the relationship between various Poincaré inequalities on a weighted Riemannian manifold. We start by introducing some Poincaré inequalities from [22].

**Definition 3.18.** We say that a complete weighted Riemannian manifold \((M, g)\) with measure \( \mu \) satisfies \((P)_{\infty}\) if there exists \( r_0 > 0, C_1 > 0, C_2 \geq 1 \) such that for all \( f \in C^\infty(M) \), for all \( x \in M \) and for all \( r \geq r_0 \), we have

\[
(P)_{\infty} \quad \int_{B(x, r)} |f(y) - f_B(x, r)|^2 \mu(dy) \leq C r_0 r^2 \int_{B(x, C_2 r)} |\nabla f(y)|^2 \mu(dy)
\]

where \( f_B(x, r) \) denote the average of \( f \) in \( B(x, r) \) with respect to \( \mu \). We say that a complete weighted Riemannian manifold \((M, g)\) with measure \( \mu \) satisfies \((P)_{\text{loc}}\) if there exists \( C_1 > 0, C_2 \geq 1 \) such that for all \( f \in C^\infty(M) \), for all \( x \in M \) and for all \( r \geq r_0 \), we have

\[
(P)_{\text{loc}} \quad \int_{B(x, r)} |f(y) - f_B(x, r)|^2 \mu(dy) \leq C r \int_{B(x, C_2 r)} |\nabla f(y)|^2 \mu(dy)
\]

where \( f_B(x, r) \) denote the average of \( f \) in \( B(x, r) \) with respect to \( \mu \).

It is clear that \((P)_{Rm}\) implies \((P)_{\infty}\) and \((P)_{\text{loc}}\). The inequality \((P)_{\text{loc}}\) is a weak assumption. For instance, manifolds with a lower bound on Ricci curvature satisfy \((P)_{\text{loc}}\). Inequality \((P)_{\infty}\) is a large scale version of \((P)_{Rm}\).

**Proposition 3.19.** ([22, Proposition 6.10]) Let \((M, g, \mu)\) be a weighted Riemannian manifold satisfying \((V D)_{\text{loc}}\) and \((P)_{\text{loc}}\) and let \((X, d, m)\) be its \( \epsilon \)-net for some \( \epsilon > 0 \). Then \((M, g)\) with measure \( \mu \) satisfies \((P)_{\infty}\) if and only if \((X, d, m)\) satisfies \((P)_1\).

Propositions 3.19 and 3.12 along with Corollary 3.17 gives the following.

**Proposition 3.20.** Let \((M, g, \mu)\) be a weighted Riemannian manifold with Riemannian distance \( d \). Denote by \((X, d_{C_2}, m)\) be an \( \epsilon \)-net of \((M, d, \mu)\) for some \( \epsilon > 0 \). Assume \((M, d, \mu)\) satisfies \((V D)_{\text{loc}}\) and \((P)_{\text{loc}}\). Then the following are equivalent:

(a) \((M, d, \mu)\) satisfies \((P)_{\infty}\).

(b) \((M, d, \mu)\) satisfies \((P)_h\) for some \( h > 0 \).
(c) \((M, d, \mu)\) satisfies \((P)_h\) for all \(h > 0\).
(d) \((X, d_G, m)\) satisfies \((P)_1\).
(e) \((X, d_G, m)\) satisfies \((P)_h\) for some \(h \geq 1\).

3.4. Poincaré inequality: Examples and Non-examples

A large class of examples for \((P)_h\) can be obtained from Proposition 3.16 and 3.20. For instance, Buser proved \((P)_{R^m}\) for Riemannian manifolds with non-negative Ricci curvature. Therefore by Proposition 3.20, Riemannian manifolds with non-negative Ricci curvature satisfy \((P)_h\) for all positive scales \(h\). The following example is from [35].

**Example 3.21.** [Euclidean space with radial weights] Consider \(\mathbb{R}^n\) with standard Riemannian metric \(g\), Euclidean distance \(d\) and measure \(d\mu_\alpha(x) = (1 + |x|^2)^{\alpha/2} \, dx\). It is easy to verify that \((\mathbb{R}^n, d, \mu_\alpha)\) satisfies \((VD)_{loc}\) and \((P)_{loc}\). Moreover \((\mathbb{R}^n, d, \mu_\alpha)\) satisfies \((VD)_\infty\) if and only if \(\alpha > -n\). If \(n \geq 2\), then \((\mathbb{R}^n, d, \mu_\alpha)\) satisfies \((P)_\infty\) and therefore \((P)_h\) for all values of \(\alpha \in \mathbb{R}\) and \(h > 0\) (See Remark 3.13 in [35]). However, \((\mathbb{R}, d, \mu_\alpha)\) does not satisfy \((P)_\infty\) if \(\alpha \geq 1\). It can be easily seen using the test function \(f_\alpha(x) = \int_0^x (1 + t^2)^{-\alpha/2} \, dt\). By [35, Theorem 7.1(i)], \((\mathbb{R}, d, \mu_\alpha)\) satisfies \((P)_\infty\) if \(-1 < \alpha < 1\). Due to an unpublished result of Grigor’yan and Saloff-Coste, \((\mathbb{R}, d, \mu_\alpha)\) satisfies \((P)_\infty\) if and only if \(\alpha < 1\).

**Example 3.22.** We describe an example of quasi-geodesic space which is neither a graph, nor a length space. Consider the ‘Broken line’ \(BL \subset \mathbb{R}\)

\[
BL = \bigcup_{n \in \mathbb{Z}} [n - 1/4, n + 1/4]
\]

It is quasi-\(b\)-geodesic if and only if \(b \geq 1/2\). We equip it with the Euclidean distance \(d\) and restriction of Lebesgue measure \(\mu\) on \(BL\). \((P)_h\) is not true for \((BL, d, \mu)\) if \(h \leq 1/2\). It can be seen using the test function \(f: BL \to \mathbb{R}\) defined by \(f(x) = (-1)^{\lfloor x+1/4 \rfloor}\). However, it can be shown that for \((BL, d, \mu)\) satisfies \((P)_h\) for all \(h > 1/2\).

**Example 3.23 (Hyperbolic space).** Consider the Hyperbolic \(n\)-space \(\mathbb{H}^n\) with Riemannian distance \(d_H\) and Riemannian measure \(\mu\). \((\mathbb{H}^n, d_H, \mu)\) satisfies \((VD)_{loc}\) and \((P)_{loc}\). However \((\mathbb{H}^n, d, \mu)\) does not satisfy \((VD)_{loc}\) because the volume of balls grows exponentially. Further \((\mathbb{H}^n, d_H, \mu)\) does not satisfy the Poincaré inequality \((P)_\infty\).

Another example in a similar spirit is the infinite \(d\)-regular tree \(T_d\) equipped with graph distance metric and counting measure. It is easy to very that if \(d \geq 3\), \(T_d\) does not satisfy \((VD)_{infty}\) and does not satisfy \((P)_h\) for all \(h > 0\).

Examples 3.21 and 3.23 illustrate all the four possibilities that can occur with properties \((VD)_\infty\) and \((P)_\infty\). It is summarized in the table below.
### Table 1. Examples of spaces in relation to the properties \((VD)_\infty\) and \((P)_\infty\)

| \((VD)_\infty\) | \((P)_\infty\) | Examples |
|------------------|-----------------|----------|
| True             | True            | \((\mathbb{R}^n, d, \mu_\alpha)\) with \(n \geq 2\) and \(\alpha > -n\) or \(n = 1\) and \(\alpha \in (-1, 1)\) |
| True             | False           | \((\mathbb{R}, d, \mu_\alpha)\) with \(\alpha \geq 1\) |
| False            | True            | \((\mathbb{R}^n, d, \mu_\alpha)\) with \(\alpha \leq -n\) |
| False            | False           | \((\mathbb{H}^n, d_H, \mu)\) |

3. POINCARÉ INEQUALITIES
Markov kernel, Semigroup and Dirichlet forms

In this chapter, we consider Markov chains on metric measure space \((M, d, \mu)\). Let \(B\) denote the Borel \(\sigma\)-algebra on \((M, d)\). Our work concerns long term behavior of a natural family of Markov chains on the state space \(M\). We will recall some standard definitions and facts about discrete time Markov chains.

A Markov transition function is a map \(P : M \times B : [0, \infty)\) such that \(x \mapsto (x, A)\) is \(B\)-measurable function on \(M\) for all \(A \in B\), and \(A \mapsto P(x, A)\) is a probability measure on \((M, B)\) for all \(x \in M\). A Markov transition function \(P\) on \((M, B)\) is \(\mu\)-symmetric if
\[
\int_M \int_M u_1(x)u_2(y)P(x, dy)\mu(dx) = \int_M \int_M u_1(x)u_2(y)P(x, dy)\mu(dx)
\]
for all measurable functions \(u_1, u_2 : M \to [0, \infty)\).

**Remark 4.1.** For the rest of this work, we assume that the our Markov transition function is \(\mu\)-symmetric with respect to some measure \(\mu\).

Associated with a \(\mu\)-symmetric Markov transition function \(P\) is a Markov operator \(P\), which is a linear operator defined by
\[
P f(x) = \int_M f(y)P(x, dy)
\]
on the set of bounded measurable functions. The operator \(P\) extends as a contraction operator on \(L^p(M) = L^p(M, \mu)\) for all \(p \in [1, \infty)\). With a slight abuse of notation, we denote this extension again by \(P : L^p(M) \to L^p(M)\) for each \(1 \leq p \leq \infty\). Moreover \(P\) is positivity preserving, i.e. if \(f \geq 0\) then \(P f \geq 0\).

The \(n\)-th iteration \(P^n\) of the operator \(P\) is just the operator associated with kernel \(P^n\) defined inductively by
\[
P^n(x, A) := \int_M P^{n-1}(z, A)P(x, dz)
\]
for all \(x \in M\), for all measurable sets \(A \in B\) and \(P^1 := P\). We now have the Markov semigroup of linear operators \((P^n)_{n \in \mathbb{N}_0}\) where \(P^0\) is the identity operator on \(L^2(M)\). The Chapman-Kolmogorov equation is given by
\[
P^{m+n}(x, A) = \int_M P^n(z, A)P^m(x, dz)
\]
for all \(A \in B\) and for all \(m, n \in \mathbb{N}^*\). By Fubini’s theorem, (4.3) implies the semigroup property \(P^{m+n}f = P^m P^n f\) for all \(m, n \in \mathbb{N}_0\) and \(f \in L^1(M)\).

The operator \(\Delta := I - P\) is the Laplacian which generates the Dirichlet form
\[
\mathcal{E}(f, f) = \langle f, \Delta f \rangle_{L^2(M)} = \frac{1}{2} \int_M \int_M (f(x) - f(y))^2 P(x, dy) \mu(dx).
\]
on $L^2(M)$ with full domain $\mathcal{D}(\mathcal{E}) = L^2(M)$.

For every Markov transition function $\mathcal{P}$ on $(M, \mathcal{B})$ there exists a Markov chain $(X_n, \mathbb{P}_x)_{n \in \mathbb{N}_0, x \in M}$ on some path space $(\Omega, \mathcal{F})$ such that

$$\mathcal{P}(x, A) = \mathbb{P}_x(X_1 \in A).$$

(one can always choose the canonical path space $\Omega = M^{\mathbb{N}_0}, \mathcal{F} = \mathcal{B}^{\mathbb{N}_0}$ and $X_n(\omega) = \omega_n$ for $\omega = (\omega_0, \omega_1, \ldots)$. The transition function $\mathcal{P}^n$ is then given by $\mathcal{P}^n(x, A) = \mathbb{P}_x(X_n \in A)$ and the operator $P^n$ by $P^n f(x) = \mathbb{E}_x f(X_n)$. The $\mu$-symmetry of $\mathcal{P}$ is equivalent to the $\mu$-reversibility of the Markov chain:

$$\mathbb{P}_\mu(x_0 \in A, X_1 \in B) = \mathbb{P}_\mu(x_1 \in A, X_0 \in B)$$

where $\mathbb{P}_\mu$ is a measure (not necessarily a probability measure) defined by $\mathbb{P}_\mu(\cdot) := \int_M \mathbb{P}_\mu(\cdot)(dx)$.

If $\mathcal{P}(x, \cdot) \ll \mu$ for all $x \in M$, we denote its kernel by $p : M \times M \to [0, \infty)$, that is

$$\mathcal{P}(x, A) = \int_A p(x, y) \mu(dy)$$

for all $x \in M$ and for all $A \in \mathcal{B}$. The kernel $p$ is called a Markov kernel with respect to $\mu$. The kernel $p(x, y)$ is the Radon-Nikodym derivative of $\mathcal{P}(x, \cdot)$ with respect to $\mu$, that is $\mathcal{P}(x, A) = \int_A p(x, y) \mu(dy)$ for all $x \in M$ and all $A \in \mathcal{B}$. The $\mu$-symmetry of $\mathcal{P}$ implies symmetry of kernel, that is $p(x, y) = p(y, x)$ for all $\mu \times \mu$ almost every $(x, y) \in M \times M$. By definition, we have $p(x, \cdot) \in L^1(M, \mu)$ for all $x \in M$. However, we assume that $p(x, \cdot) \in L^\infty(M, \mu)$ for all $x \in M$. Under the assumption $p(x, \cdot) \in L^1 \cap L^\infty$, we define iteratively

$$p_{k+1}(x, y) := [PP_k(x, \cdot)](y) = \int_M p_k(x, z) p_1(y, z) \mu(dz)$$

where $p_1 := p$ and $k \in \mathbb{N}^*$. The function $p_k$ for $k \in \mathbb{N}^*$ is called the heat kernel. We will show some basic properties of heat kernel defined in (4.4).

**Lemma 4.2.** Let $(M, d, \mu)$ be a metric measure space and let $\mathcal{P}$ be a $\mu$-symmetric Markov transition function satisfying $\mathcal{P}(x, \cdot) \ll \mu$ for all $x \in M$. Let $p_k(x, \cdot) = \frac{d\mathcal{P}(x, \cdot)}{d\mu}$ denote the corresponding Markov kernel. Assume further that $p_1(x, \cdot) \in L^\infty(M, \mu)$ for all $x \in M$. The kernel $p_k$ defined in (4.4) satisfies

(a) $p_k(x, \cdot) = \frac{d\mathcal{P}^k(x, \cdot)}{d\mu}$ for all $k \in \mathbb{N}^*$. That is $\mathcal{P}^k(x, A) = \int_A p_k(x, y) \mu(dy)$ for all $x \in M$, for all $k \in \mathbb{N}^*$ and for all $A \in \mathcal{B}$,

(b) $p_k(x, y) = p_k(y, x) \in [0, \infty)$ for all $x, y \in M$ and for all $k \geq 2$.

(c) $p_{k+t}(x, y) = p_k(p_t(x, \cdot))(y)$ for all $x, y \in M$ and for all $k, l \in \mathbb{N}^*$.

**Proof.** Since $p_1(x, \cdot) \geq 0 \mu$-almost everywhere for all $x \in M$, by induction we have that $p_k(x, y) \in [0, +\infty]$ for all $x, y \in M$ and for all $k \geq 2$. Therefore by induction on $k$, we have

$$\int_M p_{k+1}(x, y) dy = \int_M \int_M p_k(x, z)p_1(y, z) dz \, dy = \int_M p_k(x, z) \int_M p_1(z, y) dz \, dy = \int_M p_k(x, z) dz = 1.$$

In the first line above we used Fubini’s theorem and that $p_1(y, z) = p_1(z, y) \mu \times \mu$-almost everywhere. Since $\|p_k(x, \cdot)\|_1 = 1$ for all $x \in M$ and for all $k \in \mathbb{N}^*$, we
have
\[ p_{k+1}(x,y) = \|p_k(x,·)p_1(y,·)\|_1 \leq \|p_k(x,·)\|_1 \|p_1(y,·)\|_\infty \leq \|p_1(y,·)\|_\infty < \infty \]
for all \( k \in \mathbb{N}^* \) and for all \( x, y \in M \).

First we show (b) by induction. The result is obvious for \( k = 2 \). If \( k \geq 2 \), we have
\[
p_{k+1}(x,y) = \int_M p_k(x,z)p_1(y,z) \, dz = \int_M p_k(z,x)p_1(y,z) \, dz = \int_M \int_M p_{k-1}(z,w)p_1(x,w)p_1(y,z) \, dw \, dz.
\]
In the first line above, we used the induction hypothesis. By the above formula for \( p_{k+1}(x,y) \) it is clear that \( p_{k+1}(x,y) = p_{k+1}(y,x) \) for all \( x, y \in M \).

Now we verify (a) by induction. For \( k \in \mathbb{N}^* \), we have
\[
\mathcal{P}^{k+1}(x,A) = \int_M \mathcal{P}^k(z,A) \mathcal{P}(x,dz) = \int_M \left( \int_A p_k(z,w) \, dw \right) p_1(x,z) \, dz = \int_A \int_M p_k(z,w)p_1(x,z) \, dz \, dw = \int_A \int_M p_k(w,z)p_1(x,z) \, dz \, dw
\]
for all \( A \in \mathcal{B} \). In the first line above, we used induction hypothesis, the second line follows from Fubini’s theorem, (b) and the \( \mu \times \mu \)-a.e. symmetry of \( p_1 \). The last line again follows from (b).

By definition of \( p_k \) (4.4), we have
\[
p_{k+1}(x,y) = P(p_k(x,·))(y)
\]
for all \( x, y \in M \). Therefore (c) follows from repeated application of the above equality.

\[ \square \]

Remark 4.3. In light of (iii) above, we may alternatively define \( p_k(x,·) \) as the Radon-Nikodym derivative \( \frac{d\mathcal{P}^k}{dw} \). However this alternate definition for \( p_k(x,y) \) makes sense only for \( \mu \)-almost every \( y \in M \) (for a fixed value of \( x \)). Nevertheless, since \( p_1(y,·) \in L^\infty \) and \( p_{k-1}(x,·) \in L^1 \), it is clear that for all \( k \geq 2 \), the function \( (x,y) \mapsto p_k(x,y) \) defined in (4.4) is well-defined for all \( x \in M \) and for all \( y \in M \). Hence for \( k \geq 2 \), \( p_k : M \times M \to \mathbb{R}_{\geq 0} \) is a genuine function (as opposed to \( p_k(x,·) \) just being in \( L^1 \)). For \( k \geq 2 \), \( p_k \) is a genuine function on \( M \times M \) but \( p_1(x,·) \in L^1 \cap L^\infty \) for all \( x \in M \).

Many questions concerning the long term behavior of the Markov chain can be answered if we know \( p_k \). Therefore estimates on \( p_k(x,y) \) for all \( x, y \in M \) and for all \( k \in \mathbb{N}^* \) is of importance. Based on the remarks above on \( p_k \), any bound on \( p_k(x,·) \) must be understood in the \( \mu \)-almost everywhere sense for \( k = 1 \) and in a point-wise sense for \( k \geq 2 \). The estimates on heat kernel gives both qualitative (e.g. recurrence/transience, Liouville property) and quantitative (e.g. estimates on Green’s function, Hölder regularity) information on the long term behavior of the Markov chain. See Chapter 10 for applications of Gaussian estimates on the heat kernel.
4. MARKOV KERNEL, SEMIGROUP AND DIRICHLET FORMS

Example 4.4. Let \((M, d, \mu)\) satisfy \((VD)_{\text{loc}}\) and let \(h > 0\). Consider the natural ball walk with Markov kernel \(k\) with respect to \(\mu\) defined as \(k(x, y) = \frac{1_{B(x,h)}(y)}{V(x,h)}\). The corresponding Markov transition function \(\mathcal{K}\) is not necessarily \(\mu\)-symmetric because \(k(x, y) \neq k(y, x)\) in general. Consider the measure \(\mu' \ll \mu\) with \(\frac{d\mu'}{d\mu}(x) = V(x,h)\). The Markov kernel of \(\mathcal{K}\) with respect to \(\mu'\) is \(p(x, y) = \frac{1_{B(x,h)}(y)}{V(x,h)V(y,h)}\). Hence \(\mathcal{K}\) is \(\mu'\)-symmetric. Such ball walks on compact Riemannian manifolds were studied in [56].

A Markov chain \((X_n, P_x)_{n \in \mathbb{N}, x \in M}\) is said to be lazy if \(\inf_{x \in M} P_x(X_1 = x) > 0\).

Example 4.5. Consider a metric measure space \((M, d, \mu)\) with a \(\mu\)-symmetric Markov transition function \(P\). Define the Markov transition function

\[P_L(x, A) := \frac{1}{2}(P(x, A) + \delta_x(A))\]

where \(\delta_x(A) = 1_A(x)\) denotes the Dirac measure at \(x\). Note that \(P_L\) \(\mu\)-symmetric and corresponds to a lazy Markov chain. Assume \(P\) has a kernel \(p\) with respect to \(\mu\). Then \(P_L\) has a kernel with respect to \(\mu\) if and only if \(\delta_x \ll \mu\) for all \(x \in M\). If \(P\) is the Markov operator corresponding to \(P\), then \(P_L = (I + P)/2\) is the Markov operator corresponding to \(P_L\), where \(I\) is the identity operator on \(L^p(M)\). Hence the corresponding Laplacian operators \(\Delta\) and \(\Delta_L\) are related by \(\Delta_L = \Delta/2\).

Some basic properties of a symmetric Markov kernel are listed without proof in the lemma below.

Lemma 4.6 (Folklore). Let \(P\) denote a \(\mu\)-symmetric Markov transition function over a metric measure space \((M, d, \mu)\) and let \(P\) be the corresponding Markov operator. Then \(P\) is a contraction on all \(L^p(M, \mu)\), that is

\[\|Pf\|_p \leq \|f\|_p\]

for all \(p \in [1, \infty]\) and for all \(f \in L^p(M)\). A consequence of (4.5) is the inequality

\[\mathcal{E}(f, f) = \langle (I - P)f, f \rangle \leq 2\|f\|_2^2\]

for all \(f \in L^2(M)\). Moreover \(P\) is self-adjoint on \(L^2(M)\), that is

\[\langle f, Pg \rangle = \langle Pf, g \rangle\]

for all \(f, g \in L^2(M, \mu)\) where \([f_1, f_2] = \int_M f_1 f_2 d\mu\) denotes the inner product on \(L^2(M, \mu)\).

We list some elementary properties of a symmetric Markov kernel below.

Lemma 4.7 (Folklore). Let \(P\) denote a \(\mu\)-symmetric Markov transition function over a metric measure space \((M, d, \mu)\) and let \(p\) be the corresponding Markov kernel. Then for all \(x \in M\), the function

\[n \mapsto p_{2n}(x, x)\]

is non-increasing. Moreover we have

\[p_{2n}(x, y) \leq p_{2n}(x, x)^{1/2} p_{2n}(y, y)^{1/2}\]

for all \(x, y \in M\) and for all \(n \in \mathbb{N}^*\).
Proof. Note that the first claim follows from (4.5) by
\[ p_{2n+2}(x,x) = \|p_{n+1}(x,.)\|^2 = \|Pp_n(x,.)\|^2 \leq \|p_n(x,.)\|^2 = p_{2n}(x,x). \]
For (4.9), we simply use Cauchy-Schwarz inequality to obtain
\[ p_{2n}(x,y) = \langle p_n(x,.), p_n(y,.) \rangle \leq \|p_n(x,.)\|_2 \|p_n(y,.)\|_2. \]

\[ \square \]

4.1. Assumptions on the Markov chain

We introduce the main assumptions on the Markov chain in the following definition.

Definition 4.8. For \( h > 0 \), a Markov transition function \( P \) on \((M, B)\) is said to be \((h, h')\)-compatible with \((M, d, \mu)\) if

(a) \( P \) is \( \mu \)-symmetric.

(b) There exists a kernel \( p_1 \) such that \( P(x, A) = \int_A p_1(x, y) \mu(dy) \) for all \( x \in M \) and for all \( A \in B \). By (a), we have \( p_1(x,y) = p_1(y,x) \) for all \( x, y \in M \).

(c) There exists reals \( c_1, C_1 > 0 \) and \( h' \geq h \) such that

\[
\frac{c_1}{V(x,h)}1_{B(x,h)}(y) \leq p_1(x,y) \leq \frac{C_1}{V(x,h')}1_{B(x,h')}(y)
\]
for all \( x \in M \) and for \( \mu \)-almost every \( y \in M \).

(d) There exists \( \alpha > 0 \) such that

\[
p_2(x,y) \geq \alpha p_1(x,y)
\]
for all \( x \in M \) and for \( \mu \)-almost every \( y \in M \), where \( p_2 \) is defined by (4.4).

The corresponding Markov kernel \( p_1 \) is said to be \((h, h')\)-compatible with \((M, d, \mu)\).

If a Markov transition function \( P \) satisfies (a),(b),(c) above we say that \( P \) (respectively \( p_1 \)) is weakly \((h, h')\)-compatible with \((M, d, \mu)\).

Similarly, we say the corresponding Markov operator \( P \) is (weakly) \((h, h')\)-compatible with \((M, d, \mu)\) if the Markov transition function \( P \) is (weakly) \((h, h')\)-compatible with \((M, d, \mu)\).

Remark 4.9. (i) Let \((M, d, \mu)\) satisfy \((VD)_{loc}\) and \( h_1 \geq h_2 > 0 \). If a Markov kernel \( p_1 \) is \((h_1, h')\)-compatible with \((M, d, \mu)\) then \( p_1 \) is \((h_2, h')\)-compatible with \((M, d, \mu)\).

(ii) The condition (d) in Definition 4.8 may seem unnatural, but is important for certain technical reasons. The proofs on Caccioppoli inequality (Lemma 7.8) and discrete time integrated maximum principle (Proposition 7.12) and relies crucially on laziness of walks. Condition (d) enables us to compare the behavior of a given random walk with its lazy version as presented in Example 4.5.

(iii) There are several examples for which (d) is satisfied. For instance, a Markov kernel on weighted graphs satisfying \((VD)_{loc}\) is weakly \((h, h')\)-compatible if and only if it is \((h, h')\)-compatible. Consider a Markov kernel \( p \) weakly \((h, h)\)-compatible with a length space \((M, d, \mu)\) satisfying \((VD)_{loc}\), then \( p \) is \((h, h)\) compatible.

(iv) Lemmas 4.11 and 4.16 show that the assumption (d) is not restrictive for obtaining Gaussian estimates.
(v) The condition (4.10) is an analog of the uniform ellipticity condition (1.4).

We record some important consequences of Condition (d) in Definition 4.8.

**Lemma 4.10.** Let \((M,d,\mu)\) be a metric measure space and let \(P\) be Markov operator that is \((h,h')\)-compatible with \((M,d,\mu)\). Then the corresponding kernel \(p_k\) satisfies
\[
p_{k+1}(x,y) \geq \alpha p_k(x,y)
\]
for all \(x,y \in M\) and for all \(k \geq 2\) where \(\alpha\) is same as in (4.11). Moreover the operator \((P - \alpha/2)I\) is positivity preserving, that is if \(f : M \to \mathbb{R}\) satisfies \(f \geq 0\), then \((P - \alpha/2)I f \geq 0\).

**Proof.** Since \(P^k\) is a Markov operator, by (4.11) and Lemma 4.2(c) we have
\[
p_{k+2}(x,y) - \alpha p_{k+1}(x,y) = P^k [p_2(x,\cdot) - \alpha p_1(x,\cdot)](y) \geq 0
\]
for all \(k \in \mathbb{N}^*\) and for all \(x,y \in M\). This proves (4.12).

By (4.11) and \(f \geq 0\), we have
\[
(P - \alpha/2)I f(x) = (P^2 - \alpha P)f(x) + (\alpha/2)^2 f(x) \geq (P^2 - \alpha P)f(x) = \int_M f(y)(p_2(x,y) - \alpha p_1(x,y)) \, dy \geq 0
\]
for all \(x \in M\).

The following lemma shows that a large enough convolution power of a weakly compatible kernel is compatible under some mild conditions.

**Lemma 4.11.** Let \((M,d,\mu)\) be a quasi-b-geodesic space satisfying (VD)\(\text{loc}\) and let \(p_1\) be a Markov kernel weakly \((h,h')\)-compatible with \((M,d,\mu)\) for some \(h > b\). Then there exists \(k \in \mathbb{N}^*\) for which \(p_l\) is \((h,lh')\)-compatible with \((M,d,\mu)\) for all \(l \in \mathbb{N}^*\) such that \(l \geq k\).

**Proof.** Properties (a) and (b) of Definition 4.8 follows directly from the weak compatibility of \(p_1\). It only remains to check properties (c) and (d). Assume that \(p_1\) satisfies (4.10). Let \(x, y \in M\) with \(d(x,y) \leq h'\). By Lemma 2.6, there exists even number \(k \in \mathbb{N}^*\) such that for all \(l \geq k \geq 2\), there exists a \(b\)-chain \(x_0, x_1, \ldots, x_l\) with \(x_0 = x, x_l = y\). Define \(h_1 = (h - b)/2\). By Chapman-Kolmogorov equation
\[
p_l(x,y) \geq \int_{B(x_{l-1},h_1)} \cdots \int_{B(x_1,h_1)} p(x,y_1)p(y_1,y_2)\cdots p(y_{l-1},y) \, dy_1 dy_2 \cdots dy_{l-1} \geq \int_{B(x_{l-1},h_1)} \cdots \int_{B(x_1,h_1)} p_l(x,h) V(x,h) \, dy_1 dy_2 \cdots dy_{l-1}
\]
\[
\geq \int_{B(x_{l-1},h_1)} \cdots \int_{B(x_1,h_1)} \frac{\alpha^{l-1} \alpha^{2-l}}{V(x,h) V(x_1,h) \cdots V(x_{l-1},h)} \, dy_1 dy_2 \cdots dy_{l-1}
\]
\[
\geq \int_{B(x_{l-1},h_1)} \cdots \int_{B(x_1,h_1)} \frac{\alpha^{l-1} \alpha^{2-l}}{V(x,h) V(x_1,h) \cdots V(x_{l-1},h)} \, dy_1 dy_2 \cdots dy_{l-1}
\]
\[
\geq \frac{\alpha^{l-1} \alpha^{2-l}}{V(x,h) V(x_1,h) \cdots V(x_{l-1},h)}
\]
\[
(4.13)
\]

The third line above follows weakly \((h,h')\)-compatible condition (4.10) and the fourth line follows from Lemma 2.10. Combining with the fact that \(p\) is weakly
(h, h')-compatible along with Lemma 2.10 gives the following lower bound: For all $l \geq k$ and $l \in \mathbb{N}^*$, there exists $c_{1,l} > 0$ such that

$$\min(p_l(x, y), p_{l+1}(x, y)) \geq \frac{c_{1,l}}{V(x', h)} \mathbf{1}_{B(x, h')}(y)$$

for all $x, y \in M$. Hence by (4.14) and (4.10) we get $p_{l+1} \geq \alpha_l p_l$ for some $\alpha_l > 0$. Since $P$ is positivity preserving, we have

$$p_{2l}(x, y) = (P^{l-1}p_{l+1}(x, .))(y) \geq \alpha_l (P^{l-1}p_l(x, .))(y) = \alpha_l p_l(x, y)$$

which is condition (d) of Definition 4.8. Note that (4.14) implies that $p_l$ satisfies the lower bound in condition (c) of Definition 4.8.

Now we turn to the corresponding upper bound for $p_l$. Since $P$ is a contraction on $L^\infty$, there exists $C_1 > 0$ such that $p_m(x, y) \leq C_1/V(x, h)$ for all $x, y \in M$ and all $m \in \mathbb{N}^*$. By triangle inequality $p_m(x, y) = 0$ if $d(x, y) > mh'$ for all $m \in \mathbb{N}^*$ and for all $x, y \in M$. Hence by Lemma 2.10 we have the desired conclusion. □

**Remark 4.12.** We now justify the condition $h > b$ in the above lemma. It is to avoid pathological examples of the following kind: Consider a ball walk of Example 4.4 with $h \leq 1/2$ on Broken line space $(BL, d, \mu)$ from Example 3.22. It is easy to check that such a random walk never leaves a connected component. Similarly, the ball walk of Example 4.4 with $h < 1$ on a graph always stays at one point.

### 4.2. Gaussian estimates

The main property of a Markov kernel that we are interested in are Gaussian estimates for its iterated kernel $p_n$.

**Definition 4.13.** A $\mu$-symmetric Markov kernel $p$ on $(M, d, \mu)$ is said to satisfy Gaussian upper bound (GUE) if there exists $C_1, C_2 > 0$ such that

$$p_n(x, y) \leq \frac{C_1}{V(x, \sqrt{n})} \exp\left(-\frac{d(x, y)^2}{C_2 n}\right)$$

for all $x, y \in M$ and for all $n \in \mathbb{N}^*$ satisfying $n \geq 2$.

Similarly, a $\mu$-symmetric Markov kernel $p$ on a metric measure space $(M, d, \mu)$ is said to satisfy Gaussian lower bound (GLE) if there exists $c_1, c_2, c_3 > 0$ such that

$$p_n(x, y) \geq \frac{c_1}{V(x, \sqrt{n})} \exp\left(-\frac{d(x, y)^2}{c_2 n}\right)$$

for all $x, y \in M$ satisfying $d(x, y) \leq c_3 n$ and for all $n \in \mathbb{N}^*$ satisfying $n \geq 2$.

A $\mu$-symmetric Markov kernel $p$ on a metric measure space $(M, d, \mu)$ is said to satisfy two sided Gaussian bound (GE) if it satisfies (GUE) and (GLE).

The condition $d(x, y) \leq c_3 n$ in (GLE) is needed because $p_n(x, y)$ vanishes for compatible kernels if $d(x, y) \geq cn$ for some constant $c > 0$. In many situations, the above Gaussian estimates are equivalent to the following (a priori weaker) estimates which are easier to prove. We require the estimates in Definition 4.13 to hold only for large enough $n$ in the definition below.

**Definition 4.14.** A $\mu$-symmetric Markov kernel $p$ on $(M, d, \mu)$ is said to satisfy Gaussian upper bound $(GUE)_n$ if there exists $C_1, C_2, n_0 > 0$ such that

$$p_n(x, y) \leq \frac{C_1}{V(x, \sqrt{n})} \exp\left(-\frac{d(x, y)^2}{C_2 n}\right)$$
for all \( x, y \in M \) and for all \( n \in \mathbb{N}^* \) such that \( n \geq n_0 \).

The conditions \((GLE)_\infty\) and \((GE)_\infty\) are defined analogously.

Under mild conditions, we show that \((GE)_\infty\) implies \((GE)\).

**Lemma 4.15.** Let \((M, d, \mu)\) be a quasi-\( b \)-geodesic space satisfying \((VD)_{\text{loc}}\) and let \( p_1 \) be a Markov kernel weakly \((h, h')\)-compatible with \((M, d, \mu)\) for some \( h > b \). The following hold:

(a) If \( p_1 \) satisfies \((GUE)_\infty\), then \( p_1 \) satisfies \((GUE)\).

(b) If \( p_1 \) satisfies \((GLE)_\infty\), then \( p_1 \) satisfies \((GLE)\).

(c) If \( p_1 \) satisfies \((GE)_\infty\), then \( p_1 \) satisfies \((GE)\).

**Proof.** Note that \( p_1 \) satisfies \((4.10)\).

(a) The Gaussian upper estimate for \( p_n \) where \( n \geq n_0 \) follows from \((GUE)_\infty\).

If \( n < n_0 \), we simply use that \( P \) is a contraction in \( L_\infty \) along with \((4.10)\) to obtain

\[
\begin{align*}
 p_n(x, y) &\leq C_1 \frac{1_{B(x, n b)}(y)}{V(x, h')} \\
 &\leq \frac{C_2}{V(x, \sqrt{n})} \exp \left(-\frac{d(x, y)^2}{C_3 n} \right)
\end{align*}
\]

for all \( x, y \in M \) and for all \( n < n_0 \). The first line above follows from triangle inequality, \( \|P\|_{L_\infty \to L_\infty} = 1 \) and \((4.10)\). The second line follows from Lemma 2.10.

(b) The Gaussian lower bounds for \( p_n \) where \( n \geq n_0 \) follows from \((GLE)_\infty\).

Let \( h_1 = \min(h/2, h - b) \). Using ideas similar to the proof of Lemma 4.11 (see \((4.13)\)), there exists \( c_2, c_3, c_4 > 0 \) such that

\[
\begin{align*}
p_n(x, y) &\geq \int_{B(x, h_1)} \cdots \int_{B(x, h_1)} p(x, y_1)p(y_1, y_2) \cdots p(y_{n-1}, y) \, dy_1 \, dy_2 \cdots dy_{n-1} \\
&\geq \frac{c_2 c_4^3 1_{B(x, h)}(y)}{V(x, h)} \geq \frac{c_4}{V(x, \sqrt{n})} \exp \left(-\frac{d(x, y)^2}{c_4 n} \right)
\end{align*}
\]

for all \( n < n_0 \) and for all \( x, y \in M \) such that \( d(x, y) \leq (b/n_0)n \).

(c) It is a direct consequence of (a) and (b).

\( \square \)

**Lemma 4.16.** Let \((M, d, \mu)\) be a quasi-\( b \)-geodesic space satisfying \((VD)_{\text{loc}}\) and let \( p \) be a Markov kernel weakly \((h, h')\)-compatible with \((M, d, \mu)\) for some \( h > b \). For some \( k \in \mathbb{N}^* \), if \( p_k \) satisfies \((GE)_\infty\) then \( p \) satisfies \((GE)\).

**Proof.** By Lemma 4.15 it suffices to show that \( p \) satisfies \((GUE)_\infty\) and \((GLE)_\infty\).

Suppose \( p = p_1 \) satisfies \((4.10)\). For \( n \geq k \), there exists \( A = kh' > 0 \) such that

\[
(4.15) \quad p_n(x, y) \leq \sup_{z \in B(y, A)} p_{k[n/k]}(x, z)
\]

for all \( x, y \in M \) and for all \( n \in \mathbb{N}^* \) with \( n \geq k \). This follows from Chapman-Kolmogorov equation along with the fact that the support of \( p_{k[n/k]}(\cdot, y) \) is contained
in $B(y,kh')$ for all $l \leq k$. Since $p_k$ satisfies $(GUE)_\infty$, there exists $C_1, C_2 > 0$ and $n_0 > 0$ such that
\begin{equation}
(4.16) \quad p_{mk}(x, y) \leq \frac{C_1}{V(x, \sqrt{m})} \exp \left( -\frac{d(x, y)^2}{C_2m} \right)
\end{equation}
for all $x, y \in M$ and for all $m \in \mathbb{N}^*$ satisfying $m \geq n_0$. By (4.15), (4.16) and (2.4), there exists $C_3, C_4 > 0$ and $n_1 > 0$ such that
\begin{equation}
(4.17) \quad p_n(x, y) \leq \frac{C_3}{V(x, \sqrt{n})} \sup_{z \in B(y, A)} \exp \left( -\frac{d(x, z)^2}{C_4n} \right)
\end{equation}
for all $x, y \in M$ and for all $n \in \mathbb{N}^*$ satisfying $n \geq n_1$. For every $z \in B(y, A)$, we have
\begin{equation}
(4.18) \quad d(x, y)^2 \leq (d(x, z) + A)^2 \leq 2(d(x, y)^2 + A^2).
\end{equation}
By (4.17) and (4.18), we have that $p$ satisfies $(GLE)_\infty$. The proof is similar to above. As in (4.15), we have the complementary inequality,
\begin{equation}
(4.19) \quad p_n(x, y) \geq \inf_{z \in B(y, A)} p_{k|n/k}(x, z)
\end{equation}
for all $x, y \in M$ and for all $n \in \mathbb{N}^*$ with $n \geq k$. Since $p_k$ satisfies $(GLE)_\infty$, there exists $c_1, c_2, c_3, n_2 > 0$ such that
\begin{equation}
(4.20) \quad p_{mk}(x, y) \geq \frac{c_1}{V(x, \sqrt{m})} \exp \left( -\frac{d(x, y)^2}{c_2m} \right)
\end{equation}
for all $x, y \in M$ and for all $m \in \mathbb{N}^*$ satisfying $m \geq n_2$ and $d(x, y) \leq c_3m$. By (4.19), (4.20), there exists $c_4, c_5 > 0$ and $n_3 > 0$ such that
\begin{equation}
(4.21) \quad p_n(x, y) \geq \frac{c_1}{V(x, \sqrt{n})} \inf_{z \in B(y, A)} \exp \left( -\frac{d(x, y)^2}{c_4n} \right)
\end{equation}
for all $x, y \in M$ and for all $n \in \mathbb{N}^*$ satisfying $n \geq n_2$ and $d(x, y) \leq c_5n$. By interchanging $y$ and $z$ in (4.18) along with (4.21) yields $(GLE)_\infty$ for the kernel $p$.

We describe two examples that does not fall under the framework given by Definition 4.8 but nevertheless the methods developed in this work still applies.

**Example 4.17** (Random walk with jumps supported in an annulus). We consider a measured, complete, length space $(M, d, \mu)$ satisfying diam$(M) = +\infty$ and $(VD)_{loc}$ . Let $P$ be a $\mu$-symmetric Markov operator whose kernel $p(x, y)$ satisfies the following estimate: there exists $C_1 > 0$ and $h > 0$, $h_1 > 0$, $h_2 > 0$ such that
\begin{equation}
(4.22) \quad C_1^{-1} \frac{1_{B(x, 2h)}B(x, h)B(x, h)}{V(x, h)} \leq p(x, y) \leq C_1 \frac{1_{B(x, h_2)}B(x, h_2)}{V(x, h)}
\end{equation}
for all $x \in M$ and for $\mu$-almost every $y \in M$.

In this case, it is easy to verify that the density $p_2$ is weakly $(h/5, 2h_2)$-compatible with $(M, d, \mu)$. Note that for all $x \in M$, there exists $z \in M$ such that $d(x, z) = 3h/2$. Note that by Lemma 2.10 and (4.22), there exists $C_2 > 0$ such that for all $x, y \in M$ with $d(x, y) \leq h/5$
\begin{equation}
(4.23) \quad p_2(x, y) \geq \int_{B(z, h/4)} p_1(x, w)p_1(y, w) \mu(dw) \geq C_2^{-1} \frac{C_1}{V(x, h/5)}
\end{equation}
and for all \( x, y \in M \) with \( d(x, y) \leq 2h_2 \) we have
\[
p_2(x, y) \leq \int_{B(x, 2h_2)} p_1(x, w)p_1(y, w) \mu(dw) \leq \frac{C_2}{V(x, 2h_2)}.
\]
Therefore \( p_2 \) is weakly \((h/5, 2h_2)\) compatible with \((M, d, \mu)\).

For example, it is clear that the application to Liouville property will not be affected if we replace the operator \( P \) by \( P^2 \). If the underlying space satisfies volume doubling and Poincaré inequality we can use our main results to obtain Gaussian estimates \((GE)\) provided \((M, d, \mu)\) satisfies \((VD)\) and \((P)\). To prove the above statement, we simply note by Theorem 1.4, Lemma 4.11 and Lemma 4.16 that \( p_2 \) satisfies \((GE)\) and by a similar argument \( p_1 \) satisfies \((GE)\).

**Example 4.18.** We describe another example similar to Example 4.17. Consider \( \mathbb{R}^n \) equipped with Euclidean distance \( d \) and Lebesgue measure \( \mu \). Let \( e \) denote an arbitrary unit vector in \( \mathbb{R}^n \). Consider the \( \mu \)-symmetric random walk with the kernel
\[
p(x, y) = \frac{1_{B(x+2e,1)\cup B(x-2e,1)}(y)}{2V(x,1)}.
\]

Although \( p \) is not compatible with \((\mathbb{R}^n, d, \mu)\), similar to Example 4.17 one can check that \((\mathbb{R}^n, d, \mu)\) satisfies that \( p_2 \) and \( p_3 \) are \((1/3, 9)\)-compatible with \((\mathbb{R}^n, d, \mu)\) and that the kernel \( p_k \) satisfies \((GE)\).

### 4.3. Comparison of Dirichlet forms

Let \((M, d, \mu)\) be a metric measure space with a \( \mu \)-symmetric Markov operator \( P \) and corresponding kernel \( p \). Recall that we defined the Dirichlet form \( \mathcal{E}(f, g) = \langle f, \Delta g \rangle \) for \( f, g \in L^2(M) \). We define another Dirichlet form \( \mathcal{E}_* \) which is the Dirichlet form corresponding to the Markov operator \( P^2 \), that is
\[
\mathcal{E}_*(f, g) = \langle f, (I - P^2)g \rangle = \|f\|^2 - \| Pf \|^2.
\]
for all \( f, g \in L^2(M) \).

**Remark 4.19.** Functional inequalities involving the Dirichlet form (for instance Nash, Sobolev, log Sobolev, Poincaré inequalities) can be transferred to an inequality concerning the Markov semigroup, which in turn sheds light on asymptotic behavior of Markov chains. For a continuous time Markov semigroup \((P_t)_{t \geq 0}\) a crucial identity to carry out this is \( \frac{d\|P_tf\|^2}{dt} = -2\mathcal{E}(P_tf, P_tf) \) (for instance [5, Theorems 4.2.5 and 6.3.1]) By the above definition, we have a similar identity for discrete time Markov semigroup:
\[
\partial_t \|P^k f\|^2 \leq \|P^{k+1} f\|^2 - \|P^k f\|^2 = -\mathcal{E}_*(P^k f, P^k f).
\]
for all \( f \in L^2(M) \). This is the main reason why we sometimes prefer \( \mathcal{E}_* \) instead of \( \mathcal{E} \).

The above remark motivates us to compare the Dirichlet forms \( \mathcal{E} \) and \( \mathcal{E}_* \).

**Lemma 4.20.** Consider a \( \mu \)-symmetric Markov chain on \((M, d, \mu)\) with Markov operator \( P \) and Dirichlet forms \( \mathcal{E} \) and \( \mathcal{E}_* \) defined as above. We have the following:
(a) \( \mathcal{E}_*(f, f) \leq 2\mathcal{E}(f, f) \) for all \( f \in L^2(M) \).
(b) Assume further that \( P \) has a strongly \((h, h')\)-compatible kernel \( p \) with respect to \((M, d, \mu)\). Then there exists a constant \( C > 0 \) such that \( \mathcal{E}(f, f) \leq C\mathcal{E}_*(f, f) \) for all \( f \in L^2(M) \).
4.4. MARKOV CHAINS KILLED ON EXITING A BALL 49

Proof. (a) Note that
\[ \langle Pf, f \rangle \leq \frac{1}{2} (\langle Pf, Pf \rangle + \langle f, f \rangle) = \frac{1}{2} (\langle P^2 f, f \rangle + \langle f, f \rangle) \]
Hence
\[ \mathcal{E}(f, f) = \langle f, f \rangle_M - \langle Pf, f \rangle_M \geq \langle f, f \rangle - \frac{1}{2} (\langle P^2 f, f \rangle + \langle f, f \rangle) = \frac{1}{2} \mathcal{E}_*(f, f) \]

(b) The conclusion follows from Property (d) of Definition 4.8 by observing that
\begin{align*}
\mathcal{E}(f, f) &= \frac{1}{2} \int_M \int_M (f(x) - f(y))^2 p(x, y) \, dx \, dy \\
\mathcal{E}_*(f, f) &= \frac{1}{2} \int_M \int_M (f(x) - f(y))^2 p_2(x, y) \, dx \, dy
\end{align*}
□

Remark 4.21. The inequality \( \mathcal{E}(f, f) \leq C \mathcal{E}_*(f, f) \) is not true in general. Consider nearest neighbor (simple) random walk on a finite bipartite graph. Let \( f \) be a function on the graph that assigns +1 to one partition and -1 to the other. It is easy to check that \( Pf = -f \) and therefore \( 2 \|f\|^2_2 = \mathcal{E}(f, f) \leq C \mathcal{E}_*(f, f) = 0 \) fails.

4.4. Markov chains killed on exiting a ball

To obtain lower bounds on the heat kernel, we consider the corresponding Markov process killed on exiting a ball \( B \) (See Chapter 8). Moreover functional inequalities like Nash and Sobolev inequalities that we will encounter are local to balls. Motivated by these considerations, we introduce Markov chains killed on exiting a ball and their corresponding Markov operator and kernel. Let \((X_n)_{n \in \mathbb{N}}\) be a Markov chain on \((M, d, \mu)\) driven by a \(\mu\)-symmetric Markov operator \(P\) with kernel \(p_1\) with respect to \(\mu\). The corresponding Markov chain \((X^B_n)_{n \in \mathbb{N}}\) that is killed on exiting a ball \(B\) has state space \(B \cup \{\partial B\}\) where \(\partial B\) is the absorbing cemetery state. The Markov chain \((X^B_n)_{n \in \mathbb{N}}\) killed on exiting \(B\) is defined as
\[ X^B_n = \begin{cases} 
X_n & \text{if } n < \zeta \\
\partial B & \text{if } n \geq \zeta
\end{cases} \]
where \(\zeta\) is the lifetime of the process defined by
\[ \zeta = \min \{k : X_k \notin B\} \]
For the killed Markov chain, we consider functions \(f : B \cup \partial B \to \mathbb{R}\) with the ‘Dirichlet’ boundary condition \(f(\partial B) = 0\). Therefore, we can define corresponding quantities like Markov kernel and Markov operator just by restriction to \(B\). Define the restricted kernel \(p_B : B \times B \to \mathbb{R}\), as a restriction of \(p_1\) on \(B \times B\). We endow \(B\) with the measure \(\mu_B\) which is the restriction of \(\mu\) to all Borel subsets of \(B\). We denote by \(L^2(B) = L^2(B, \mu_B)\). We define the Markov operator \(P_B\) with kernel \(p_B\) with respect to \(\mu_B\) as
\[ P_Bf(x) := \int_B f(y)p_1(x, y) \mu(dy) = \int_B p_B(x, y)f(y)\mu_B(dy). \]
Define the corresponding Dirichlet forms
\[ \mathcal{E}^B(f, f) := \langle f, (I - P_B)f \rangle_{L^2(B)}, \quad \mathcal{E}_*(f, f) := \langle f, (I - P_B^2)f \rangle_{L^2(B)} \]
for all $f \in L^2(B)$. Similar to (4.4), we define the kernel $p^B_k(x,y)$ iteratively as
\begin{equation}
(4.27) \quad p^B_{k+1}(x,y) := \left[ P_B p^B_k(x,\cdot) \right](y) = \int_B p^B_k(x,z)p^B_1(y,z) \mu(dz)
\end{equation}
for all $k \in \mathbb{N}^*$ and for all $x,y \in B$. It is easy to check that the proof of Lemma 4.2 (b),(c) applies to the kernel $p^B_k$. As before, the function $(x,y) \mapsto p^B_k(x,y)$ is well-defined for all $k \geq 2$. Further $p_B(x,\cdot) \in L^1(B)$ for all $x \in M$. It is easy to see that
\begin{equation}
(4.28) \quad p^B_k(x,y) \leq p^B_k(x,y)
\end{equation}
for all $x,y \in M$ and for all $k \geq 2$.

The operator $P_B$ is positivity preserving, that is $f \geq 0$ implies $P_B f \geq 0$. However unlike $P$, the operator $P_B$ is not necessarily conservative, that is $P_B 1 \neq 1$ in general. Analogous to (4.5), we have that $P_B$ is a contraction on all $L^p(B)$ for all $1 \leq p \leq +\infty$. We also define the corresponding ‘Dirichlet Laplacian’ $\Delta p_B := I - P_B$.

We will compare Dirichlet forms on balls with Dirichlet forms on $M$ below.

**Lemma 4.22.** Let $f \in L^2(B)$ and let $\tilde{f} \in L^2(M)$ denote an extension of $f$ defined by
\begin{equation}
(4.29) \quad \tilde{f} = \begin{cases} 
 f & \text{in } B \\
 0 & \text{in } B^c.
\end{cases}
\end{equation}

Then
\begin{itemize}
  \item[(a)] $\mathcal{E}^B(f,f) = \mathcal{E}(\tilde{f},\tilde{f})$.
  \item[(b)] $\mathcal{E}^B(f,f) \geq \mathcal{E}(\tilde{f},\tilde{f})$.
\end{itemize}

**Proof.** For (a), observe that
\begin{align*}
\mathcal{E}^B(f,f) &= \langle f, f \rangle_{L^2(B)} - \langle P_B f, f \rangle_{L^2(B)} \\
&= \langle \tilde{f}, \tilde{f} \rangle_{L^2(M)} - \langle P_B \tilde{f}, \tilde{f} \rangle_{L^2(M)} = \mathcal{E}(\tilde{f},\tilde{f}).
\end{align*}

For (b), we have
\begin{align*}
\mathcal{E}^B(f,f) &= \langle f, f \rangle_{L^2(B)} - \langle P_B f, P_B f \rangle_{L^2(B)} \\
&= \langle \tilde{f}, \tilde{f} \rangle_{L^2(M)} - \langle 1_B P \tilde{f}, 1_B P \tilde{f} \rangle_{L^2(M)} \\
&\geq \langle \tilde{f}, \tilde{f} \rangle_{L^2(M)} - \langle P \tilde{f}, P \tilde{f} \rangle_{L^2(M)} = \mathcal{E}(\tilde{f},\tilde{f}).
\end{align*}

\[\square\]

We warn the reader of the following abuse of notation. We may consider a function $f \in L^2(B)$ as a function in $L^2(M)$ using the extension given by (4.29). Alternatively we may consider a function $f \in L^2(M)$ as a function in $L^2(B)$ by the restriction $f|_B$. 
CHAPTER 5

Sobolev-type inequalities

J. Moser proved parabolic Harnack inequalities for second-order uniformly elliptic divergence form operators in \( \mathbb{R}^d \) [62]. This approach was successfully adapted by numerous authors. The previous versions of Theorem 1.4 as given in [69, 27, 76] used Moser’s iterative method as a crucial ingredient. Along with Poincaré inequality and volume doubling, Moser’s iteration relies on repeated applications of a Sobolev inequality.

We recall the difficulty arising due to Sobolev inequalities mentioned in the introduction. The Sobolev inequalities in the previous works [69, 25, 27, 76] are of the form

\[
\|f\|_{2 \delta/(\delta-2)}^2 \leq C r^2 V_{\mu}(x, r)^{2/\delta} \left( \mathcal{E}(f, f) + r^{-2} \|f\|_2^2 \right)
\]

for all 'nice' functions \( f \) supported in \( B(x, r) \). However (5.1) along with (4.6) implies that \( L^2(B(x, r)) \subseteq L^{2\delta/(\delta-2)}(B(x, r)) \) for all balls \( B(x, r) \) which can happen only if the space is discrete. Hence for discrete time Markov chains on continuous spaces the Sobolev inequality (5.1) fails to hold. In this chapter, we prove a weaker form of the above Sobolev inequality (see (5.2)) and study its properties. In the next two sections, we will use the Sobolev inequality (5.2) to run the Moser’s iterative method and obtain elliptic Harnack inequality and Gaussian upper bounds.

We adapt the approach of [69] to obtain a Sobolev inequality using \((VD)_\infty\) and \((P)_\infty\). The main result of this chapter is the following Sobolev inequality.

**Theorem 5.1.** Let \((M, d, \mu)\) be a quasi-b-geodesic metric measure space satisfying \((VD)_{\text{loc}}\), \((VD)_\infty\) and Poincaré inequality at scale \((P)_h\). Suppose that a Markov operator \(P\) has a kernel \(p\) that is \((h,h')\)-compatible with respect to \(\mu\). Let \(P_B\) and \(\mathcal{E}_B\) denote the corresponding Markov operator and Dirichlet form restricted to a ball \(B \subset M\). Then there exists \(\delta > 2\) and \(C_S > 0\) such that for all \(r > 0\), for all \(x \in M\), and for all \(f \in L^2(B)\), we have

\[
\|P_B f\|_{2 \delta/(\delta-2)}^2 \leq C S r^2 V_{\mu}(x, r)^{2/\delta} \left( \mathcal{E}_B(f, f) + r^{-2} \|f\|_2^2 \right)
\]

where \(B = B(x, r)\).

**Remark 5.2.** Since \(P_B\) is a contraction, note that (5.1) implies (5.2). Since we rely on the weaker Sobolev inequality (5.2), our methods give an unified approach to Gaussian bounds for graphs and continuous spaces. However we will encounter new difficulties due to (5.2).

Let \(s > 0\) and \(f \in L^1_{\text{loc}}(M, \mu)\). We define \(f_s\) as

\[
f_s(x) := f_{B(x,s)} = \frac{1}{V(x,s)} \int_{B(x,s)} f(x) \mu(dx).
\]
5.1. Pseudo-Poincaré and Nash inequalities

As in [69, Lemma 2.4], we need a pseudo-Poincaré inequality.

**Lemma 5.3 (Pseudo-Poincaré inequality).** Under the hypotheses of Theorem 5.1, there exists \( C_0 > 0 \) and \( s_0 > 0 \) such that

\[
\|f - f_s\|_2^2 \leq C_0 s^2 \mathcal{E}(f, f)
\]

for all \( f \in L^2(M) \) and for all \( s \geq s_0 \).

**Proof.** Let \( (X, d, m) \) be a 2s-net of \( (M, d, \mu) \) as given in Definition 2.21. By Proposition 2.22(a), the collection of balls \( J = \{B(x, 2s) \mid x \in X\} \) cover \( M \). Therefore

\[
\|f - f_s\|_2^2 \leq \sum_{2B \in J} \int_{2B} |f(x) - f_s(x)|^2 \mu(dx)
\]

\[
\leq 2 \left( \sum_{2B \in J} \int_{2B} |f(x) - f_{3B}|^2 \mu(dx) + \int_{2B} |f_s(x) - f_{3B}|^2 \mu(dx) \right).
\]

For the first term, we use \((P)_h\), to obtain \( C_1, C_2, s_1 > 0 \) such that

\[
\int_{2B} |f(x) - f_{3B}|^2 \mu(dx) \leq \int_{3B} |f(x) - f_{3B}|^2 \mu(dx) \leq C_1 s^2 \int_{3C_2 B} |\nabla f^2_h(x)| \mu(dx)
\]

for all \( s \geq s_0 \) and for all \( f \in L^2(M) \). For the second term in (5.5), we use Jensen’s inequality to obtain

\[
\int_{2B} |f_s(x) - f_{3B}|^2 \mu(dx) \leq \int_{2B} \frac{1}{V(x, s)} \int_{B(x,s)} |f(y) - f_{3B}|^2 \mu(dy) \mu(dx)
\]

\[
\leq \left( \int_{2B} V(x, s)^{-1} \mu(dx) \right) \cdot \left( \int_{3B} |f(y) - f_{3B}|^2 \mu(dy) \right)
\]

for all \( f \in L^2(M) \) and for all \( 2B \in J \). By (2.4), there exists \( C_3 > 0 \) such that

\[
\int_{2B} \frac{\mu(dx)}{V(x, s)} = \frac{1}{\mu(2B)} \int_{2B} \mu(2B) \mu(dx) \leq \frac{1}{\mu(2B)} \int_{2B} \frac{V(x, 4s) \mu(dx)}{V(x, s)} \leq C_3
\]

for all \( s \geq s_0 \) and for all \( 2B \in J \). By (5.5), (5.6), (5.7) and (5.8), there exists \( C_0 > 0 \) such that

\[
\|f - f_s\|_2^2 \leq C_1 (1 + C_3) s^2 \sum_{2B \in J} \int_{3C_2 B} |\nabla f^2_h(x)| \mu(dx) \leq C_0 s^2 \mathcal{E}(f, f)
\]

for all \( f \in L^2(M) \). The last inequality in (5.9) follows from Proposition 2.22(h), (4.23) along with (4.10). \( \Box \)

The following lemma is a consequence of doubling hypothesis.

**Lemma 5.4.** Let \( (M, d, \mu) \) be a measure space satisfying \((VD)_loc\) and \((VD)_\infty\). Then for all \( b > 0 \), there exists \( C_b > 0, \delta > 2 \) such that

\[
\|f_s\|_2^2 \leq \frac{C_b}{V(x, r)} \left( \frac{r}{s} \right)^\delta \|f\|_1^2
\]

for all \( f \in L^1(M) \) is supported in \( B = B(x, r) \) and for all \( b \leq s \leq r \).
5.1. PSEUDO-POINCARÉ AND NASH INEQUALITIES

**Proof.** By Hölder inequality, we have

\[ \|f_s\|_2^2 \leq \|f_s\|_\infty \|f_s\|_1. \]

(5.11)

Since \( f \) is supported in \( B(x, r) \) and \( s \leq r \) we have

\[ \|f_s\|_\infty \leq \|f\|_1 \sup_{y \in B(x, r+s)} \frac{1}{V(y, s)} \|f(y)\|_1 \sup_{y \in B(x, r)} V(y, 3r). \]

(5.12)

By (2.4), there exists \( C_1 > 0 \) and \( \delta > 2 \) such that

\[ \|f_s\|_\infty \leq \frac{C_1}{V(x, r)} \left( \frac{r}{s} \right)^\delta \|f\|_1 \]

for all \( b \leq s \leq r \) and for all \( f \in L^1 \) supported in \( B(x, r) \). Further there exists \( C_2 > 0 \) such that

\[ \|f_s\|_1 = \int_{B(x, r+s)} |f_s(y)| \mu(dy) \leq \int_{B(x, r+s)} \frac{1}{V(y, s)} \int_{B(y, s)} \|f(z)\|_1 \mu(dy) \mu(dz) \]

\[ \leq \int_{B(x, r+s)} |f(z)| \int_{B(y, s)} \frac{1}{V(y, s)} \mu(dy) \mu(dz) \]

for all \( b \leq s \leq r \) and for all \( f \in L^1 \) supported in \( B(x, r) \). The second line follows from Fubini’s theorem and (5.13) above follows from (2.5). The desired conclusion (5.10) follows from (5.11), (5.12) and (5.13).

Next, we show a Nash inequality using the pseudo-Poincaré inequality and doubling hypotheses by adapting the approach of [69, Theorem 2.1].

**Proposition 5.5.** Let \((M, d, \mu)\) be a quasi-b-geodesic metric measure space satisfying \( (VD)_{loc} \), \( (VD)_\infty \) and Poincaré inequality at scale \( h(P)h \). Suppose that a Markov operator \( P \) has a kernel \( K \) that is \( (h, h')\) compatible with respect to \( \mu \). Let \( \mathcal{E} \) denote the Dirichlet form corresponding to \( P \). Then there exists \( \delta > 2, C_N > 0 \) such that

\[ \| Pf \|_2^{2+(4/\delta)} \leq \frac{C_N r^2}{V(x, r)^{2/\delta}} \left( \mathcal{E}(f, f) + r^{-2} \| f \|_2^2 \right) \| f \|_1^{4/\delta} \]

for all \( r > 0 \), for all \( x \in M \), and for all \( f \in L^2(M) \) with \( f \) supported in \( B(x, r) \).

**Proof.** We start with an observation that (5.14) follows directly for small values of \( r \). Let \( r_0 > 0 \) be an arbitrary constant. If \( r \leq r_0 \), by (4.10) and (2.2), there exists \( C_1, C_2 > 0 \) such that for all functions \( f \in L^1(M) \) supported in \( B(x, r) \), we have

\[ \| Pf \|_\infty \leq \| f \|_1 \sup_{y \in B(x, r+h')} \frac{C_1}{V(y, h')} \leq \| f \|_1 \sup_{y \in B(x, r_0+h')} \frac{C_1}{V(y, h')} \]

(5.15)

\[ \leq \frac{C_1}{V(x, r_0)} \| f \|_1 \sup_{y \in B(x, r_0+h')} \frac{V(y, 2r_0+h')}{V(y, h')} \leq \frac{C_2}{V(x, r)} \| f \|_1. \]

By Hölder inequality along with (5.15) and (4.5), we have \( C_3 > 0 \) such that

\[ \| Pf \|_2 \leq \| Pf \|_\infty^{1/2} \| Pf \|_1^{1/2} \leq \frac{C_3}{V(x, r)^{1/2}} \| f \|_1 \]

(5.16)
for all function $f \in L^2(M)$ supported in $B(x, r)$ with $r \leq r_0$. By (5.16) and (4.5) and by the choice $C_N \geq C_3^{4/\delta}$, it suffices to show (5.14) for the case $r > r_0$.

Note that

\begin{equation}
\| Pf \|_2 \leq \| Pf - (Pf)_s \|_2 + \| (Pf)_s \|_2.
\end{equation}

We use pseudo-Poincaré inequality (Lemma 5.3) to bound the first term and use the $(h, h')$-compatibility of $P$ along with doubling hypotheses to bound the second term. To obtain (5.14), we minimize the bound on right hand side of (5.17) by varying $s$.

By Lemma 5.4, there exists $C_0 \geq 1$ and $r_0 > 0$ such that

\begin{equation}
\| Pf - (Pf)_s \|_2 \leq C_0^s \sqrt{\mathcal{E}(Pf, Pf)}
\end{equation}

for all $f \in L^2(M)$ and for all $s \geq r_0$.

By (5.10) and (4.5), there exists $C_4 > 0$ and $\delta > 2$ such that

\begin{equation}
\| (Pf)_s \|_2 \leq \frac{C_4}{V(x, r)^{1/2}} \left( \frac{r}{s} \right)^{\delta/2} \| f \|_1
\end{equation}

for all $f \in L^2(M)$ supported in $B(x, r)$ and for all $r_0 \leq s \leq r$. Combining (5.17), (5.18), (5.19), we obtain

\begin{equation}
\| Pf \|_2 \leq C_0^s \left( \sqrt{\mathcal{E}(Pf, Pf)} + r^{-1} \| Pf \|_2 \right) + \frac{C_4}{V(x, r)^{1/2}} \left( \frac{r}{s} \right)^{\delta/2} \| f \|_1
\end{equation}

for all $f \in L^2(M)$ supported in $B(x, r)$ and for all $s \geq r_0$ and for all $r \geq r_0$. In order to minimize the right side of (5.20), the choice of $s$ (up to a constant factor) is

\begin{equation}
s_1(f) := \left( \frac{\| f \|_1^2 r^\delta}{\mathcal{E}(Pf, Pf) + r^{-2} \| Pf \|_2^2 V(x, r)} \right)^{1/(\delta + 2)}.
\end{equation}

However, we want to choose $s \geq r_0$ in (5.20). We will do that by showing that $s_1(f)$ is bounded below. For all $r \geq r_0$, by (4.6) we have

\begin{equation}
\mathcal{E}(Pf, Pf) + r^{-2} \| Pf \|_2^2 \leq (2 + r_0^{-2}) \| Pf \|_2^2 \leq (2 + r_0^{-2}) \| Pf \|_\infty \| f \|_1
\end{equation}

for all $f \in L^2(M)$. Since $f$ is supported in $B(x, r)$, there exists $C_5, C_6 > 0$

\begin{equation}
\| Pf \|_\infty \leq C_5 \| f \|_1 \sup_{y \in B(x, r + h')} \frac{1}{V(y, h')} \leq \frac{C_5}{V(x, r)} \| f \|_1 \sup_{y \in B(x, r + h')} \frac{V(y, 2r + h')}{V(y, h')}
\end{equation}

for all $f \in L^2$ supported in $B(x, r)$ with $r \geq r_0$. The first line above follows from (4.10) and the second line follows from (2.4) and $r \geq r_0$. By (5.22) and (5.23), there exists $c_1 > 0$ such that

\begin{equation}
s_1(f) = \left( \frac{\| f \|_1^2 r^\delta}{\mathcal{E}(Pf, Pf) + r^{-2} \| Pf \|_2^2 V(x, r)} \right)^{1/(\delta + 2)} \geq c_1
\end{equation}

for all $x \in M$, for all $r \geq r_0$ and for all $f \in L^2(M)$ supported in $B(x, r)$. By plugging in $s = (r_0/c_1)s_1(f)$ in (5.20), there exists $C_N \geq C_3^{4/\delta}$ such that

\begin{equation}
\| Pf \|_2^{2 + (4/\delta)} \leq \frac{C_N r^2}{V(x, r)^{2/\delta}} \left( \mathcal{E}(Pf, Pf) + r^{-2} \| Pf \|_2^2 \right) \| f \|_1^{4/\delta}
\end{equation}
for all \( x \in M \), for all \( r \geq r_0 \) and for all \( f \in L^2(M) \) supported in \( B(x, r) \). By (4.5), we have
\[
\sqrt{\mathcal{E}(Pf, Pf)} = \left\| P(I - P)^{1/2}f \right\|_2 \leq \left\| (I - P)^{1/2}f \right\|_2 = \sqrt{\mathcal{E}(f, f)}
\]
for all \( f \in L^2(M) \). By (5.24),(5.25) and (4.5), we obtain the desired Nash inequality (5.14).

Before we proceed, we restate the above Nash inequality for functions defined on balls.

**Corollary 5.6.** Let \((M, d, \mu)\) be a quasi-b-geodesic metric measure space satisfying \((V,D)_{\text{loc}}, (V,D)_{\infty}\) and Poincaré inequality at scale \((P)_{\text{h}} \). Suppose that a Markov operator \( P \) has a kernel \( p \) that is \((h,h')\)-compatible with respect to \( \mu \). Let \( P_B \) and \( \mathcal{E}^B \) denote the corresponding Markov operator and Dirichlet form restricted to a ball \( B \subset M \). Then there exists \( \delta > 2, C_N > 0 \) such that
\[
\| P_B f \|_2^{2+(4/\delta)} \leq \frac{C_N r^2}{V(x,r)^{2/\delta}} \left( \mathcal{E}^B(f, f) + r^{-2} \| f \|_2^2 \right) \| f \|^{4/\delta}_1
\]
for all \( r > 0 \), for all \( x \in M \), and for all \( f \in L^2(M) \) with \( f \) supported in \( B(x,r) \).

**Proof.** We define \( \tilde{f} \in L^2(M) \) as in (4.29). Since \( P \tilde{f} = P_B f \) on \( B \), we have \( \| P_B f \|_2 \leq \| P \tilde{f} \|_2 \). Combining this observation along with \( \| f \|_p = \| \tilde{f} \|_p \), Lemma 4.22(a) and Proposition (5.5) yields (5.14).

**Remark 5.7.** It is easy to prove Nash inequality (5.27) using Sobolev inequality (5.2) just by an application of Hölder inequality
\[
\| P_B f \|_2 \leq \| P_B f \|_p^{\delta/(\delta+2)} \| P_B f \|_1^{2/(\delta+2)} \leq \| P_B f \|_p^{\delta/(\delta+2)} \| f \|_1^{2/(\delta+2)}
\]
along with the fact that \( P_B \) is a contraction on \( L^1(B) \). However proving (5.2) using (5.27) is harder. There is a direct and elementary approach using slicing of functions developed in [4]. Their approach was used by Delmotte in the setting of graphs [25, Theorem 4.4] to prove a Sobolev inequality. However those slicing techniques not so seem to apply directly for proving (5.2), since the (sub-Markov) operator \( P_B \) does not commute with the slicing maps \( f \mapsto (f - s)_+ \wedge t \). It is an interesting open problem to make this approach work for our Sobolev-type inequalities.

### 5.2. Ultracontractivity estimate on balls

In light of the above remark, we adapt a different approach based on Hardy-Littlewood-Sobolev theory for discrete time Markov semigroups as developed in [21, Theorems 5 and 6]. Our approach is to obtain an upper bound for \( \| P^k_B \|_{1 \to \infty} \) using (5.27) which in turn is used to prove the Sobolev inequality (5.2).

**Lemma 5.8.** Let \((M, d, \mu)\) be a quasi-b-geodesic metric measure space satisfying \((V,D)_{\text{loc}}, (V,D)_{\infty}\). Suppose that a Markov operator \( P \) has a kernel \( p \) that is \((h,h')\)-compatible with respect to \( \mu \). Let \( P_B \) and \( \mathcal{E}^B \) denote the corresponding Markov operator and Dirichlet form restricted to a ball \( B \subset M \). Further assume that the operators \( P_B \) satisfy the Nash inequality (5.27) with constant \( \delta > 2 \). There exists \( C_u > 0 \) such that
\[
\| P^k_B \|_{1 \to \infty} \leq \frac{C_u (1 + r^2)^{\delta/2} (1 + r^{-2})^{k-1}}{V(x,r)^{\delta/2} k^{\delta/2}}
\]
for all \( x \in M, \) for all \( r > 0 \) and for all \( k \in \mathbb{N}^* \) where \( B = B(x, r) \).

**Remark 5.9.** If two side Gaussian estimate \((GE)\) holds for \( p_k \) and if we choose \( r \approx \sqrt{k} \), then the upper bound (5.28) is sharp up to a constant factor.

**Proof of Lemma 5.8.** Let \( x \in M, \) \( r > 0 \) and \( B = B(x, r) \). Our first step is an upper bound for \( \|P_k^B\|_{1 \to 2^*} \). Let \( f \in L^1(B) \) be an arbitrary function with \( \|f\|_1 = 1 \). The constants in this proof do not depend on the choice of \( x \in M, \) \( k \in \mathbb{N}^*, \) \( r > 0 \) or \( f \in L^1(B) \).

Then by Hölder inequality,

\[
\|P_B f\|_2^2 \leq \|P_B f\|_1 \|P_B f\|_\infty \leq \|f\|_1 \|P_B f\|_\infty = \|P_B f\|_\infty.
\]

By (5.15) and (5.23), there exists \( C_1 > 0 \) such that

\[
(5.29) \quad \|P_B f\|_2^2 \leq \|P_B f\|_\infty \leq \frac{C_1 (1 + r^2)^{\delta/2}}{V(x, r)}.
\]

By (5.27), along with Lemma 4.22 and Lemma 4.20(b), there exists \( C_N > 0 \) such that

\[
(5.30) \quad \|P_B g\|_{2+(4/\delta)}^2 \leq \frac{C_N r^2}{V(x, r)^{2/\delta}} \left( \mathcal{E}_B^*(g, g) + r^{-2} \|g\|_2^2 \right) \|g\|_1^{4/\delta}
\]

for all \( r > 0, \) for all \( x \in M, \) and for all \( g \in L^2(B) \) where \( B = B(x, r) \). Define

\[
v_k := (1 + r^{-2})^{-(k-1)} \|P_B^k f\|_2^2
\]

for all \( k \in \mathbb{N}^* \). Substituting \( g = P_k f \) in (5.30) and using the fact that \( \|P_k^B f\|_1 \leq \|f\|_1 = 1 \) and \( \mathcal{E}_B^*(P_k^B f, P_k^B f) = \|P_k^B f\|_2^2 - \|P_k^B f\|_1^2 \), we obtain the following difference inequality for \( v_k \):

\[
(5.31) \quad v_{k+1}^{1+(2/\delta)} \leq \frac{C_N (1 + r^2)}{V(x, r)^{2/\delta}} (v_k - v_{k+1})
\]

for all \( k \in \mathbb{N}^* \). Next, we ‘solve’ the difference inequality given by (5.31). Define

\[
(5.32) \quad C_2 := \max \left( C_1, (\delta C_N)/2 \right)^{\delta/2} (1 + (\delta/2))^{(1+\delta/2)}
\]

We claim that

\[
(5.33) \quad v_k \leq C_2 \left( \frac{1 + r^2)^{\delta/2}}{V(x, r)} \right)^{k^{-\delta/2}}
\]

for all \( k \in \mathbb{N}^* \). We prove (5.33) by induction. The base case \( k = 1 \) follows from (5.29) and (5.32). For the inductive step, assume that (5.33) holds for \( k = 1, 2, \ldots, n \) for some \( n \in \mathbb{N}^* \). We will show that (5.33) holds for \( k = n + 1 \). Assume to the contrary that

\[
(5.34) \quad v_{n+1} > C_2 \left( \frac{1 + r^2)^{\delta/2}}{V(x, r)} \right)^{(n+1)^{-\delta/2}}
\]
By (5.31), (5.34) and the induction hypothesis, we obtain
\[
\psi_{n+1}^{1+(2/\delta)} \leq \frac{C_N C_2 (1 + r^2)^{1+(\delta/2)}}{V(x, r)^{1+(2/\delta)}} \left( n^{-\delta/2} - (n + 1)^{-\delta/2} \right)
\]
\[
< \frac{C_N C_2 (1 + r^2)^{1+(\delta/2)}}{V(x, r)^{1+(2/\delta)}} \frac{\delta}{2} n^{-(1+(\delta/2))}
\]
\[
\leq \frac{C_2 (1 + r^2)^{1+(\delta/2)}}{V(x, r)^{1+(2/\delta)}} \left( (\delta C_N)/2 \right)^{1+(\delta/2)} (n + 1)^{-(1+(\delta/2))}
\]
\[
\leq \left( \frac{C_2 (1 + r^2)^{\delta/2}}{V(x, r)} (n + 1)^{-\delta/2} \right)^{1+(2/\delta)}.
\]
(5.35)

The second line above follows from intermediate value theorem, the third line follows from \(n \geq 1\) and the last line follows from (5.34) and (5.35). Using (5.31), we obtain the estimate
\[
\|P_B^k\|_{1 \to 2} \leq \frac{C_2 (1 + r^2)^{\delta/2}}{V(x, r)} (1 + r^{-2})^{k-1} k^{\delta/2}
\]
for all \(x \in M\) and all \(r > 0\) where \(B = B(x, r)\). Since \(P_B\) is self-adjoint operator in \(L^2(B)\), by duality we have the bound
\[
\|P_B^k\|_{1 \to \infty} \leq \left\| P_B^{(k/2)} \right\|_{1 \to 2} \left\| P_B^{(k/2)} \right\|_{1 \to 2}.
\]
Using the above bound along with (5.36) yields (5.28) for \(k \geq 2\). The case \(k = 1\) follows from (5.29).

We are ready to prove the Sobolev inequality (5.2) using the ultracontractivity estimate (5.28) above.

For an operator \(T\), we define the operator \((I - T)^{1/2}\) as
\[
(I - T)^{1/2} = \sum_{k=0}^{\infty} a_k T^k
\]
where \(a_k\) is defined by the Taylor series \((1 - x)^a = \sum_{k=0}^{\infty} a_k x^k\) for \(x \in (-1, 1)\). By a classical estimate on coefficient of Taylor series, there exists \(C_a > 0\) such that
\[
\frac{C_a^{-1}}{(k + 1)^{1/2}} \leq a_k \leq \frac{C_a}{(k + 1)^{1/2}}
\]
for all \(k \in \mathbb{N}_{\geq 0}\).

## 5.3. Local Sobolev inequality

We use the ultracontractivity estimate (5.28) to obtain Sobolev inequality (5.2). The proof uses Riesz-Thorin and Marcinkiewicz interpolation theorems which we briefly review in Appendix A.

**Proposition 5.10.** Let \((M, d, \mu)\) be a quasi-\(b\)-geodesic metric measure space satisfying \((V D)_{loc} , (V D)_{\infty}\). Suppose that a Markov operator \(P\) has a kernel \(p\) that is \((h, h')\)-compatible with respect to \(\mu\). Let \(P_B\) and \(E^B\) denote the corresponding Markov operator and Dirichlet form restricted to a ball \(B \subset M\). Assume that there exists \(C_a > 0\) such that
\[
\|P_B^k\|_{1 \to \infty} \leq \frac{C_a (1 + r^2)^{\delta/2}}{V(x, r)} (1 + r^{-2})^{k-1} k^{\delta/2}
\]
(5.38)
for all $x \in M$, for all $r > 0$ and for all $k \in \mathbb{N}^*$ where $B = B(x, r)$. Then we have the Sobolev inequality (5.2).

**Proof.** As in the proof of Nash inequality (5.14), we start by considering the case $r \leq 1$. By (5.15), there exists $C_2 > 0$ such that

$$
\| P_B \|_{1 \to \infty} \leq \frac{C_1}{V(x, r)}
$$

(5.39)

for all balls $B = B(x, r)$ with $r \leq 1$. Since $P_B$ is a contraction on all $L^p(B)$, we have

$$
\| P_B \|_{2(\delta-1)/(\delta-2) \to 2(\delta-1)/(\delta-2)} \leq 1.
$$

(5.40)

Applying Riesz-Thorin interpolation between (5.39) and (5.40) yields

$$
\| P_B \|_{2 \to 2\delta/(\delta-2)} \leq \left( \frac{C_1}{V(x, r)} \right)^{1/\delta}
$$

for all balls $B = B(x, r)$ with $r \leq 1$. By choosing $C_S \geq C_1^{2/\delta}$, we have (5.2) for all balls $B(x, r)$ with $r \leq 1$.

Next we consider the case $r > 1$. Since

$$
E^B(f, f) + r^{-2} \|f\|^2_2 = \left\| (1 + r^{-2}) I - P_B \right\|^{1/2}_2 f \right\|^2,
$$

it suffices to show that there exists $C_2 > 0$ such that

$$
\left\| P_B \left( I - (1 + r^{-2})^{-1} P_B \right)^{-1/2} \right\|_{2 \to 2\delta/(\delta-2)} \leq C_2 \frac{1 + r^2}{V(x, r)^{1/\delta}}
$$

(5.41)

for all balls $B = B(x, r)$ with $r > 1$. To see this, note that $C_S = \max(C_1^{2/\delta}, 2C_2^2)$ satisfies (5.2). Define

$$
E(B) := \frac{(1 + r^2)}{\mu(B)}, \quad T_B := P_B \left( I - (1 + r^{-2})^{-1} P_B \right)^{-1/2}.
$$

(5.42)

Let $p \in [1, \delta)$ and $q \in [\delta/(\delta-1), \infty)$ satisfy

$$
p^{-1} = q^{-1} + \delta^{-1}.
$$

(5.43)

For all $p \in [1, \delta)$ and $q \in [\delta/(\delta-1), \infty)$ satisfying (5.43), we show that the operator $T_B$ is of weak-type $(p, q)$. An application of Marcinkiewicz interpolation then yields (5.2). Recall that $T_B = \sum_{k=1}^{\infty} a_{k-1}(1 + r^{-2})^{-(k-1)} P_B^k$. For $N \in \mathbb{N}^*$, we define operators

$$
R_{B,N} := \sum_{k=1}^{N} a_{k-1}(1 + r^{-2})^{-(k-1)} P_B^k, \quad S_{B,N} := T_B - R_{B,N}.
$$

By (5.38) and Riesz-Thorin interpolation, we obtain

$$
\left\| P_B^k \right\|_{p \to \infty} \leq C_u^{1/p} E(B)^{\delta/(2p)} \frac{1 + r^{-2}^{(k-1)/p}}{k^{1/p}}
$$

(5.44)
for all balls $B$, for all $k \in \mathbb{N}^*$ and for all $1 \leq p < \infty$. For each $p \in [1, \delta)$, there exists $C_3 > 0$ such that
\[
\|S_{B,N}\|_{p \to \infty} \leq \sum_{k=N+1}^{\infty} a_{k-1}(1 + r^{-2})^{-(k-1)} \|P_B^k\|_{p \to \infty} \\
\leq C_3^{1/p} E(B)^{\delta/(2p)} C_a \sum_{k=N+1}^{\infty} k^{-1/2} k^{-\delta/(2p)} \\
(5.45)
\]
for all balls $B$, where $q$ is given by (5.43). In (5.45) $C_3$ depends only on $p, q, \delta$ but not on $B = B(x, r)$. In the second line above we use (5.44) and (5.37) and we used (5.43) and $p \in [1, \delta)$ in the last line. By the same argument as above and increasing $C_3 = C_3(p)$ if necessary, we may assume that
\[
\|T_B\|_{p \to \infty} \leq C_3 E(B)^{\delta/(2p)} \\
(5.46)
\]
for all balls $B$.

Let $g \in L^p(B)$ satisfy $\|g\|_p = 1$. For $\lambda > 0$, let $N_0 = N_0(\lambda, B)$ denote the smallest positive integer such that $C_3 E(B)^{\delta/(2p)} N_0^{-\delta/(2q)} \leq \lambda/2$. By union bound, for each $p \in [1, \delta)$ and $q$ given by (5.43), there exists $C_4, C_5 > 0$ such that
\[
\mu_B \{ x \in B : |T_B g(x) | > \lambda \} \leq \mu_B \{ x \in B : |R_{B,N_0} g(x) | > \lambda/2 \} \\
\leq \mu_B \{ x \in B : |S_{B,N_0} g(x) | > \lambda/2 \} \\
\leq \mu_B \{ x \in B : |R_{B,N_0} g(x) | > \lambda/2 \} \\
\leq (2/\lambda)^p \|R_{B,N_0} g\|_p^p \\
\leq C_4^p (2/\lambda)^p \left( \sum_{k=1}^{N_0} k^{-1/2} \right)^p \\
\leq C_4 (2C_a)^p \lambda^{-p} N_0^{p/2} \lambda^{-q} \\
(5.47)
\]
for all balls $B = B(x, r)$. In the second step above we used the definition of $N_0$. The third step follows from Chebyshev inequality, the fourth step follows from (5.37) and $\|P_B^k\|_{p \to p} \leq 1$. The last step (5.47) follows from (5.37), (5.43), (5.46) and the definition of $N_0$. By Marcinkiewicz interpolation theorem and the estimates given by (5.47), there exists $C_6 > 0$ such that
\[
\|T_B\|_{2 \to 2/(\delta-2)} \leq C_6 \sqrt{E(B)}
\]
for all balls $B = B(x, r)$. This is precisely (5.41) which we intended to prove. \qed

We record two important consequences of Proposition 5.10 first of which is the proof of Theorem 5.1

**Proof of Theorem 5.1.** Theorem 5.1 follows from Corollary 5.6, Lemma 5.8 and Proposition 5.10. \qed

The next corollary shows that Sobolev inequality is necessarily true under doubling hypothesis and Gaussian upper bounds $(GUE)$.

**Corollary 5.11.** Let $(M, d, \mu)$ be a quasi-$b$-geodesic metric measure space satisfying $(V D)_{loc}$, $(V D)_\infty$. Suppose that a Markov operator $P$ has a kernel $p$ that is $(h, h')$ compatible with respect to $\mu$. Further assume that iterated kernel $p_k$ that
null
Combining (5.54), Lemma 2.10 and (5.51), we obtain
\[ V(x, r + h') \leq \sum_{y \in Y \cap B(x, r-h')} V(y, (C_1 + 1)h') \]
\[ \leq C_{h'/2, (C_1+1)h'} \sum_{y \in Y \cap B(x, r-h')} V(y, h'/2) \leq C_{h'/2, (C_1+1)h'} V(x, r). \]
\[ \square \]

**Proof of Proposition 5.12.** We adapt the argument of [19, Proposition 2.1]. However unlike in [19, Proposition 2.1], we do not consider volumes of arbitrarily small balls.

Let \( x \in M \) and \( r \geq 3h' \) be arbitrary. For \( s > 0 \), define the ‘tent function’
\[ f_s(y) = \max(s - d(x, y), 0). \]

By \((h, h')\) compatibility of \( P \), we have \( P_{B(x, r)} f_{3h'} \geq h' \mathbf{1}_{B(x, h')} \). Therefore by applying (5.2), we have
\[ (h')^2 V(x, h')^{(\delta-2)/\delta} \leq \frac{C_{\gamma r^2}}{V(x, r)^{2/\delta}} \left( (h')^2 V(x, 4h') + r^{-2} (3h')^2 V(x, 3h') \right) \]
for all \( r \geq 3h' \) and for all \( x \in M \). Combined with Lemma 2.10, there exists \( C_1 > 0 \) such that
\[ (5.55) \quad \frac{V(x, r)}{V(x, h')} \leq C_1 r^\delta \]
for all \( r \geq 3h' \) and for all \( x \in M \).

Let \( 3h' \leq s \leq r \). Then by \((h, h')\) compatibility of \( P \), we have \( P_{B(x, r)} f_s \geq (s/6) \mathbf{1}_{B(x, s/2)} \). Hence by Sobolev inequality (5.2), (4.10) and Lemma 4.22(a), we obtain
\[ (s/6)^2 V(x, s/2)^{(\delta-2)/\delta} \leq \frac{C_{\gamma r^2}}{V(x, r)^{2/\delta}} \left( (h')^2 V(x, s + h) + r^{-2} s^2 V(x, s) \right) \]

Combined with Lemma 5.13, there exists \( C_2 > 0 \) such that
\[ (5.56) \quad V(x, s) \geq \left( \frac{s^2 V(x, r)}{C_{2r^\delta}} \right)^{2/\delta} \left( \frac{V(x, s/2)^{(\delta-2)/\delta}}{C_{2r^\delta}} \right) \]
for all \( x \in M \) and for all \( 3h' \leq s \leq r \). We replace \( s \) by \( s/2 \) in (5.56) and iterate to obtain
\[ (5.57) \quad V(x, s) \geq 4^{-\sum_{i=0}^{i-1} j(\delta-2)_i / \delta} \left( \frac{s^2 V(x, r)}{C_{2r^\delta}} \right)^{(2/\delta) \sum_{j=0}^{i-1} (\delta-2)_j / \delta} \left( \frac{V(x, s/2)^{(\delta-2)_i / \delta}}{C_{2r^\delta}} \right) \]
for all \( 3h' \leq s/2^{i-1} \leq s \leq r \). In particular if we choose \( i = \lfloor \log_2(s/3h') \rfloor \), we have \((3h')/2 \leq s/2^i \leq 3h' \). Hence by (5.57) and (5.55), we have
\[ (5.58) \quad V(x, s) \geq 4^{-\sum_{i=0}^{i-1} j(\delta-2)_i / \delta} \left( \frac{s^2 V(x, r)}{C_{2r^\delta}} \right)^{(2/\delta) \sum_{j=0}^{i-1} (\delta-2)_j / \delta} \left( \frac{V(x, r)}{C_{1r^\delta}} \right)^{(\delta-2)_i / \delta} \]

for all $x \in M$ and for all $3h' \leq s \leq r$, where $i = \lceil \log_2(s/3h') \rceil$. By (5.58), there exists $C_3 > 0$ such that
\[
\frac{V(x,r)}{V(x,s)} \leq C_3 \left( \frac{r}{s} \right)^{\delta(i-1)/\delta - 1}
\]
for all $x \in M$ and for all $3h' \leq s \leq r$, where $i = \lceil \log_2(s/3h') \rceil$. Since the map $s \mapsto \exp \left( \frac{\delta((\delta - 2)/\delta)^{\lceil \log_2(s/3h') \rceil} \ln s}{\delta} \right)$ is bounded in $[3h', \infty)$, by (5.59) there exists $C_4 > 0$ such that
\[
\frac{V(x,r)}{V(x,s)} \leq C_4 \left( \frac{r}{s} \right)^{\delta}
\]
for all $x \in M$ and for all $3h' \leq s \leq r$. The above equation clearly implies $(VD)_\infty$. \qed
Elliptic Harnack inequality

In this chapter, we prove elliptic Harnack inequality for non-negative harmonic functions. As before, we consider a metric measure space \((M,d,\mu)\) and a Markov operator \(P\) that is \((h,h')-\text{compatible with } (M,d,\mu)\). Recall that the operator \(\Delta := I - P\) is the Laplacian corresponding to \(P\).

### 6.1. Harmonic functions

**Definition 6.1.** Let \(P\) be a Markov operator on \((M,d,\mu)\). A function \(f : U \to \mathbb{R}\) is \(P\)-harmonic in \(B(x,r)\) if

\[
\Delta f(y) = f(y) - Pf(y) = 0
\]

for all \(y \in B(x,r)\).

Similarly, we say \(f : M \to \mathbb{R}\) is \(P\)-subharmonic (resp. \(P\)-superharmonic) in \(B(x,r)\) if

\[
\Delta f(y) \leq 0 \text{ (resp. } \geq 0)\]

for all \(y \in B(x,r)\).

We say a function \(f : M \to \mathbb{R}\) is \(P\)-harmonic (resp. subharmonic, superharmonic) if \(\Delta f \equiv 0\) (resp. \(\Delta f \leq 0\), \(\Delta f \geq 0\)).

**Remark 6.2.**

(a) Consider a Markov operator \(P\) that is \((h,h')-\text{compatible with } (M,d,\mu)\). By (4.10), \(Pf(y)\) depends only on \(f\) in \(B(y,h')\). Therefore the property that \(f : M \to \mathbb{R}\) is \(P\)-harmonic in \(B(x,r)\) depends only on the values of \(f\) in \(B(x,r + h')\). Hence in this case it suffices to have \(B(x,r + h') \subseteq \text{Domain}(f)\).

(b) We use the term harmonic instead of \(P\)-harmonic if the Markov operator \(P\) is clear from the context. Same holds for superharmonic or subharmonic functions.

The main result of the chapter is the following elliptic Harnack inequality.

**Theorem 6.3 (Elliptic Harnack inequality).** Let \((M,d,\mu)\) be a quasi-b-geodesic metric measure space satisfying \((VD)_{\text{loc}}, (VD)_{\infty}\) and Poincaré inequality at scale \(h(P)\). Suppose that a Markov operator \(P\) has a kernel \(p\) that is \((h,h')-\text{compatible with respect to } \mu\) for some \(h > b\). Then there exists \(c > 0, r_0 > 0, C_E > 0\) such that for all \(x \in M\), for all \(r \geq r_0\) and for all non-negative functions \(u : B(x,r) \to \mathbb{R}_{\geq 0}\) that are \(P\)-harmonic in \(B(x,r)\) the following Harnack inequality holds:

\[
\sup_{x \in B(x,cr)} u \leq C_E \inf_{x \in B(x,cr)} u.
\]

In (6.1), the sup and inf must be understood as essential sup and essential inf with respect to \(\mu\).
We follow Moser’s iteration method [61] to prove the elliptic Harnack inequality. Our approach is an adaptation of Delmotte’s approach except that we have to rely on a weaker version of Sobolev inequality and a modified version of John-Nirenberg inequality. Moser’s iteration relies on estimating the quantities

\[
\phi(u, p, B') := \left( \frac{1}{\mu(B')} \int_{B'} |u|^p \, d\mu \right)^{1/p}
\]

for different balls \( B' \subset B \) and for different values of \( p \in \mathbb{R} \setminus \{0\} \). By Jensen’s inequality, \( p \mapsto \phi(u, p, B') \) is non-decreasing function. The function \( \phi \) satisfies \( \lim_{p \to -\infty} \phi(u, p, cB) = \inf_{x \in B} u \) and \( \lim_{p \to +\infty} \phi(u, p, cB) = \sup_{x \in B} u \) [49, Lemma 14.1.4]. To obtain (6.1), Moser’s iterative method relies on establishing bounds of the form \( \phi(u, p_1, B') \leq C_{p_1, p_2} \phi(u, p_2, B'') \) for different values of \( p_1, p_2 \in \mathbb{R} \setminus \{0\} \) satisfying \( p_1 < p_2 \). Sobolev inequality and Poincaré inequality are crucial ingredients to run this iterative procedure. For a function \( f \) that is defined on a ball \( B \), we denote the mean integral by

\[
f_B = \int_B f \, d\mu = \frac{1}{\mu(B)} \int_B f \, d\mu.
\]

We start with a local version of the above elliptic Harnack inequality.

**Lemma 6.4.** Let \((M, d, \mu)\) be a quasi-b-geodesic space satisfying \((VD)_{loc}\) and let \(P\) be a weakly \((h, h')\)-compatible Markov operator with \((M, d, \mu)\) for some \(h > h'\). There exists \(C > 0\) and \(r_0 > 0\) such that

\[
u(y) \leq Cu(z)
\]

for all \( x \in M \), for all \( r \geq r_0 \), for all \( y, z \in B(x, r/2) \) satisfying \( d(y, z) \leq h'\) and for all non-negative functions \( u : B(x, r + h') \to \mathbb{R} \) harmonic in \( B(x, r) \).

**Proof.** There exists \(c_1 > 0\) and \( l \in \mathbb{N}^+\) such that

\[
\rho_l(z, w) = \rho_l(w, z) \geq \frac{c_1 B(z, 2h')(w)}{V(w, h')}
\]

for all \( y, w \in M \). The proof of (6.4) is analogous to that of (4.13). Therefore by (6.4), \((VD)_{loc}\) weak \((h, h')\)-compatibility of \( p_l\) and triangle inequality, there exists \(c_2 > 0\) such that

\[
p_l(z, w) \geq \frac{c_1 B(z, 2h')(w)}{V(w, h')} \geq \frac{c_1 B(y, h')(w)}{V(w, h')} \geq c_2 p_1(w, y) = c_2 p_1(y, w)
\]

for all \( y, z, w \in M\) satisfying \( d(y, z) \leq h'\).

Choose \(r_0\) large enough so that \( r/2 + lh' \leq r + h'\) for all \( r \geq r_0\). Note that for every harmonic function \( u : B(x, r + h') \to \mathbb{R} \) in \( B(x, r) \) with \( r \geq r_0\) and for all \( z \in B(x, r/2)\), we have

\[
u(z) = p' u(z) = \int_{B(z, lh')} p_l(z, w) u(w) \, d\mu(dw)
\]

By (6.6) and (6.5), we obtain

\[
u(z) = \int_{B(z, lh')} p_l(z, w) u(w) \, d\mu(dw) \geq c_2 \int_{B(y, h')} p_l(y, w) u(w) \, d\mu(dw) = c_2 v(y)
\]

for all non-negative harmonic functions \( u \) in \( B(x, r) \) for all \( x \in M \), for all \( z, y \in B(x, r/2) \) with \( r \geq r_0\). The choice \( C = c_2^{-1}\) satisfies (6.3). \(\square\)
6.2. John-Nirenberg inequality

Moser [61], used John-Nirenberg inequality to obtain an estimate of the form
\[ \phi(u, -q, B') \leq C' \phi(u, q, B') \]
for some \( q, C' > 0 \). An alternative approach is to use an abstract lemma of Bombieri and Guisti was later proposed by Moser [72, Section 2.2.3].

John-Nirenberg inequality is an estimate on distribution of functions of bounded mean oscillation which were introduced in [48]. A locally integrable function \( f : B \to \mathbb{R} \) define is of bounded mean oscillation (BMO) if
\[
\| f \|_{BMO(B)} := \sup_{B' \subseteq B} \frac{1}{\mu(B')} \int_{B'} |f - f_{B'}| \, d\mu < \infty.
\]

John-Nirenberg inequality states that functions of bounded mean oscillation have an exponentially decaying distribution function.

In [1, Theorem 5.2] a version of John-Nirenberg inequality is shown for spaces satisfying the doubling hypothesis \((VD)\). However for us, the metric measure space \((M, d, \mu)\) only satisfies \((VD)_{\text{loc}}\) and \((VD)_{\infty}\). Since we do not have doubling hypothesis on arbitrarily small balls, we introduce a modified version of BMO seminorm (BMO seminorm at scale \( h \)) defined as
\[
(6.8) \quad \| f \|_{BMO(B(x_0, r_0)), h} = \sup_{B(y, r) \subseteq B(x_0, r_0), r \geq h} \frac{1}{V(y, r)} \int_{B(y, r)} |f - f_{B(y, r)}| \, d\mu.
\]

Our proof is motivated by the presentation in [1]. We start by recalling the Vitali covering lemma.

**Lemma 6.5 (Vitali covering lemma).** Let \( F \) be a family of balls with positive and uniformly bounded radii in a metric space \((M, d)\). Then there exists a disjoint subfamily \( G \subseteq F \) such that
\[
\bigcup_{B \in F} B \subseteq \bigcup_{B \in G} 5B.
\]
In fact, every ball \( B \in F \) meets a ball \( B' \in G \) with radius at least half that of \( B \) and therefore satisfies \( B \subseteq 5B' \).

The proof of Vitali covering lemma follows from an application of Zorn’s lemma. We refer the reader to [46, Theorem 1.2] for a proof of Lemma 6.5. A crucial ingredient in the proof of John-Nirenberg inequality is the following version of Calderón-Zygmund decomposition lemma. Since we replaced \((VD)\) by weaker assumptions \((VD)_{\text{loc}}\) and \((VD)_{\infty}\), we need some other method to control the behavior of a BMO function at small length scales. This is why we assume a local Harnack inequality (by Lemma 6.4 the local Harnack inequality holds for harmonic functions).

**Lemma 6.6 (Calderón-Zygmund decomposition lemma).** Suppose \((M, d, \mu)\) be a metric measure space satisfying \((VD)_{\text{loc}}\) and \((VD)_{\infty}\). Let \( f \) be a non-negative locally integrable function on \( B(x_0, 11r_0) \) for some \( r_0 \geq r_1 \geq h > 0 \). Further we assume that there exists \( C_1 \geq 1 \) such that \( f \) satisfies the local Harnack inequality
\[
(6.9) \quad f(y) \leq C_1 f(z)
\]
for all \( y, z \in B(x_0, r_0 + h) \) satisfying \( d(y, z) \leq h \). Further, assume that
\[
(6.10) \quad \lambda_0 \geq \frac{1}{V(x_0, r)} \int_{B(x_0, 11r_0)} f \, d\mu.
\]
Then there exists countable (possibly finite) family of disjoint balls $\mathcal{F} = \{B_i\}$ of disjoint balls centered in $B(x_0, r)$ and satisfying $5B_i \subseteq B(x_0, 11r_0)$ for all $B_i \in \mathcal{F}_0$ so that

(i) $f(x) \leq C_1 \lambda_0$ for all $x \in B(x_0, r) \setminus (\bigcup_{B_i \in \mathcal{F}_1} 5B_i)$.
(ii) $\lambda_0 < f_{B_i} f \, d\mu \leq C_2 \lambda_0$ for all $B_i \in \mathcal{F}_0$.
(iii) $C^{-1}_2 \lambda_0 < f_{5B_i} f \, d\mu \leq \lambda_0$ for all $B_i \in \mathcal{F}_0$.

The family of balls $\mathcal{F}_0$ satisfying the above conditions are called Calderón-Zygmund balls at level $\lambda_0$. Moreover if $\lambda_0 \leq \lambda_1 \leq \cdots \leq \lambda_N$, then the family Calderón-Zygmund balls $\mathcal{F}_n$ corresponding to different levels $\lambda_n$ may be chosen in such a way that every $B_i(\lambda_{n+1}) \in \mathcal{F}_n+1$ is contained in some $5B_j(\lambda_n)$ where $B_j(\lambda_n) \in \mathcal{F}_n$.

**Proof.** We denote $B(x_0, r_0)$ as $B_0$. Define a maximal function

$$M_{B_0} f(x) = M_{B(x_0, r_0)} f(x) = \sup_{B(y, r) \subseteq B(x_0, r_0 + h), y \in B(x_0, r_0), r \geq h, B(y, r) \ni x} \int_{B(y, r)} f \, d\mu$$

for all $x \in B(x_0, r)$. We define

$$E_x = \{x \in B(x_0, r_0) : M_{B(x_0, r_0)} f(x) > \lambda\}.$$

First consider $\lambda_N$. By definition for every $x \in E_{\lambda_N}$, there exists a ball $B_x = B(y_x, r_x)$ satisfying $y_x \in B_0$, $x \in B_x$, $B_x \subseteq B(x_0, r_0 + h)$, $r_x \geq h$ and

$$\lambda_0 \leq \lambda_1 \leq \cdots \leq \lambda_N < \int_{B_x} f \, d\mu.$$  

Let $k = k_x \in \mathbb{N}^*$ be such that $5^k - 1 x \leq 2r_0 \leq 5^k x$. Then $B_0 \subseteq 5^kB_x \subseteq 11B_0$. Combining this with (6.10), we have

$$\int_{5^kB_x} f \, d\mu \leq \frac{1}{\mu(B_0)} \int_{11B_0} f \, d\mu \leq \lambda_0 \leq \lambda_N.$$ 

However since $\int_{B_x} f \, d\mu > \lambda_N$, there exist smallest $n_x \geq 1$ such that

$$\int_{5^n B_x} f \, d\mu \leq \lambda_N$$

and

$$\int_{5^n B_x} f \, d\mu > \lambda_N$$

for all $j = 0, 1, \ldots, n_x - 1$. The balls $5^{n_x - 1} B_x$ forms a covering of $E_{\lambda_N}$. Therefore by Vitali covering lemma (Lemma 6.5), we pick a family $\mathcal{F}_N$ of pairwise disjoint balls $B_i = 5^{n_x - 1} B_x$ satisfying $E_{\lambda_N} \subseteq \bigcup_{B_i \in \mathcal{F}_N} 5B_i$. We now check the construction above satisfies the desired properties. By (6.12), (6.13) and (2.4), there exists $C_h > 0, \delta > 0$ such that

$$\lambda_N < \int_{5^n B_x} f \, d\mu \leq C_h 5^{\delta} \int_{5^n B_x} f \, d\mu \leq C_h 5^{\delta} \lambda_N.$$ 

Choosing $C_2 = 5^{\delta} C_h$, we obtain properties (ii) and (iii) of Calderón-Zygmund decomposition.
It remains to verify (i). If \( x \in B_0 \setminus (\bigcup_{B_i \in \mathcal{F}} 5B_i) \subseteq B_0 \setminus E_{\lambda_N} \), we have \( M_{B_0} f(x) \leq \lambda_N \). Therefore by (6.9), we have
\[
\lambda_N \geq M_{B_0} f(x) \geq \int_{B(x,h)} f \, d\mu \geq C^{-1}_1 f(x).
\]
This gives property (i). We have now constructed the desired decomposition at level \( \lambda_N \). Next we consider \( \lambda_{N-1} \).

Since \( E_{\lambda_N} \subseteq E_{\lambda_{N-1}} \), for every \( x \in E_{\lambda_N} \), we may start with exactly the same ball satisfying (6.11) as before. For every \( x \in E_{\lambda_{N-1}} \setminus E_{\lambda_N} \), we choose a ball \( B_x = B(y_x, r_x) \) satisfying \( B_x \ni x, y_x \in B_0, r_x \geq h, B_x \subset B(x_0, r_0 + h) \) and
\[
\lambda_0 \leq \ldots \leq \lambda_{N-1} < \int_{B_x} f \, d\mu.
\]
As before for each ball \( B_x \), we choose the smallest integer \( m_x \geq 1 \) such that
\[
\int_{5^{m_x} B_x} f \, d\mu \leq \lambda_{N-1}
\]
and
\[
\int_{5^{j} B_x} f \, d\mu > \lambda_{N-1}
\]
for \( j = 0, 1, \ldots, m_x - 1 \). Note that if \( x \in E_{\lambda_N} \), then \( n_x \leq m_x \). As before, we apply Vitali’s covering lemma to the balls \( \left\{ 5^{m_x - 1} B_x : x \in E_{\lambda_{N-1}} \right\} \) to obtain a pairwise disjoint family of balls \( \mathcal{F}_{N-1} \) satisfying (i)-(iii) with \( \lambda_0 \) replaced by \( \lambda_{N-1} \).

Let \( B_i(\lambda_N) \in \mathcal{F}_N \). Then \( B_i(\lambda_N) = 5^{m_x - 1} B_x \) for some \( x \in E_{\lambda_N} \). Since \( n_x \leq m_x \), we have \( B_i(\lambda_N) \subset 5^{m_x - 1} B_x \). By Vitali’s covering lemma, there exists \( B_j(\lambda_{N-1}) \in \mathcal{F}_{N-1} \) such that \( B_i(\lambda_N) \subset 5^{m_x - 1} B_x \subseteq 5B_j(\lambda_{N-1}) \). We continue this procedure to get decomposition at all levels \( \lambda_0 \leq \ldots \leq \lambda_N \).

**Remark 6.7.** In the above proof, we use (6.9) to obtain property (i) of the Calderón-Zygmund decomposition. Typically property (i) is proved using Lebesgue differentiation theorem. However the proof of Lebesgue differentiation theorem requires (VD). (See [1] and [46, Theorem 1.8])

Next, we prove the John-Nirenberg inequality for spaces satisfying (VD)$_{\text{loc}}$ and (VD)$_{\infty}$.

**Proposition 6.8 (John-Nirenberg inequality).** Let \( (M, d, \mu) \) be a metric measure space satisfying (VD)$_{\text{loc}}$ and (VD)$_{\infty}$. Let \( f \) be a non-negative locally integrable function on \( B(x_0, 11r_0) \) for some \( r_0 \geq h > 0 \). Further we assume that there exists \( C_1 \geq 1 \) such that \( f \) satisfies the local Harnack inequality
\[
f(y) \leq C_1 f(z)
\]
for all \( y, z \in B(x_0, r_0 + h) \) satisfying \( d(y, z) \leq h \). Then there exists \( C_2 > 0 \) such that
\[
\mu \left\{ x \in B_0 : |f - f_{B_0}| > \lambda \right\} \leq C_2 \mu(B_0) \exp(-\lambda/(C_2 \|f\|_{\text{BMO}(11B_0,h)}))
\]
for all \( \lambda > 0 \). The constant \( C_2 \) depends only on \( C_1, h \) and constants associated with doubling hypotheses (VD)$_{\text{loc}}$ and (VD)$_{\infty}$.
PROOF. Let $B_0 = B(x_0, r_0)$. Without loss of generality, we assume $f_{B_0} = 0$ and $\|f\|_{BMO(11B_0), h} = 1$. It suffices to consider $f$ such that $f_{B_0} = 0$ and $\|f\|_{BMO(11B_0), h} = 1$ as we may replace the function $f$ by $(f - f_{B_0})/\|f\|_{BMO(11B_0), h}$.

By (2.4), there exists $C_3 > 0$ such that

$$
\frac{1}{\mu(B_0)} \int_{11B_0} |f - f_{B_0}| \, d\mu \leq C_3 \int_{11B_0} |f - f_{11B_0}| \, d\mu + C_3 |f_{B_0} - f_{11B_0}|
$$

$$
\leq C_4 \|f\|_{BMO(11B_0), h'} + C_3 \int_{B_0} |f - f_{11B_0}| \, d\mu
$$

$$
\leq 2C_2^2 \|f\|_{BMO(11B_0), h} = 2C_2^2.
$$

If $B_j$ is the Calderón-Zygmund balls at level $C_1^{-1}\lambda$ where $\lambda \geq 2C_1C_3^2$, then by Lemma 6.6

1. $|f(x)| \leq \lambda$ for all $x \in B_0 \setminus \bigcup J_2B_j$.
2. $C_1^{-1}\lambda < f_{B_j} \, |f| \, d\mu \leq C_3C_1^{-1}\lambda$ for all $j$.
3. $C_1^{-1}C_3^{-1}\lambda < f_{5B_j} \, |f| \, d\mu \leq C_1^{-1}\lambda$ for all $j$.

By (i) and (2.4), we have

$$
\mu(\{x \in B_0 : |f(x)| > \lambda\}) \leq \sum_j \mu(5B_j) \leq C_3 \sum_j \mu(B_j)
$$

In order to estimate $\sum_j \mu(B_j)$, we consider Calderón-Zygmund decomposition at levels $C_1^{-1}\lambda > C_1^{-1}\gamma \geq 2C_2^2$ as in Lemma 6.6. We partition the family $\{B_j(C_1^{-1}\lambda)\}_j$ as follows: First we collect those which are contained in $5B_2(C_1^{-1}\gamma)$. From the remaining balls we collect those balls which are contained in $5B_2(C_1^{-1}\gamma)$ and so on. More precisely, we partition the Calderón-Zygmund balls at level $C_1^{-1}\lambda$ as

$$
\{B_j(C_1^{-1}\lambda)\} = \bigcup_k \{B_j(C_1^{-1}\lambda)\}_j \in J_k,
$$

where $J_k$’s are defined as

$$
J_1 = \{j : B_j(C_1^{-1}\lambda) \subseteq 5B_2(C_1^{-1}\gamma)\}
$$

$$
J_2 = \{j : B_j(C_1^{-1}\lambda) \subseteq 5B_2(C_1^{-1}\gamma), j \in J_1\}
$$

$$
J_3 = \{j : B_j(C_1^{-1}\lambda) \subseteq 5B_3(C_1^{-1}\gamma), j \notin J_1 \cup J_2\}
$$

and so on. By (ii), we have

$$
\lambda \sum_j \mu(B_j(C_1^{-1}\lambda)) \leq C_1 \sum_j \int_{B_j(C_1^{-1}\lambda)} |f| \, d\mu
$$

$$
\leq C_1 \sum_k \sum_{j \in J_k} \int_{B_j(C_1^{-1}\lambda)} |f| \, d\mu.
$$
In addition for each $k$, we have
\[
\sum_{j \in J_k} \int_{B_j(C_1^{-1}\lambda)} |f| \, d\mu \leq \sum_{j \in J_k} \int_{B_j(C_1^{-1}\lambda)} \left| \left[ f + C_1^{-1}\gamma - f_{5B_k(C_1^{-1}\gamma)} \right] \right| \, d\mu
\]
\[
\leq \sum_{j \in J_k} \int_{B_j(C_1^{-1}\lambda)} \left| f - f_{5B_k(C_1^{-1}\gamma)} \right| \, d\mu + C_1^{-1}\gamma \sum_{j \in J_k} \mu(B_j(C_1^{-1}\lambda))
\]
\[
\leq \int_{5B_k(C_1^{-1}\lambda)} \left| f - f_{5B_k(C_1^{-1}\gamma)} \right| \, d\mu + C_1^{-1}\gamma \sum_{j \in J_k} \mu(B_j(C_1^{-1}\lambda))
\]
\[
\leq \mu(5B_k(C_1^{-1}\lambda)) + C_1^{-1}\gamma \sum_{j \in J_k} \mu(B_j(C_1^{-1}\lambda))
\]
\[
\leq C_3 \mu(B_k(C_1^{-1}\lambda)) + C_1^{-1}\gamma \sum_{j \in J_k} \mu(B_j(C_1^{-1}\lambda)).
\]

The fourth line above follows from $\|f\|_{BMO(11B_0), h} = 1$. We sum over $k$ and use (6.20)
\[
\lambda \sum_j \mu(B_j(C_1^{-1}\lambda)) \leq C_1 C_3 \sum_k \mu(B_k(C_1^{-1}\gamma)) + \gamma \sum_j \mu(B_j(C_1^{-1}\lambda))
\]
for all $\lambda \geq \gamma \geq 2C_1 C_3^2$. This implies
\[
(\lambda - \gamma) \sum_j \mu(B_j(C_1^{-1}\lambda)) \leq C_1 C_3 \sum_k \mu(B_k(C_1^{-1}\gamma))
\]
for all $\lambda \geq \gamma \geq 2C_1 C_3^2$.

In particular if $\lambda \geq a := 2C_1 C_3^2$, we have
\[
(6.21) \quad \sum_j \mu(B_j(C_1^{-1}(\lambda + a))) \leq \frac{1}{2} \sum_k \mu(B_k(C_1^{-1}\lambda)).
\]

Let $\lambda \geq a$ and let $N = \lfloor \lambda/a \rfloor$. Then we apply the Calderón-Zygmund decomposition at levels $C_1^{-1}a < 2C_1^{-1}a < \ldots < C_1^{-1}Na$. By (6.19) and repeated application of (6.21), we obtain
\[
\mu \left( \{ x \in B_0 : |f(x)| > \lambda \} \right) \leq \mu \left( \{ x \in B_0 : |f(x)| > Na \} \right)
\]
\[
\leq C_3 \sum_j \mu(B_j(C_1^{-1}Na)) \leq C_3 2^{-N+1} \sum_j \mu(B_j(C_1^{-1}a))
\]
\[
\leq 2C_3 2^{-N} \mu(11B_0) \leq 4C_3^2 2^{-\lambda/a} \mu(B_0)
\]
\[
(6.22) \quad \leq 4C_3^2 \exp(-\lambda \ln 2)/a) \mu(B_0)
\]

The case $\lambda < a$ follows easily since
\[
\mu \left( \{ x \in B_0 : |f(x)| > \lambda \} \right) \leq \mu(B_0) \leq 4C_3^2 \exp(-\lambda \ln 2)/a) \mu(B_0).
\]

The choice $C_2 = \max(4C_3^2, a/\ln 2)$ satisfies (6.18).

We have the following corollary.

**Corollary 6.9.** Let $(M, d, \mu)$ be a metric measure space satisfying $(VD)_{\text{loc}}$ and $(VD)_{\infty}$. Let $f$ be a non-negative locally integrable function on $B(x_0, 11r_0)$ for some $r_0 \geq h' > 0$. Further we assume that there exists $C_1 \geq 1$ such that $f$ satisfies the local Harnack inequality
\[
(6.23) \quad f(y) \leq C_1 f(z)
\]
for all \( y, z \in B(x_0, r_0 + h') \) satisfying \( d(y, z) \leq h \). Then there exists \( c_0, C_0 > 0 \) such that

\[
\int_{B_0} e^{\left(\frac{c_0 f(y)}{\|f\|_{\text{BMO}(11B_0) \cup h'}}\right)} \, dy \int_{B_0} e^{\left(-\frac{c_0 f(y)}{\|f\|_{\text{BMO}(11B_0) \cup h'}}\right)} \, dy \leq C_0^2 \mu(B_0)^2
\]

where \( B_0 = B(x_0, r_0) \). The constants \( c_0, C_0 \) depends only on \( C_1, h' \) and constants associated with doubling hypotheses \( (VD)_{\text{loc}} \) and \( (VD)_{\infty} \).

**Proof.** There exists \( C_2, C_3 > 0 \) such that

\[
\int_{B_0} \exp\left(\frac{c_0 (f(y) - f_{B_0})}{\|f\|_{\text{BMO}(11B_0) \cup h'}}\right) \, dy \\
\leq \mu(B_0) + \sum_{k=0}^{\infty} \mu \left( \left\{ y \in B_0 : k < \frac{f(y) - f_{B_0}}{\|f\|_{\text{BMO}(11B_0) \cup h'}} \leq k + 1 \right\} \right) e^{c_0(k+1)}
\]

\[
\leq \mu(B_0) \left( 1 + C_2 \sum_{k=0}^{\infty} e^{c_0(k+1)} e^{-k/C_2} \right) \leq C_0 \mu(B_0)
\]

In the last line above, we fix \( c_0 = 1/(2C_2) \) where \( C_2 \) is the constant from Proposition 6.8. Replacing \( f \) by \(-f\) in the above inequality and multiplying those two inequalities yields (6.24). \( \square \)

### 6.3. Discrete Calculus

Before we dive into computations, we introduce simplifying notations and collect basic rules that mimic calculus rules in a discrete setting. Let \( f \) be a function on \( \mathbb{N} \times M \) or on \( M \). Depending on context, we may abbreviate \( f(k,x) \) to \( f_k(x), f_k \) or even \( f \).

1. ‘Gradient’

\[
\nabla_{xy} f := f(y) - f(x)
\]

and the ‘time derivative’

\[
\partial_k f(x) := f(k+1,x) - f(k,x).
\]

2. Differentiation of product

\[
\nabla_{xy} (fg) = (\nabla_{xy} f)(g) + (\nabla_{xy} g)f(x).
\]

3. Differentiation of square

\[
\nabla_{xy} f^2 = 2(\nabla_{xy} f)f(x) + (\nabla_{xy} f)^2.
\]

4. The same formulas for the ‘time derivatives’:

\[
\partial_k (fg) = (\partial_k f)g_{k+1} + (\partial_k g)f_k
\]

and

\[
\partial_k (f^2) = 2(\partial_k f)f_k + (\partial_k f)^2.
\]

5. Let \( \Delta = I - P \) denote the Laplacian corresponding to a \( \mu \)-symmetric Markov operator \( P \) with kernel \( p_1 \). Then

\[
\Delta f(x) := (I - P)f(x) = \int_M p_1(x, y) \nabla_{yx} f \, dy.
\]
6. Integration by parts: If \( f, g \in L^2(M, \mu) \), then
\[
\int_M \Delta f(x) g(x) \, dx = \frac{1}{2} \int_M \int_M (\nabla_{xy} f)(\nabla_{xy} g) p_1(x, y) \, dy \, dx.
\]

7. Consider a \( \mu \)-symmetric Markov operator with kernel \( p_1 \). We define \( |\nabla f| \) corresponding to the Markov operator \( P \) as
\[
|\nabla_P f|^2(x) := \int_M (|\nabla_{xy} f|^2) p_1(x, y) \, dy.
\]

We caution the reader to be aware of different uses of the symbol \( \nabla \) in (3.1), (6.25) and (6.32) with slight change in subscript. The subscript could be a positive real number, a pair of points or a Markov operator. We hope the different notations of \( \nabla \) would be clear from the context.

### 6.4. Logarithm of a harmonic function

If \( u \) is a positive harmonic function, then we show that \( \log u \) has bounded BMO seminorm. This combined with John-Nirenberg inequality yields \( \phi(u, -q, c_1 B) \leq C' \phi(u, q, c_1 B) \) for some \( q, C' > 0 \) and \( c_1 \in (0, 1) \).

**Lemma 6.10.** Let \( (M, d, \mu) \) be a quasi-b-geodesic metric measure space satisfying \((VD)_{\text{loc}}, (VD)_{\infty}\) and Poincaré inequality at scale \( h \) \((P)_h\). Suppose that a Markov operator \( P \) has a kernel \( p \) that is \((h, h')\)-compatible with respect to \( \mu \) for some \( h > b \). Let \( u \) be a positive \( P \)-harmonic function on \( B = B(x, r) \). Let \( \eta \) be a non-negative function on \( B \) satisfying \( \text{supp}(\eta) \subset B(x, (r/2) - h') \). There exists \( C_0 > 0 \) and \( r_0 > 2h' \) satisfies
\[
\int_{B/2} \int_{B/2} \left( \frac{\ln u(y)}{u(z)} \right)^2 \eta(z)^2 \, dy \, dz \leq C_0 \int_{B/2} \int_{B/2} (\nabla_{y z} \eta)^2 p_1(y, z) \, dy \, dz
\]
for all balls \( B \), for all functions \( u, \eta \) satisfying the above requirements.

**Proof.** Define \( \psi := \eta^2 / u \). By product rule (6.27)
\[
\nabla_{y z} \psi = \nabla_{y z} (1/u) \eta(z)^2 + (1/u(y)) \nabla_{y z} \eta(z)^2.
\]

Using integration by parts (6.31) along with \( \text{supp}(\eta) \subset B(x, (r/2) - h') \), we deduce
\[
\int_{B/2} \int_{B/2} p_1(y, z) (\nabla_{y z} \psi)(\nabla_{y z} u) \, dy \, dz = 0.
\]
Combining (6.34), (6.35), we have
\[
-\int_{B/2} \int_{B/2} p_1(y, z)(\nabla_{y z} u) \left( \nabla_{y z} \frac{1}{u} \right) \eta(z)^2 \, dy \, dz \\
\leq \int_{B/2} \int_{B/2} p_1(y, z) |\nabla_{y z} u| |\nabla_{y z} \eta|^2 \frac{1}{u(y)} \, dy \, dz.
\]

By Lemma 6.4, \( u \) satisfies the local Harnack inequality on \( B/2 \) for large enough balls \( B \). Hence there exists \( c_1, C_1 > 0 \) and \( r_0 > 2h' \) such that
\[
(\nabla_{y z} u) \left( \nabla_{y z} \frac{1}{u} \right) \geq c_1 \left( \frac{u(y) - u(z)}{u(y) u(z)} \right)^2 \\
|\nabla_{y z} u|/u(y) \leq C_1 \left| \ln \frac{u(y)}{u(z)} \right|
\]
for all positive $P$-harmonic functions $u$ on $B = B(x, r)$, for all $y, z \in B/2$ with $d(y, z) \leq h'$ and $r > r_0$. Combining (6.36), (6.37) and (6.38), we obtain
\[
\int_{B/2} \int_{B/2} p_1(y, z) \left( \ln \frac{u(y)}{u(z)} \right)^2 \eta(z)^2 \, dy \, dz
\]
(6.39)
\[
\leq \frac{C_1}{C_1} \int_{B/2} \int_{B/2} p_1(y, z) |\nabla_y z\eta(\eta(y) + \eta(z))| \ln \frac{u(y)}{u(z)} \, dy \, dz
\]
Since $p_1(y, z) = p_1(z, y)$ for $\mu \times \mu$-almost every $(y, z) \in M \times M$, we have
\[
\int_{B/2} \int_{B/2} p_1(y, z) |\nabla_y z\eta| \ln \frac{u(y)}{u(z)} \, dy \, dz
\]
(6.40)
\[
= \int_{B/2} \int_{B/2} p_1(y, z) |\nabla_y z\eta| \ln \frac{u(y)}{u(z)} \, dy \, dz
\]
By (6.39) and (6.40)
\[
\int_{B/2} \int_{B/2} p_1(y, z) \left( \ln \frac{u(y)}{u(z)} \right)^2 \eta(z)^2 \, dy \, dz
\]
(6.41)
\[
\leq \frac{2C_1}{C_1} \int_{B/2} \int_{B/2} p_1(y, z) |\nabla_y z\eta| \ln \frac{u(y)}{u(z)} \, dy \, dz
\]
By Hölder inequality
\[
\left( \int_{B/2} \int_{B/2} p_1(y, z) |\nabla_y z\eta| \ln \frac{u(y)}{u(z)} \, dy \, dz \right)^2
\]
(6.42)
\[
\leq \int_{B/2} \int_{B/2} p_1(y, z) |\nabla_y z\eta|^2 \, dy \, dz \cdot \int_{B/2} \int_{B/2} p_1(y, z) \left( \ln \frac{u(y)}{u(z)} \right)^2 \eta(z)^2 \, dy \, dz.
\]
Combining (6.41) and (6.42), we obtain (6.33) with $C_0 = 4C_1^2/C_1^2$. \qed

In the next proposition, we show that logarithm of a harmonic function has bounded mean oscillation. Then using John-Nirenberg inequality we prove a weak form of elliptic Harnack inequality.

**Proposition 6.11.** Under the assumptions of Theorem 6.3, there exists $q > 0$, $c_0 \in (0, 1)$ and $C_0, r_0 > 0$ such that
\[
\phi(u, -q, c_0 B) \leq C_0 \phi(u, q, c_0 B)
\]
(6.43)
for all $P$-harmonic functions $u$ on $B = B(x, r)$ with $r \geq r_0$ and for all $x \in M$.

**Proof.** Let $c_1 \in (0, 1)$ (its value will be determined later in the proof). Let $B = B(x, r)$ and let $B_1 = B(x_1, r_1) \subseteq B$ with $r_1 \geq h'$. For any positive harmonic function $u$ on $B$, by $(P)_\infty$ there exists $C_1, C_2, C_3 > 1$ such that
\[
\int_{B_1} \ln u(y) - (\ln u)_B(1)^2 \, dy \leq C_1 r_1^2 \int_{C_2 B_1} |\nabla (\ln u)|^2_{h_1}(y) \, dy
\]
(6.44)
\[
\leq C_3 r_1^2 \int_{(C_2 + 1)B_1} \int_{(C_2 + 1)B_1} p_1(y, z) \left( \ln \frac{u(y)}{u(z)} \right)^2 \, dy \, dz
\]
6.5. Mean value inequality for subharmonic functions

We used \((P)_{h}\) in the first line and \((4.10)\) and \(r \geq h'\) We choose \(c_1 = 1/(3(C_2 + 2))\), so that \((C_2 + 1)B_1 \subseteq B/3\) for all \(B_1 \subseteq c_1 B\). We define \(\eta\) as

\[
\eta(y) = \max \left(1, \min \left(0, \frac{(C_2 + 2)r_1 - d(y, x_1)}{r_1}\right)\right).
\]

Note that for large enough \(r\), we have \(\text{supp} \eta \subseteq (C_2 + 2)B_1 \subseteq (C_2 + 2)c_1 B \subseteq B(x, (r/2) - h')\). Since \(\eta \equiv 1\) on \((C_2 + 1)B_1\), there exists \(C_4, C_5 > 0\)

\[
\int_{(C_2+1)B_1} \int_{(C_2+1)B_1} p_1(y, z) \left(\frac{\ln u(y)}{u(z)}\right)^2 dy \, dz \\
\leq \int_{(C_2+2)B_1} \int_{(C_2+2)B_1} p_1(y, z) \left(\frac{\ln u(y)}{u(z)}\right)^2 \eta(z)^2 dy \, dz \\
\leq C_4 \int_{B/2} \int_{B/2} p_1(y, z) (\nabla_{yz} \eta)^2 dy \, dz \leq C_5 r_1^{-2} \mu(B_1)
\]

(6.45)

In the last line above we used Lemma 6.10, \((4.10)\), definition of \(\eta\), triangle inequality and \((2.4)\). By Hölder inequality

\[
\left(\int_{B_1} |\ln u(y) - (\ln u)_{B_1}| \, dy\right)^2 \leq \mu(B_1) \int_{B_1} |\ln u(y) - (\ln u)_{B_1}|^2 \, dy
\]

(6.46)

Combining (6.44), (6.45) and (6.46) we obtain

\[
\|\ln u\|_{\text{BMO}(c_1 B), h'} \leq (C_3 C_5)^{1/2}
\]

(6.47)

for all positive harmonic functions \(u\) on \(B = B(x, r)\) and for all \(r\) sufficiently large. By Lemma 6.4, (6.47) and Corollary 6.9, there exists \(q > 0, C_6 > 0\) such that

\[
\phi(u, q, (c_1/11)B)^q \phi(u, -q, (c_1/11)B)^{-q} \leq C_6^q
\]

for all sufficiently large balls \(B\) and for all positive \(P\)-harmonic functions \(u\) on \(B\). This immediately yields (6.43). \(\square\)

6.5. Mean value inequality for subharmonic functions

For the rest of the chapter, we will rely on \((VD)_{\infty}\), \((VD)_{\text{loc}}\) and the Sobolev inequality \((5.2)\) to prove Theorem 6.3. We obtain various inequalities on subharmonic functions. The following elementary property of subharmonic and superharmonic functions is useful.

**Lemma 6.12.** Let \(P\) be a Markov operator.

(a) If \(f\) is a non-negative function that is \(P\)-subharmonic in \(B(x, r)\), then \(f^p\) is \(P\)-subharmonic in \(B(x, r)\) for all \(p \in [1, \infty)\).

(b) If \(f\) is a positive function that is \(P\)-superharmonic in \(B(x, r)\), then \(f^p\) is \(P\)-subharmonic in \(B(x, r)\) for all \(p < 0\).

**Proof.** If \(y \in B(x, r)\), then by Jensen’s inequality and the fact that \(f\) is \(P\)-subharmonic in \(B(x, r)\)

\[
f^p(y) \leq (Pf(y))^p \leq (Pf^p)(y).
\]

This proves (a). We again use Jensen’s inequality, \(f\) is \(P\)-superharmonic in \(B(x, r)\) and \(p < 0\) to obtain

\[
f^p(y) \leq (Pf(y))^p \leq (Pf^p)(y)
\]

\(\square\)
Moser’s iteration relies on repeated application of the following Lemma.

**Lemma 6.13.** Let $\langle M, d, \mu \rangle$ be a quasi-b-geodesic metric measure space satisfying $(V D)_\infty$ and $(V D)_\infty$. Suppose that a Markov operator $P$ has a kernel $p$ that is $(h, h')$-compatible with respect to $\mu$ for some $h > b$. Further assume that $P$ satisfies the Sobolev inequality (5.2). There exists $C_0 > 0$ such that

\[ \phi(u, 2(1 + 2/\delta), B(x, (1 - \sigma)r - h')) \leq C_0 \sigma^{-\delta/(\delta + 2)} \phi(u, 2, B(x, r + h')) \]

for all $x \in M$, for all $r \geq 3h'$, for all $\sigma \in (0, 1/2)$ and for all functions $u$ that are non-negative and $P$-subharmonic on $B(x, r)$.

**Proof.** Define

\[ \psi(y) := \max \left(0, \min \left(1, \frac{r - d(x, y)}{\sigma r}\right)\right). \]

Note that $\psi \equiv 0$ in $B(x, r)\mathbb{C}$ and $\psi \equiv 1$ in $B(x, (1 - \sigma)r)$. Since $\Delta u \leq 0$ in $B(x, r)$ and $u \geq 0$, we have

\[ 0 \leq -\int_{B(x,r)} \psi^2(y)u(y)\Delta u(y) \, dy \]

\[ = -\frac{1}{2} \int_{B(x,r+h')} \int_{B(x,r+h')} p_1(y, z) \left(\nabla_{yz}(\psi^2u)\right) \left(\nabla_{yz}u\right) \, dy \, dz \]

\[ = -\frac{1}{2} \int_{B(x,r+h')} \int_{B(x,r+h')} p_1(y, z) \psi^2(y) \left(\nabla_{yz}u\right)^2 \, dy \, dz \]

\[ -\frac{1}{2} \int_{B(x,r+h')} \int_{B(x,r+h')} p_1(y, z) u(z) \left(\nabla_{yz}\psi\right)^2 \left(\nabla_{yz}u\right) \, dy \, dz. \]

The above steps follows from integration by parts (6.31) and product rule (6.27). We use the inequality $ab \leq a^2/4 + b^2$ to obtain

\[ |u(z) \left(\nabla_{yz}\psi\right)^2 \left(\nabla_{yz}u\right)| = \left|\left(\psi(y) + \psi(z)\right)u(z) \left(\nabla_{yz}\psi\right) \left(\nabla_{yz}u\right)\right| \]

\[ \leq \frac{1}{4} \left(\psi^2(y) + \psi^2(z)\right) \left(\nabla_{yz}u\right)^2 + 2u^2(z) \left(\nabla_{yz}\psi\right)^2. \]

Since $p_1(y, z) = p_1(z, y)$ for $\mu \times \mu$-almost every $(y, z)$, we have

\[ \int_{B_1} \int_{B_3} p_1(y, z) \psi^2(y) \left(\nabla_{yz}u\right)^2 \, dy \, dz = \int_{B_1} \int_{B_3} p_1(y, z) \psi^2(z) \left(\nabla_{yz}u\right)^2 \, dy \, dz \]

where $B_1 := B(x, r + h')$. Combining (6.50), (6.51) and (6.52)

\[ \int_{B_1} \int_{B_3} p_1(y, z) \psi^2(y) \left(\nabla_{yz}u\right)^2 \, dy \, dz \leq 4 \int_{B_1} \int_{B_1} p_1(y, z) u^2(z) \left(\nabla_{yz}\psi\right)^2 \, dy \, dz. \]

The inequality $(a + b)^2 \leq 2(a^2 + b^2)$ along with product rule (6.27) implies

\[ \int_{B_1} \int_{B_1} p_1(y, z) \left(\nabla_{yz}u\right)^2 \, dy \, dz \leq 2 \int_{B_1} \int_{B_1} p_1(y, z) \psi^2(y) \left(\nabla_{yz}u\right)^2 \, dy \, dz \]

\[ + 2 \int_{B_1} \int_{B_1} p_1(y, z) u^2(z) \left(\nabla_{yz}\psi\right)^2 \, dy \, dz. \]

Combining (6.53) and (6.54), we obtain

\[ \int_{B_1} \int_{B_1} p_1(y, z) \left(\nabla_{yz}u\right)^2 \, dy \, dz \leq 10 \int_{B_1} \int_{B_1} p_1(y, z) u^2(z) \left(\nabla_{yz}\psi\right)^2 \, dy \, dz. \]
By (6.49) and (4.10), there exists $C_1 > 0$ such that
\[
(\nabla y z \psi)^2 p_1(y, z) \leq (h')^2 \sigma^{-2} r^{-2} p_1(y, z)
\]
for all $y \in M$ and for $\mu$-almost every $z \in M$. Combined with (6.55), we have
\[
\int_{B_1} \int_{B_1} p_1(y, z) (\nabla y z (\psi u))^2 \, dy \, dz \leq 10 (h')^2 \sigma^{-2} r^{-2} \int_{B_1} u^2(z) \, dz.
\]
We define
\[
u_1 := P_{B(x, (1-\sigma)r)} u, \quad \nu_2 := P_{B_1}(\nu).\]
Since $\psi \equiv 1$ in $B(x, (1-\sigma)r)$, by (4.10) we have
\[
\nu_2(y) = \nu_1(y) = \nu(y) = u(y) - \Delta u(y) \geq u(y)
\]
for all $y \in B(x, (1-\sigma)r - h')$. By (6.57) along with Hölder inequality, we have
\[
\int_{B(x, (1-\sigma)r - h')} \nu_2^{2(1+2/\delta)} \, d\mu \leq \int_{B(x, (1-\sigma)r)} \nu_1^{2(1+2/\delta)} \, d\mu
\]
\[
\leq \left( \int_{B(x, (1-\sigma)r)} \nu_2^2 \, d\mu \right)^{2/\delta} \left( \int_{B(x, (1-\sigma)r)} \nu_1^{2(2\delta)/(\delta-2)} \, d\mu \right)^{(\delta-2)/\delta}
\]
\[
\leq \left( \int_{B(x, (1-\sigma)r)} \nu_1^2 \, d\mu \right)^{2/\delta} \left( \int_{B(x, (1-\sigma)r)} \nu_1^{2(2\delta)/(\delta-2)} \, d\mu \right)^{(\delta-2)/\delta}
\]
In (6.58), we used that $P_{B(x, (1-\sigma)r)}$ is a contraction in $L^2$ and that $\nu_2 \geq \nu_1$ in $B(x, (1-\sigma)r)$. By Sobolev inequality (5.2), Lemma 4.22(a) and integration by parts (6.31)
\[
\left( \int_{B_1} \nu_2^{2(2\delta)/(\delta-2)} \, d\mu \right)^{(\delta-2)/\delta}
\leq C_S \frac{(r + h')^2}{2 (x, r + h')^{2/\delta}} \int_{B_1} \int_{B_1} p_1(y, z) (\nabla y z (\psi u))^2 \, dy \, dz
\]
\[
\quad + C_S \frac{1}{(x, r + h')^{2/\delta}} \int_{B_1} \psi u^2 \, d\mu
\]
By using (6.58), (6.59), (6.56), $\psi \leq 1$, $r \geq 3h'$ and (2.4), there exists $C_2 > 0$ such that
\[
\int_{B(x, (1-\sigma)r - h')} \nu_2^{2(1+2/\delta)} \, d\mu \leq C_2 \sigma^{-2} \left( \int_{B(x, r + h')} \nu_2^2 \, d\mu \right)^{1+(2/\delta)}.
\]
This immediately yields (6.48). 

We modify the proof of the Lemma 6.13 to obtain a reverse Poincaré inequality for all $P$-harmonic functions (not necessarily non-negative). The below reverse Poincaré inequality and its proof is essentially same as (6.56).

**Lemma 6.14 (Reverse Poincaré inequality).** Let $(M, d, \mu)$ be a quasi-$b$-geodesic metric measure space satisfying $(VD)_{\text{loc}}$ and $(VD)_{\infty}$ Suppose that a Markov operator $P$ has a kernel $p$ that is weakly $(h, h')$-compatible with respect to $\mu$ for some $h > b$. For all $\Omega > 1$, there exists $C = C(\Omega)$ such that for all $P$-harmonic functions $u$, for all $x \in M$ and for all $r > 3h'/(\Omega - 1)$
\[
\int_{B(x, r)} |\nabla p u|^2 \, d\mu \leq C r^{-2} \int_{B(x, \Omega r)} u^2 \, d\mu.
\]
In particular, there exists $C_R = C(2)$ such that such that for all $P$-harmonic functions $u$, for all $x \in M$ and for all $r > 3h'$

\begin{equation}
\int_{B(x,r)} |\nabla_P u|^2 \, d\mu \leq C_R r^{-2} \int_{B(x,2r)} u^2 \, d\mu.
\end{equation}

**Proof.** We repeat the steps in the proof of Lemma 6.13. Define

\begin{equation}
\psi(y) := \max \left( 0, \min \left( 1, \frac{\Omega r - h' - d(x,y)}{(\Omega - 1)r - 2h'} \right) \right).
\end{equation}

Note that $\psi \equiv 0$ in $B(x, \Omega r - h')^C$ and $\psi \equiv 1$ in $B(x, r + h')$. Since $\Delta u = (I - P)u = 0$, for all $r > 3h'/\Omega - 1$ and for all $x \in M$ we have

\begin{equation}
0 = -\int_M \psi^2(y)u(y)\Delta u(y) \, dy - \int_{B(x,\Omega r - h')} \psi^2(y)u(y)\Delta u(y) \, dy
\end{equation}

\begin{equation}
= -\frac{1}{2} \int_{B(x,\Omega r)} \int_{B(x,\Omega r)} p_1(y,z) (\nabla_{yz} (\psi^2 u)) (\nabla_{yz} u) \, dy \, dz
\end{equation}

\begin{equation}
= -\frac{1}{2} \int_{B(x,\Omega r)} \int_{B(x,\Omega r)} p_1(y,z)\psi^2(y) (\nabla_{yz} u)^2 \, dy \, dz
\end{equation}

\begin{equation}
- \frac{1}{2} \int_{B(x,\Omega r)} \int_{B(x,\Omega r)} p_1(y,z)\psi(y) (\nabla_{yz} \psi)^2 (\nabla_{yz} u) \, dy \, dz.
\end{equation}

The above steps follows from integration by parts (6.31) and product rule (6.27). We use the inequality $ab \leq a^2/4 + b^2$ to obtain

\begin{equation}
|u(z) (\nabla_{yz} \psi^2) (\nabla_{yz} u)| = |(\psi(y) + \psi(z))u(z)(\nabla_{yz} \psi)(\nabla_{yz} u)|
\end{equation}

\begin{equation}
\leq \frac{1}{4}(\psi^2(y) + \psi^2(z)) (\nabla_{yz} u)^2 + 2u^2(z) (\nabla_{yz} \psi)^2.
\end{equation}

Since $p_1(y,z) = p_1(z,y)$ for $\mu \times \mu$-almost every $(y,z)$, we have

\begin{equation}
\int_{B_1} \int_{B_1} p_1(y,z)\psi^2(y) (\nabla_{yz} u)^2 \, dy \, dz = \int_{B_1} \int_{B_1} p_1(y,z)\psi^2(z) (\nabla_{yz} u)^2 \, dy \, dz
\end{equation}

\begin{equation}
\int_{B_1} \int_{B_1} p_1(y,z)\psi^2(y) (\nabla_{yz} u)^2 \, dy \, dz \leq 4 \int_{B_1} \int_{B_1} p_1(y,z)u^2(z) (\nabla_{yz} \psi)^2 \, dy \, dz.
\end{equation}

The inequality $(a + b)^2 \leq 2(a^2 + b^2)$ along with product rule (6.27) implies

\begin{equation}
\int_{B_1} \int_{B_1} p_1(y,z) (\nabla_{yz} (\psi u))^2 \, dy \, dz \leq 2 \int_{B_1} \int_{B_1} p_1(y,z)\psi^2(y) (\nabla_{yz} u)^2 \, dy \, dz
\end{equation}

\begin{equation}
+ 2 \int_{B_1} \int_{B_1} p_1(y,z)u^2(z) (\nabla_{yz} \psi)^2 \, dy \, dz.
\end{equation}

Combining (6.66) and (6.67), we obtain

\begin{equation}
\int_{B_1} \int_{B_1} p_1(y,z) (\nabla_{yz} (\psi u))^2 \, dy \, dz \leq 10 \int_{B_1} \int_{B_1} p_1(y,z)u^2(z) (\nabla_{yz} \psi)^2 \, dy \, dz.
\end{equation}

By (6.62) and (4.10), there exists $C_1 > 0$ such that

\begin{equation}
(\nabla_{yz} \psi)^2 p_1(y,z) \leq (3h')^2(\Omega - 1)^{-2}r^{-2}p_1(y,z)
\end{equation}
for all \( y \in M \), for \( \mu \)-almost every \( z \in M \) and for all \( r > 3h'/(\Omega - 1) \). Combined with (6.55), we have
\[
(6.69) \quad \int_{B_1} \int_{B_1} p_1(y, z) (\nabla y z (\psi u))^2 \, dy \, dz \leq (3h')^2(\Omega - 1)^{-2} r^{-2} \int_{B_1} u^2(z) \, dz.
\]
for all \( P \)-harmonic functions \( u \), for all \( r > 3h'/(\Omega - 1) \) and for all \( x \in M \). Since \( \psi \equiv 1 \) in \( B(x, r + h') \) the desired inequality (6.60) follows from (6.69). \( \square \)

The next lemma is a \( L^2 \)-mean value inequality for positive \( P \)-subharmonic functions.

**Lemma 6.15.** Let \((M, d, \mu)\) be a quasi-b-geodesic metric measure space satisfying \((V D)_{loc}\) and \((V D)_{\infty}\). Suppose that a Markov operator \( P \) has a kernel \( p \) that is \((h, h')\)-compatible with respect to \( \mu \) for some \( h > b \). Further assume that \( P \) satisfies the Sobolev inequality (5.2). There exists \( C_1 > 0 \) and \( r_1 > 0 \) such that
\[
(6.70) \quad \phi(u, \infty, B(x, r/6)) \leq C \phi(u, 2, B(x, r + h'))
\]
for all \( x \in M \), for all \( r \geq r_1 \) and for all functions \( u \) that are non-negative and \( P \)-subharmonic on \( B(x, r) \).

**Proof.** Define a sequence of radii iteratively by \( r(1) = r + h' \),
\[
r(i + 1) = (r(i) - h') \left( 1 - \frac{1}{3^{i+1}} \right) - h'
\]
for \( i = 1, 2, \ldots, [\log r] \). By the above definition, there exists \( r_0 > 0 \) such that
\[
(6.71) \quad r([\log r] + 2) - h' \geq r \left( 1 - \sum_{j=1}^{i} 3^{-(i+1)} \right) - 4h' \log r + 3 \geq r/2 \geq 3h'
\]
for all \( r \geq r_0 \). We define the balls \( B_i = B(x, r(i)) \) for \( i \in \mathbb{N}^* \) and exponents \( p_i = (1 + 2/\delta)i \) for \( i \in \mathbb{N}_{\geq 0} \). By applying Lemma 6.13 to the function \( u^{p_i} \) that is \( P \)-subharmonic in \( B_i \), we obtain
\[
(6.72) \quad \phi(u, 2p_i, B_{i+1}) \leq C_0^{1/p_i-1} \phi(u, 2p_i-1, B_i)
\]
for \( i = 1, 2, \ldots, [\log r] \) and \( r \geq r_0 \). Combining the estimates in (6.72), there exists \( C_2 > 0 \) such that
\[
(6.73) \quad \phi(u, 2p_{[\log r]}, B_{[\log r] + 1}) \leq C_2 \phi(u, 2, B(x, r + h'))
\]
for all \( x \in M \), for all \( r \geq r_0 \) and for all non-negative subharmonic \( u \) in \( B(x, r) \). There exists \( C_3, C_4 > 0 \) such that
\[
\begin{align*}
\sup_{B(x, r/2)} u^{2p_{[\log r]}} & \leq \sup_{B(x, r/2)} P(u^{2p_{[\log r]}}) \\
& \leq \sup_{y \in B_{[\log r] + 1}} \frac{C_3}{V(y, h')} \int_{B_{[\log r] + 1}} u^{2p_{[\log r]}} \, d\mu \\
& \leq \frac{C_3}{\mu(B_{[\log r] + 1})} \left( \sup_{y \in B(x, r)} \frac{V(y, 2r)}{V(y, h')} \right) \int_{B_{[\log r] + 1}} u^{2p_{[\log r]}} \, d\mu \\
& \leq C_4 \delta \int_{B_{[\log r] + 1}} u^{2p_{[\log r]}} \, d\mu
\end{align*}
\]
The first line above follows from Lemma 6.12, the second line follows from (4.10) and (6.71), the third line follows from (6.71) and the last line from (2.4) and (6.71). Combining (6.73) and (6.74), we obtain (6.70).

The next lemma is analogous to Lemma 6.13 and will be used for an iteration procedure.

**Lemma 6.16.** Let \((M, d, \mu)\) be a quasi-\(b\)-geodesic metric measure space satisfying \((V D)_{loc}\) and \((V D)_\infty\). Suppose that a Markov operator \(P\) has a kernel \(p\) that is \((h, h')\)-compatible with \((M, d, \mu)\) for some \(h > b\). Further assume that \(P\) satisfies the Sobolev inequality (5.2). There exists \(C_0 > 0, r_0 > 0\) such that

\[
\int_{B(x, r/2)} \int_{B(x, r/2)} \psi(y)^2 |\nabla_{yz}(u^p)| p_1(y, z) \, dy \, dz 
\leq C_0 \left( \frac{2p}{2p - 1} \right)^2 \int_{B(x, r/2)} \int_{B(x, r/2)} u(y)^2 |\nabla_{yz} \psi| p_1(y, z) \, dy \, dz 
\]  

(6.75)

for all \(x \in M\), for all \(r \geq r_0\), for all \(p \in (0, 1] \setminus \{1/2\}\), for all positive functions \(u\) that are \(P\)-harmonic on \(B(x, r)\) and for all \(\psi \geq 0\) with \(\text{supp}(\psi) \subset B(x, r/2 - h')\).

**Proof.** Let \(\eta := u^{2p-1} \psi\), where \(\psi \geq 0\) satisfies \(\text{supp}(\psi) \subset B(x, r/2 - h')\) and \(u > 0\) is \(P\)-harmonic in \(B(x, r)\). By product rule (6.27)

\[
\nabla_{yz} \eta = (\nabla_{yz}(u^{2p-1})) \psi(y)^2 + u(z)^{2p-1} (\nabla_{yz} \psi^2). 
\]

By integration by parts (6.31), we obtain

\[
\int_B \int_B p_1(y, z)(\nabla_{yz} u) (\nabla_{yz}(u^{2p-1})) \psi(y)^2 \, dy \, dz
= - \int_B \int_B p_1(y, z) (\nabla_{yz} u) u(z)^{2p-1} (\nabla_{yz}(\psi^2)) \, dy \, dz
\]

(6.76)

where \(B := B(x, r/2)\). There exists \(C_1 > 0\) such that

\[
\|2p - 1\| (\nabla_{yz}(u^p))^2 \leq p^2 (\nabla_{yz} u) (\nabla_{yz}(u^{2p-1}))
\]

(6.77)

\[
|\nabla_{yz} u| u(z)^{2p-1} \leq C_1 p^{-1} |\nabla_{yz}(u^p)|.
\]

(6.78)

for all \(p \in (0, 1]\), for all \(y, z \in M\) with \(d(y, z) \leq h'\) and for all positive \(u\). The estimate (6.77) is elementary and is a version of Stroock-Varopoulos inequality. The proof of (6.77) is essentially contained in [63, Lemma 2.4]. The estimate (6.78) follows from mean value theorem and the local Harnack inequality given by Lemma 6.4. Combining (6.76), (6.77) and (6.78), we have

\[
C_1^{-1} \frac{2p - 1}{p} \int_B \int_B p_1(y, z) \psi(y)^2 |\nabla_{yz}(u^p)|^2 \, dy \, dz
\leq \int_B \int_B p_1(y, z) u(z)^p |\nabla_{yz} \psi| |\psi(y)| + \psi(z) |\nabla_{yz}(u^p)| \, dy \, dz
\leq \left( \int_B \int_B p_1(y, z) u(y)^{2p} |\nabla_{yz} \psi|^2 \, dy \, dz \right)^{1/2}
\times \left( \int_B \int_B p_1(y, z) 2(\psi(y)^2 + \psi(z)^2) |\nabla_{yz}(u^p)|^2 \, dy \, dz \right)^{1/2}
\]

(6.79)
We use Cauchy-Schwarz inequality and \((a + b)^2 \leq 2(a^2 + b^2)\) in the last step. By the \(\mu \times \mu\)-almost everywhere symmetry of \(p_1\), we have

\[
\int_B \int_B p_1(y, z) \psi(z)^2 |\nabla_{yz}(u^p)|^2 \, dz \, dy = \int_B \int_B p_1(y, z) \psi(y)^2 |\nabla_{yz}(u^p)|^2 \, dy \, dz.
\]

Combining \((6.79)\) and \((6.80)\) yields \((6.75)\).

We do another iteration procedure between the exponents \(q\) and 2 using Lemma 6.16.

**Lemma 6.17.** Let \((M, d, \mu)\) be a quasi-\(b\)-geodesic metric measure space satisfying \((VD)_{\text{loc}}\) and \((VD)_{\infty}\). Suppose that a Markov operator \(P\) has a kernel \(p\) that is \((h, h')\)-compatible to \((M, d, \mu)\) for some \(h > b\). Further assume that \(P\) Sobolev inequality \((5.2)\). For any fixed \(q > 0\), there exists \(C_1 > 0, c_1 \in (0, 1/2)\) and \(r_1 > 0\) such that

\[
\phi(u, 2, B(x, c_1 r)) \leq C_1 \phi(u, q, B(x, r/2))
\]

for all \(x \in M\), for all \(r \geq r_1\) and for all functions \(u\) that are non-negative and \(P\)-subharmonic on \(B(x, r)\).

**Proof.** If \(q \geq 2\), then \((6.81)\) follows from Jensen’s inequality. Hence it suffices to consider \(q \in (0, 2)\).

Define \(\theta := \delta/(\delta - 2)\). We slightly decrease \(q\) if necessary so that \(q \theta^k \neq 1/2\) for all \(i \in \mathbb{N}\). Define \(k \in \mathbb{N}^+\) as the integer that satisfies \(q \theta^{k-1} < 2 \leq q \theta^k\). Define \(c_1 := 4^{-k}\) and iteratively define

\[
s_i := 2s_{i-1} + 2h'
\]

for \(i = 1, \ldots, k\), where \(s_0 := c_1 r\). Fix \(r_0 > 0\) such that \(s_k \leq r/2 - h'\) for all \(r \geq r_0\) where \(k\) and \(s_k\) are defined as above.

Define \(q_i := \theta^i/2, B_i = B(x, s_{k-i})\) for \(i = 0, 1, \ldots, k\). Define the functions

\[
\psi_i(y) = \max\left(0, \min\left(1, \frac{2s_{k-i-1} + h' - d(x, y)}{s_{k-i-1}}\right)\right)
\]

for \(i = 0, 1, \ldots, k - 1\). Note that \(\psi_i \equiv 1\) in \(B(x, s_{k-i-1} + h')\) and \(\psi \equiv 0\) in \(B(x, s_{k-i} - h')\).

By Sobolev inequality \((5.2)\) there exists \(C_2 > 0\) such that

\[
\left(\int_{B_i} (P_{B_i}(\psi_i u^p))(y)^{2q} \, dy\right)^{1/q} \leq C_2 s_{k-i}^2 \int_{B_i} \int_{B_i} p_1(y, z) |\nabla_{yz}(\psi_i u^p)|^2 \, dz \, dy
\]

\[
+ \frac{C_2}{\mu(B_i)^{2/3}} \int_{B_i} \psi_i(y)^2 u(y)^{2q} \, dy
\]

for all \(i = 0, 1, \ldots, k - 1\). By \((4.10)\) and Lemma 6.4 there exists \(C_3 > 0\) such that

\[
P_{B_i}(\psi_i u^p)(y) = \int_{B(y, h')} u^p(z) p_1(y, z) \, dz \geq C_3^{-q} u^p(y)
\]

for all \(y \in B_{i+1}\). Therefore

\[
\left(\int_{B_{i+1}} u(y)^{2q-i+1} \, dy\right)^{1/q} \leq C_3^{q} \int_{B_i} (P_{B_{i+1}}(\psi_i u^p))(y)^{2q} \, dy^{1/q}
\]
for $x \in B_{i+1}$. There exists $C_4, C_5, C_6 > 0$ such that

$$
\int_{B_i} \int_{B_i} p_1(y, z) \phi(y)^2 \phi(z)^2 dy \, dz \\
\leq 2 \int_{B_i} \int_{B_i} p_1(y, z) \phi(y)^2 \phi(z)^2 dy \, dz + 2 \int_{B_i} \int_{B_i} p_1(y, z) \phi(y)^2 \phi(z)^2 dy \, dz \\
\leq C_4 \left[ \left( \frac{2q_i}{2q_i - 1} \right)^2 + 1 \right] \int_{B_i} \int_{B_i} p_1(y, z) \phi(y)^2 \phi(z)^2 dy \, dz \\
\leq \frac{C_5}{s_{k-1}^2} \left[ \left( \frac{2q_i}{2q_i - 1} \right)^2 + 1 \right] \int_{B_i} \phi(z)^{2q_i} dz
$$

(6.84)

$$
\leq \frac{C_6}{s_{k-1}^2} \int_{B_i} \phi(z)^{2q_i} dz.
$$

In the first step above, we used product rule (6.27) and the inequality $(a + b)^2 \leq 2(a^2 + b^2)$. In the second step we use Lemma 6.16 and in the third step we use (4.10). In the last step, we simply bound $2q_i/2q_i - 1$ by $\max_{0 \leq i \leq k} 2p_i/2p_i - 1 < \infty$.

Combining (6.82), (6.83), (6.84) along with $s_{k-1}/s_{k-i-1} \leq 4^k$ yields

$$
\left( \int_{B_{i+1}} u(y)^{2q_i+1} dy \right)^{1/\theta} \leq \frac{C_7}{\mu(B_i)^{2/\theta}} \int_{B_i} u(y)^{2q_i} dy
$$

for some $C_7 > 0$. Combined with $r \geq r_0$ and (2.4), we deduce

(6.85)

$$
\phi(u, 2q_i+1, B_{i+1}) \leq C_8 \phi(u, 2q_i, B_i)
$$

for $i = 0, 1, \ldots, k - 1$, for all $x \in M$, for all $r \geq r_0$ and for all $P$-harmonic $u > 0$. The estimates (6.85) along with Jensen’s inequality implies (6.81) with $C_1 = C_8^k$ and $c_1 = 4^{-k}$.

We are now ready to prove elliptic Harnack inequality.

**Proof of Theorem 6.3.** It suffices to consider the case $u > 0$ because we can replace $u \geq 0$ by $u + \epsilon$ and let $\epsilon \downarrow 0$.

Note that we have Sobolev inequality (5.2) by Theorem 5.1. There exists $r_0 > 0$ $C_i > 0$, $c_i \in (0, 1)$ for $1 \leq i \leq 5$ such that for all $x \in M$ and for all $r \geq r_0$ and for all positive functions $u$ that are $P$-harmonic on $B := B(x, r)$

$$
\phi(u, \infty, c_1 B) \leq C_1 \phi(u, c_2, B) \\
\leq C_2 \phi(u, q, c_3 B) \\
\leq C_3 \phi(u, -q, c_4, B) \\
\leq C_4 \phi(u, -\infty, c_5 B).
$$

The first line above follows from Lemma 6.15, the second line above follows from Lemma 6.17 and the third line follows from Proposition 6.11. The last line follows from applying Lemma 6.15 to the function $u^{-q/2}$ which is subharmonic by Lemma 6.12(b). Choosing $c = \min(c_1, c_5)$ yields the elliptic Harnack inequality.

The constant $c \in (0, 1)$ in (6.1) is flexible. More precisely, we can slightly improve the conclusion of Theorem 6.3 for $b$-geodesic spaces by an easy chaining.
6.6. Applications of elliptic Harnack inequality

Corollary 6.18 (Elliptic Harnack inequality). Let $(M, d, \mu)$ be a $b$-geodesic space satisfying $(VD)_{\text{loc}}, (VD)_{\infty}$ and Poincaré inequality $(P)_h$ at scale $h$. Suppose that a Markov operator $P$ has a kernel $p$ that is $(h, h')$-compatible with $(M, d, \mu)$ for some $h > b$. Then for all $c \in (0, 1)$, there exists $r_0 > 0, C_E > 0$ such that for all $x \in M$, for all $r \geq r_0$ and for all non-negative functions $u : B(x, r) \to \mathbb{R}_{\geq 0}$ that are $P$-harmonic in $B(x, r)$ the following Harnack inequality holds:

\begin{equation}
\sup_{x \in B(x, cr)} u \leq C_E \inf_{x \in B(x, cr)} u.
\end{equation}

The above corollary is a consequence of Theorem 6.3 applied repeatedly to a sequence of points in an approximate geodesic. We do not use the above corollary. The proof of Corollary 6.18 is left to the reader.

6.6. Applications of elliptic Harnack inequality

We present two immediate and well-known applications of elliptic Harnack inequality.

Proposition 6.19 (Liouville property). Assume that $(M, d, \mu)$ is a quasi-$b$-geodesic metric measure space satisfying $(VD)_{\text{loc}}, (VD)_{\infty}$ and Poincaré inequality $(P)_h$ at scale $h$. Suppose that a Markov operator $P$ has a kernel $p$ that is $(h, h')$-compatible with $(M, d, \mu)$ for some $h > b$. Then all non-negative $P$-harmonic functions are constant (strong Liouville property). Therefore all bounded harmonic functions are constant (weak Liouville property).

Proof. Let $u$ be a non-negative harmonic function. Then $v = u - \inf u$ is a non-negative harmonic function with $\inf v = 0$. By elliptic Harnack inequality, there exists $c \in (0, 1)$ and $C > 1$ such that $\sup_{B(x, cr)} u \leq C \inf_{B(x, cr)} u$ for all large enough $r$. Letting $r \to \infty$, we have $\sup_M v \leq 0$ which implies $v \equiv 0$. This proves strong Liouville property. The weak Liouville property follows from the observation that for any bounded harmonic function $h$, the function $h - \inf h$ is a non-negative harmonic function.

The following Hölder regularity-type estimate is a direct consequence of elliptic Harnack inequality. Our argument is an adaptation of Moser’s argument [61, Section 5] which uses an oscillation inequality.

Proposition 6.20. There exists $c \in (0, 1), \alpha > 0, C > 0$ and $r_1 > 0$ such that

\begin{equation}
|u(y) - u(z)| \leq C \left( \max \left( \frac{d(y, z)}{r} \right) \right)^\alpha \sup_{B(x, r)} u
\end{equation}

for all $y, z \in B(x, cr)$, for all $x \in M$, for all $r \geq r_1$ and for all non-negative functions $u : M \to \mathbb{R}$ that is $P$-harmonic on $B(x, r)$ with $B(x, r) \neq M$.

Proof. Let $c, r_0, C_E$ be constants from from Theorem 6.3. We optionally decrease the $c$ so that $c \leq 1/4$. Let $B = B(x, r)$ be an arbitrary ball with $r \geq r_0, B(x, r) \neq M$ and $y, z \in B(x, cr)$. Define a sequence of balls by

\[ s_i := c^{-1+i}r_1, \quad B_i := B(y, s_i) \]

for $i \in \mathbb{N}^*$, where $s_1 := \max(r_0, d(y, z) + h')$. Note that $B(y, h') \cup B(z, h') \subseteq B_1$. Choose $r_1 := 2 \max(h', r_0)$ so that $B_1 \subseteq B(x, r)$ for all $r \geq r_1$ and for all $y, z \in$
\( B(x, cr) \). Let \( r \geq r_1 \) and let \( k := \max \{ i \in \mathbb{N}^* : B_i \subset B \} \). Since \( B(x, r) \neq M \) there exists \( C_1 > 0 \) such that

\[
(6.88) \quad k \leq C_1 \log(r/s_1) + 1.
\]

Denote by \( M_i := \sup_{B_i} u \) and \( m_i := \inf_{B_i} u \) for \( i = 1, \ldots, k \), where \( u \) is an arbitrary non-negative function \( u : M \to \mathbb{R} \) that is \( P \)-harmonic on \( B(x, r) \). By elliptic Harnack inequality of Theorem 6.3, we have

\[
(6.89) \quad M_i - m_{i-1} = \sup_{B_i} (M_i - u) \leq C_E \inf_{B_i} (M_i - m_i) = C_E (M_i - M_{i-1}),
\]

\[
(6.90) \quad M_{i-1} - m_i = \sup_{B_i} (u - m_i) \leq C_E \inf_{B_i} (u - m_i) = C_E (m_{i-1} - m_i)
\]

for \( i = 2, 3, \ldots, k \). By adding (6.89) and (6.90), we obtain

\[
(6.91) \quad M_{i-1} - m_{i-1} \leq \frac{C_E - 1}{C_E + 1} (M_i - m_i)
\]

for \( i = 2, 3, \ldots, k \). Combining (6.91) along with (6.88), we obtain

\[
(6.92) \quad M_1 - m_1 \leq \left( \frac{C_E - 1}{C_E + 1} \right)^{k-1} (M_k - m_k) \leq \left( \frac{C_E - 1}{C_E + 1} \right) C_1 \log(r/s_1) \sup_{B(x, r)} u.
\]

Since \( u \) is \( P \)-harmonic in \( B(x, r) \), we have

\[
|u(y) - u(z)| = |P(y) - P(z)| \leq \sup_{B(y, h')} u - \inf_{B(y, h')} u \leq M_1 - m_1.
\]

The above inequality along with (6.92) implies (6.87).

Note that above result does not give Hölder continuity for harmonic functions which is in contrast to [61, Section 5]. However we will see that Proposition 6.20 is useful. In particular, we use Proposition 6.20 to prove Gaussian lower bounds in Chapter 8.
CHAPTER 7

Gaussian upper bounds

The goal of this chapter is to prove the following Gaussian upper bounds using Sobolev inequality. The results of this chapter rely only on \((VD)_{\text{loc}}\), \((VD)_{\infty}\) and the Sobolev inequality (5.2). We do not assume the Poincaré inequality \((P)_{h}\) to show Gaussian upper bounds. More precisely, we show

**Proposition 7.1.** Let \((M,d,\mu)\) be a quasi-\(b\)-geodesic metric measure space satisfying \((VD)_{\text{loc}}\) and \((VD)_{\infty}\). Suppose that a Markov operator \(P\) has a kernel \(p\) that is \((h,h')\)-compatible with \((M,d,\mu)\) for some \(h > b\). Further assume that \(P\) satisfies the Sobolev inequality (5.2). There exists \(C > 0\) such that

\[
 p_n(x,y) \leq \frac{C}{V(x,\sqrt{n})} \exp \left( -\frac{d(x,y)^2}{Cn} \right)
\]

for all \(x \in M\) and for all \(n \in \mathbb{N}_{\geq 2}\).

The first step is to obtain the following on-diagonal upper bound.

**Proposition 7.2.** Let \((M,d,\mu)\) be a quasi-\(b\)-geodesic metric measure space satisfying \((VD)_{\text{loc}}\) and \((VD)_{\infty}\). Suppose that a Markov operator \(P\) has a kernel \(p\) that is \((h,h')\)-compatible with \((M,d,\mu)\) for some \(h > b\). Further assume that \(P\) satisfies the Sobolev inequality (5.2). There exists \(C_0 > 0\) such that

\[
 p_n(x,x) \leq \frac{C}{V(x,\sqrt{n})}
\]

for all \(x \in M\) and for all \(n \in \mathbb{N}_{\geq 2}\).

A crucial ingredient in the proof of Proposition 7.2 is a \(L^1\) to \(L^\infty\) mean value inequality for the solutions of a heat equation. We again rely on Moser’s iterative method and the calculations are similar but more involved than those encountered in Section 6.5 for harmonic functions. The lazy walk defined in Example 4.5 will play an important role in this chapter. Recall that for a Markov operator \(P\), the corresponding ‘lazy’ versions of Markov operator and Laplacian are given by

\[
 P_L = (I + P)/2 \quad \text{and} \quad \Delta_L = \Delta/2 = (I - P)/2.
\]

For \(a, b \in \mathbb{N}\), we denote the integer intervals by

\[
 [a, b] := \{ i \in \mathbb{N} : a \leq i \leq b \}.
\]

The following definition is analogous to Definition 6.1. Caloric functions are solutions to heat equation.

**Definition 7.3.** Let \(P\) be a Markov operator on \((M,d,\mu)\) and let \(a, b \in \mathbb{N}\). A function \(u : \mathbb{N} \times M \to \mathbb{R}\) is \(P\)-caloric (respectively \(P_L\)-caloric) in \([a, b] \times B(x,r)\) if

\[
 \partial_k u(y) + \Delta u_k(y) = 0 \quad \text{(respectively } \partial_k u(y) + \Delta_L u_k(y) = 0)\]

for all \(x \in M, y \in B(x,r), k \in [a, b]. \)
for all $k \in [a, b]$ and for all $y \in B(x, r)$.

Similarly, we say a function $u : \mathbb{N} \times R \to R$ is $P$-subcaloric (resp. $P$-supercaloric) in $[a, b] \times B(x, r)$ if

$$\partial_k u(y) + \Delta u_k(y) \leq 0 \quad \text{(respectively} \geq 0)$$

for all $k \in [a, b]$ and for all $y \in B(x, r)$. Analogously, we define $P_L$-subcaloric and $P_L$-supercaloric functions simply by replacing $\Delta$ with $\Delta_L$ in the equation above.

**Remark 7.4.**

(a) We can restate the above definitions using $\partial_k u + \Delta u_k = u_{k+1} - Pu_k$ and $\partial_k u + \Delta_L u_k = u_{k+1} - P_L u_k$.

(b) Consider a Markov operator $P$ that is $(h, h')$-compatible with $(M, d, \mu)$. Similar to Remark 6.2(a), the property that $u : \mathbb{N} \times M \to \mathbb{R}$ is $P$-caloric (or $P_L$-caloric) in $[a, b] \times B(x, r)$ depends only on the value of $u$ in $[a, b+1] \times B(x, r+h')$. Therefore it suffices if the function $u$ has a domain that satisfies $[a, b+1] \times B(x, r+h') \subseteq \text{domain}(u)$.

Although our eventual goal is to prove parabolic Harnack inequality for $P$-caloric functions, the Moser’s iteration procedure is applied to $P_L$-caloric functions. The laziness is introduced to handle certain technical difficulties that arise due to discreteness of time. Another method to avoid these technical difficulties that arise due to discreteness of time is to carry out Moser’s iteration method for solutions of the continuous time heat equation $\frac{\partial u}{\partial t} + \Delta u = 0$ (See [27, Section 2] for this method on graphs).

In continuous time case the product rule of differentiation implies $\frac{\partial (u^2)}{\partial t} = 2u \frac{\partial u}{\partial t}$; however for discrete time the analogous formula is $\partial_k (u^2) = 2u_k \partial u_k + (\partial_k u)^2$. The ‘error term’ $(\partial_k u)^2$ due to discreteness of time is a source of difficulty in the proofs of Caccioppoli inequality and an integral maximum principle for $P$-caloric and $P$-subcaloric functions. However as we shall see, this ‘error term’ can be handled using a Cauchy-Schwarz inequality for $P_L$-caloric and $P_L$-subcaloric functions (See Remark 7.9). As a result, we will primarily be concerned with $P_L$-caloric and $P_L$-subcaloric functions for now. The assumption (d) in Definition 4.8 will allow to compare the random walks driven by $P$ and $P_L$.

As mentioned in the beginning of Chapter 5, we rely on a version of Sobolev inequality that is weaker than the ones assumed in previous works. This causes new difficulties for Moser’s iteration method which relied on a Sobolev inequality. The difficulty is even more significant in the parabolic case compared to that of the elliptic case in Chapter 6. This is because the difference between the strong (5.1) and weak (5.2) formulations of Sobolev inequalities is not significant for harmonic functions. To see why this might be true, note that if a function $u$ is $P$-harmonic in $B = B(x, r)$ then $P_B u = u$ in $B(x, r-h)$ and therefore the weaker formulation (5.2) yields an estimate that is close to that of (5.1). However the same cannot be said about $P$-caloric functions.

The following lemma and its proof is analogous to that of Lemma 6.12.

**Lemma 7.5.** Let $P$ be a Markov operator. Assume that the function $u : \mathbb{N} \times M \to \mathbb{R}_{\geq 0}$ is $P$-subcaloric in $[a, b] \times B(x, r)$ for some $x \in M$, $r > 0$ and $a, b \in \mathbb{N}$. Then $u^p$ is a $P$-subcaloric in $[a, b] \times B(x, r)$ for all $p \geq 1$. 
7.1. Mean value inequality for subcaloric functions

PROOF. Note that
\[ u^p_{k+1}(y) = (\partial_k u + u_k)^p(y) \leq (-\Delta u_k + u_k)^p = (Pu_k(y))^p \leq P(u_k^p)(y) \]
for all \((k, y) \in [a, b] \times B(x, r)\). The first inequality above follows from the fact that \(u\) is \(P\)-subcaloric in \([a, b] \times B(x, r)\) and the second follows from Jensen's inequality. \(\square\)

For a function \(f : N \times M \to \mathbb{R}\) and a Markov operator \(P\) on \(M\), we denote the function \(Pf : N \times M \to \mathbb{R}\)
\[ Pf(k, x) := (Pf(k, \cdot))(x) = (Pf_k)(x) \]
for all \(k \in N\) and for all \(x \in M\). We require the following property of subcaloric functions.

Lemma 7.6. Let \((M, d, \mu)\) be a metric measure space and let \(P\) be a Markov operator that is \((h, h')\)-compatible to \((M, d, \mu)\). If \(u : N \times M \to \mathbb{R}\) is \(P_L\)-subcaloric in \([a, b] \times B(x, r)\), then \(Pu\) is \(P_L\)-subcaloric in \([a, b] \times B(x, r - h')\) for all \(x \in M\) and for all \(r > h'\).

PROOF. If \((k, y) \in [a, b] \times B(x, r - h')\) and \(u : N \times M \to \mathbb{R}\) is \(P_L\)-subcaloric in \([a, b] \times B(x, r)\), then
\[ \frac{1}{(Pu)_k(y)} - \frac{1}{P_L(Pu)_k(y)} \leq P(\frac{u_{k+1}}{u_k} - \frac{Pu_{k+1}}{Pu_k})(y) \leq 0. \]
In the above equality, we used that \(P\) and \(P_L\) commute. The inequality follows from (4.10) and the fact that any Markov operator is positivity preserving. \(\square\)

7.1. Mean value inequality for subcaloric functions

We will prove the following mean value inequality in a weak form. The inequality bounds from above a weak version of \(L^1\) norm on a space-time cylinder by a weak version of \(L^1\) norm. Our version of the mean value inequality in Lemma 7.7 is weaker than the one known for graphs [19, Theorem 4.1] mainly because we rely on a weaker Sobolev-type inequality (5.2). Although the mean value inequality is weaker, we will obtain on-diagonal upper bounds using Lemma 7.7. Using an integral maximum principle argument, we will obtain Gaussian upper bounds in Chapter 7.

Lemma 7.7. Under the assumptions of Proposition 7.2, there exists constants \(C_1 > 0, n_1 > 0\) such that
\begin{equation}
\inf_{k \in [0, n]} \sup_{y \in B(x, \sqrt{n}/2)} \frac{P^2 \log \sqrt{n} + 2} u_k(y) \leq \frac{C_1}{\sqrt{x, \sqrt{n}}} \sup_{k \in [0, n]} \int_{B(x, \sqrt{n}/2)} u_k \, d\mu
\end{equation}
for all \(n \in \mathbb{N}\) satisfying \(n > n_1\), for all \(x \in M\), for all non-negative functions \(u : N \times M \to \mathbb{R}\) that is \(P_L\)-subcaloric in \([0, n] \times B(x, \sqrt{n})\).

The proof of Lemma 7.7 relies on Moser’s iteration procedure. Coifman and Grigor’yan [19, Section 4] obtained a similar (stronger) mean value inequality in the graph setting using an iteration procedure. However they relied on a Faber-Krahn inequality that is equivalent to the Sobolev inequality (5.1) and therefore does not hold for discrete time Markov chains on continuous spaces.

In this section, we carry out Moser’s iteration procedure for subcaloric functions relying on the weaker Sobolev inequality (5.2). To prove the elementary iterative

\footnote{weaker’ compared to Sobolev inequalities in [69, 70, 76, 25, 27, 45].}
step of iteration, we need the following discrete Caccioppoli inequality. The proof is an adaptation [19, Proposition 4.5]. The next two Lemmas together may be regarded as the parabolic version of Lemma 6.13.

**Lemma 7.8 (Caccioppoli inequality).** Under the assumptions on Proposition 7.2, we have

\[
\int_M \partial_k (u^2) \psi^2 \, d\mu + \frac{1}{8} \mathcal{E}(u_k \psi, u_k \psi) \leq \frac{17}{8} \int_M \int_M |\nabla_{yz} \psi|^2 u_k^2(y) p_1(y, z) \, dy \, dz
\]

for all \( x \in M \), for all \( r > 0 \), for all non-negative functions \( \psi : M \to \mathbb{R}_{\geq 0} \) satisfying \( \text{supp}(\psi) \subseteq B(x, r) \), for all \( a, b \in \mathbb{N} \), for all \( k \in [a, b] \) and for all non-negative functions \( u : \mathbb{N} \times M \to \mathbb{R}_{\geq 0} \) such that \( u \) is \( P_L \)-subcaloric in \([a, b] \times B(x, r)\).

**Proof.** Fix \( x \in M, r > h' \) and define \( B := B(x, r + h') \). Let \( u : \mathbb{N} \times M \to \mathbb{R}_{\geq 0} \) be such that \( u \) is \( P_L \)-subcaloric in \([a, b] \times B(x, r)\). We start with the elementary inequality

\[
\partial_k (u^2)(y) \leq -u_k(y) \Delta u_k(y) + \frac{1}{4} (\Delta u_k(y))^2
\]

for all \((k, y) \in [a, b] \times B(x, r)\), as we now show. Since \( u \) is \( P_L \)-subcaloric in \([a, b] \times B(x, r)\), we have \( u_{k+1}(y) \leq P_L u_k(y) \) for all \((k, y) \in [a, b] \times B(x, r)\). Combined with the fact that \( u \) is non-negative, we have \( u_{k+1}^2(y) \leq (P_L u_k(y))^2 \) for all \((k, y) \in [a, b] \times B(x, r)\) which can be rearranged into (7.6).

Let \((k, y) \in [a, b] \times B(x, r)\). Recall that \( B = B(x, r + h') \). Using (7.6), integration by parts (6.31) and \( \text{supp}(\psi) \subseteq B(x, r) \), we have

\[
\int_B \psi^2 \partial_k (u^2) \, d\mu \leq -\frac{1}{2} \int_B \int_B (\nabla_{yz} u_k) (\nabla_{yz} (u_k \psi^2)) \, p_1(y, z) \, dy \, dz + \frac{1}{4} \int_B (\Delta u_k(y))^2 \psi^2(y) \, dy.
\]

The second term in (7.7) can be handled using Cauchy-Schwarz inequality as

\[
(\Delta u_k(y))^2 = \left( -\int_M (\nabla_{yz} u_k) p_1(y, z) \, dz \right)^2 \leq \left( \int_M p_1(y, z) \, dz \right) \left( \int_M (\nabla_{yz} u_k)^2 p_1(y, z) \, dz \right) = \int_M (\nabla_{yz} u_k^2) p_1(y, z) \, dz.
\]

For the first term in (7.7), we use product rule (6.27)

\[
\nabla_{yz} (u_k \psi^2) = u_k(z) \nabla_{yz} \psi^2 + \psi^2(y) \nabla_{yz} u_k.
\]

Combining (7.7), (7.8) and (7.9), we have

\[
\int_B \psi^2(y) \partial_k (u^2)(y) \, dy + \frac{1}{4} \int_B \int_B (\nabla_{yz} u_k)^2 \psi^2(y) p_1(y, z) \, dy \, dz \\
\leq -\frac{1}{2} \int_B \int_B u_k(z) (\nabla_{yz} \psi^2) (\nabla_{yz} u_k) p_1(y, z) \, dy \, dz.
\]
The right side of (7.10) can be bounded using \( t_1 t_2 \leq t_1^2/8 + 2t_2^2 \) as
\[
\begin{aligned}
- u_k(z) \left( \nabla_y \psi^2 \right) (\nabla_y u_k) &\leq u_k(z) \psi(y) (\nabla_y \psi) \left( \nabla_y u_k \right) \\
&\quad + u_k(z) \psi(z) \left( \nabla_y \psi \right) (\nabla_y u_k) \\
&\leq \frac{1}{8}(\psi^2(y) + \psi^2(z)) (\nabla_y u_k)^2 \\
&\quad + 4u_k^2(z) |\nabla_y \psi|^2.
\end{aligned}
\]
(7.11)

Using \( p_1(y, z) = p_1(z, y) \) for \( \mu \times \mu \)-almost every \((y, z)\), we obtain
\[
\int_B \int_B \psi^2(y) (\nabla_y u_k)^2 p_1(y, z) \, dy \, dz = \int_B \int_B \psi^2(z) (\nabla_y u_k)^2 p_1(y, z) \, dy \, dz.
\]
Combining (7.10), (7.11) and (7.12), we deduce
\[
\begin{aligned}
\int_B \psi^2(y) \partial_k (u^2)(y) \, dy &+ \frac{1}{8} \int_B \int_B (\nabla_y u_k)^2 \psi^2(y) p_1(y, z) \, dy \, dz \\
&\leq 2 \int_B \int_B u_k^2(z) (\nabla_y \psi)^2 p_1(y, z) \, dy \, dz.
\end{aligned}
\]
(7.13)

Since \( \text{supp}(\psi) \subseteq B(x_0, r - h') \), using integration by parts (6.31) we have
\[
(\psi u_k, \psi u_k) = \frac{1}{2} \int_B \int_B |\nabla_y (u_k \psi)|^2 p_1(y, z) \, dy \, dz.
\]
(7.14)

Using product rule (6.27) and the inequality \((t_1 + t_2)^2 \leq 2(t_1^2 + t_2^2)\), we obtain
\[
|\nabla_y (u_k \psi)|^2 = |\psi(y)(\nabla_y u_k) + u_k(z)(\nabla_y \psi)|^2 \\
\leq 2 (\psi^2(y)(\nabla_y u_k)^2 + u_k^2(z)(\nabla_y \psi)^2).
\]
(7.15)

Combining (7.13), (7.14), (7.15) and \( \mu \times \mu \)-almost everywhere symmetry of \( p_1 \) yields (7.5).

Remark 7.9. Recall the product rule of differentiation \( \partial_k (u^2) = 2u_k \partial_k u + (\partial_k u)^2 \) gives rise to the ‘error term’ \( (\partial_k u)^2 \) which occurs due to discreteness of time. This error term occurs in (7.7) and is controlled using Cauchy-Schwarz inequality in (7.8). However the estimate given by (7.8) is sufficient to prove Caccioppoli inequality only in the presence of some laziness. A similar difficulty arises in the proof of discrete integral maximum principle and is the reason behind considering the operator \( P_L \) as opposed to \( P \) in this section.

Next, we prove the elementary iterative step of Moser’s iteration in parabolic setting. The proof relies on Caccioppoli inequality (7.5) and Sobolev inequality (5.2). Let \( \mu_c \) denote the counting measure on \( \mathbb{N} \) and let \((M, d, \mu)\) be a metric measure space. We denote the product measure on \( \mathbb{N} \times M \) by \( \tilde{\mu} := \mu_c \times \mu \). Similar to (6.2), we define
\[
\tilde{\phi}(u, p, Q) := \left( \frac{1}{\tilde{\mu}(Q)} \int_Q u^p \, d\tilde{\mu} \right)^{1/p}
\]
for all \( p > 0 \), for all \( Q \subseteq \mathbb{N} \times M \) and for all functions \( u : \mathbb{N} \times M \to \mathbb{R}_{\geq 0} \).
Lemma 7.10. Under the assumptions of Proposition 7.2, for all $K_1 \geq 1$, there exists $C_1 > 0, r_1 > 0$ (depending on $K_1$) such that

$$
\tilde{\phi}(Pu, 2 + (4/\delta), [(1 - \sigma^2)a_0 + \sigma^2a_1], a_1) \leq C_1\sigma^{-1}\tilde{\phi}(u, 2, [a_0, a_1] \times B(x, (1 - \sigma)r - h'))
$$

(7.17)

for all $\sigma \in (0, 1/2)$, for all $x \in M$, for all $r \geq r_1$, for all $a_0, a_1 \in \mathbb{N}$ satisfying $K_1^{-1}r^2 \leq a_2 - a_1 \leq K_1r^2$ and for all non-negative functions $u : \mathbb{N} \times M \to \mathbb{R}_{\geq 0}$ such that $u$ is $P_L$-subcaloric in $[a_0, a_1] \times B(x, r)$.

Proof. Let $x \in M$, $\sigma \in (0, 1/2)$ and let $r > r_1 \geq 4h'$, where $r_1$ will be determined later. Let $u$ be a non-negative function that is $P_L$-subcaloric in $[a_0, a_1] \times B(x, r)$.

We start by defining appropriate cut-off functions in space and time. Define $B := B(x, r + h')$ and $\psi : M \to \mathbb{R}_{\geq 0}$ as

$$
\psi_\sigma(y) := \max\left(0, \min\left(1, \frac{r - d(x, y)}{\sigma r}\right)\right).
$$

Note that $\text{supp}(\psi_\sigma) \subseteq B(x, r)$ and $\psi \equiv 1$ on $B(x, (1 - \sigma)r)$. Define $a_\sigma := [(1 - \sigma^2)a_0 + \sigma^2a_1]$ and $\chi : \mathbb{N} \to \mathbb{R}$ as

$$
\chi_\sigma(k) = \begin{cases} 
1 & \text{if } k \geq a_\sigma \\
0 & \text{if } k < a_\sigma \\
\frac{k-a_0}{a_\sigma-a_0} & \text{otherwise.} 
\end{cases}
$$

Since $u$ is non-negative and $P_L$-subcaloric in $[a_0, a_1] \times B(x, r)$, by Caccioppoli inequality (Lemma 7.8) and product rule (6.29), we obtain

$$
\int_B (\partial_k(\chi_\sigma u)^2) \psi_\sigma^2 d\mu + \frac{\chi_\sigma^2(k+1)}{8} \mathcal{E}^B(\psi_\sigma u_k, \psi_\sigma u_k)
$$

(7.18)

$$
\leq \frac{17}{8} \chi_\sigma^2(k+1) \int_B |\nabla_{yz}\psi_\sigma|^2 u_k^2(y) p_1(y, z) dy dz + \partial_k \chi_\sigma \int_B u_k^2 \psi_\sigma^2 d\mu
$$

for all $k \in [a, b]$. Since $p_1$ is $(h, h')$-compatible with $(M, d, \mu)$, we have

$$
|\nabla_{yz}\psi|^2 p_1(y, z) \leq \frac{(h')^2}{(\sigma r)^2} p_1(y, z).
$$

(7.19)

We use product rule (6.29), triangle inequality, $\chi_\sigma \leq 1$ and $a_\sigma - a_0 \geq \sigma^2(a_1 - a_0) \geq \sigma^2 K_1^{-1}r^2$ to deduce

$$
|\partial_k \chi_\sigma^2| \leq (\chi_\sigma(k+1) + \chi_\sigma(k))|\partial_k \chi_\sigma| \leq 2|\partial_k \chi_\sigma| \leq \frac{2}{(a_\sigma - a_0)} \leq \frac{2K_1}{\sigma^2 r^2}
$$

(7.20)

Combining (7.18), (7.19) and (7.20), there exists $C_2 > 0$ such that

$$
\int_B \psi_\sigma^2 (\partial_k(\chi_\sigma u)^2) d\mu + \frac{\chi_\sigma^2(k+1)}{8} \mathcal{E}^B(\psi_\sigma u_k, \psi_\sigma u_k) \leq \frac{C_2}{\sigma^2 r^2} \int_B u_k^2 d\mu
$$

(7.21)

for all $k \in [a_0, a_1]$. In (7.21), $C_2$ depends only on $K_1$ and $h'$. 

Adding (7.21), from \( k = a_0 \) to \( k \in [a_0, a_1] \), yields

\[
\sup_{k \in [a_\sigma, a_1]} \int_B \psi^2 \sigma_k^2 \, d\mu \leq \frac{C_2}{\sigma^2 r^2} \sum_{k=a_0}^{a_1} \int_B \sigma_k^2 \, d\mu \tag{7.22}
\]

\[
\sum_{k=a_\sigma}^{a_1} \mathcal{E}(\psi, \sigma_k u_k, \psi, u_k) \leq \frac{8C_2}{\sigma^2 r^2} \sum_{k=a_0}^{a_1} \int_B \sigma_k^2 \, d\mu. \tag{7.23}
\]

Define \( w_k := P_B(\psi, u_k) \). Since \( \psi \equiv 1 \) on \( B(x, (1-\sigma)r) \), by (4.10) \( w_k = P_B(\psi, u_k) = Pu_k \) on \( B(x, (1-\sigma)r - h') \). Combined with Hölder inequality, we have

\[
\int_{B(x, (1-\sigma)r - h')} (P_B u_k)^{2(1+\gamma/\delta)} \, d\mu \leq \left( \int_B w_k^2 \, d\mu \right)^{2/\delta} \left( \int_B w_k^{2\gamma/(\delta-2)} \, d\mu \right)^{\gamma/(\delta-2)/\delta}. \tag{7.24}
\]

Since \( P_B \) is a contraction in \( L^2(B) \), we have

\[
\int_B w_k^2 \, d\mu \leq \int_B \psi^2 \sigma_k^2 \, d\mu. \tag{7.25}
\]

By Sobolev inequality (5.2), Lemma 4.22(a) and (4.10), we obtain

\[
\left( \int_B w_k^{2\gamma/(\delta-2)} \, d\mu \right)^{(\gamma/(\delta-2)/\delta)} \leq \frac{C_{sr^2}}{V(x, r)^{2/\delta}} \left( \mathcal{E}(\psi, u_k, \psi, u_k) + r^{-2} \int_B \psi^2 \sigma_k^2 \, d\mu \right). \tag{7.26}
\]

By (7.22), (7.23), (7.24), (7.25), (7.26) and \( a_1 - a_0 \leq K_1 r^2 \), there exists \( C_3 > 0 \) such that

\[
\sum_{k=a_\sigma}^{a_1} \int_{B(x, (1-\sigma)r - h')} (P_B u_k)^{2(1+\gamma/\delta)} \, d\mu \leq \frac{C_{sr^2}}{V(x, r)^{2/\delta}} \left( (r\sigma)^{-2} \sum_{k=a_0}^{a_1} \int_B \sigma_k^2 \, d\mu \right)^{1+\gamma/\delta}. \tag{7.27}
\]

We choose \( r_1 \geq 4h' \) so that \( a_\sigma \leq a_1/2 \leq (a_0 + a_1)/2 \) for all \( a_0, a_1 \in \mathbb{N} \) so that \( a_1 - a_0 \geq K_1^{-1} r^2 \). Since \( r \geq 4h' \) and \( \sigma < 1/2 \), we have \((1-\sigma)r - h' \geq (r/2) - h' \geq r/4 \). Hence by (2.4), \( K_1^{-1} r^2 \leq a_1 - a_0 \leq K_1 r^2 \) along with (7.27), we have (7.17). \( \square \)

**Proof of Lemma 7.7.** We carry out Moser’s iteration in two stages. In the first stage of the iteration, we obtain a \( L^1 \) to \( L^2 \) mean value inequality and in the second stage we show a \( L^2 \) to \( L^\infty \) mean value inequality. Combining the two stages yields the desired \( L^1 \) to \( L^\infty \) mean value inequality. The proof relies on repeated application of the elementary iterative step given by Lemma 7.10.

Let \( r_1(0) := \sqrt{n} + h' \), \( a_1(0) := 0 \), \( N := \lceil \log \sqrt{n} \rceil \) and \( \theta := 1 + (2/\delta) \). For the first stage of iteration, we iteratively define the quantities

\[
r_1(i+1) := (r_1(i) - h') \left( 1 - \frac{4^{-1}}{3^{N+1-t}} \right) - h'
\]

\[
a_1(i+1) := \left[ 1 - \frac{4^{-2}}{9^{N+1-t}} \right] a_1(i) + \frac{4^{-2}}{9^{N+1-t}} n
\]

for \( i = 0, 1, \ldots, N \). We define a non-increasing sequence of space-time cylinders

\[
Q_i(i) = [a_1(i), n] \times B(x, r_i), \quad \text{for } i = 0, 1, \ldots, N + 1.
\]
The following estimates are straightforward from definitions of \( r_1 \) and \( a_1 \): There exists \( n_0 > 0 \) such that for all \( n \geq n_0 \), we have

\[
\begin{align*}
n(n + 1) & \geq \sqrt{n} \left( 1 - 4^{-1} \sum_{j=1}^{N+n} \right) - 2(\log \sqrt{n} + 3 + h') \\
& \geq (7/8)\sqrt{n} - 2(\log \sqrt{n} + 3 + h') \geq (6/7)\sqrt{n}, \\
n - a_1(n + 1) & \geq n \left( 1 - 4^{-2} \sum_{j=1}^{N+n} 9^{-j} \right) - 2(N + 1) \\
& \geq (31/32)n - 2(\log \sqrt{n} + 2) \geq (15/16)n.
\end{align*}
\]

Let \( u : \mathbb{N} \times M \to \mathbb{R}_{\geq 0} \) be an arbitrary non-negative function that is \( P_L \)-subcaloric in \([0, n] \times B(x, \sqrt{n})\) where \( n \geq n_1 \). By Lemma 7.6 \( P^u \) is \( P_L \)-subcaloric in \([0, n] \times B(x, \sqrt{n} - i\hbar')\) and therefore \( P_L \)-subcaloric in \([a_i(i), n] \times B(x, r_i(i) - h')\) for all \( i = 0, 1, \ldots, N + 1 \). Hence by applying Lemma 7.10 for the function \( P^u \) which is \( P_L \)-subcaloric on \([a_i(i), n] \times B(x, r_i(i) - h')\) with \( \sigma = 4^{-1}3^{-1} \), we have \( C_2 > 0 \) such that

\[
\phi(P^{i+1}u, 2\theta, Q_{i+1}) \leq C_23^{N+1-i}\phi(P^iu, 2, Q_i)
\]

for all \( i = 0, 1, \ldots, N \). We may choose \( K_1 = 8 \) in the application of Lemma 7.10 above due to (7.28) and (7.29).

By Hölder inequality along with (7.28), (7.29) and (2.4), there exists \( C_3 > 0 \) such that

\[
\phi(P^{i+1}u, 2, Q_1(i + 1)) \leq C_3\phi(P^{i+1}u, 1, Q_1(i + 1))\phi(P^{i+1}u, 2\theta, Q_1(i + 1))^{\beta}
\]

for all \( i = 1, 2, \ldots, N \), where \( \alpha = 1 - \beta = 2/(\delta + 4) \). By (4.10), \( u \geq 0 \), (7.28),(7.29) and (2.4), there exists \( C_4 > 0 \) such that

\[
\phi(P^iu, 1, Q_1(i)) \leq C_4\phi(u, 1, Q_1(0))
\]

for all \( i = 0, 1, \ldots, N + 1 \). Combining (7.30), (7.31), (7.32), there exists \( C_5 > 0 \) such that

\[
\phi(P^{i+1}u, 2, Q_1(i + 1)) \leq C_53^{\beta(N+1-i)}\phi(u, 1, Q_1(0))^{\alpha}\phi(P^iu, 2, Q_1(i))^{\beta}
\]

for \( i = 1, \ldots, N \). By iterating (7.33), we obtain

\[
\phi(P^{N+1}u, 2, Q_1(N + 1)) \leq C_5^{\sum_{i=0}^{N}\beta^i}3^{\sum_{i=1}^{N}i\beta^i}\phi(u, 1, Q_1(0))^{(1-\beta^N)}\phi(P^u, 2, Q_1(1))^{\beta^N}.
\]

Since \( u \geq 0 \), by Hölder inequality, (4.10) and (2.4), there exists \( C_6, C_7 > 0 \) such that

\[
\int_{B(x, r_1(1))} (Pu)_i^2 \, d\mu \leq \left( \sup_{B(x, r_1(1))} Pu_i \right)^2 \int_{B(x, r_1(1))} Pu_i \, d\mu
\]

\[
\leq \left( \int_{B(x, \sqrt{n} + h')} u_i \, d\mu \right)^2 \sup_{y \in B(x, \sqrt{n})} \frac{C_5}{V(x, h')}
\]

\[
\leq \frac{C_7n^{\delta/2}}{V(x, \sqrt{n})} \left( \sup_{i \in [0, n]} \int_{B(x, \sqrt{n} + h')} u_i \, d\mu \right)^2
\]

(7.35)
for all $i \in [0, n]$. Combining (7.34), (7.35) along with (2.4) yields

$$\tilde{\phi}(P^{N+1}u, 2, Q_1(N + 1)) \leq \frac{C_8}{V(x, \sqrt{n})} \sup_{k \in [0, n]} \int_{B(x, \sqrt{n+1})} u_k \, d\mu$$

for some $C_8 > 0$. The inequality (7.36) is a $L^1$ to $L^2$ mean value inequality and this concludes the first part of iteration.

For the second part, we define $v = P^{N+1}u$, $a_2(0) = a_1(N + 1)$ and $r_2(0) = r_1(N + 1)$. As before, we iteratively define

$$r_2(i + 1) := (r_2(i) - h') \left(1 - \frac{4^{-1}}{3^{i+1}}\right) - h',$$
$$a_2(i + 1) := \left[\left(1 - \frac{4^{-2}}{9^{i+1}}\right) a_2(i) + \frac{4^{-2}}{9^{i+1}} n\right]$$

for $i = 1, 2, \ldots, N + 1$. As before, define a non-increasing sequence of space-time cylinders by $Q_2(i) := \{a_2(i), n\} \times B(x, r_2(i))$ for $i = 0, 1, \ldots, n$. Note that $Q_2(0) = Q_1(N + 1)$.

Similar to (7.28) and (7.29), there exists $n_1 \geq n_0$ such that for all $n \geq n_1$,

$$r_2(i) \geq r_2(N + 1) \geq \sqrt{n}/2$$
$$n - a_2(i) \geq n - a_2(N + 1) \geq n/2$$

for all $i = 0, 1, \ldots, N + 1$. By Jensen’s inequality, we have

$$\left((P^{i+1}v)^{\theta+1}\right)^\theta \leq \left(P \left[\left((P^iv)^\theta\right)^\theta\right]\right)^\theta$$

for all $i \in \mathbb{N}$. By Lemma 7.6 and Lemma 7.5, the function $(P^iv)^\theta$ is $P_L$-subcaloric in $[a_2(i), n] \times B(x, r_2(i) - h)$ for all $i = 0, 1, \ldots, N + 1$. Therefore by Lemma 7.10 for the function $(P^iv)^\theta$ and (7.39), there exists $C_9 > 0$ such that

$$\tilde{\phi}(P^{i+1}v, 2^{i+1}, Q_2(i+1)) \leq C_9^{\theta^{-i}} 3^{(i+1)\theta^{-i}} \tilde{\phi}(P^iv, 2^i, Q_2(i))$$

for $i = 0, 1, \ldots, N - 1$. Iterating the inequalities (7.40), there exists $C_{10} > 0$ such that

$$\tilde{\phi}(P^Nv, 2^N, Q_2(N)) \leq C_{10} \tilde{\phi}(v, 2, Q_2(0)) = C_{10} \tilde{\phi}(v, 2, Q_1(N + 1)).$$

There exists $C_{11}, C_{12}, C_{13} > 0$ such that, for all $k \in N$

$$\sup_{y \in B(x, r_2(N + 1))} P^{N+1}v_k(y) \leq C_{11} \left(\int_{B(y, h')} (P^N v_k)^{2^N} d\mu\right)^{1/(2^N)}$$
$$\leq C_{11} \left(\int_{B(y, h')} \frac{(P^N v_k)^{2^N} d\mu}{(P^N v_k)^{2^N} d\mu}\right)^{1/(2^N)}$$
$$\leq C_{12} h^{\delta/(4^N)} \left(\int_{B(x, r_2(N))} (P^N v_k)^{2^N} d\mu\right)^{1/(2^N)}$$
$$\leq C_{13} \left(\int_{B(x, r_2(N))} (P^N v_k)^{2^N} d\mu\right)^{1/(2^N)}$$

The first line above follows from (4.10), the second line follows from Jensen’s inequality, the third line follows from (2.4) and the last line follows from the fact that
\( n \mapsto n^{\frac{\delta}{4(\log n)}} \) is bounded in \([2, \infty)\). By (7.41), (7.42) and \( v = P^{N+1}u \), we have a \( L^2 \) to \( L^\infty \) mean value inequality

\[
\inf_{k \in [0, n]} \sup_{B(x, r/(N+1))} P^{2N+2}u \leq C_{10} C_{13} \phi(P^{N+1}u, 2, Q_1(N + 1)).
\]

Combining (7.36) and (7.43), we have the desired inequality (7.4).

### 7.2. On-diagonal upper bound

The following lemma provides a useful example of \( P_L \)-caloric function.

**Lemma 7.11.** Let \((M, d, \mu)\) be a metric measure space. Let \( P \) be Markov operator equipped with kernel \((p_k)_{k \in \mathbb{N}}\) that is \((h, h')\)-compatible with \((M, d, \mu)\). Define for all \( k \in \mathbb{N} \), the function \( h_k : M \times M \to \mathbb{R} \) by

\[
h_k(x, y) := \left( P_k^L p_2(x, \cdot) \right)(y) = 2^{-n} \sum_{i=0}^{n} \binom{n}{i} p_{i+2}(x, y)
\]

where \( P_L = (I + P)/2 \) as before. Then for all \( x \in M \), the function

\[
(k, y) \mapsto h_k(x, y)
\]

is \( P_L \)-caloric in \( \mathbb{N} \times M \).

**Proof.** The second equality in (7.44) is a consequence of binomial theorem and Lemma 4.2(c). Note that

\[
P_L(h_k(x, \cdot))(y) = P_L(P_k^L p_2(x, \cdot))(y) = P_k^L(p_2(x, \cdot))(y) = h_{k+1}(x, y).
\]

Therefore \((k, y) \mapsto h_k(x, y)\) is \( P_L \)-caloric in \( \mathbb{N} \times M \) for all \( x \in M \).

We are ready to prove Proposition 7.2 using the mean value inequality (7.4).

**Proof of Proposition 7.2.** Let \( h_k(x, y) \) be defined as (7.44). Choose \( n_1 \in \mathbb{N} \) such that

\[
2[\log \sqrt{n}] + 4 \leq n
\]

for all \( n \geq n_1 \). By Lemma 7.7, Lemma 7.11 and \( \int_M h_k(x, y) \, d\mu = 1 \), there exists \( n_2 \geq n_1 \) and \( C_1 > 0 \) such that the \( P_L \)-caloric function \((k, y) \mapsto h_k(x, y)\) satisfies the mean value inequality

\[
\inf_{k \in [0, n]} P^{2[\log \sqrt{n]} + 2} h_k(x, x) \leq \inf_{k \in [0, n]} \sup_{y \in B(x, \sqrt{n}/2)} P^{2[\log \sqrt{n]} + 2} h_k(x, y) \leq \frac{C_1}{V(x, \sqrt{n})}
\]

for all \( x \in M \) and for all \( n \in \mathbb{N} \) satisfying \( n \geq n_2 \).

By (4.11), we have \( p_2(x, \cdot) - \alpha p_1(x, \cdot) \geq 0 \) \( \mu \)-almost everywhere for each \( x \in M \). By (4.12) of Lemma 4.10 and Lemma 4.7, we have

\[
p_k(x, x) \leq \alpha^{-1} p_{2[k/2]}(x, x) \leq \alpha^{-1} p_{2[k/2]}(x, x) \geq \alpha^{-1} p_{2n}(x, x)
\]

for all \( x \in M \) and for all \( 2 \leq k \leq 2n \). By (7.47) and (7.45),

\[
P^{2[\log \sqrt{n]} + 2} h_k(x, x) \geq \alpha^{-1} p_{2n}(x, x)
\]

for all \( x \in M \), for all \( k \in [0, n] \) and for all \( n \geq n_2 \). Combining (7.48), (4.12), (7.44) and (7.46), there exists \( C_2 > 0 \) such that

\[
p_n(x, x) \leq \frac{C_2}{V(x, \sqrt{n})}
\]
for all \( n \geq 2n^2 \). Since \( P \) is a contraction in \( L^\infty \) by (4.10), Lemma 4.2(c) and (2.4), there exists \( C_3, C_4 > 0 \) and \( \delta > 2 \) such that

\[
(7.50) \quad p_n(x, x) \leq \frac{C_3}{V(x, h')} \leq \frac{C_4 n^{\delta/2}}{V(x, \sqrt{n})}
\]

for all \( x \in M \) and for all \( n \in \mathbb{N} \) with \( n \geq 2 \). Combining (7.49) and (7.50) gives the diagonal bound (7.2).

\[\square\]

### 7.3. Discrete integral maximum principle

We use Discrete integral maximum principle and diagonal upper bound to obtain Gaussian upper bounds. This approach is detailed in [20] for graphs. A crucial assumption in [20] is the laziness assumption for the corresponding Markov chain \((X_n)_{n \in \mathbb{N}}\) given by \( \inf_{x \in M} P_x(X_1 = x) > 0 \). As explained in [20, Section 3] this laziness assumption is not too restrictive for graphs because under natural conditions the iterated operator \( P^2 \) corresponds to a lazy Markov chain. However this fails to be true for continuous spaces.

Since the laziness assumption is unavoidable for discrete integral maximum principle, we consider the Markov operator \( P_L = (I + P)/2 \) instead of \( P \). Using discrete integral maximum principle corresponding to \( P_L \) and diagonal estimate on \( p_k \), we obtain off-diagonal estimates on \( h_k \) defined in (7.44). We rely on careful comparison between off-diagonal estimates of \( h_k \) and the Markov kernel \( p_k \). The comparison arguments are new but elementary and involves Stirling's approximation. Our comparison arguments rely crucially on the compatibility assumption (4.11). Similar comparison arguments for off-diagonal estimates was carried out in [27, Section 3.2] to compare Markov chains on graphs with its corresponding continuous time version.

The main technical tool to prove Gaussian upper bounds is the following discrete integral maximum principle. The statement below and its proof is adapted from [20, Proposition 2.1].

**Proposition 7.12 (Discrete integral maximum principle).** Suppose that \( P \) is a Markov operator that is \((h, h')\)-compatible with a metric measure space \((M, d, \mu)\). Let \( f \) be a strictly positive continuous function on \([0, n - 1] \times M\) such that,

\[
(7.51) \quad \partial_k f(x) + \frac{\nabla P f_{k+1}^2}{4f_{k+1}}(x) \leq 0.
\]

for all \( x \in M \) and \( k \in [0, n - 1] \) where \( \nabla P f \) is as defined in (6.32). Let \( u : \mathbb{N} \times M \to \mathbb{R} \) bounded function that is \( P_L \)-caloric on \([0, n - 1] \times M\) satisfying \( \text{supp}(u_0) \subset B(w, R) \) for some \( w \in M, R \in (0, \infty) \). Then the function

\[
k \mapsto J_k = J_k(u) := \int_M u_k^2 f_k \, d\mu
\]

is non-increasing in \([0, n]\).

**Proof.** Since \( \text{supp}(u_0) \subset B(w, R) \), by (4.10) \( \text{supp}(u_k) \subset B(w, R + kh') \). Therefore by continuity of \( f_k \) and boundedness of \( u \) all the integrals \( J_k \) are finite.
By product rule (6.29), (6.30) and $\partial_k u = -\Delta u_k/2$, we have for all $k \in [0, n-1]$

$$
\partial_k J(u) = \int_M \partial_k (u^2 f) \, d\mu \\
= 2 \int_M u_k \partial_k u f_{k+1} \, d\mu + \int_M (\partial_k u)^2 f_{k+1} \, d\mu + \int_M u_k^2 \partial_k f \, d\mu
$$

Using integration by parts (6.31) and product rule (6.27), the first term in (7.52) is

$$
- \int_M u_k f_{k+1} \Delta u_k \, d\mu
$$

and

$$
= -\frac{1}{2} \int_M \int_M (\nabla_{xy} u_k) \nabla_{xy} (u_k f_{k+1}) p_1(x, y) \, dy \, dx
$$

In order to get the last equation we switch $x$ and $y$ and use the fact that $p_1(x, y) = p_1(y, x)$ for $\mu \times \mu$-almost every $(x, y)$. To handle the second term in (7.52), we use $\partial_k u = -\Delta u_k/2$ (7.8) to obtain

$$
\int_M (\partial_k u)^2 f_{k+1} \, d\mu \leq \frac{1}{4} \int_M (\nabla_{xy} u_k)^2 f_{k+1} \, p_1(x, y) \, dy \, dx
$$

for all $k \in [0, n-1]$. Substituting (7.53) and (7.54) in (7.52), we deduce

$$
\partial_k J(u) \leq -\frac{1}{4} \int_M \int_M (\nabla_{xy} u_k)^2 f_{k+1} \, p_1(x, y) \, dy \, dx + \int_M u_k^2 \partial_k f(x) \, dx
$$

and

$$
= -\frac{1}{4} \int_M \int_M \left( \nabla_{xy} u_k \sqrt{f_{k+1}(x)} + \frac{u_k(x)}{\sqrt{f_{k+1}(x)}} \nabla_{xy} f_{k+1} \right)^2 p_1(x, y) \, dy \, dx
$$

The given condition (7.51) ensures that $\partial_k J \leq 0$, that is $J_{k+1} \leq J_k$ for all $k \in [0, n-1]$.

The following lemma essentially follow from [20, Proposition 2.5]. We repeat the proof for completeness. Lemma 7.13 provides a weight function $f$ that will be used in the application of discrete integral maximum principle.

**Lemma 7.13.** Let $(M, d, \mu)$ be a metric measure space and let $P$ be a Markov operator that is $(h, h')$-compatible with $(M, d, \mu)$. Let $\sigma : M \to \mathbb{R}$ be a 1-Lipschitz function such that $\inf \sigma \geq h'$. There exists a positive number $D_1$ such that for all $D \geq D_1$, the weight function

$$
f_k(x) = f_k^D(x) := \exp \left( -\frac{\sigma^2(x)}{D(n+1-k)} \right)
$$
for all \( x \in M \), for all \( n \in \mathbb{N}^+ \) and \( k \in [0, n-1] \).

**Proof.** Note that

\[
-\partial_k f(x) = \left( \exp \left( \frac{\sigma^2(x)}{D(n+1-k)(n-k)} \right) - 1 \right) f_{k+1}(x)
\]

(7.56)

\[
\geq \left( \exp \left( \frac{\sigma^2(x)}{2D(n-k)^2} \right) - 1 \right) f_{k+1}(x)
\]

and

\[
\nabla_P f_{k+1}(x)^2 = \int_M p_1(x, y) \left( \exp \left( -\frac{\sigma^2(y)}{D(n-k)} \right) - \exp \left( -\frac{\sigma^2(x)}{D(n-k)} \right) \right)^2 dy
\]

\[
= f_{k+1}^2(x) \int_M p_1(x, y) \left( \exp \left( \frac{\sigma^2(x) - \sigma^2(y)}{D(n-k)} \right) - 1 \right)^2 dy
\]

for all \( k \in [0, n-1] \). By the Lipschitz condition and the hypothesis \( \sigma(x) \geq 1 \), we have

\[
|\sigma^2(x) - \sigma^2(y)| = |\sigma(x) - \sigma(y)||\sigma(x) + \sigma(y)| \leq 2h'\sigma(x) + (h')^2 \leq 3h'\sigma(x)
\]

for all \( x, y \in M \) such that \( d(x, y) \leq h' \). Next we use the following elementary inequality: if \( |\sigma| \leq s \), then

\[
|e^\sigma - 1| \leq e^s - 1.
\]

Combining together the previous lines and (4.10), we obtain

(7.57)

\[
|\nabla_P f_{k+1}(x)|^2 \leq f_{k+1}^2(x) \left( \exp \left( \frac{3h'\sigma(x)}{D(n-k)} \right) - 1 \right)^2.
\]

Next let us use another elementary fact: there exists \( B > 0 \) such that, for all \( t > 0 \),

\[
(e^t - 1)^2 \leq 4(e^{Bt^2} - 1).
\]

Setting \( t = 3h'\sigma(x)/(D(n-k)) \), we obtain that

\[
\frac{1}{4} \left( \exp \left( \frac{3h'\sigma(x)}{D(n-k)} \right) - 1 \right)^2 \leq \exp \left( \frac{B(3h')^2\sigma^2(x)}{D^2(n-k)^2} \right) - 1.
\]

Hence, if \( D \geq D_1 := 2B \{3h'\}^2 \), then the right hand side of the above inequality is bounded from above by

\[
\exp \left( \frac{\sigma^2(x)}{2D(n-k)^2} \right) - 1.
\]

Combining with (7.56) and (7.57), we obtain

\[
\frac{\nabla f_{k+1}(x)}{4f_{k+1}(x)} \leq f_{k+1}(x) \left( \exp \left( \frac{3h'\sigma(x)}{D(n-k)} \right) - 1 \right)^2
\]

\[
\leq f_{k+1}(x) \left( \exp \left( \frac{\sigma^2(x)}{2D(n-k)^2} \right) - 1 \right) \leq -\partial_k f(x)
\]

for all \( x \in M \) and for all \( k \in [0, n-1] \). \( \square \)

Next, we need the following estimate on \( h_k \) defined in (7.44). The proof uses the diagonal estimate in Proposition 7.2.
Lemma 7.14. Under the assumptions of Proposition 7.1, there exists $C_0 > 0$ such that
\begin{equation}
\int_M h^2_n(x,y) \, dy \leq \frac{C_0}{V(x, \sqrt{n+2})}
\end{equation}
for all $n \in \mathbb{N}$ and for all $x \in M$ where $h$ is as defined in (7.44).

Proof. By (7.44) of Lemma 7.11, Lemma 4.2(c) and Vandermonde’s convolution formula, we have
\begin{equation}
\int_M (h_n(x,y))^2 \, dy = 4^{-n} \sum_{i=0}^{n} \binom{n}{i} p_{i+2}(x,y) \leq 4^{-n} \sum_{i=0}^{2n} \binom{2n}{i} p_{i+4}(x,x)
\end{equation}
for all $x \in M$. By Proposition 7.2, there exists $C_1 > 0$ such that
\begin{equation}
p_k(x,x) \leq \frac{C_1}{V(x, \sqrt{k})}
\end{equation}
for all $k \geq 2$ and all $x \in M$. Combined with (7.59) and (2.4), we obtain $C_2 > 0, \delta > 2$ such that
\begin{equation}
\int_M (h_n(x,y))^2 \, dy \leq \frac{C_2}{V(x, \sqrt{2n+4})} \left( \sum_{i=0}^{2n} \binom{2n}{i} \frac{2n+4}{i+4} \right)^{\delta/2}
\end{equation}
for all $n \in \mathbb{N}$ and all $x \in M$. By the above inequality, we have
\begin{equation}
4^{-n} \sum_{i=0}^{2n} \binom{2n}{i} \left( \frac{2n+4}{i+4} \right)^{\delta/2} \leq 4^{-n} \sum_{i=0}^{2n} \binom{2n}{i} \left( \frac{2n+4}{i+4} \right)^{\kappa} \leq 4^{2\kappa} \kappa ! \sum_{i=0}^{2n} \binom{2n+\kappa}{i+\kappa} 2^{-(2n+\kappa)} \leq 4^{2\kappa} \kappa !
\end{equation}
where $\kappa := [\delta/2] \in \mathbb{N}^*$. Combining (7.60), (7.61) along with (2.4) implies (7.58). □

Our next result involves repeated application of the discrete integral maximum principle.

Lemma 7.15. Let $(M, d, \mu)$ be a quasi-b-geodesic metric measure space satisfying $(VD)_0$ and $(VD)_\infty$. Suppose that a Markov operator $P$ has a kernel $p$ that is $(h, h')$-compatible with $(M, d, \mu)$ for some $h > b$. Further assume that $P$ satisfies the Sobolev inequality (5.2). Define
\begin{equation}
E_D(k, x) := \int_M h^2_k(x,z) \exp \left( \frac{d_1^2(x,z)}{Dk} \right) \, dz
\end{equation}
for all $k \in \mathbb{N}^*$ and $x \in M$, where $d_1(x,z) := \max(d(x,z), h')$ and $h_k$ is defined by (7.44). There exists $C, D > 0$ such that
\begin{equation}
E_D(k, x) \leq \frac{C}{V(x, \sqrt{k})}
\end{equation}
for all \( x \in M \) and for all \( k \in \mathbb{N}^* \).

**Proof.** Let \( x \in M \) be an arbitrary point. The constants below do not depend on the choice of \( x \). Define

\[
I(R, k) = I(R, k, x) := \int_{B(x, R)^{\mathbb{F}}} h_k^2(x, z) \, dz
\]

for \( R > 0 \) and \( k \in \mathbb{N} \). We start by estimating \( I(R, k) \) using iteration. The iterative step is contained in the following estimate: There exists \( D_1 > 0 \) such that

\[
I(R, n) \leq \exp((h')^2/D_1) \left( I(r, k) + \exp \left( -\frac{(R - r)^2}{2D_1(n - k)} \right) \int_M h_k^2(x, z) \, dz \right)
\]

for all \( R, r \) satisfying \( R > r > 0 \), for all \( n \in \mathbb{N}^* \) and for all \( k \in [0, n - 1] \).

To prove (7.64), we define

\[
\sigma_R(z) := \max(R - d(x, z), 0) + h'.
\]

Note that \( \sigma_R \) is 1-Lipschitz with \( \inf \sigma_R \geq h' \). Define

\[
f_k(z) := \exp \left( -\frac{\sigma_R^2(z)}{D_1(n + 1 - k)} \right)
\]

for all \( z \in M \) and all \( k \in [0, n] \), where \( D_1 \) is the constant from Lemma 7.13. Since \( f_k \geq \exp(-(h')^2/D_1) \) in \( B(x, R)^{\mathbb{F}} \), we have

\[
I(R, n) = \int_{B(x, R)^{\mathbb{F}}} h_n^2(x, z) \, dz \leq \exp((h')^2/D_1) \int_M h_n^2(x, z) f_n(z) \, dz.
\]

By Lemma 7.13 and Proposition 7.12, we have

\[
\int_M h_n^2(x, z) f_n(z) \, dz \leq \int_M h_k^2(x, z) f_k(z) \, dz
\]

for all \( k \in [0, n] \). Since \( \sigma_R \geq R - r \) in \( B(x, r) \) and \( f_k \leq 1 \), we have

\[
\int_M h_k^2(x, z) f_k(z) \, dz = \int_{B(x, r)^{\mathbb{F}}} h_k^2(x, z) f_k(z) \, dz + \int_{B(x, r)} h_k^2(x, z) f_k(z) \, dz
\]

\[
\leq I(r, k) + \exp \left( -\frac{(R - r)^2}{D_1(n + 1 - k)} \right) \int_{B(x, r)} h_k^2(x, z) \, dz
\]

\[
\leq I(r, k) + \exp \left( -\frac{(R - r)^2}{2D_1(n - k)} \right) \int_M h_k^2(x, z) \, dz
\]

for all \( k \in [0, n - 1] \) and for all \( R > r > 0 \). Combining (7.65), (7.66) and (7.67), we obtain (7.64). Now by Lemma 7.14 and (7.64), there exists \( C_1 > 1 \) such that

\[
I(R, n) \leq \exp((h')^2/D_1) \left( I(r, k) + \exp \left( -\frac{(R - r)^2}{2D_1(n - k)} \right) \frac{C_1}{V(x, \sqrt{k})} \right)
\]

for all \( n \in \mathbb{N}^* \), for all \( k \in [0, n - 1] \) and for all \( R > r > 0 \).

Next, we show that there exists \( C_2, C_3 > 0 \) such that

\[
I(R, k) \leq \frac{C_2}{V(x, \sqrt{k})} \exp \left( -\frac{R^2}{C_3 k} \right)
\]

for all \( R > 10h' \) and for all \( k \in \mathbb{N}^* \). By (4.10) and (7.44), we have \( I(R, k) = 0 \) if \( R > (k + 2)h' \). Hence it suffices to consider the case \((k + 2)h' \geq R\).
Given any finite decreasing sequence \( \{R_j\}_{j=1}^{j_0} \) of real numbers and any finite strictly decreasing sequence \( \{k_j\}_{j=1}^{j_0} \) such that \( R_1 = R, k_1 = k \) and \( I(R_{j_0}, k_{j_0}) = 0 \), we can iterate (7.65) and obtain

\[
I(R, k) \leq \sum_{j=1}^{j_0-1} \frac{C_1 \exp(j(h')^2/D_1)}{V(x, \sqrt{k_{j+1}})} \exp\left(-\frac{(R_j - R_{j+1})^2}{2D_1(k_j - k_{j+1})}\right). \tag{7.70}
\]

Let \( R > 10h' \) and define

\[
R_j := R/2 + R/(j + 1), \quad t_j := k/2j^{-1}, \quad k_j := \left\lceil t_j \right\rceil
\]

so that \( R_1 = R \) and \( k_1 = k \). Let \( j_0 = \min \{j : R_j > h'(k_j + 2)\} \) (note that \( j_0 > 1 \) since \((k + 2)h' \geq R\)). By construction one has \( I(R_{j_0}, k_{j_0}) = 0 \). Also, for all \( j < j_0 \) we have \( k_j > R_j - 1 > R/2 - 1 \). Since \( R > 10h' \), we have

\[
t_j - t_{j+1} = t_j/2 \geq (k_j - 1)/2 \geq \frac{1}{2} \left( \frac{R}{h'} - 3 \right) \geq \frac{1}{2} \left( \frac{R}{2h'} - 3 \right) > 1
\]

which means \( k_j > k_{j+1} \) for all \( j \in [1, j_0 - 1] \). Therefore

\[
k_j - k_{j+1} \leq k/2j^{-1} - k/2j + 1 = k/2j + 1 \leq k/2j^{-1}
\]

for all \( j \in [1, j_0 - 1] \). Using (7.71) and the identity

\[
(R_j - R_{j+1})^2 = \frac{R^2}{(j+1)^2(j+2)^2},
\]

we obtain

\[
\frac{(R_j - R_{j+1})^2}{2D_1(k_j - k_{j+1})} \geq \frac{R^2}{C_3k} (j+1), \tag{7.72}
\]

where

\[
C_3 := \max_{j \geq 1} \frac{D_1(j+1)^3(j+1)^2}{2j^{-2}} \in (0, \infty)
\]

Therefore by (7.70) and (7.72), we have

\[
I(R, k) \leq \sum_{j=1}^{j_0-1} \frac{C_1}{V(x, \sqrt{k_{j+1}})} \exp\left(\frac{j(h')^2}{D_1} - \frac{R^2}{C_3k} (j+1)\right) \tag{7.73}
\]

By (7.71) and (2.4), there exists \( C_4 > 1 \) such that

\[
\frac{V(x, \sqrt{t_j})}{V(x, \sqrt{k_{j+1}})} \leq C_4
\]

for all \( j \in [1, j_0 - 1] \). Therefore

\[
\frac{V(x, \sqrt{t_1})}{V(x, \sqrt{k_{j+1}})} \leq \frac{V(x, \sqrt{t_1})}{V(x, \sqrt{t_2})} \frac{V(x, \sqrt{t_2})}{V(x, \sqrt{t_3})} \cdots \frac{V(x, \sqrt{t_j})}{V(x, \sqrt{t_{j+1}})} \leq C_4^j
\]

Thus setting \( L := \log(C_1C_4) \), we obtain

\[
\frac{C_1}{V(x, \sqrt{k_{j+1}})} \leq \frac{1}{V(x, \sqrt{k})} \exp(jL)
\]

for all \( j \in [1, j_0 - 1] \). Therefore by (7.73), we have

\[
I(R, k) \leq \frac{1}{V(x, \sqrt{k})} \exp\left(-\frac{R^2}{C_3k}\right) \sum_{j=1}^{j_0-1} \exp\left(-j \left( \frac{R^2}{C_3k} - L - (h')^2 \right) / D_1 \right) \tag{7.74}
\]
for all $R > 10h'$ and for all $k \in \mathbb{N}^*$ satisfying $R \leq (k + 2)h'$. We consider two cases.

Case 1: Let

$$\frac{R^2}{C_3k} - L - \frac{(h')^2}{D_1} \geq \log 2$$

In this case, by (7.74) we have

$$I(R, k) \leq \frac{1}{V(x, \sqrt{k})} \exp \left( - \frac{R^2}{C_3k} \right) \sum_{j=1}^{j_0-1} 2^{-j} \leq \frac{1}{V(x, \sqrt{k})} \exp \left( - \frac{R^2}{C_3k} \right)$$

Case 2: Let

$$\frac{R^2}{C_3k} - L - \frac{(h')^2}{D_1} < \log 2$$

In this case we estimate $I(R, k)$ differently as

$$I(R, k) \leq \int_M h_k^2(x, z) \, dz \leq \frac{C_1}{V(x, \sqrt{k})} \leq \frac{2C_1}{V(x, \sqrt{k})} \exp \left( L + \frac{(h')^2}{D_1} - \frac{R^2}{C_3k} \right) = \frac{C_6}{V(x, \sqrt{k})} \exp \left( - \frac{R^2}{C_3k} \right).$$

Combining the two cases we have (7.69).

Finally, we are ready to prove (7.63). Define for $j \in \mathbb{N}$,

$$A_j^R := \left\{ \{ z \in M : d_1(x, z) \leq R \}, \quad j = 0 \right\} \cup \left\{ \{ z \in M : 2^{j-1}R < d_1(x, z) \leq 2^jR \}, \quad j \geq 1, \right\}$$

and

$$(7.75) \quad E_D(k, x) = \sum_{j=0}^{\infty} \int_{A_j^R} h_k^2(z) \exp \left( \frac{d_1^2(x, z)}{Dk} \right) \, dz.$$ 

For all $D > 0$ and for all $R \geq h'$ the first term admits the estimate

$$(7.76) \quad \int_{A_0^R} h_k^2(x, z) \exp \left( \frac{d_1^2(x, z)}{Dk} \right) \, dz \leq \frac{C_1}{V(x, \sqrt{k})} \exp \left( \frac{R^2}{Dk} \right).$$

Now for the remaining terms we have

$$(7.77) \quad \int_{A_j^R} h_k^2(x, z) \exp \left( \frac{d_1^2(x, z)}{Dk} \right) \, dz \leq \exp \left( \frac{4^j R^2}{Dk} \right) I(2^j-1 R, k)$$

for all $R > 10h'$ and $j \in \mathbb{N}^*$. By (7.69)

$$I(2^j-1 R, k) \leq \frac{C_2}{V(x, \sqrt{k})} \exp \left( - \frac{4^j-1 R^2}{C_3k} \right).$$

Combining with (7.77)

$$\int_{A_j^R} h_k^2(x, z) \exp \left( \frac{d_1^2(x, z)}{Dk} \right) \, dz \leq \exp \left( \frac{4^j R^2}{Dk} \right) \frac{C_2}{V(x, \sqrt{k})} \exp \left( - \frac{4^j-1 R^2}{C_3k} \right) \leq \frac{C_2}{V(x, \sqrt{k})} \exp \left( - \frac{4^j-1 R^2}{Dk} \right)$$

for all $j \in \mathbb{N}^*$, provided $D \geq 5C_3$ and $R > 10h'$. Define

$$(7.79) \quad D := \max \left( 5C_3, \frac{(11h')^2}{\log 2} \right).$$
Then by (7.75), (7.76) and (7.78) we obtain, for all $R > 10h'$

\[ E_D(k, x) \leq \frac{C_1}{V(x, \sqrt{k})} \exp \left( \frac{R^2}{Dk} \right) + \frac{C_2}{V(x, \sqrt{k})} \sum_{j=1}^{\infty} \exp \left( -\frac{4^{j-1}R^2}{Dk} \right). \tag{7.80} \]

Given $k \in \mathbb{N}^*$ choose $R$ so that $R^2/(Dk) = \log 2$ which by (7.79) satisfies $R > 10h'$. Therefore by (7.80), we conclude

\[ E_D(k, x) \leq \frac{2C_1}{V(x, \sqrt{k})} + \frac{C_2}{V(x, \sqrt{k})} \sum_{j=1}^{\infty} 2^{-4^{j-1}} \leq \frac{2C_1 + C_2}{V(x, \sqrt{k})} \]

which is the desired estimate (7.63).

We use Lemma 7.15 to prove a Gaussian upper bound for $h_k$.

**Lemma 7.16.** Under the assumptions of Proposition 7.1, there exists positive reals $C_0, D_0$ such that

\[ h_{2k}(x, y) \leq \frac{C_0}{V(x, \sqrt{k})} \exp \left( -\frac{d^2(x, y)}{D_0 k} \right) \tag{7.81} \]

for all $x, y \in M$ and for all $k \in \mathbb{N}^*$.

**Proof.** By triangle inequality and the inequality $(a + b)^2 \leq 2(a^2 + b^2)$, we have

\[ d_1(x,y)^2 \leq 2(d_1(x,z)^2 + d_1(y,z)^2) \tag{7.82} \]

for all $x, y, z \in M$, where $d_1(x,y) := \max(d(x,y), h')$ as before. By (4.12), (7.82) and Cauchy-Schwarz inequality we have

\[
\begin{align*}
h_{2k}(x, y) & = \sum_{i=0}^{2k} \binom{2k}{i} \left( \frac{1}{2} \right)^{2k} p_{i+2}(x, y) \\
& \leq \alpha^{-2} \sum_{i=0}^{2k} \binom{2k}{i} \left( \frac{1}{2} \right)^{2k} p_{i+4}(x, y) = \alpha^{-2} \int_M h_k(x,z) h_k(z,y) \, dz \\
& \leq \alpha^{-2} \int_M h_k(x,z) h_k(z,y) e^{d_1(x,z)^2/2Dk} e^{d_1(z,y)^2/2Dk} e^{-d_1(x,y)^2/4Dk} \, dz \\
& \leq \alpha^{-2} \sqrt{E_D(k,x) E_D(k,y)} e^{-d_1(x,y)^2/4Dk} \\
& \leq \alpha^{-2} \sqrt{E_D(k,x) E_D(k,y)} e^{-d_1(x,y)^2/4Dk}
\end{align*}
\tag{7.83} \]

for all $x, y \in M$, for all $k \in \mathbb{N}^*$ and for all $D > 0$, where $\alpha > 0$ is from (4.11). The equality in the second line above follows from a calculation analogous to (7.59).

The bound (7.83) and Lemma 7.15 implies that there exists $C_1, D_1 > 0$ such that

\[ h_{2k}(x, y) \leq \frac{C_1}{(V(x, \sqrt{k}) V(y, \sqrt{k}))^{1/2}} \exp \left( -\frac{d^2(x, y)}{D_1 k} \right) \tag{7.84} \]
for all \( x, y \in M \) and for all \( k \in \mathbb{N}^* \). However by (2.4), there exists \( C_2, C_3, C_4 > 0, \delta > 0 \) such that

\[
\frac{V(x, \sqrt{k}) - V(y, \sqrt{k})}{V(y, \sqrt{k})} \leq C_2 \left( 1 + \frac{d(x, y)}{\sqrt{k}} \right) \delta
\]

(7.85)

\[
\leq C_3 \left( 1 + \frac{d^2(x, y)}{k} \right)^{\delta/2} \leq C_4 \exp \left( \frac{d^2(x, y)}{2D_1 k} \right)
\]

for all \( x, y \in M \). Combining (7.84) and (7.85) yields the desired Gaussian upper bound (7.81). □

### 7.4. Comparison with lazy random walks

We want to convert the Gaussian bounds on \( h_k \) given by Lemma 7.16 to Gaussian bounds on \( p_k \). To accomplish this we need the following elementary polynomial identities.

**Lemma 7.17.** For all \( \beta > 0 \) and for all \( n \in \mathbb{N}^* \), we have the following polynomial identities

\[
z^n = \sum_{k \in [1,n], k \text{ odd}} \binom{n}{k} \beta^{n-k} (z - \beta)^{k-1} z
\]

(7.86)

\[
+ \sum_{k \in [1,n-1], k \text{ odd}} \binom{n-1}{k} \beta^{n-1-k} (z - \beta)^{k-1} (z^2 - 2\beta z),
\]

(7.87)

\[
\left( \frac{1+z}{2} \right)^n = \frac{1}{2^n} + \sum_{k \in [1,n], k \text{ odd}} \binom{n}{k} \left( \frac{1+\beta}{2} \right)^{n-k} \left( \frac{1}{2} \right)^k (z - \beta)^{k-1} z
\]

\[
+ \sum_{k \in [1,n-1], k \text{ odd}} s_{n,k} \left( \frac{1+\beta}{2} \right)^{n-1-k} \left( \frac{1}{2} \right)^{k+1} (z - \beta)^{k-1} (z^2 - 2\beta z)
\]

where \( (z - \beta)^0 = 1 \) and

\[
s_{n,k} = (1+\beta)^{(n-1-k)} \sum_{i=k+1}^n \binom{n}{i} \binom{i-1}{k} \beta^{i-1-k} \geq \binom{n-1}{k}.
\]

**Proof.** Note that

\[
z^n = z \left( \frac{z^n - (2\beta - z)^n}{2(z - \beta)} \right) + (z^2 - 2\beta z) \left( \frac{z^{n-1} - (2\beta - z)^{n-1}}{2(z - \beta)} \right)
\]

(7.88)

for all \( z \neq \beta \). To obtain (7.86), we expand \( z^n, z^{n-1}, (2\beta - z)^n, (2\beta - z)^{n-1} \) in (7.88) using binomial expansion and the substitution

\[
z = \beta + (z - \beta) \text{ and } 2\beta - z = \beta - (z - \beta).
\]
To show (7.87), we use binomial expansion on \((1 + z)^n\) and then use (7.86) to obtain
\[
(1 + z)^n = 1 + \sum_{i=1}^{n} \binom{n}{i} z^i
= 1 + \sum_{i=1}^{n} \sum_{k \in [1, i], k \text{ odd}} \binom{n}{i} \binom{i}{k} \beta^{i-k} (z - \beta)^{k-1} z
+ \sum_{i=1}^{n} \sum_{k \in [1, i-1], k \text{ odd}} \binom{n}{i} \binom{i-1}{k} \beta^{i-1-k} (z - \beta)^{k-1} (z^2 - 2\beta z).
\]
(7.89)

The coefficient of \((z - \beta)^{k-1} z\) in (7.89) is
\[
\sum_{i=k}^{n} \binom{n}{i} \binom{i}{k} \beta^{i-k} = \binom{n}{k} \sum_{i=k}^{n} \binom{n-k}{i-k} \beta^{i-k} = \binom{n}{k} (1 + \beta)^{n-k}.
\]

Similarly, the coefficient of \((z - \beta)^{k-1} (z^2 - 2\beta z)\) in (7.89) is
\[
\sum_{i=k+1}^{n} \binom{n}{i} \binom{i-1}{k} \beta^{i-1-k} = \binom{n-1}{k} \sum_{i=k+1}^{n} \frac{n-1-k}{i-1-k} \beta^{i-1-k}
\geq \binom{n-1}{k} \sum_{i=k+1}^{n} \frac{n-k}{i-1-k} \beta^{i-1-k}
= \binom{n-1}{k} (1 + \beta)^{n-1-k}.
\]

This gives (7.87) with \(s_{n,k} \geq \binom{n-1}{k} \).
\(\square\)

We are now prepared to prove Gaussian upper bounds for \(p_k\).

**Proof of Proposition 7.1.** By Lemma 4.10 there exists \(\beta > 0\) such that \(u_k, v_k : M \times M \to \mathbb{R}\) satisfy
\[
\begin{align*}
\text{(7.90)} & \quad u_k(x, y) := [(P - \beta I)^k p_2(x, \cdot)] (y) \geq 0, \\
\text{(7.91)} & \quad v_k(x, y) := [(P - \beta I)^k (p_3(x, \cdot) - 2\beta p_2(x, \cdot))] (y) \geq 0
\end{align*}
\]
for all \(x, y \in M\) and for all even non-negative integers \(k\). For instance \(\beta = \alpha/2\) where \(\alpha\) is given by (4.11) would satisfy the above requirements.

Using Lemma 4.2(c) and (7.86) of Lemma 7.17, we have
\[
p_{n+1}(x, y) = [P^n p_1(x, \cdot)] (y)
= \sum_{k \in [1, n], k \text{ odd}} \binom{n}{k} \beta^{n-k} u_{k-1}(x, y)
+ \sum_{k \in [1, n-1], k \text{ odd}} \binom{n-1}{k} \beta^{n-1-k} v_{k-1}(x, y)
\]
(7.92)
for all \( n \in \mathbb{N}^* \) and for all \( x, y \in M \). By (7.90), (7.91), Lemma 4.10 and Lemma 7.17, we have

\[
h_{2n}(x, y) = \left[ ((I + P)/2)^{2n} p_2(x, \cdot) \right](y) \\
\geq \alpha \sum_{k \in [1, 2n], k \text{ odd}} \binom{2n}{k} \left( \frac{1 + \beta}{2} \right)^{2n-k} \left( \frac{1}{2} \right)^k u_{k-1}(x, y) \\
+ \alpha \sum_{1 \leq k \leq 2n-1, k \text{ odd}} s_{2n,k} \left( \frac{1 + \beta}{2} \right)^{2n-1-k} \left( \frac{1}{2} \right)^{k+1} v_{k-1}(x, y)
\]

(7.93)

for all \( x, y \in M \). Define the ratio of coefficients in (7.92) and (7.93) as

\[
a_{k,n} = \frac{(2n)!}{\binom{n}{k} \beta^{n-k}} \left( \frac{1}{2} \right)^k \quad \text{and} \quad b_{l,n} = \frac{(2n-1)!}{\binom{n-1}{l} \beta^{n-1-l}} \left( \frac{1}{2} \right)^{l+1}
\]

for each \( k \in [1, n] \) and for each \( l \in [1, l-1] \). If \( k \in [1, n-1] \), then

\[
a_{k+1,n} \geq a_{k,n} \quad \text{if and only if} \quad k \geq n(1 - \beta). \quad \text{Thus} \quad a_{k,n} \text{ reaches minimum for} \quad k = \lceil n(1 - \beta) \rceil.
\]

By Stirling’s approximation there exists constant \( C_1 > 0 \) such that for all \( r \in \mathbb{N}^* \),

\[
C_1^{-1} r^{r+(1/2)} e^{-r} \leq r! \leq C_1 r^{r+(1/2)} e^{-r}.
\]

We use the Stirling’s approximation to estimate \( a_{k,n} \) at \( k = n(1 - \beta) + \epsilon \) where \( \epsilon = [n(1 - \beta)] - n(1 - \beta) \in [0, 1) \). There exists \( c_1 > 0 \) such that

\[
\min_{k \in [1, n]} a_{k,n} \geq \min_{k \in [n(1 - \beta), n]} a_{k,n} \geq \frac{C_1^{-4}(2n)!2^{n+(1/2)} e^{-2n(\beta n - \epsilon)\beta n+(1/2) - \epsilon}e^{-\beta n+\epsilon}(1 + \beta)^{[n(1 + \beta)n - \epsilon]}}{2^{2n} n^{n(1 + \beta) + (1/2) - \epsilon} e^{-n(1 + \beta) + \epsilon} \beta^{n - \epsilon}} \geq c_1
\]

for all \( n \in \mathbb{N}^* \) satisfying \( n \geq 2/\beta \). Therefore there exists \( c_2 > 0 \) such that

\[
a_{k,n} \geq c_2
\]

(7.95)

for all \( n \in \mathbb{N}^* \) and for all \( k \in [1, n] \). Similarly,

\[
b_{l,n} = \frac{1}{2} a_{l+1,n} \geq \frac{1}{2} c_2
\]

(7.96)

for all \( n \in \mathbb{N}^* \) and for all \( l \in [1, n - 1] \). Combining (7.90), (7.91), (7.92), (7.93), (7.94), (7.95) and (7.96), there exists \( c_3 > 0 \) such that

\[
h_{2n}(x, y) \geq c_3 p_{n+1}(x, y)
\]

(7.97)

for all \( n \in \mathbb{N}^* \), and for all \( x, y \in M \). Combining (7.97) along with Lemma 7.16 yields the Gaussian upper bound (7.1).

We have shown the following equivalence

**Theorem 7.18.** Let \((M, d, \mu)\) be a quasi-\( b \)-geodesic metric measure space satisfying (V.D)_{loc}. Suppose that a Markov operator \( P \) has a kernel \( p \) that is \((h, h')\)-compatible with \((M, d, \mu)\) for some \( h > b \). Then the following are equivalent:
(i) Sobolev inequality (5.2).
(ii) Large scale volume doubling property $(VD)_\infty$ and Gaussian upper bounds $(GUE)$.

**Proof.** By Corollary 5.11, (ii) implies (i).

Next, we assume the Sobolev inequality (5.2). By Proposition 5.12 we have $(VD)_\infty$. In addition, by Proposition 7.1 we have $(GUE)$. This proves (i) implies (ii). □
CHAPTER 8

Gaussian lower bounds

In this chapter, we use elliptic Harnack inequality and Gaussian upper bounds to establish Gaussian lower bounds. The proofs in this chapter is adapted from [45]. In [45], Hebisch and Saloff-Coste provide an alternate approach to prove parabolic Harnack inequality using elliptic Harnack inequality and Gaussian upper bounds. This method avoids relying on the full strength of Moser’s iteration method in parabolic setting.

Although [45] concerns diffusions on strictly local Dirichlet spaces, we will see that their methods can be extended to discrete time Markov chains on quasi-geodesic spaces. This extension was alluded to in [45] where the authors say “This route to the parabolic Harnack inequality seems especially valuable in the setting of analysis on graphs which is not covered by the present strictly local Dirichlet space framework. In fact, the results above originated from our desire to overcome some of the difficulties that appear in the case of graphs. This will be developed elsewhere.”

The main result of this chapter is the following Gaussian lower bound.

**Proposition 8.1.** Let \((M, d, \mu)\) be a quasi-b-geodesic metric measure space satisfying \((VD)_{loc}, (VD)_\infty, \text{diam}(M) = \infty\) and Poincaré inequality at scale \(h (P)_h\). Suppose that a Markov operator \(P\) has a kernel \(p\) that is \((h, h')\)-compatible with respect to \(\mu\) for some \(h > b\). Then the corresponding kernel \(p_k\) satisfies Gaussian lower bounds \((GLE)\).

Note that under the assumptions of Proposition 8.1, we have Gaussian upper bounds \((GUE)\). This is a direct consequence of Theorem 5.1 and Proposition 7.1.

We focus on the case \(\text{diam}(M) = \infty\) just for simplicity. In fact, we expect these methods to work when \(\text{diam}(M) < \infty\). However when the space has finite diameter, it is important to find optimal constants (or close to optimal) for various functional inequalities. To compute these optimal constants, one has to exploit the specific structure of the Markov chain under consideration. We plan to address the finite diameter case in a sequel.

### 8.1. On-diagonal lower bounds

The first step is to obtain lower bounds on \(p_k(x, x)\). It is well-known that Gaussian upper bounds implies a matching diagonal lower bounds. We repeat the proof for convenience.

**Lemma 8.2.** Under the assumption of Proposition 8.1, there exists \(c_0 > 0\) such that

\[
p_n(x, x) \geq \frac{c_0}{V(x, \sqrt{n})}
\]

for all \(x \in M\) and for all \(n \in \mathbb{N}\) satisfying \(n \geq 2\).
Proof. By Lemma 4.10 it suffices to prove the inequality for even \( n \), since there exists \( \alpha > 0 \) such that
\[
p_{2k+1}(x, x) \geq \alpha p_{2k}(x, x)
\]
for all \( x \in M \) and for all \( k \in \mathbb{N}^* \).

Let \( n \in \mathbb{N}^* \) be even. By Cauchy-Schwarz inequality and Lemma 4.2(c), we have
\[
p_{n}(x, x) = \int_{M} p_{n/2}^2(x, y) \, dy \geq \int_{B(x, \sqrt{T})} p_{n/2}^2(x, y) \, dy
\]
\[
\geq \frac{1}{V(x, \sqrt{T})} \left( \int_{B(x, \sqrt{T})} p_{n/2}(x, y) \, dy \right)^2
\]
\[
= \frac{1}{V(x, \sqrt{T})} \left( 1 - \int_{B(x, \sqrt{T})} \, p_{n/2}(x, y) \, dy \right)^2
\]
(8.1)

for all \( T > 0 \) and for all \( n \in 2\mathbb{N}^* \).

By Theorem 5.1 and Proposition 7.1 we have \((GUE)\). By \((GUE)\), there exists \( C_1, C_2 > 0 \)
\[
p_k(x, y) \leq \frac{C_1}{V(x, \sqrt{k})} \exp \left( \frac{d^2(x, y)}{C_2 k} \right)
\]
(8.2)

for all \( x, y \in M \) and \( k \in \mathbb{N}^* \). There exists \( C_3 > 1 \) such that for all \( A > \max(1, (8C_2\delta)^2) \), we have
\[
\int_{B(x, \sqrt{Ak})^c} p_k(x, y) \, dy = \sum_{i=1}^{\infty} \int_{2^{i-1} \sqrt{Ak} < d(x, y) \leq 2^i \sqrt{Ak}} p_k(x, y) \, dy
\]
\[
\leq C_1 \sum_{i=1}^{\infty} \frac{V(x, 2^i \sqrt{Ak})}{V(x, \sqrt{k})} \exp \left( -\frac{4^i T}{4C_2 k} \right)
\]
\[
\leq C_3 \sum_{i=1}^{\infty} \exp \left( \delta \log \left( 2^i \sqrt{A} \right) - \frac{4^i A}{4C_2} \right)
\]
\[
\leq C_3 \sum_{i=1}^{\infty} \exp \left( \delta 2^i \sqrt{A} - \frac{4^i A}{4C_2} \right)
\]
\[
\leq C_3 \sum_{i=1}^{\infty} \exp \left( -\frac{4^i A}{8C_2} \right) \leq C_4 \exp \left( -\frac{A}{2C_2} \right)
\]
(8.3)

for all \( k \in \mathbb{N}^* \) and for all \( x \in M \). We used (8.2) in the second line above and (2.4) in the third line. By (8.3), there exists \( A_1 > 1 \) such that
\[
\int_{B(x, \sqrt{A_1 k})^c} p_k(x, y) \, dy < 1/2
\]
(8.4)

for all \( k \in \mathbb{N}^* \) and for all \( x \in M \). We choose \( T = A_1(n/2) \) in (8.1) and use (8.4) and (2.4), to obtain
\[
p_n(x, x) \geq \frac{1}{2V(x, (A_1 n/2)^{1/2})} \geq \frac{c_1}{V(x, \sqrt{n})}
\]
for all \( n \in 2\mathbb{N}^* \) and for all \( x \in M \).  \( \square \)
8.1. ON-DIAGONAL LOWER BOUNDS

The following lemma is a discrete time analog of [45, Lemma 3.7], where we transfer the on-diagonal lower bound given by Lemma 8.2 to on-diagonal lower bound for the ‘Dirichlet kernel’ $p^B_n$ on a ball $B$ defined in (4.27).

**Lemma 8.3.** Under the assumptions of Proposition 8.1, there exists $c > 0$ and $A > \max(1, h')$ such that

$$p_n^{B(x,r)}(x,x) \geq \frac{c}{V(x, \sqrt{n})}$$

for all $x \in M$, for all $n \in \mathbb{N}^*$ with $n \geq 2$ and for all $r \geq A\sqrt{n}$

**Proof.** We abbreviate $B(x,r)$ by $B$. We denote the exit time from ball $B$ by

$$\tau := \min \{k : X_k \notin B\}$$

where $(X_k)_{k \in \mathbb{N}}$ is the Markov chain driven by the kernel $p_k$.

By strong Markov property, the Dirichlet kernel $p_n^B$ can be expressed in terms of $p_k$ as

$$p_n^B(x,x) = p_n(x,x) - \mathbb{E}_x [p_{n-\tau}(X_\tau, x)1_{[1,n-1]}(\tau)] \quad \text{(8.5)}$$

for all $n \geq 2$ and for all $x \in M$, where $\mathbb{E}_x$ denotes that $X_0 = x$. If we choose $A > h'$, by (4.10), we can rewrite (8.5) as

$$p_n^B(x,x) = p_n(x,x) - \mathbb{E}_x [p_{n-\tau}(X_\tau, x)1_{[2,n-2]}(\tau)] \quad \text{(8.6)}$$

for all $n \geq 2$ and for all $x \in M$ with $B = B(x,r)$ satisfying $r > h'$. For the first term in (8.6), by Lemma 8.2, there exists $c_1 > 0$ such that

$$p_n(x,x) \geq \frac{c_1}{V(x, \sqrt{n})} \quad \text{(8.7)}$$

for all $x \in M$ and for all $n \geq 2$.

We use Gaussian upper bound $(GUE)$ to estimate the second term in (8.6). There exists $C_1, C_2, C_3, C_4, \delta > 0$ and such that

$$\mathbb{E}_x [p_{n-\tau}^B(X_\tau, y)1_{[1,n-1]}(\tau)] \leq \sup_{l \in [2,n-2]} \sup_{y \notin B(x,r)} \frac{C_1}{V(x, \sqrt{l})} e^{-d(x,y)^2/(C_2 l)}$$

$$\leq \sup_{l \in [2,n-2]} \frac{C_1}{V(x, \sqrt{l})} e^{-A^2 n}/(C_2 l)$$

$$\leq \frac{C_3}{V(x, \sqrt{n})} \sup_{l \in [2,n-2]} (n/l)^{\delta/2} e^{-A^2 n}/(C_2 l)$$

$$\leq \frac{C_4}{A^3 V(x, \sqrt{n})} \quad \text{(8.8)}$$

for all $x \in M$, for all $n \geq 2$, for all $A > h'$ and for all $B = B(x,r)$ with $r \geq A\sqrt{n} > h'$. In the first line above we used (8.2), in the second line we used $d(x,y) \geq r \geq A\sqrt{n}$ and in the third line we used (2.4).

Clearly we can choose $A > h'$ large enough such that $C_4/A^3 < c_1/2$. Therefore by (8.6), (8.7) and (8.8), we obtain the desired bound. □
8.2. Spectrum of the Dirichlet Laplacian on balls

Our next result is a bound on the spectrum of $P_B$ or alternatively on the
Dirichlet Laplacian $\Delta_{P_B}$. The following Proposition is a discrete time analog of
[45, Theorem 2.5]. However unlike [45], we cannot apply the stronger Sobolev
inequality (5.1).

Proposition 8.4. Let $(M,d,\mu)$ be a quasi-$b$-geodesic metric measure space
satisfying $(VD)_{loc}$, $(VD)_\infty$ and Poincaré inequality at scale $h$ \((P)_h\). Suppose that
a Markov operator $P$ has a kernel \(p\) that is \((h,h')\)-compatible with respect to \(\mu\) for
some \(h > b\). Then there exists positive reals \(a, \epsilon_0\) such that

\[
\tag{8.13}
\|P_B(x,r)\|_{2\to2} := \sup_{f \in L^2(B(x,r)), \|f\|_2 = 1} \|P_B(x,r)f\|_2 \leq 1 - \frac{a}{r^2}
\]

for all \(x \in M\) and for all \(r \in \mathbb{R}\) satisfying \(r \geq h'\) and \(r \leq \epsilon_0 \text{diam}(M)\).

Proof. We abbreviate the ball \(B(x,r)\) by \(B\). Note that \(P_B\) is a contraction in
\(L^2(B)\), that is \(\|P_B\|_{2\to2} \leq 1\). Since \(P_B\) is a bounded, self-adjoint operator in
\(L^2(B)\), by [18, Proposition 2.13] we have

\[
\tag{8.10}
\|P_B\|_{2\to2} = \sup_{f \in L^2(B), f \neq 0} \left| \frac{\langle f, P_B f \rangle_B}{\|f\|_2^2} \right|
\]

where \(\langle \cdot, \cdot \rangle_B\) denotes the inner product in \(L^2(B)\). Therefore it suffices to show that
there exists positive reals \(a, \epsilon_0\) such that

\[
\tag{8.11}
- \left(1 - \frac{a}{r^2}\right) \leq \frac{\langle f, P_B f \rangle_B}{\|f\|_2^2} \leq 1 - \frac{a}{r^2}
\]

for all \(f \in L^2(B)\) and for all \(B = B(x,r)\) with \(r \geq h'\) and \(r \leq \epsilon_0 \text{diam}(M)\).

We prove (8.10) in two steps. We start with the proof of upper bound in (8.11).
With slight abuse of notation, we consider \(L^2(B) \subseteq L^2(M)\) using the map given
by (4.29). By this identification, a function \(f \in L^2(M)\) with \(\text{supp}(f) \subseteq B\) can be
considered to be in \(L^2(B)\).

By Lemma 4.22(a), we can rewrite the upper bound in (8.11) as

\[
\tag{8.12}
\mathcal{E}(f,f) = \mathcal{E}(f,f) \geq \frac{C_N r^2}{V(x,r)^{2/3}} \left( \mathcal{E}_*(f,f) + r^{-2} \|P f\|_2^2 \right) \|f\|_1^{4/3}
\]

Since \(\mathcal{E}(f,f) \leq \mathcal{E}(f,f)\), in order to show (8.12) it suffices to consider the case
\(f \geq 0\).

By (5.25) and (5.26) of Proposition 5.5 along with Lemma 4.20(b), there exists
\(C_N > 0\) such that

\[
\tag{8.13}
\|P f\|_2^{2+(4/3)} \leq \frac{C_N r^2}{V(x,r)^{2/3}} \left( \mathcal{E}_*(f,f) + r^{-2} \|P f\|_2^2 \right) \|f\|_1^{4/3}
\]

for all \(x \in M\), for all \(r > 0\) and for all functions \(f \in L^2(M)\) supported in \(B(x,r)\).
By (8.13), we have

\[
\tag{8.14}
\|P f\|_2^2 \left( \frac{\|P f\|_2^{4/3}}{\|f\|_1^{4/3}} - \frac{C_N}{V(x,Kr)^{2/3}} \right) \leq \frac{C_N (Kr)^2}{V(x,Kr)^{2/3}} \left( \|f\|_2^2 - \|P f\|_2^2 \right)
\]
for all $x \in M$, for all $r > 0$, for all $K > 1$ and for all functions $f \in L^2(M)$ supported in $B(x, r)$. If $f \geq 0$, we have
\[
\|Pf\|_1 = \langle Pf, 1 \rangle = \langle f, P1 \rangle = \langle f, 1 \rangle = \|f\|_1.
\]

Hence by Hölder inequality, (4.10) and (2.4), there exists $C_1 > 0$ such that
\[
\|f\|_1 = \|Pf\|_1 \leq (V(x, r + h'))^{1/2} \|Pf\|_2 \leq C_1 V(x, r)^{1/2} \|Pf\|_2
\]
for all $f \geq 0$ with $f \in L^2(M)$ and $\operatorname{supp}(f) \subseteq B(x, r)$ and $r \geq h'$. Combining (8.11) and (8.15), we have
\[
\|Pf\|_2^2 \left(C_1^{-4/\delta} - \frac{C_N V(x, r)^{2/\delta}}{V(x, Kr)^{2/\delta}} \right) \leq C_N (Kr)^2 \left(\|f\|_2^2 - \|Pf\|_2^2 \right)
\]
for all $K > 1$, for all $r \geq h'$, for all $x \in M$ and for all $f \in L^2(M)$ with $\operatorname{supp}(f) \subseteq B(x, r)$ and $f \geq 0$. By Lemma 2.12, there exists $K > 1$ such that
\[
\frac{C_N V(x, r)^{2/\delta}}{V(x, Kr)^{2/\delta}} \leq \frac{1}{2} C_1^{-4/\delta}
\]
for all $x \in M$, for all $r \geq h'$ and all $r \leq \diam(M)/K$. Combining (8.16) and (8.17), there exists $\epsilon_0 = K^{-1} > 0, C_2 > 0$ such that
\[
\|Pf\|_2 \leq C_2 r^2 \left(\|f\|_2^2 - \|Pf\|_2^2 \right)
\]
for all $x \in M$, for all $f \in L^2(M)$ with $\operatorname{supp}(f) \subseteq B(x, r)$ and $f \geq 0$, where $r$ satisfies $r \geq h'$ and $r \leq \epsilon_0 \diam(M)$. By Lemma 4.20(a) and (8.18), there exists $\alpha > 0$ such that
\[
\frac{\mathcal{E}(f, f)}{\|f\|_2^2} \geq \frac{\mathcal{E}(|f|, |f|)}{\|f\|_2^2} \geq \frac{\mathcal{E}_*(|f|, |f|)}{2 \|f\|_2^2} = \frac{1}{2} \left(1 - \frac{\|P|f|\|_2^2}{\|f\|_2^2}\right) \geq \frac{1}{2(1 + C_2 r^2)} \geq \frac{\alpha}{r^2}
\]
for all $x \in M$, for all $f \in L^2(M)$ with $\operatorname{supp}(f) \subseteq B(x, r)$, where $r$ satisfies $r \geq h'$ and $r \leq \epsilon_0 \diam(M)$. Therefore by (8.12) and (8.19), there exists $\epsilon_0 > 0$ and $\alpha > 0$ such that
\[
\frac{\langle f, Pf \rangle_B}{\|f\|_2^2} \leq 1 - \frac{\alpha}{r^2}
\]
for all $f \in L^2(B)$ and for all $B = B(x, r)$ with $r \geq h'$ and $r \leq \epsilon_0 \diam(M)$. By integration by parts (6.31) and symmetry of $p_1$ we have
\[
\mathcal{E}(f, f) + \mathcal{E}(|f|, |f|) = \frac{1}{2} \int_M \int_M p_1(x, y) \left[ (\nabla_x f)^2 + (\nabla_y |f|)^2 \right] \, dy \, dx
\]
\[
\leq \int_M \int_M p_1(x, y) (f(x)^2 + f(y)^2) \, dy \, dx = 2 \|f\|_2^2
\]
for all $f \in L^2(M)$. Combining (8.19) and (8.21), there exists $\alpha, \epsilon_0 > 0$ such that
\[
\frac{\mathcal{E}(f, f)}{\|f\|_2^2} \leq 2 - \frac{\mathcal{E}(|f|, |f|)}{\|f\|_2^2} \leq 2 - \frac{\alpha}{r^2}
\]
for all $x \in M$, for all $f \in L^2(M)$ with $\operatorname{supp}(f) \subseteq B(x, r)$, where $r$ satisfies $r \geq h'$ and $r \leq \epsilon_0 \diam(M)$. Therefore by (8.22) and Lemma 4.22(a), there exists $\epsilon_0 > 0$
and \( a > 0 \) such that
\[
(8.23) \quad \frac{(f, P_B f)_B}{\|f\|^2} \geq - \left(1 - \frac{a}{r^2}\right)
\]
for all \( f \in L^2(B) \) and for all \( B = B(x,r) \) with \( r \geq h' \) and \( r \leq \epsilon_0 \text{diam}(M) \).

Combining (8.20) and (8.23) yields (8.11), which along with (8.10) implies (8.9).

**Remark 8.5.**
(a) A simple consequence of Proposition 8.4 is that there exists \( a, \epsilon_0 > 0 \) such that
\[ \text{Spectrum}(P_B) \subseteq [-(1-ar^{-2}),1-ar^{-2}], \quad \text{Spectrum}(\Delta P_B) \subseteq [ar^{-2},2-ar^{-2}] \]
for all \( x \in M \) and for all \( r \) satisfying \( r \geq h' \) and \( r \leq \epsilon_0 \text{diam}(M) \).
(b) If \( \text{diam}(M) = \infty \), then for all balls \( B = B(x,r) \) with \( r \in (0,\infty) \), we have
\[ \|P_B\|_{2\rightarrow 2} < 1. \]
The case \( r \geq h' \) is clear from Proposition 8.4. The case \( r < h' \) follows from
\[ \|P_B\|_{2\rightarrow 2} \leq \|P_{B(x,h')}\|_{2\rightarrow 2}. \]
(c) Note that if \( \text{diam}(M) < \infty \), then the conclusion Proposition 8.4 is vacuously true as one can choose \( \epsilon_0 = h'/(2\text{diam}(M)). \)
However if \( h' \ll \text{diam}(M) \) and if we have good control of the constants in various functional inequalities, we can prove useful estimates which in turn yields applications to estimates on mixing times. We will extend the techniques developed here to finite diameter spaces elsewhere.
(d) Note that the condition \( r \leq \epsilon_0 \text{diam}(M) \) is necessary. Too see this consider the case when \( \text{diam}(M) < \infty \) and \( B(x,r) = M \). It is clear that (8.9) fails to be true because \( P_{B(x,r)}1 = 1 \).

### 8.3. Near diagonal lower bound

As in [45, Proposition 3.5], the following near diagonal estimate is an important step in obtaining Gaussian lower bounds.

**Proposition 8.6 (Near diagonal lower bound).** Under the same assumptions as in Proposition 8.1, there exists positive reals \( \epsilon_1, c_1 \) such that \( p_k \) satisfies the lower bound
\[
(8.24) \quad \inf_{y \in B(x,\epsilon_1 \sqrt{k})} p_k(x, y) \geq \frac{c_1}{V(x, \sqrt{k})}
\]
for all \( x \in M \) and for all \( k \in \mathbb{N}^* \) satisfying \( k \geq 2 \).

From the above near diagonal lower bound, we will see that the Gaussian lower bound follows by a well-established ‘chaining argument’.

The idea behind the proof of Proposition 8.6 is to convert the elliptic Hölder-like regularity estimate (Proposition 6.20) into a parabolic Hölder-like regularity estimate for the function \( (k, y) \mapsto p_k^B(x, y) \) as follows:

**Lemma 8.7.** Under the assumptions of Proposition 8.1, for all \( \sigma > 0 \) and all \( A \geq 1 \), there exists three positive reals \( C_{\sigma, A}, \epsilon_0 \leq A \) and \( N_0 \geq 2 \) such that
\[
(8.25) \quad \left| p_k^B(x, y) - p_k^B(x, x) \right| \leq \left[ \sigma + C_{\sigma, A} \left( \frac{d(x, y) \vee 1}{\sqrt{k}} \right)^\alpha \right] \frac{1}{V(x, \sqrt{k})}
\]
for all \( x \in M \), \( k \in \mathbb{N}^* \) with \( k \geq N_0 \) and for all \( y \in B(x, \epsilon_0 \sqrt{k}) \), where \( B = B(x, A \sqrt{k}) \) and \( \alpha \) is the exponent in (6.87).
The proof of Lemma 8.7 is long and involves many technical estimates. We will need some upper bounds on \( p^B_k(y, z) \) and its ‘time derivative’

\[
\partial_k p^B_k(y, z) := p_{k+1}(y, z) - p_k(y, z)
\]

for all \( y, z \in B \).

**Lemma 8.8.** Under the assumptions of Proposition 8.1, the following estimates hold:

(i) There exists \( C_1, D_1 > 0 \) such that

\[
p^B_{j, k}(x, y, z) \leq \frac{C_1}{V(y, \sqrt{j})} \exp \left( -\frac{d(y, z)^2}{D_1 j} \right)
\]

for all \( x \in M \), for all \( k \in \mathbb{N}^* \), for all \( j \geq 2 \), for all \( A \geq 1 \) and for all \( y, z \in B(x, A\sqrt{k}) \).

(ii) There exists \( C_2, \delta > 0 \) such that

\[
\left| \partial_k p^B_{j, k}(x, y, z) \right| \leq \frac{C_2 A^\delta}{k V(x, \sqrt{k})}
\]

for all \( x \in M \), for all \( k \in \mathbb{N}_{\geq 2} \), for all \( A \geq 1 \) and for all \( y, z \in B(x, A\sqrt{k}) \).

(iii) For all \( A > 1 \) and \( h' \), there exists \( \epsilon, A_1 > 0 \), such that for all \( \theta \in (0, 1) \), there exists \( C_0 \) such that

\[
p^B_{j, k}(x, y, z) \leq \frac{C_0 A^\delta}{V(x, \sqrt{k})} \left( 1 - \frac{a_1}{A^2 k} \right)^j
\]

for all \( x \in M \), for all \( k \in \mathbb{N}^* \), for all \( j \in \mathbb{N} \) satisfying \( j \geq \max(2, \theta k) \) and for all \( y, z \in B(x, A\sqrt{k}) \).

**Proof.** The first inequality (8.26) follows from Proposition 7.1 and the inequality \( p^B_{j, k}(x, y, z) \leq p_j \) for all \( j \geq 2 \).

For \( k \geq 20 \), we decompose \( k = k_1 + k_2 + k_3 + k_4 \) such that \( k_1, k_3 \in 2\mathbb{N}^* \), \( k_i \in \mathbb{N}^* \) and \( k = k_i/5 \) for \( i = 1, 2, 3, 4 \). Note that, we require \( k_1, k_3 \) to be even. We abbreviate \( B(x, A\sqrt{k}) \) by \( B \). By Cauchy-Schwarz inequality and Lemma 4.22 and Lemma 4.20(b) there exists \( C_4 > 0 \) such that

\[
|\partial_k p^B_k(y, z)| = |\langle (I - P_B)p^B_{k_1+k_2}(y \cdot), p^B_{k_3+k_4}(z \cdot) \rangle_B| \\
= |\langle (I - P_B)^{1/2}p^B_{k_1+k_2}(y \cdot), (I - P_B)^{1/2}p^B_{k_3+k_4}(z \cdot) \rangle_B| \\
\leq \left[ \mathcal{E}(p^B_{k_1+k_2}(y \cdot), p^B_{k_1+k_2}(y \cdot)), \mathcal{E}(p^B_{k_3+k_4}(z \cdot), p^B_{k_3+k_4}(z \cdot)) \right]^{1/2} \\
\leq C_4 \left[ \mathcal{E}(p^B_{k_1+k_2}(y \cdot), p^B_{k_1+k_2}(y \cdot)), \mathcal{E}(p^B_{k_3+k_4}(z \cdot), p^B_{k_3+k_4}(z \cdot)) \right]^{1/2}.
\]
Since $k_1$ is even and $k_1 \geq k/5$, by spectral decomposition and Proposition 7.1 there exists $C_5, C_6, \delta > 0$ such that
\[
\epsilon^B_{x}(p_{k_1+k_2}(y,\cdot),p_{k_1+k_2}(y,\cdot)) = \left\| (I - P^2_B)^{1/2} P^k_B (y,\cdot) \right\|^2_2
\leq \left\| (I - P^2_B)^{1/2} P^k_B \right\|^2_{2 \to 2} \left\| p_k(y,\cdot) \right\|^2_2
\leq \left( \sup_{\lambda \in [0,1]} (1 - \lambda)^{1/2} \lambda^{k/10} \right)^2 \sup_{y \in B} p_{2k_2}(y,y)
\leq C_5 k^{-1} \sup_{y \in B(x,A\sqrt{k})} \frac{1}{V(y,\sqrt{k})} \frac{V(y,z)}{V(y,\sqrt{k})}
\leq \frac{C_5}{kV(x,\sqrt{k})} \sup_{y \in B(x,A\sqrt{k})} \frac{V(y,z)}{V(y,\sqrt{k})}
\leq \frac{C_6}{kV(x,\sqrt{k})}
\]
(8.30)
for all $k \geq 20$, for all $x \in M$, for all $A > 1$ and for all $y \in B = B(x,A\sqrt{k})$. In the last line above we used (2.4). By (8.30) and (8.29), we obtain the desired bound (8.27) for $k \geq 20$.

If $2 \leq k \leq 20$, we use (8.26) and triangle inequality $|\varphi_k p^B| \leq p_{k+1}^B + p_k^B$ to obtain (8.27).

For the proof of (8.28), we use Proposition 8.4. As before we denote $B(x,A\sqrt{k})$ by $B$.

We first consider the case where $j \in \mathbb{N}^*$ is even. By Proposition 8.4, for each $A \geq (1 + h')$, there exists $a > 0, \epsilon > 0$ such that
\[
\sup_{y,z \in B} p^B_j(y,z) = \sup_{x \in B} \left\| p^B_{j/2}(y,\cdot) \right\|^2_2 = \left\| p^{j/2}_B \right\|^2_{2 \to \infty}
\leq \left\| P^B_{2j-1} \right\|^2_{2 \to 2} \left\| p^B_{j/2} \right\|^2_{2 \to \infty}
\leq \left( 1 - \frac{a}{A^2 k} \right)^{j-2j} \sup_{y \in B} p_{2j_1}(y,y)
\]
(8.31)
for all $x \in M$, for all $1 \leq j_1 \leq (j/2)$, for all $k \in \mathbb{N}^*$. We choose $j_1 := \lceil \theta k/4 \rceil$ in (8.31) and use (2.4) to obtain positive reals $\delta > 0$ and $C_7 = C_7(\theta)$
\[
\left. \sup_{y \in B(x, A \sqrt{k})} p_{2j_1}(y,y) \right| \leq \frac{C_7 A^\delta}{V(x, \sqrt{k})}
\]
(8.32)
for all $x \in M$, for all $\theta \in (0, 1)$, for all $A \geq 1$ and for all $k \in \mathbb{N}^*$ where $j_1 = \lceil (\theta k/4) \rceil$.
For all $\theta \in (0, 1)$, there exists $C_8 = C_8(\theta) > 0$ such that
\[
\left( 1 - \frac{a}{A^2 k} \right)^{-2(\lceil \theta k/4 \rceil)} \leq (1 - a)^{-2} \left( 1 - \frac{a}{k} \right)^{-2(\theta k/2)} \leq C_8
\]
(8.33)
for all $k \in \mathbb{N}^*$, for all $A \geq 1 \lor h'$. Combining (8.31), (8.32) and (8.33), we obtain the bound (8.28) for all even $j \geq 2N^*$.

For all odd $j \in N^*$ satisfying $j \geq 3$, we use the even case and the bound
\[
\sup_{y,z \in B} p^B_j(y,z) \leq \sup_{y,z \in B} p^B_{j-1}(y,z)
\]
to obtain (8.28). \qed
Remark 8.9. The constants $C_1, C_1, C_2, C_0$ and $a_1$ in Lemma 8.8 do not depend on $A$, $x$ and $k$.

Proof of Lemma 8.7. One of the consequences of Proposition 8.4 as noted in Remark 8.5(b) is that $\|P_{B(x,r)}\|_{2 \to 2} < 1$ for all $x \in M$ and for all $r \in (0, \infty)$.

Therefore $\Delta_{P_B} : L^2(B) \to L^2(B)$ is invertible with inverse

$$
\Delta_{P_B}^{-1} = (I - P_B)^{-1} = \sum_{j=0}^{\infty} P_B^j.
$$

Further the inverse $\Delta_{P_B}^{-1}$ is bounded with $\|\Delta_{P_B}\|_{2 \to 2} \leq (1 - \|P_B\|_{2 \to 2})^{-1}$. Motivated by this remark, we define ‘Green’s function on a ball’

$$
G^B(y, \cdot) := \sum_{i=1}^{\infty} p_i^B(y, \cdot)
$$

for all balls $B$ with $\|P_B\|_{2 \to 2} < 1$ and for all $y \in B$. By (8.34) and (8.35)

$$
p_k^B(y, z) = [\Delta_{P_B}^{-1} \Delta_{P_B} p_k^B(y, \cdot)](z) = [\Delta_{P_B}^{-1} \partial_k p^B(y, \cdot)](z)
$$

$$
= \partial_k p^B(y, z) + \int_B G^B(z, w) \partial_k p^B(y, w) \, dw
$$

for all $x \in M$, for all $A \geq 1 \lor h'$, for all $y, z \in B = B(x, \sqrt[1]{k})$ and for all $k \geq 2$. By (8.36) and triangle inequality, we obtain

$$
|p_k^B(x, y) - p_k^B(x, x)| \leq |\partial_k p^B(x, y)| + |\partial_k p^B(x, x)|
$$

$$
+ \int_B |G^B(x, w) - G^B(y, w)| |\partial_k p^B(x, w)| \, dw
$$

for all $x \in M$, for all $A \geq 1$, and for all $y \in B = B(x, \sqrt[1]{k})$. We write the right side in (8.37) by splitting it into four parts as

$$
K = |\partial_k p^B(x, y)| + |\partial_k p^B(x, x)|
$$

$$
I_1 + I_2 + J = \int_B |G^B(x, w) - G^B(y, w)| |\partial_k p^B(x, w)| \, dw.
$$

where $I_1, I_2, J$ are terms corresponding to the integration over the sets

$$W_1 = \{ w \in B : d(x, w) \leq \eta \sqrt[1]{k} \}, \quad W_2 = \{ w \in B : d(y, w) \leq \eta \sqrt[1]{k} \}
$$

for $I_1, I_2$ and

$$W = \{ w \in B : d(x, w) > \eta \sqrt[1]{k} \text{ and } d(y, w) > \eta \sqrt[1]{k} \}
$$

for $J$, where $\eta > 0$ will be chosen later.

As before, we will abbreviate $B(x, \sqrt[1]{k})$ by $B$. By Lemma 8.8(b), there exists $C_2 > 0, \delta > 0$ such that

$$
K \leq 2 \sup_{y, z \in B} |\partial_k p^B(y, z)| \leq \frac{2C_2 A^\delta}{kV(x, \sqrt[1]{k})} \leq \frac{\tau}{V(x, \sqrt[1]{k})}
$$

for all $\tau > 0$, for all $A \geq 1$, for all $x \in M$ and for all $k \in \mathbb{N}^*$ satisfying $k \geq 2$ and $k \geq (2C_2 A^\delta)/\tau$.  

8.3. NEAR DIAGONAL LOWER BOUND
Next, we bound \( I_1 \) and \( I_2 \). We treat \( I_2 \) in detail but the same estimate applies to \( I_1 \). By Lemma 8.8(b), we have

\[
I_2 \leq \left( \sup_{z_1, z_2 \in B} \partial_k \nu^{B}(z_1, z_2) \right) \int_{W_2} (G^B(x, w) + G^B(y, w)) \, dw \\
\leq \frac{C_2 A^\delta}{k V(x, \sqrt{A})} \int_{W_2} (G^B(x, w) + G^B(y, w)) \, dw
\]

(8.39) for all \( k \geq 2 \). By Lemma 8.8(c), there exists \( C_9 > 0, a_1 > 0 \) such that

\[
\int_{W_2} G^B(z, w) \, dw \leq \int_{W_2} \sum_{j=1}^{\lfloor \theta k \rfloor} p_j^B(z, w) \, dw + \int_{W_2} \sum_{j=\lfloor \theta k \rfloor + 1}^{\infty} p_j^B(z, w) \, dw \\
\leq \theta k + \sum_{j=\lfloor \theta k \rfloor + 1}^{\infty} \int_{W_2} p_j^B(z, w) \, dw \\
\leq \theta k + \frac{C_9 A^\delta}{V(x, \sqrt{A})} \left( 1 - \frac{a_1}{A^2 k} \right)^{\theta k} A^{2k} a_1 \mu(W_2) \\
\leq \theta k + \frac{C_9 A^{3+2k}}{a_1 V(x, \sqrt{A})} V(y, \eta \sqrt{A})
\]

(8.40) for all \( x \in M \), for all \( A \geq 1 \) \& \( h' \), for all \( \theta \in (0, 1) \), for all \( k \in \mathbb{N}^* \) with \( k \geq 2/\theta \) and for all \( y, z \in B = B(x, A \sqrt{A}) \). For all \( y \in B(x, A \sqrt{A}) \), by Lemma 2.12 and (2.4) there exists \( C_3 > 1, \gamma > 0 \) such that

\[
\frac{V(y, \eta \sqrt{A})}{V(x, \sqrt{A})} \leq \frac{V(y, \eta \sqrt{A})}{V(x, 2A \sqrt{A})} \leq C_3 A^\delta \eta^\gamma
\]

(8.41) for all \( x \in M \), for all \( A \geq 1 \), for all \( y \in B(x, A \sqrt{A}) \), for all \( \eta \in (0, 1) \) and for all \( k \in \mathbb{N}^* \) with \( k \geq (b/\eta)^2 \).

For all \( \tau > 0 \), we choose \( \theta \in (0, 1) \) and \( \eta \in (0, 1) \) such that

\[
\theta \leq \frac{\tau}{4 C_2 A^\delta}, \quad \frac{2 C_9 C_3 A^{2k+2} \eta^\gamma}{a_1} \leq \frac{\tau}{4 C_2 A^\delta}
\]

(8.42) Given the above choice of \( \theta, \eta \), for all \( \tau > 0 \), for all \( A \geq 1 \) \& \( h' \), by (8.39), (8.40), (8.41) there exists \( N_1 \geq 2 \) such that

\[
\max(I_1, I_2) \leq \frac{\tau}{V(x, \sqrt{A})}
\]

(8.43) for all \( x \in M \) and for all \( k \in \mathbb{N}^* \) with \( k \geq N_1 \). By (8.38) and (8.43), for all \( \sigma > 0, A \geq 1 \) \& \( h' \) there exists \( N_2 \geq 2 \) and \( \eta \in (0, 1) \) such that

\[
K + I_1 + I_2 \leq \frac{\sigma}{V(x, \sqrt{A})}
\]

(8.44) for all \( x \in M \) and for all \( k \in \mathbb{N}^* \) with \( k \geq N_2 \).

It remains to handle \( J \). For the rest of the proof, we fix the choice of \( \eta \in (0, 1) \) from (8.42). Since \( p_j^B(x, \cdot) \) is only defined up to \( \mu \)-almost everywhere, so is \( G^B(x, \cdot) \). However since \( p_j^B(x, \cdot) \) is a genuine function for all \( j \geq 2 \), by (4.10) we can redefine \( G^B \) in (8.35) as

\[
G^B(y, z) = \sum_{j=2}^{\infty} p_j^B(y, z)
\]

(8.45)
For all \( y, z \in B \) with \( d(y, z) > h' \). In other words \( G^B(y, \cdot) \) can be defined as a genuine function in \( B \setminus B(y, h') \) with \( G^B(y, z) = G^B(z, y) \) for all \( y, z \in B \) with \( d(y, z) > h' \). Further the function

\[
z \mapsto G^B(w, z) = G^B(z, w)
\]

is \( P \)-harmonic in \( B(y, d(y, z) - 3h') \), whenever \( y \in B \), \( B(y, d(x, w) - 2h') \subseteq B \) and \( d(y, w) > 3h' \). Therefore for all \( x \in M \), for all \( A \geq 1 \) and for all \( k \in \mathbb{N}^* \) with \( k \geq (6h'/\eta)^2 \), for all \( w \in B(x, A\sqrt{k}) \setminus B(x, \eta\sqrt{k}) \), the function \( z \mapsto G^{B(x, A\sqrt{k})}(z, w) \) is \( P \)-harmonic in \( B(x, \eta\sqrt{k}/2) \). By the Hölder-type regularity estimate for harmonic functions (Proposition 6.20), there exists \( C_4 > 0, N_3 \geq 2 \vee (6h'/\eta)^2, \alpha > 0, \epsilon_0 \in (0, \eta/2) \) such that

\[
|G^B(x, w) - G^B(y, w)| \leq C_4 \left( \frac{d(x, y) \vee 1}{\eta \sqrt{k}} \right)^\alpha \sup_{z \in B(x, \eta\sqrt{k}/2)} G^B(z, w)
\]

for all \( x \in M \), for all \( y \in B(x, \epsilon_0 \eta\sqrt{k}) \), for all \( A \geq 1 \), \( w \in B(x, A\sqrt{k}) \setminus B(x, \eta\sqrt{k}) \) and for all \( k \in \mathbb{N}^* \) with \( k \geq N_3 \).

Following (8.46), we need to estimate \( \sup_{w \in B \setminus B(x, \eta\sqrt{k}), z \in B(x, \eta\sqrt{k}/2)} G^B(z, w) \). For all \( z, w \in B \) such that \( d(z, w) > h' \), we have

\[
G^B(z, w) = \sum_{j=2}^{k} p_j^B(z, w) + \sum_{j=k+1}^{\infty} p_m^B(z, w).
\]

For the first term, by Lemma 8.8(a) and (2.4) there exists \( C_1, D_1, C_5, C_6 > 1 \) and \( \delta > 0 \) such that

\[
\begin{align*}
\sum_{j=2}^{k} p_j^B(z, w) &\leq \sum_{j=2}^{k} \frac{C_1}{V(z, \sqrt{j})} \exp \left( \frac{d(y, z)^2}{D_1 j} \right) \frac{V(z, 2\sqrt{k})}{V(x, \sqrt{k})} \\
&\leq \frac{C_5}{V(x, \sqrt{k})} \sum_{j=2}^{k} \left( \frac{k}{j} \right)^{\delta/2} \exp \left( -\eta^2 k \frac{j}{4D_1 j} \right) \\
&\leq \frac{C_6 k}{V(x, \sqrt{k})}
\end{align*}
\]

for all \( z \in B(x, \sqrt{k}) \), for all \( w \in B \) such that \( d(z, w) > \eta\sqrt{k}/2 \geq h' \). To obtain (8.47) above, we used that the function \( t \mapsto t^{\delta/2} \exp(-\eta^2 t/(4D_1)) \) is bounded in \( (0, \infty) \).

Next, we bound \( p_j \) for large values of \( j \). By Lemma 8.8(c) there exists \( C_7 > 0 \) such that

\[
\begin{align*}
\sum_{j=k+1}^{\infty} p_j^B(z, w) &\leq C_7 \frac{A^\delta}{V(x, \sqrt{k})} \sum_{j=k+1}^{\infty} \left( 1 - \frac{a_1}{A^2 k} \right)^j \\
&\leq \frac{C_7 A^{\delta+2} k}{a_1 V(x, \sqrt{k})}
\end{align*}
\]

for all \( k \in \mathbb{N}^*, A \geq 1 \), for all \( x \in M \) and for all \( z, w \in B = B(x, A\sqrt{k}) \).

Combining (8.46), (8.47), (8.48) along with Lemma 8.8(b) and (2.4), for each \( A \geq 1 \) and any choice of \( \eta \in (0, 1) \), there exists \( C_8 \geq 1, N_4 \geq 2, \epsilon_0 \in (0, 1) \) (depending on \( A, \eta \)) and \( \alpha > 0 \) such that

\[
|G^B(x, w) - G^B(y, w)| \leq C_8 \left( \frac{d(x, y) \vee 1}{\sqrt{k}} \right)^\alpha \frac{1}{V(x, \sqrt{k})}
\]
for all \( x \in M \), for all \( y \in B(x, \epsilon_0 \sqrt{k}) \) and for all \( k \in \mathbb{N}^* \) satisfying \( k \geq N_4 \), where \( B = B(x, A \sqrt{k}) \) and \( \alpha \) is as in (6.87). Combining (8.44) and (8.49), we obtain the desired estimate (8.25).

Now, we are ready to prove the near diagonal lower bound using Lemma 8.7 and Lemma 8.3.

**Proof of Proposition 8.6.** By Lemma 8.3, there exists \( A \geq 1 \vee k' \) and \( c > 0 \) such that

\[
p^B_{k}(x,A \sqrt{k})(x,x) \geq \frac{c}{V(x, \sqrt{k})}
\]

for all \( x \in M \) and for all \( k \in \mathbb{N}^* \) with \( k \geq 2 \). By Lemma 8.7, there exists \( C_1 > 1, N_1 \geq 2, \epsilon \in (0,1), \alpha > 0 \) such that

\[
|p^B_{k}(x,y) - p^B_{k}(x,x)| \leq \left[ \frac{c}{3} + C_1 \left( \frac{d(x,y) \lor 1}{\sqrt{k}} \right)^\alpha \right] \frac{1}{V(x, \sqrt{k})}
\]

for all \( x \in M \), for all \( k \in \mathbb{N}^* \) with \( k \geq N_0 \), for all \( y \in B(x, \epsilon \sqrt{k}) \) where \( B = B(x, A \sqrt{k}) \). Next, we choose \( \epsilon_1 \in (0, \epsilon) \) and \( N_1 \geq N_0 \) such that for all \( k \geq N_1 \), we have

\[
C_1 \left( \frac{\epsilon_1 \sqrt{k} \lor 1}{\sqrt{k}} \right)^\alpha \leq C_1 \max(\epsilon^\alpha, N_0^{-\alpha/2}) \leq \frac{c}{3}.
\]

By the above choice of \( \epsilon_1, N_1 \) along with (8.50),(8.51) and the triangle inequality, we have

\[
\inf_{y \in B(x, \epsilon_1 \sqrt{k})} p^B_{k}(x,A \sqrt{k})(x,y) \geq \frac{c}{3V(x, \sqrt{k})}
\]

for all \( x \in M \) and for all \( k \in \mathbb{N}^* \) with \( k \geq N_1 \). Since \( p^B_{k} \leq p_k \), the above equation yields the desired near diagonal lower bound (8.24) for all \( k \geq N_1 \).

If \( k \in [2, N_1] \), then we reduce \( \epsilon \) if necessary so that \( \epsilon \leq h/\sqrt{N_1} \). Hence \( d(x, y) \leq \epsilon \sqrt{k} \) and \( k \leq N_1 \) implies \( d(x, y) \leq h \). Therefore by (4.12) of Lemma 4.10 and (4.10), we obtain (8.24) for all \( k \in [2, N_1] \). \( \square \)

### 8.4. Off-diagonal lower bounds

The near diagonal lower bound of Proposition 8.6 can be easily upgraded to full Gaussian lower bounds \((GLE)\) by a well-known chaining argument (See [44, Theorem 5.1], [27, Theorem 3.8]). For general quasi-geodesic spaces, we rely on the chain lemma (Lemma 2.6). We now prove the main result of this chapter, i.e. Gaussian lower bound.

**Proof of Proposition 8.1.** By Lemma 2.6 there exists \( C_1 > 1 \) such that for all \( b_1 \geq b \) and for all \( x, y \in M \), there exists a \( b_1 \)-chain \( x = x_0, x_1, \ldots, x_m = y \) with

\[
m \leq \left[ \frac{C_1 d(x, y)}{b_1} \right].
\]

By Proposition 8.6, there exists \( \epsilon > 0, c_1 > 0 \) such that

\[
\inf_{y \in B(x, \epsilon \sqrt{k})} p_k(x, y) \geq \frac{c_1}{V(x, \sqrt{k})}
\]
8.4. OFF-DIAGONAL LOWER BOUNDS

for all \( x \in M \) and for all \( k \geq 2 \). If

\[
(8.54) \quad s := \frac{C_1 \varepsilon^2 k}{C_2 d(x, y)} \geq b,
\]

then there exists a \( s \)-chain \( x = x_0, x_1, \ldots, x_m = y \) between \( x \) and \( y \) with

\[
(8.55) \quad m := \left\lceil \frac{C_2 d(x, y)^2}{\varepsilon^2 k} \right\rceil.
\]

However (8.54) holds whenever \( d(x, y) \leq c_3 k \) and \( c_3 \leq C_1 \varepsilon^2 / C_2 b \). If \( C_2 \geq 1 \) and \( d(x, y) \geq \epsilon \sqrt{k} \), we have

\[
(8.56) \quad m := \left\lceil \frac{C_2 d(x, y)^2}{\varepsilon^2 k} \right\rceil \leq 2C_2 d(x, y)^2 / \varepsilon^2 k.
\]

If \( d(x, y) \leq c_3 k \) and \( c_3 \leq \epsilon / \sqrt{2C_2} \), we have

\[
(8.57) \quad k / m \geq C_2 d(x, y)^2 / \varepsilon^2 \geq C_2 \varepsilon / \sqrt{2C_2} \geq 2.
\]

We fix \( c_3 = \min \left( \epsilon / \sqrt{(2C_2)}, C_1 \varepsilon^2 / C_2 b \right) \), so that (8.54),(8.55) and (8.57) are satisfied. We will fix \( C_2 \geq 1 \) later.

We will require

\[
(8.58) \quad d(x_i, x_{i+1}) \leq s = \frac{C_1 \varepsilon^2 k}{C_2 d(x, y)} \leq \frac{\epsilon}{3} \sqrt{\frac{k}{2m}} \leq \frac{\epsilon}{3} \sqrt{\frac{k}{m}}
\]

for all \( i = 0, 1, \ldots, m-1 \) and for all \( k \geq m \). We fix \( C_2 := 36C_1^2 \geq 1 \), so that by (8.56) we deduce

\[
(8.59) \quad s = \frac{C_1 \varepsilon^2 k}{C_2 d(x, y)} \leq \frac{\epsilon}{3} \sqrt{\frac{k}{4C_2 d(x, y)^2}} \leq \frac{\epsilon}{3} \sqrt{\frac{k}{2m}} \leq \frac{\epsilon}{3} \sqrt{\frac{k}{m}}
\]

for all \( x, y \in M \) and \( k \in \mathbb{N}^* \) such that \( d(x, y) \geq \epsilon \sqrt{k} \) and \( k / m \geq 2 \), where \( s, m \) is as defined in (8.54) and (8.55). Define \( k_0, \ldots, k_{m-1} \) such that

\[
k_i := \left\lfloor \frac{k}{m} \right\rfloor \text{ or } \left\lceil \frac{k}{m} \right\rceil + 1
\]

satisfying \( \sum_{i=0}^{m-1} k_i = k \). Consider the \( s \)-chain \( x = x_0, \ldots, x_m = y \) between \( x \) and \( y \) where \( s, m \) are given by (8.54),(8.55). By (8.59) and definition of \( k_i \), for all \( w_i \in B(x_i, \epsilon / 3 \sqrt{[k/m]}) \), for \( i = 0, 1, \ldots, m-1 \) we have

\[
d(w_i, w_{i+1}) \leq \epsilon \sqrt{[k/m]} \leq \epsilon \sqrt{k_i}.
\]

Therefore by (8.53), (8.57) and (2.5), there exists \( c_4, c_5 \in (0, 1) \) such that for all \( i = 0, 1, \ldots, m-1, w_i \in B(x_i, \epsilon / 3 \sqrt{[k/m]}) \), we have

\[
(8.60) \quad p_{k_i}(w_i, w_{i+1}) \geq \frac{c_1}{V(w_i, \sqrt{k_i})} \geq \frac{c_4}{V(w_i, \sqrt{[k/m]})} \geq \frac{c_5}{V(x_i, \sqrt{[k/m]})}
\]

for all \( x, y \in M, k \geq 2 \) satisfying \( d(x, y) \geq \epsilon \sqrt{k} \) and \( d(x, y) \leq c_3 k \).
Define $B_i = B(x_i, (\epsilon/3)\sqrt{\lceil k/m \rceil})$. By Chapman-Kolmogorov equation and (8.60), for all $x, y \in M$, $k \geq 2$ satisfying $d(x, y) \geq \epsilon\sqrt{k}$ and $d(x, y) \leq c_3k$, we obtain

$$p_k(x, y) = \int_M \ldots \int_M p(x_0, w_1)p(w_1, w_2)\ldots p(w_{m-2}, w_{m-1})p(w_{m-1}, y) \, dw_1 \ldots dw_{m-1} \geq \int_{B_{m-1}} \ldots \int_{B_1} p(x_0, w_1)p(w_1, w_2)\ldots p(w_{m-2}, w_{m-1})p(w_{m-1}, y) \, dw_1 \ldots dw_{m-1}$$

(8.61)

$$\geq \frac{c_5^{m-1}}{V(x, \sqrt{k})} \prod_{i=1}^{m-1} \frac{V(x_i, (\epsilon/3)\sqrt{\lceil k/m \rceil})}{V(x_i, \sqrt{[k/m]})}$$

By (2.4), (8.56), (8.57) and (8.61), there exists $c_6, c_7 \in (0, 1)$ such that

$$p_k(x, y) \geq \frac{c_6^m}{V(x, \sqrt{k})} \geq \exp \left( \frac{2C_2d(x, y)^2 \log c_6}{\epsilon^2k} \right) \frac{1}{V(x, \sqrt{k})} \geq \frac{1}{V(x, \sqrt{k})} \exp \left( -\frac{d(x, y)^2}{c_7k} \right)$$

(8.62)

for all $x, y \in M$, $k \geq 2$ satisfying $d(x, y) \geq \epsilon\sqrt{k}$ and $d(x, y) \leq c_3k$. This yields (GLE) for the case $d(x, y) \geq \epsilon\sqrt{k}$.

The case $d(x, y) \leq \epsilon\sqrt{k}$ follows from (8.53). This completes the proof of (GLE). □
CHAPTER 9

Parabolic Harnack inequality

In this chapter, we use the two sided Gaussian estimates on the heat kernel to prove parabolic Harnack inequality. Moreover, we show the necessity of Poincaré inequality and large scale volume doubling using parabolic Harnack inequality.

Based on ideas of Nash [64], Fabes and Stroock [31] gave a proof of parabolic Harnack inequality using Gaussian bounds on the heat kernel for uniformly elliptic operators on $\mathbb{R}^n$. This idea of using Gaussian estimates on the heat kernel to prove parabolic Harnack inequality was extended in various settings [74, 68, 27, 10]. Delmotte [27] introduced a discrete version of balayage formula to prove parabolic Harnack inequality on graphs. We use a direct adaptation of Delmotte’s method to prove parabolic Harnack inequality.

Recall that we defined caloric function as solutions to the discrete time heat equation $\partial_k u + \Delta u_k = 0$ in Definition 7.3. We introduce the parabolic Harnack inequality for non-negative caloric functions.

**Definition 9.1.** Let $(M, d, \mu)$ be a metric measure space and let $P$ be a Markov operator on $(M, d, \mu)$. Let $0 < \zeta < 1$ and $0 < \theta_1 < \theta_2 < \theta_3 < \theta_4$. We that a $\mu$-symmetric Markov operator $P$ (or equivalently its heat kernel $p_k$) on $(M, d, \mu)$ satisfies the discrete-time parabolic Harnack inequality $H(\zeta, \theta_1, \theta_2, \theta_3, \theta_4)$ if there exists positive reals $C, R$ such that for all $x \in M, r \in \mathbb{R}, a \in \mathbb{N}$ with $r > R$ and every non-negative $P$-caloric function $u : \mathbb{N} \times M \to \mathbb{R}_{\geq 0}$ on

$$Q = [a, a + [\theta_4 r^2]] \times B(x, r),$$

we have

$$\sup_{Q_\ominus} u \leq C \inf_{Q_\oplus} u,$$

where

$$Q_\ominus := [a + [\theta_1 r^2], a + [\theta_2 r^2]] \times B(x, \zeta r),$$

$$Q_\oplus := [a + [\theta_3 r^2], a + [\theta_4 r^2]] \times B(x, \zeta r).$$

**Remark 9.2.**

(i) The exact values of the constants $\zeta \in (0, 1)$ and $\theta_1, \theta_2, \theta_3, \theta_4$ are unimportant. For example, for graphs and length spaces if the parabolic Harnack inequality is satisfied for one set of constants, then it is satisfied for every other set of constants. The argument in [10, Proposition 5.2(iv)] can be adapted for graphs and length spaces in the above discrete-time setting.

(ii) It suffices to consider the case $a = 0$ in the definition above by simply by shifting the function in the time component.
(iii) Analogous to Remark 7.4(b), if $P$ is $(h, h')$-compatible with $(M, d, \mu)$ we may only require the function $u$ to be defined on a smaller domain.

## 9.1. Gaussian estimates implies parabolic Harnack inequality

In this section, we prove the following parabolic Harnack inequality using two sided Gaussian bounds.

**Proposition 9.3.** Let $(M, d, \mu)$ be a quasi-$b$-geodesic metric measure space satisfying $(VD)_{\text{loc}}$. Suppose that a Markov operator $P$ has a kernel $p_k$ that is weakly $(h, h')$-compatible with respect to $\mu$ for some $h > b$. Moreover, suppose that $p_k$ satisfies two sided Gaussian estimate $(GE)$. Then there exists $\eta \in (0, 1)$ such that $P$ satisfies the parabolic Harnack inequality $H(\eta/2, \sqrt[4]{\eta^2/2}, \sqrt{\eta^2}, 4\eta^2)$.

First we start by verifying that Gaussian lower bound implies large scale volume doubling property.

**Lemma 9.4.** Let $(M, d, \mu)$ be a quasi-$b$-geodesic metric measure space satisfying $(VD)_{\text{loc}}$. Suppose that a Markov operator $P$ has a kernel $p_k$ that satisfies $(GLE)$. Then $(M, d, \mu)$ satisfies $(VD)_{\infty}$.

**Proof.** By $(GLE)$ there exists $c_1, c_2, c_3 > 0$ such that

$$p_n(x, y) \geq \frac{c_1}{V(x, \sqrt{n})} \exp\left(-d(x, y)^2/c_2n\right)$$

for all $x, y \in M$ satisfying $d(x, y) \leq c_3n$ and for all $n \in \mathbb{N}^*$. Therefore there exists $N_1 \geq 1$ such that $4\sqrt{n} \leq c_3n$ for all $n \geq N_1$. By the Gaussian lower bound above

$$1 = \int_M p_n(x, y) \, dy \geq \int_{B(x, 4\sqrt{n})} p_n(x, y) \, dy \geq \frac{V(x, 4\sqrt{n})}{V(x, \sqrt{n})} c_1 \exp(-4/c_2)$$

for all $x \in M$ and for all $n \geq N_1$. Therefore there exists $R := N_1^2$ such that for all $x \in M$ and for all $r \geq R$, we have

$$V(x, r) \geq V(x, \lfloor r \rfloor) \geq c_1 \exp(-4/c_2)V(x, 4\lfloor r \rfloor) \geq c_1 \exp(-4/c_2)V(x, 2r).$$

We show the following near diagonal lower bounds as a consequence of two sided Gaussian bound $(GE)$.

**Lemma 9.5.** Under the assumptions of Proposition 9.3, there exists $c_1 > 0$, $\eta \in (0, 1)$ and $R_0 > 0$ such that for all $x \in M$, for all $r \geq R_0$, for all $y, z \in B(x, \eta r)$, for all $k \in \mathbb{N}^*$ satisfying $(\eta r)^2 \leq k \leq (2\eta r)^2$, we have

$$p_k^{B(x,r)}(y, z) \geq \frac{c_1}{V(x, \sqrt{k})}.$$  \tag{9.1}

**Proof.** We abbreviate $B(x, r)$ by $B$. We denote the exit time from ball $B$ by $\tau := \min \{n : X_n \notin B\}$ where $(X_n)_{n \in \mathbb{N}}$ is the Markov chain on $M$ corresponding to the kernel $p_k$.

By strong Markov property and $\mu$-symmetry, the Dirichlet kernel $p_k^B$ can be expressed in terms of $p_k$ as

$$p_k^B(y, z) = p_k(y, z) - E_y[p_{k-\tau}(z, X_{\tau})1_{[1, k-1]}(\tau)]$$  \tag{9.2}

$$p_k^B(y, z) \geq c_1 \frac{1}{V(x, \sqrt{k})}.$$
for all \( n \geq 2 \) and for all \( x \in M \), where \( \mathbb{E}_y \) denotes that the Markov chain starts at \( X_0 = y \). We choose \( R_0 > (1 - \eta)^{-1} h' \), so that by (4.10)

\[
\mathbb{E}_y \left[ p_{k-r}(z, X_r) \mathbf{1}_{[1,k-1]}(\tau) \right] = \mathbb{E}_y \left[ p_{k-r}(z, X_r) \mathbf{1}_{[2,k-2]}(\tau) \right]
\]

for all \( y, z \in B(x, B r) \), for all \( k \geq 2 \), for all \( x \in M \) and for all \( r \in \mathbb{R} \) with \( r \geq R_0 \). Combining this with (9.2) and \( X_r \notin B \), we have

\[
p_k^B(y, z) \geq \sup_{l \in [2,k]} \sup_{w \notin B(x,r)} p_l(z, w)
\]

for all \( y, z \in B(x, B r) \), for all \( k \geq 2 \), for all \( x \in M \) and for all \( r \in \mathbb{R} \) with \( r \geq (1 - \eta)^{-1} h' \).

Note that by Lemma 9.4 we have \((V D)_{\infty} \). Therefore by \((G L E)\), (2.4) and \( k \geq (\eta r)^2 \), there exists \( c_2, c_3 > 0 \) and \( R_1 > 0 \) such that

\[
p_k(y, z) \geq \frac{c_2}{V(y, \sqrt{k})} \exp \left( -\frac{(2\eta r)^2}{c_2(\eta r)^2} \right) \geq \frac{c_3}{V(x, \sqrt{k})}
\]

for all \( x \in M \), for all \( r \geq R_1 \), for all \( \eta \in (0,1) \), for all \( y, z \in B(x, B r) \) and for all \( k \in \mathbb{N}^* \) satisfying \((\eta r)^2 \leq k \).

For the second term in (9.3) by \((G U E)\), there exists \( C_1 > 0 \) such that

\[
p_l(z, w) \leq \frac{C_1}{V(z, \sqrt{l})} \exp \left( -\frac{d(z, w)^2}{C_1 l} \right) \leq \frac{C_1}{V(z, \sqrt{l})} \exp \left( -\frac{(1 - \eta)^2 r^2}{C_1 l} \right)
\]

for all \( l \in \mathbb{N}^* \) with \( l \geq 2 \), for all \( x \in M \), for all \( r > 0 \), for all \( \eta \in (0,1) \), for all \( z \in B(x, B r) \) and for all \( w \notin B(x, r) \). Combined this with (2.4) and \( k \leq (2\eta r)^2 \), there exists \( C_2, C_3, C_4, \delta > 0 \) such that for all \( \eta \in (0,1/2) \), for all \( x \in M \), for all \( z \in B(x, B r) \), for all \( k \in \mathbb{N}^* \) satisfying \((\eta r)^2 \leq k \leq (2\eta)^2 \), for all \( l \in [2,k] \) and for all \( w \notin B(x, r) \), we have

\[
p_l(z, w) \leq \frac{C_2}{V(z, \sqrt{k})} \left( \frac{k}{7} \right)^{\delta} \exp \left( -\frac{(1 - \eta)^2 r^2}{C_1 l} \right) \\
\leq \frac{C_4 \eta^{2\delta}}{V(x, \sqrt{k})} \left( \frac{r^2}{l} \right)^{\delta} \exp \left( -\frac{r^2}{4C_1 l} \right)
\]

The second line above follows from \( \eta < 1/2 \) and (2.4) and the last line follows from the fact the function \( t \mapsto t^\delta \exp(-t/4C_1) \) is bounded in \((0, \infty)\). Combining (9.3), (9.4) and (9.5), there exists \( c_1 > 0 \) and \( R_0 > 0 \) such that \( p_k^B \) satisfies (9.1).

The following lemma provides a discrete time version of Balayage decomposition for the heat equation.

**Lemma 9.6.** Let \((M, d, \mu)\) be a quasi-b-geodesic metric measure space satisfying \((V D)_{\infty} \). Suppose that a Markov operator \( P \) has a kernel \( p_k \) that is weakly \((h, h')\)-compatible with respect to \( \mu \) for some \( h > b \). Then for all \( x \in M \), for all \( r > h' \), for all \( r_1 \) such that \( 0 < r_1 < r_1 + h' < r \), for all \( a, b \in \mathbb{N} \), for all non-negative function \( u : N \times M \rightarrow \mathbb{R}_{\geq 0} \) that is \( P \)-caloric in \([a, b] \times B(x, r) \), there exists a non-negative function \( v : N \times M \rightarrow \mathbb{R} \) (depending on \( u \)) such that \( \text{supp}(v) \subseteq \)
\( [a+1, b] \times (B(x, r_1 + h') \setminus B(x, r_1)) \) and for all \( y \in B(x, r_1) \) and for all \( k \in [a, b+1] \), we have

\[
(9.6) \quad u(k, y) = \int_{B(x, r_1 + h')} p^B_{k-a}(y, z) u(a, z) \, dz + \sum_{i=a+1}^{k-1} \int_{B(x, r_1 + h')} p^B_{k-i}(y, w) v(l, w) \, dw,
\]

where \( B = B(x, r) \).

**Proof.** Denote by \( B_1 = B(x, r_1 + h') \) and \( B = B(x, r) \). Define

\[
v_1(k, y) = u(k, y) - \int_{B(x, r_1 + h')} p^B_{k-a}(y, z) u(a, z) \, dz
\]

for all \( (k, y) \in [a+1, b+1] \times B(x, r_1 + h') \). Note that

\[
(k, y) \mapsto \int_{B_1} p^B_{k-a}(y, z) u(a, z) \, dz
\]

is \( P \)-caloric in \([a+1, b] \times B(x, r_1)\). Since \( u \geq 0 \), by (4.10) we have \( v_1(a+1, y) = 0 \) for all \( y \in B(x, r_1) \) and by maximum principle \( v_1 \geq 0 \) in \([a+1, b+1] \times B(x, r_1)\).

Next, we construct \( v : \mathbb{N} \times M \to \mathbb{R} \) iteratively. We assume that \( \text{supp}(v) \subseteq [a+1, b] \times (B(x, r_1 + h') \setminus B(x, r_1)) \). Define \( v(a+1, y) = v_1(a+1, y) \) for all \( y \in B(x, r_1 + h') \setminus B(x, r) \).

Since \( v_1 \) is a difference of two \( P \)-caloric functions, we have \( v_1 \) is \( P \)-caloric in \([a+1, b] \times B(x, r_1)\). We repeat this construction iteratively by defining

\[
(9.7) \quad v_{i+1}(k, y) = v_i(k, y) - \int_{B(x, r_1 + h')} p^B_{k-a-i}(y, z) v_i(a+i, z) \, dz
\]

for all \( (k, y) \in [a+i+1, b+1] \times B(x, r_1 + h') \) and

\[
v(a+i+1, w) = v_{i+1}(a+i+1, w)
\]

for all \( w \in B(x, r_1 + h') \setminus B(x, r_1) \) and \( i = 0, 1, \ldots, b-a-1 \). By the same argument as above, \( v_i \) is non-negative and caloric in \([a+i, b] \times B(x, r_1)\) for all \( i = 0, 1, \ldots, b-a-1 \). Further

\[
u_i(a+i, z) = 0
\]

for all \( z \in B(x, r_1) \) and \( i = 1, 2, \ldots, b-a \). Combining (9.7), (9.8) and gives (9.6). \( \square \)

We are now ready to prove the parabolic Harnack inequality.

**Proof of Proposition 9.3.** Let \( \eta \in (0, 1) \) be as given by Lemma 9.5. Note that for all \( r > 12h'/\eta \), we have \( \eta r - h' > 2\eta r / 3 > \eta / 2 \). Moreover for all \( r > 12h'/\eta \), for all \( y \in B(x, \eta r / 2) \) and for all \( z \in B(x, \eta r) \setminus B(x, \eta r - h') \) we have \( d(y, z) > 2h' \).

Let \( R_1 := 1 + \max(R_0, 12h'/\eta, 10/\eta) \) where \( R_0 \) is the constant from Lemma 9.5. By the above remarks, (4.10) and Lemma 9.6, for all \( x \in M \), for all \( r \geq R_1 \), for all non-negative function \( u \) that is \( P \)-caloric in \([0, [4\eta^2 r^2]] \times B \) where \( B = B(x, r) \), there exists a non-negative function \( v \) supported in \( B(x, \eta r) \setminus B(x, \eta r - h') \) such that

\[
(9.9) \quad u(k, y) = \int_{B(x, \eta r)} p^B_{k}(y, z) u(a, z) \, dz + \sum_{i=1}^{k-2} \int_{B(x, \eta r)} p^B_{k-i}(y, w) v(l, w) \, dw
\]

for all \( (k, y) \in [1, [4\eta^2 r^2] + 1] \times B(x, \eta r / 2) \).
For some fixed \( x \in M \) and \( r > R_1 \), we define

\[
Q_\ominus := \left[ [\eta^2r^2/2], \eta^2r^2 \right] \times B(x, \eta r/2), \quad Q_\oplus := \left[ [2\eta^2r^2], 4\eta^2r^2 \right] \times B(x, \eta r/2)
\]
and \( Q := [0, 4\eta^2r^2] \times B(x, \eta r) \).

By Lemma 9.4 we have \((VD)_\infty\). Therefore by Lemma 9.5 and \((2.4)\) there exists \( c_1, c_2 > 0 \) such that for all \( x \in M \), for all \( r \geq R_1 \), for all \( y \in B(x, \eta r/2) \), for all \( z \in B(x, \eta r) \), we have

\[
\inf_{(k,y) \in Q_\ominus} p_k^B(y, z) \geq \inf_{k \in \left[[2\eta^2r^2], [4\eta^2r^2]\right]} \frac{c_1}{V(x, \sqrt{\eta^2r^2})} \geq c_1 \frac{1}{V(x, 2\eta r)} \geq c_2 \frac{1}{V(x, \eta r)}.
\]

Similarly by Lemma 9.5 for all \( x \in M \), for all \( r \geq R_1 \), for all \( y \in B(x, \eta r/2) \), for all \( z \in B(x, \eta r) \setminus B(x, \eta r - h') \), for all \( l \in [1, [\eta^2r^2] - 2] \) we have

\[
\inf_{(k,y) \in Q_\ominus} p_{k-l}^B(y, z) \geq \inf_{k \in \left[[2\eta^2r^2], [4\eta^2r^2]\right]} \frac{c_1}{V(x, \sqrt{(k-l)^2})} \geq c_2 \frac{1}{V(x, \eta r)}.
\]

For upper bounds in \( Q_\ominus \) we simply use \((GUE)\) as follows. By \((GUE)\) and \((2.5)\), there exists \( C_1, C_2 > 0 \) such that for all \( x \in M \), for all \( r \geq R_1 \), for all \( y \in B(x, \eta r/2) \), for all \( z \in B(x, \eta r) \), we have

\[
\sup_{(k,y) \in Q_\ominus} p_k^B(y, z) \leq \sup_{(k,y) \in Q_\ominus} p_k(y, z) \leq \sup_{(k,y) \in Q_\ominus} \frac{C_1}{V(y, \sqrt{k})} \leq \frac{C_2}{V(x, \eta r)}.
\]

Similarly by \((GUE)\) and \((2.4)\), there exists \( C_3, C_4, C_5, \delta > 0 \) such that for all \( x \in M \), for all \( r \geq R_1 \), for all \( y \in B(x, \eta r/2) \), for all \( z \in B(x, \eta r) \setminus B(x, \eta r - h') \), for all \( (k,y) \in Q_\ominus \) and for all \( l \in [1, [k-l] - 2] \) we have

\[
p_{k-l}^B(y, z) \leq c_3 \exp \left(-\frac{d(y, z)^2}{C_3(k-l)}\right) \]
\[
\leq \frac{C_4}{V(y, \eta r)} \left(\frac{\eta^2r^2}{(k-l)^2}\right)^{\delta/2} \exp \left(-\frac{\eta^2r^2}{36C_5(k-l)}\right) \]
\[
\leq c_5 \frac{1}{V(x, \eta r)}.
\]

The last line follows from the fact that the function \( t \mapsto \exp(-t/(36C_3)) \) is bounded in \((0, \infty)\) along with \((2.5)\).

Combining the inequalities \((9.11),(9.12),(9.13)\) and \((9.14)\) along with the balayage formula \((9.9)\) for all \( x \in M \), for all \( r \geq R_1 \), for all non-negative function \( u \) that is \( P \)-caloric in \([[0, [\eta^2r^2]],[\eta^2r^2]] \times B(x, r) \), we have

\[
\sup_{(k,y) \in Q_\ominus} u(k, y) \leq c_2^{-1} \max(C_2, C_5) \inf_{(k,y) \in Q_\ominus} u(k, y)
\]
where \( Q_\ominus, Q_\oplus \) are as defined in \((9.10)\). Note that by Remark 9.2(ii), we have the desired Harnack inequality.

9.2. Necessity of Poincaré inequality and large scale volume doubling

In the previous sections, we have obtain two-sided Gaussian bounds on the heat kernel and parabolic Harnack inequality assuming large scale volume doubling and a Poincaré inequality. Now we show that large scale volume doubling and Poincaré inequality are necessary to have two-sided Gaussian bounds on the heat kernel and parabolic Harnack inequality. The was first proved by Saloff-Coste in [69, Theorem 3.1] using an argument due to Kusuoka and Stroock [55]. Delmotte [27] followed the
Proposition 9.7. Let \((M, d, \mu)\) be a quasi-\(b\)-geodesic metric measure space satisfying \((VD)_{\text{loc}}\). Suppose that a Markov operator \(P\) has a kernel \(p_k\) that is weakly \((h, h')\)-compatible with respect to \(\mu\) for some \(h > b\) and there exists \(\eta \in (0, 1)\) such that \(P\) satisfies the parabolic Harnack inequality \(H(\eta/2, \eta^2/2, \eta^2, 2\eta^2, 4\eta^2)\). Then \((M, d, \mu)\) satisfies \((VD)_{\infty}\) and \((P)_{h'}\).

Proof. Let \(x \in M\) and \(r > 0\). Define \(u = u_{x, r}\) as

\[
u(l, y) = \begin{cases} 
1 & \text{if } l \in [0, [\eta^2 r^2] - 1] \\
B(x, r)(y) & \text{if } l = [\eta^2 r^2] \\
\int_{B(x, r_2(k))} B(x, r) P_l_{(\eta^2 r^2)} (y, w) \, dw & \text{if } l > [\eta^2 r^2].
\end{cases}
\]

Note that \(u\) is non-negative and \(u\)-caloric in \(\mathbb{N} \times B(x, r)\). For \(k \in \mathbb{N}^+\), we choose \(r\) such that \(\eta^2 r^2 = k\). By applying \(H(\eta/2, \eta^2/2, \eta^2, 2\eta^2, 4\eta^2)\) to the function \(u\), there exists \(C_H, N_1 > 1\) such that

\[
1 = u(k, x) \leq C_H u(2k, x) = C_H \int_{B(x, \sqrt{k}/\eta)} p_k^{B(x, \sqrt{k}/\eta)} (x, z) \, dz
\]

for all \(x \in M\), for all \(k \in \mathbb{N}^+\) with \(k \geq N_1\). Squaring (9.15) and applying Cauchy-Schwarz inequality we obtain

\[
1 \leq C_H^2 \left( \int_{B(x, \sqrt{k}/\eta)} p_k^{B(x, \sqrt{k}/\eta)} (x, z) \, dz \right)^2 \\
\leq C_H^2 V(x, \sqrt{k}/\eta) \int_{B(x, \sqrt{k}/\eta)} \left( p_k^{B(x, \sqrt{k}/\eta)} (x, z) \right)^2 \, dz \\
= C_H^2 V(x, \sqrt{k}/\eta) p_{2k}^{B(x, \sqrt{k}/\eta)} (x, x)
\]

for all \(x \in M\) and for all \(k \in \mathbb{N}^+\) satisfying \(k \geq N_1\). Therefore

\[
p_{2k}^{B(x, \sqrt{k}/\eta)} (x, x) \geq C_H^{-2} \frac{1}{V(x, \sqrt{k}/\eta)}
\]

for all \(x \in M\) and for all \(k \in \mathbb{N}^+\) satisfying \(k \geq N_1\).

Next we apply \(H(\eta/2, \eta^2/2, \eta^2, 2\eta^2, 4\eta^2)\) to the non-negative, \(P\)-caloric function \((l, y) \mapsto p_{l+2}(x, y)\) on \([0, [4\eta^2 r^2]], \mathbb{B}(x, r)\) where \(r\) is chosen such that \(\eta^2 r^2 = k - 2 \geq k/2\). Then there exists \(N_2 \geq \max(4, N_1)\) such that for all \(k \geq N_1\), we have

\[
p_k(x, x) \leq C_H p_{2k}(x, y)
\]

for all \(x \in M\), for all \(k \geq N_2\) and for all \(y \in B(x, \sqrt{k}/2)\). Integrating (9.17) over \(y \in B(x, \sqrt{k}/2)\), we obtain

\[
p_k(x, x) \leq C_H \frac{1}{V(x, \sqrt{k}/2)}
\]

for all \(x \in M\), for all \(k \geq N_2\). Iterating (9.17) with \(y = x\), we obtain

\[
p_{2k}(x, x) \leq C_H^d p_{2^{d+1}k}(x, x)
\]
for all \( x \in M \), for all \( k \geq N_2 \) and for all \( l \in \mathbb{N} \). Combining (9.16), (9.18), (9.19) along with \( p_{2k}^H \leq p_{2k} \), we obtain

\[
\frac{1}{V(x, \eta^{-1}\sqrt{k})} \leq \frac{C_H^{l+3}}{V(x, 2^{l/2}\sqrt{k})}
\]

for all \( l \in \mathbb{N} \), for all \( x \in M \) and for all \( k \in \mathbb{N} \) satisfying \( k \geq N_2 \). Next we choose \( l \) such that \( 2^{l/2} > 4\eta^{-1} \) so that there exists \( C_1 > 1 \) such that

\[
V(x, 4\eta^{-1}\sqrt{k}) \leq C_1 V(x, \eta^{-1}\sqrt{k})
\]

for all \( x \in M \) and for all \( k \in \mathbb{N} \) satisfying \( k \geq N_2 \). Therefore there exists \( R_1 > 0 \) such that for all \( r > R_1 \) and for all \( x \in M \) we have

\[
V(x, r) \geq V(x, \eta^{-1}\sqrt{|\eta^2 r^2|}) \geq C_1^{-1} V(x, 4\eta^{-1}\sqrt{|\eta^2 r^2|}) \geq C_1^{-1} V(x, 2r).
\]

This completes the proof of \((VD)_\infty\).

It remains to prove the Poincaré inequality \((P)_H^r\). We start by showing a near diagonal lower bound for the `Dirichlet kernel' \( p_{B(x, \eta^{-1}\sqrt{k})} \).

By \( H(\eta/2, \eta^2/2, \eta^2, 2\eta^2, 4\eta^2) \) applied to the function \((l, y) \mapsto p_{2k+l}^{B(x, \eta^{-1}\sqrt{k})}(x, y)\) that is \( P \)-caloric on \([0, 4k] \times B(x, \eta^{-1}\sqrt{k})\), we have

\[
p_{2k}^{B(x, \eta^{-1}\sqrt{k})}(x, x) \leq C_H \inf_{y \in B(x, \sqrt{k}/2)} p_{3k}^{B(x, \eta^{-1}\sqrt{k})}(x, y)
\]

for all \( k \geq N_2 \) and for all \( x \in M \). Similarly by \( H(\eta/2, \eta^2/2, \eta^2, 2\eta^2, 4\eta^2) \) applied to the function \((l, z) \mapsto p_{2k+l}^{B(x, \eta^{-1}\sqrt{k})}(z, y)\) that is \( P \)-caloric on \([0, 4k] \times B(x, \eta^{-1}\sqrt{k})\), we have

\[
p_{3k}^{B(x, \eta^{-1}\sqrt{k})}(x, y) \leq C_H \inf_{z \in B(x, \sqrt{k}/2)} p_{4k}^{B(x, \eta^{-1}\sqrt{k})}(z, y)
\]

for all \( k \geq N_2 \), for all \( x \in M \) and for all \( y \in B(x, \sqrt{k}/2) \). Combining (9.16), (9.20), (9.21) and (2.4) there exists \( c_1 > 0 \) such that for all \( x \in M \) and for all \( k \in \mathbb{N}^* \) satisfying \( k \geq N_2 \), we have

\[
\inf_{y, z \in B(x, \sqrt{k}/2)} p_{4k}^{B(x, \eta^{-1}\sqrt{k})}(y, z) \geq \frac{c_1}{V(x, \sqrt{k})}.
\]

For a ball \( B = B(x, \eta^{-1}\sqrt{k}) \), we define a Markov operator

\[
Q_B f(y) := P_B f(y) + \left( 1 - \int_B p_B^1 (y, z) \, dz \right) f(y)
\]

for all \( y \in B \) and for all functions \( f \) on \( B \). Note that unlike \( P_B \), the operator \( Q_B \) is conservative, that is

\[
Q_B 1_B = 1_B.
\]
For the rest of the this proof we abbreviate $B(x, \eta^{-1}\sqrt{k})$ by $B$. By (9.22) for all $B = B(x, \eta^{-1}\sqrt{k})$ satisfying $k \geq N_2$ and for all $y \in B(x, \sqrt{k}/2)$, we have

$$Q_k^k [f - Q_k^k f(y)](y) \geq P_k^k [f - Q_k^k f(y)](y) \geq \int_{B(x, \sqrt{k}/2)} (f(z) - Q_k^k f(y))^2 p_k^k (y, z) \, dz$$

$$\geq \frac{c_1}{V(x, \sqrt{k})} \int_{B(x, \sqrt{k}/2)} (f(z) - Q_k^k f(y))^2 \, dz$$

$$\geq \frac{c_1}{V(x, \sqrt{k})} \int_{B(x, \sqrt{k}/2)} \left( f(z) - f_B(x, \sqrt{k}/2) \right)^2 \, dz.$$  \hfill (9.23)

The first line above follows from $Q_B g \geq P_B g$ for all $g \geq 0$, the third line above follows from (9.22) and the last line above follows from the fact that mean minimizes square error (3.2). By (9.23) along with (2.4) there exists $c_2 > 0$ such that for all $x \in M$ and for all $k \in \mathbb{N}^*$, we have

$$\int_B Q_k^k [f - Q_k^k f(y)](y) \, dy \geq \int_{B(x, \sqrt{k}/2)} Q_k^k [f - Q_k^k f(y)](y) \, dy \geq c_2 \int_{B(x, \sqrt{k}/2)} \left( f(z) - f_B(x, \sqrt{k}/2) \right)^2 \, dz \quad \hfill (9.24)$$

where $B = B(x, \eta^{-1}\sqrt{k})$.

By linearity of the operator $Q_k^k$, we have

$$Q_k^k [f - Q_k^k f(y)]^2(y) = (Q_k^k f^2)(y) - (Q_k^k f(y))^2$$

Therefore by the symmetry of the operator $Q_B$ and $Q_B 1_B = 1_B$, we have

$$\int_B Q_k^k [f - Q_k^k f(y)]^2(\eta) \, dy = (1_B, Q_k^k f^2)_{L^2(B)} - \|Q_k^k f\|^2_{L^2(B)}$$

$$= \langle Q_k^k 1_B, f^2 \rangle_{L^2(B)} - \|Q_k^k f\|^2_{L^2(B)}$$

$$= \|f\|^2_{L^2(B)} - \|Q_k^k f\|^2_{L^2(B)}$$

$$= \sum_{l=0}^{4k-1} \left( \|Q_B f\|^2_{L^2(B)} - \|Q_B^{l+1} f\|^2_{L^2(B)} \right). \quad \hfill (9.25)$$

The identity $\|f\|^2_{L^2(B)} - \|Q_B f\|^2_{L^2(B)} = \|f\|_{L^2(B)}$ along with the fact that $Q_B$ is a contraction in $L^2$ yields

$$\|Q_B f\|^2_{L^2(B)} - \|Q_B^{l+1} f\|^2_{L^2(B)} = \left\| Q_B (I - Q_B^2)^{1/2} f \right\|^2_{L^2(B)} \leq \|f\|^2_{L^2(B)} - \|Q_B f\|^2_{L^2(B)}$$

for all $l \in \mathbb{N}$. Combining (9.25) and (9.26), we obtain

$$\int_B Q_k^k [f - Q_k^k f(y)]^2(\eta) \, dy \leq 4k \left( \|f\|^2_{L^2(B)} - \|Q_B f\|^2_{L^2(B)} \right). \quad \hfill (9.27)$$
9.2. NECESSITY OF POINCARÉ INEQUALITY AND LARGE SCALE VOLUME DOUBLING

Using the inequality \(a^2 - b^2 \leq 2a(a - b)\), we have

\[
\|f\|_{L^2(B)}^2 - \|Q_B f\|_{L^2(B)}^2 = \int_B (f(y))^2 - (Q_B f(y))^2 \, dy \\
\leq 2 \int_B f(y) (f(y) - Q_B f(y)) \, dy \\
= \int_B \int_B (f(y) - f(z))^2 p_B(y, z) \, dy \, dz \\
- 2 \int_B \left(1 - \int_B p_B(y, z) \, dz\right) (f(y))^2 \, dy \\
\leq \int_B \int_B (f(y) - f(z))^2 p_B(y, z) \, dy \, dz.
\]

(9.28)

Combining (9.24), (9.27) and (9.28), for all \(x \in M\), for all \(k \in \mathbb{N}^+\) with \(k \geq N_2\) and for all \(f \in L^2(M)\), we have

\[
\int_{B(x, \sqrt{2}k)} (f(z) - f_{B(x, \sqrt{2}k)})^2 \, dz \leq 4C_2^{-1}k \int_B (f(y) - f(z))^2 p(y, z) \, dy \, dz
\]

where \(B = B(x, \eta^{-1}\sqrt{k})\). Therefore there exists \(R > 0, C_1, C_2 > 0\) such that for all \(x \in M\), for all \(r > R\) and for all \(f \in L^2(M)\), we have

\[
\int_{B(x, r)} (f(z) - f_{B(x, r)})^2 \, dz \leq \int_{B(x, r)} (f(z) - f_{B(x, \sqrt{\frac{4r^2}{r}}/2)})^2 \\
\leq \int_{B(x, \sqrt{\frac{4r^2}{r}}/2)} (f(z) - f_{B(x, \sqrt{\frac{4r^2}{r}}/2)})^2 \, dz \\
\leq C_1 R^2 \int_{B(x, C_2r)} \int_{B(x, C_2r)} (f(y) - f(z))^2 p(y, z) \, dy \, dz.
\]

(9.29)

By (4.10) and (9.29), we have the desired Poincaré inequality \((P)_{h'}\). \(\square\)

We now have all the ingredients to prove our main result in a slightly weaker form.

**Proposition 9.8.** Let \((M, d, \mu)\) be a quasi-b-geodesic metric measure space satisfying \((VD)_{\text{loc}}\) and \(\text{diam}(M) = +\infty\). Suppose that a Markov operator \(P\) has a kernel \(p\) that is \((h, h')\)-compatible with \((M, d, \mu)\) with either \(h = h' > b\) or \(h' > h \geq 5b\). Then the following are equivalent:

(i) **Parabolic Harnack inequality:** there exists \(\eta \in (0, 1)\) such that \(P\) satisfies \(H(\eta/2, \eta^2/2, \eta^2, 2\eta^2, 4\eta^2)\).

(ii) **Gaussian bounds on the heat kernel:** the heat kernel \(p_k\) satisfies \((GE)\).

(iii) **The conjunction of large scale volume doubling property \((VD)_{\infty}\) and Poincaré inequality \((P)_{h}\).**

**Proof.** The implication “(iii) implies (ii)” follows from Theorem 5.1, Proposition 7.1 and Proposition 8.1. (ii) implies (i) follows from Proposition 9.3. (i) implies (iii) follows from Proposition 9.7 and Corollary 3.17. \(\square\)

Next, we answer the question raised in Remark 3.6.

**Proposition 9.9.** Let \((M, d, \mu)\) be a quasi-b-geodesic metric measure space satisfying \((VD)_{\text{loc}}, (VD)_{\infty}, (P)_{h'}\) for some \(h' > b\) and \(\text{diam}(M) = +\infty\). Then \((M, d, \mu)\) satisfies \((P)_{h}\) for all \(h > b\).
Proof. By Lemma 3.5 it suffices to consider the case \( b < h < h' \). Consider the Markov chain with density
\[
p(x, y) = \frac{1_{B(x,h)}(y)}{Q(x)Q(y)\sqrt{V(x,h)V(y,h)}}
\]
that is symmetric with respect to the measure \( \mu'(dx) = Q(x)\mu(dx) \), where
\[
Q(x) = \int_M \frac{1_{B(x,h)}(y)}{\sqrt{V(x,h)V(y,h)}} \mu(dy).
\]
By \((VD)_{\text{loc}}\), there exists \( C_1 > 0 \) such that
\[
(9.30) \quad C_1^{-1} \leq Q(x) \leq C_1
\]
for all \( x \in M \). Therefore the space \((M, d, \mu')\) satisfies \((VD)_{\text{loc}}\), \((VD)_{\infty}\), \((P)_{h'}\) for some \( h' > b \). Moreover by \((9.30)\), \( p \) is weakly \((h, h')\)-compatible with \((M, d, \mu')\).

By the same argument as Lemma 4.11, there exists \( l \in \mathbb{N}^* \) such that \( p_1 \) is \((h', lh)\)-compatible with \((M, d, \mu')\). Therefore by Proposition 9.8 and Lemma 4.16 the kernel \( p_k \) satisfies \((GE)\). The Poincaré inequality \((P)_{h'}\) for \((M, d, \mu')\) then follows from Propositions 9.3 and 9.7. An easy comparison argument using \((9.30)\) gives \((P)_{h}\) for \((M, d, \mu)\).

The following is the main result of our work.

**Theorem 9.10.** Let \((M, d, \mu)\) be a quasi-\(b\)-geodesic metric measure space satisfying \((VD)_{\text{loc}}\) and \( \text{diam}(M) = +\infty \). Suppose that a Markov operator \( P \) has a kernel \( p \) that is \((h, h')\)-compatible with \((M, d, \mu)\), where \( h' \geq h > b \). Then the following are equivalent:

(i) **Parabolic Harnack inequality:** there exists \( \eta \in (0, 1) \) such that \( P \) satisfies \( H(\eta/2, \eta^2/2, \eta^2, 2\eta^2, 4\eta^2) \).

(ii) **Gaussian bounds on the heat kernel:** the heat kernel \( p_k \) satisfies \((GE)\).

(iii) **The conjunction of large scale volume doubling property** \((VD)_{\infty}\) **and Poincaré inequality** \((P)_{h}\).

Proof. Combining Propositions 9.8, 9.7 and 9.9 yields the desired result. □

As announced in the introduction, we will show Theorem 1.4 and Theorem 1.3 are covered by our results. Theorem 1.3 is clearly a special case of Theorem 9.10. So it remains to verify Theorem 1.4.

**Proof of Theorem 1.4.** We need only to check the implication (c) implies (b) as the other implications follow as in Theorem 9.10. Although \( p_1 \) is only weakly \((h, h')\)-compatible to \((M, d, \mu)\), by Lemma 4.11, Theorem 9.10 and Lemma 4.16, we have that \( p_k \) satisfies \((GE)\). □
Applications

Perhaps the most important application of the characterization of parabolic Harnack inequality and Gaussian bounds on the heat kernel is the stability under quasi-isometries.

**Theorem 10.1.** Let \((M_i, d_i, \mu_i)\) be a quasi-bi-geodesic metric measure spaces satisfying \((V D)_{loc}\) and \(\text{diam}(M_i) = +\infty\), for \(i = 1, 2\). Moreover we assume that \((M_1, d_1, \mu_1)\) and \((M_2, d_2, \mu_2)\) are quasi-isometric metric measure spaces. Suppose that a Markov operator \(P_i\) has a kernel that is \((h_i, h'_i)\)-compatible with \((M_i, d_i, \mu_i)\) with \(h'_i \geq h_i > b_i\) for \(i = 1, 2\). Then

(i) The kernel corresponding to \(P_1\) satisfies \((GE)\) if and only if the kernel corresponding to \(P_2\) satisfies \((GE)\).

(ii) The operator \(P_1\) satisfies the Harnack inequality \(H(\eta/2, \eta^2/2, \eta^2, 2\eta^2, 4\eta^2)\) for some \(\eta \in (0, 1)\) if and only if \(P_2\) satisfies \(H(\zeta/2, \zeta^2/2, \zeta^2, 2\zeta^2, 4\zeta^2)\) for some \(\zeta \in (0, 1)\).

**Proof.** The is a direct consequence of Theorem 9.10 along with stability of \((V D)_{\infty}\) given by Proposition 2.20, stability of \((P)_{h}\) given by Proposition 3.16, Proposition 9.9 and Lemma 3.5.

As mentioned in the introduction, it is a long standing open problem to prove such a stability result for elliptic Harnack inequality. A partial result in this direction is obtained by Bass. In [12], Bass proves stability of elliptic Harnack inequality for weighted graphs under bounded perturbation of the conductances. However the weighted graphs were assumed to be transient and they satisfy certain regularity hypotheses. In [6], Barlow introduced the dumbbell condition that is stable under bounded perturbation of weights of a weighted graph and asks if the dumbbell condition is equivalent to elliptic Harnack inequality.

Recall that we proved an elliptic Hölder regularity estimate for \(P\)-harmonic functions in Proposition 6.20 and we used the regularity in the proof of Gaussian lower bounds (Lemma 8.7). There is an analogous parabolic Hölder regularity estimate which follows from parabolic Harnack inequality. The proof is similar, for example the proof given in [72, Theorem 5.4.7] can be adapted for the present setting. Such parabolic Hölder continuity estimates were first obtained by Nash [64].

**Proposition 10.2.** Let \((M, d, \mu)\) be a quasi-bi-geodesic metric measure space satisfying \((V D)_{loc}\) and \(\text{diam}(M) = +\infty\). Suppose that a Markov operator \(P\) has a kernel \(p\) that is weakly \((h, h')\)-compatible with \((M, d, \mu)\) and satisfies parabolic Harnack inequality \(H(\eta/2, \eta^2/2, \eta^2, 2\eta^2, 4\eta^2)\) for some \(\eta \in (0, 1)\). Then there exists \(C > 0, R > 0\) and \(\alpha > 0\) such that for all \(x \in M, r > R\) and for any non-negative function \(u : \mathbb{N} \times M \rightarrow \mathbb{R}\) that is \(P\)-caloric in \([0, 4\eta^2 r^2]\) \times B(x, r) = Q,
we have the regularity estimate

\[
\sup_{(k_1,x_1),(k_2,x_2) \in [2\eta^2r^2],[4\eta^2r^2] \times B(x,r)} \frac{|u(k_1,x_1) - u(k_2,x_2)|}{(\max(1,|k_1 - k_2| + d(x_1,x_2)))^\alpha} \leq C r^\alpha \sup_Q u.
\]

Note that we do not obtain continuity, because we do not have Hölder continuity estimate at arbitrarily small distances. Another application of elliptic Harnack inequality is Liouville property for harmonic functions that was shown in Proposition 6.19.

Next, we turn attention to application of two sides Gaussian estimates \((GE)\). Of course, the estimates given by \((GE)\) has enough information to determine whether or not the the random walk is transient. The estimate given by [27, Proposition 4.3] can be easily generalized to metric measure spaces in which case we obtain

**Proposition 10.3.** Let \((M,d,\mu)\) be a quasi-b-geodesic metric measure space satisfying \((VD)_{loc}\) and \(\text{diam}(M) = +\infty\). Consider a \(\mu\)-symmetric Markov operator \(P\) that is \((h,h')\)-compatible with \((M,d,\mu)\) for some \(h > b\) and whose kernel \(p_k\) satisfies \((GE)\). Then the random walk corresponding to \(P\) is transient if and only if

\[
\sum_{n=1}^{\infty} \frac{n}{V(x,n)} < +\infty
\]

for some \(x \in M\).

It is easy to see that the convergence of the series in (10.1) does not depend on the choice of \(x \in M\). Unless the space is discrete, we do not have a ‘Green’s function’ as the Green operator \(\Delta^{-1} = \sum_{i=0}^{\infty} P^i\) does not have a kernel as there is ‘delta mass’ singularity at the starting point. However, we may consider the off-diagonal part of the Green operator given by the “Green’s function” \(G(x,y) = \sum_{i=1}^{\infty} p_i(x,y)\). The estimate given by [27, Proposition 4.3] can be again generalized as follows.

**Proposition 10.4.** Under the assumptions of Proposition 10.3, there exists \(C > 0\) such that

\[
C \sum_{n=\lfloor d(x,y) \rfloor}^{\infty} \frac{n}{V(x,n)} \leq G(x,y) := \sum_{i=1}^{\infty} p_i(x,y) \leq C \sum_{n=\lfloor d(x,y) \rfloor}^{\infty} \frac{n}{V(x,n)}
\]

for some \(x \in M\) and for all \(y \in M\) with \(d(x,y) > h'\).

As noted in [44, Theorem 9.1], the Gaussian estimate is sufficient to prove law of iterated logarithm in a weak form. The proof in [44] can be generalized for metric measure spaces.

**Proposition 10.5.** Under the assumptions of Proposition 10.3, there exist \(C > 0\) such that for all starting points \(X_0 \in M\)

\[
C^{-1} \leq \limsup_{n} \frac{d(X_0,X_n)}{(n \log \log n)^{1/2}} \leq C
\]

almost surely, where \((X_k)_{k \in \mathbb{N}}\) is the Markov chain corresponding to \(P\).

We refer the reader to [44, Section 9] for other probabilistic applications in similar spirit.

We sketch a possible application to mixing times of Markov chains that will be developed elsewhere. If the space has finite diameter the techniques developed
here can be used to prove upper and lower bounds on mixing times. In this case \( \mu \) is a finite measure on \( M \) and can be normalized if necessary to be the stationary probability measure. Roughly speaking, in this case for \((h, h')\)-compatible Markov operator on a space with diameter \( D \), it takes \((D/h)^2\) steps of the Markov chain to get close to the stationary distribution \( \mu \). The Poincaré inequality and Gaussian upper bounds can be used to obtain upper bounds on mixing time as outlined in [30, Lemma 2.1 and Remark 1 after Lemma 2.2]. For lower bounds on the mixing time one would need Gaussian lower bounds. We plan to address these questions in a sequel and obtain results complementary to those in [56]. We refer the reader to [28, 29] for other recent works in this direction.

10.1. Harmonic functions with polynomial volume growth

In [17], Colding and Minicozzi proved that the space of harmonic functions with polynomial volume growth with fixed rate on a manifold satisfying volume doubling and Poincaré inequality is finite dimensional. As a corollary, they prove a conjecture of S. T. Yau on manifolds that asserts the above property for Riemannian manifolds with non-negative Ricci curvature. A recent surprising application of this result is an alternate proof of Gromov’s theorem on groups of polynomial volume growth due to Kleiner [53]. This new proof avoids the solution to Hilbert’s fifth problem (Montgomery-Zippin-Yamabe structure theory). To precisely state a theorem we need the following definition.

**Definition 10.6.** For a metric measure space \((M, d, \mu)\) and a \(\mu\)-symmetric Markov operator \(P\) on \(M\), we define the space of \(P\)-harmonic functions with growth rate \(d\) as the vector space \(H_d(M, P)\) consisting of all \(P\)-harmonic functions \(u\) such that there exists \(C > 0, p \in M\) (depending on \(u\)) such that \(|u(x)| \leq C(1 + d(x, p)\gamma)\) for all \(x \in M\).

We have the following theorem that extends the result of Colding and Minicozzi to random walks on metric measure spaces.

**Theorem 10.7.** Let \((M, d, \mu)\) be a quasi-geodesic metric measure spaces satisfying \(\text{diam}(M) = +\infty\), volume doubling hypotheses \((VD)_{loc}, (VD)_{\infty}\) and Poincaré inequality \((P)_{h}\). Let \(P\) be a Markov operator that is \((h, h')\)-compatible with \((M, d, \mu)\). Then the space of \(P\)-harmonic functions \(H_d(M, P)\) with a fixed growth rate \(d\) is finite dimensional for any \(d \geq 0\).

The proof of Colding and Minicozzi’s theorem in [17] relies on three ingredients: volume doubling hypotheses \((VD)\), a Poincaré inequality \(1.7\) and a reverse Poincaré inequality for harmonic functions. We have all the three ingredients as we showed the reverse Poincaré inequality in Lemma 6.14. A caveat is that we have to rely on weaker versions of all the three ingredients but nevertheless we will see that Theorem 10.7 can be proved using the techniques introduced of [17]. T. Delmotte adapted an alternate approach due to P. Li [57] to prove a similar statement for random walks on graphs satisfying doubling and Poincaré inequality [26].

The next proposition below is a slightly weaker version of [17, Proposition 2.5].

**Proposition 10.8.** Let \((M, d, \mu)\) be a quasi-geodesic metric measure spaces satisfying \(\text{diam}(M) = +\infty\), volume doubling hypotheses \((VD)_{loc}, (VD)_{\infty}\) and Poincaré inequality \((P)_{h}\) and let \(P\) be a Markov operator that is \((h, h')\)-compatible
with \((M,d,\mu)\). There exists \(\epsilon \in (0,1)\) such that for all \(p \in M\), for all \(k \geq 1\) satisfying \(r \geq k/\epsilon\) and for all functions \(f_1,f_2,\ldots,f_n \in L^\infty_{\text{loc}}(M)\) satisfying
\[
(10.3) \quad \int_{B(p,r)} f_i^2 \, d\mu = V(p,r) 
\]
for all \(i = 1,2,\ldots,n\);
\[
(10.4) \quad \left| \int_{B(p,r)} f_if_j \, d\mu \right| < \frac{V(p,r)}{2} 
\]
for all \(1 \leq i < j \leq n\); and
\[
(10.5) \quad \int_{B(p,2r)} \left( f_i^2 + (2r)^2 |\nabla_p f_i|^2 \right) \, d\mu \leq k^2 V(p,r) 
\]
for all \(i = 1,2,\ldots,n\). We have \(n \leq N\), where \(N\) depends on \(k\) but does not depend on \(r \geq k/\epsilon\) or \(p \in M\).

**Proof.** By Lemma 2.11 there exists \(C_D > 0\) such that
\[
(10.6) \quad V(x,2r_1) \leq V(x,r_1) 
\]
for all \(r_1 \geq 1\) and for all \(x \in M\). Moreover if we set \(\delta := \log_2 C_D\), we have
\[
(10.7) \quad \frac{V(x,r_2)}{V(x,r_1)} \leq C_D \left( \frac{r_2}{r_1} \right)^\delta 
\]
for all \(x \in M\) and for all \(1 \leq r_1 \leq r_2\). By Lemma 3.7 and (4.10), there exists constants \(C_A > 0\) and \(A \geq 1\) such that for all \(x \in M\), for all \(r_1 \geq 1\), for all functions \(f \in L^\infty_{\text{loc}}(M)\), we have
\[
(10.8) \quad \int_{B(x,r_1)} |f - f_{B(x,r_1)}|^2 \, d\mu \leq C_A r_1^2 \int_{B(x,r_1)} |\nabla_p f|^2 \, d\mu. 
\]
Let \(p \in M\), \(r > 0\), \(k \geq 1\) and \(\epsilon r \leq k\). Define
\[
(10.9) \quad r_0 := \frac{\epsilon r}{k} \geq 1, 
\]
where \(\epsilon \in (0,1)\) will be determined later.

Let \(x_1,x_2,\ldots,x_\nu\) be a \(2r_0\)-net of \(B(p,r)\). We set
\[
(10.10) \quad \epsilon := \min \left( \frac{1}{2A}, \frac{1}{20C_A^{1/2}C_D^{1/2}(4A + 1)\delta/2} \right). 
\]
Since \(\epsilon \leq 1/2\) and \(r > r_0 \geq 1\), by (10.6), (10.7), we have
\[
(10.11) \quad \frac{1}{C_D} \leq \frac{V(x_j,r)}{V(x_j,2r)} \leq \frac{V(x_j,r)}{V(p,r)} \leq \frac{V(x_j,r_0)}{V(p,r)} \leq \frac{V(x_j,r_0)}{V(p,r)} \leq C_D \left( \frac{k}{\epsilon} \right)^\delta \frac{V(x_j,r_0)}{V(p,r)} 
\]
for all \(j = 1,2,\ldots,\nu\) and for all \(r \geq 1\). Since \(r_0 \leq r\) by Proposition 2.22(a), (10.11) and (10.6), we have
\[
(10.12) \quad \sum_{j=1}^\nu V(x_j,r_0) \leq V(p,r + r_0) \leq V(p,2r) \leq C_D V(p,r). 
\]
By (10.11) and (10.12), we have
\[
(10.13) \quad \nu \leq C_D^3 (k/\epsilon)^\delta. 
\]
Next we bound the overlap of the balls \((B(x_j, 2Ar_0))_{1 \leq j \leq \nu}\). Define \(\eta(y)\) as the cardinality of the set \(\{ j : y \in B(x_j, 2Ar_0) \}\). If \(y \in \bigcap_{m=1}^{\eta(y)} B(x_{j_m}, 2Ar_0)\), then \(B(y, (2A+1)r_0)\) contains the disjoint balls \(B(x_{j_m}, r_0)\) and hence

\[
\sum_{m=1}^{\eta(y)} V(x_{j_m}, r_0) \leq V(y, (2A+1)r_0)
\]  

(10.14)

However by (10.6), (10.7), for all \(y \in M\), for all \(j_m\) such that \(y \in B(x_{j_m}, 2Ar_0)\), we have

\[
V(y, (2A+1)r_0) \leq V(x_{j_m}, (4A+1)r_0) \leq C_D(4A+1)^\delta V(x_{j_m}, r_0)
\]

(10.15)

By (10.14) and (10.15), we have

\[
\tilde{C} := \sup_{y \in M} \eta(y) \leq C_D(4A+1)^\delta.
\]  

(10.16)

By Proposition 2.22 the balls \(B(x_j, 2r_0)\) covers \(B(p, r)\). We now partition \(B(p, r)\) into \(\nu\) disjoint subsets \(S_1, S_2, \ldots, S_\nu\), where \(B(x_j, r_0) \cap B(p, r) \subset S_j \subset B(x_j, 2r_0)\). Let \(P = \{x_j : 1 \leq j \leq \nu\}\) denote the finite set of points in \(B(p, r)\). For any function \(f \in L^\infty_{loc}(M)\), we set

\[
A_{i, j} := \int_{B(x_j, 2r_0)} f_i \, d\mu = \frac{1}{V(x_j, 2r_0)} \int_{B(x_j, 2r_0)} f_i \, d\mu.
\]  

(10.17)

By Cauchy-Schwarz inequality, (10.11), (10.5), we have

\[
|A_{i, j}|^2 \leq \int_{B(x_j, 2r_0)} f_i^2 \, d\mu \leq \frac{1}{V(x_j, r_0)} \int_{B(x_j, 2r_0)} f_i^2 \, d\mu \\
\leq C_D^2(k/\epsilon)^\delta \frac{1}{V(p, r)} \int_{B(x_j, 2r_0)} f_i^2 \, d\mu \leq C_D^2(k/\epsilon)^\delta \frac{1}{V(p, r)} \int_{B(p, 2r)} f_i^2 \, d\mu
\]

(10.18)

for all \(i = 1, \ldots, n\) and for all \(j = 1, \ldots, \nu\).

Let \(\Lambda := \{ \frac{m}{10} : s \in \mathbb{Z}, |s| \leq 10C_D k(\epsilon/\delta)^{\delta/2} \}\). Next, we define a map \(f_i \mapsto \mathcal{M}(f_i)\), where \(\mathcal{M}(f_i) : P \to \Lambda\) is a function from a finite set \(P\) to another finite set \(\Lambda\). With a slight abuse of notation, we interpret the function \(\mathcal{M}(f_i)\) as a piecewise constant function on \(B(p, r)\) that takes the value \(\mathcal{M}(f_i)(x_j)\) on \(S_j\), where \(j = 1, \ldots, \nu\). For all \(i = 1, \ldots, n\) and for all \(j = 1, \ldots, \nu\), we define \(\mathcal{M}(f_i)(x_j) \in \Lambda\) as any closest point of \(\Lambda\) to \(A_{i, j}\). By definition of \(\Lambda\) and (10.18), for all \(i, j\) we have

\[
|A_{i, j} - \mathcal{M}(f_i)(x_j)|^2 \leq \frac{1}{400}.
\]  

(10.19)

Combining the Poincaré inequality (10.8), (10.19) and \(S_j \subset B(x_i, 2Ar_0)\), we obtain

\[
\int_{S_j} |f_i - \mathcal{M}(f_i)(x_j)|^2 \, d\mu \\
\leq 2 \int_{B(x_j, 2r_0)} |f_i - A_{i, j}|^2 \, d\mu + 2 \int_{S_j} |A_{i, j} - \mathcal{M}(f_i)(x_j)|^2 \, d\mu \\
\leq 8r_0^2 C_A \int_{B(x_j, 2Ar_0)} |\nabla f_i|^2 \, d\mu + \frac{\mu(S_j)}{200}
\]
10. APPLICATIONS

for all $i = 1, \ldots, n$ and for all $j = 1, \ldots, \nu$. Hence by (10.16), (10.5) and (10.10), we have

\[
\int_{B(p,r)} |f_i - M(f_i)|^2 \, d\mu \leq 8r^2 C_A \bar{C} \int_{B(p,2r)} |\nabla_p f_i|^2 \, d\mu + \sum_{j=1}^{\nu} \frac{\mu(S_j)}{200} \tag{10.20}
\]

By the triangle inequality along with (10.20), we obtain

\[
\left(\int_{B(p,r)} |f_i - f_j|^2 \, d\mu\right)^{1/2} \leq \left(\int_{B(p,r)} |M(f_i) - M(f_j)|^2 \, d\mu\right)^{1/2} \tag{10.21}
\]

\[
\leq \left(\int_{B(p,r)} |f_i - M(f_i)|^2 \, d\mu\right)^{1/2} + \left(\int_{B(p,r)} |f_j - M(f_j)|^2 \, d\mu\right)^{1/2} \leq \frac{\sqrt{V(p,r)}}{5}
\]

for all $i \neq j$. By (10.4) and (10.3), we have for $i \neq j$

\[
\left(\int_{B(p,r)} |f_i - f_j|^2 \, d\mu\right)^{1/2} > \sqrt{V(p,r)}. \tag{10.22}
\]

Combining (10.21) and (10.22), for all $i \neq j$ we obtain

\[
\left(\int_{B(p,r)} |M(f_i) - M(f_j)|^2 \, d\mu\right)^{1/2} > 0.\]

Hence the map $M$ is injective. Therefore by (10.13)

\[
n \leq |\Lambda|^3 = |\Lambda|^\nu \leq N := \left(20C_D k(\epsilon/s)^{3/2} + 1\right)^{C_D (k/s)^{3/2}}.
\]

Note that the value of $N$ does not depend on the value of $p \in M$ or $r$ but only on $k$ and the constants associated with doubling properties and Poincaré inequality. \hfill \Box

Next, we recall the a result due to Colding and Minicozzi [17, Proposition 4.16]. We omit the proof as it is identical to that of [17, Proposition 4.16].

**Proposition 10.9.** Consider a metric measure space $(M, d, \mu)$ satisfying the hypotheses $(V D)_\text{loc}$, $(V D)_\infty$ and $\text{diam}(M) = +\infty$. Let $P$ be a Markov operator that is $(h, h')$-compatible with $(M, d, \mu)$ for some $0 < h \leq h'$. Suppose that $u_1, u_2, \ldots, u_{2k} \in H_d(M, P)$ are linearly independent. There exists $\delta > 0$, $p \in M$ such that for all $d > 0$, $\Omega > 1$ and $m_0 > 0$, there exists $m \geq m_0$, $I \geq \Omega^{-4d-\delta}$, and functions $v_1, \ldots, v_l$ in the linear span of $u_i$ such that

\[
2\Omega^{4d+2\delta} V(p, \Omega^m) = 2\Omega^{4d+2\delta} \int_{B(p,\Omega^m)} v_i^2 \, d\mu \geq \int_{B(p,\Omega^{m+1})} v_i^2 \, d\mu \tag{10.23}
\]

and

\[
\int_{B(p,\Omega^m)} v_i v_j \, d\mu = \delta_{i,j} V(p, \Omega^m). \tag{10.24}
\]

In Proposition 10.9, we may choose $\delta$ as the constant in (10.7). We are now ready to prove Theorem 10.7.
Proof of Theorem 10.7. Fix $\Omega > \max(4,3h')$, $d > 0$ and $p \in M$. Let $C_R$ be as given by Lemma 6.14 and set $k^2 = (8C_R + 2)\Omega^{4d+25}$. Let $\epsilon \in (0,1)$ be given by Proposition 10.8. We choose $m_0 \in \mathbb{N}^*$ such that $\Omega^{m_0} > k/\epsilon$. Let $\dim \mathcal{H}_d(M, P) \geq N_0 := 4\Omega^{4d+25}N$ where $N$ is given by Proposition 10.8 where $k$ is as defined above.

Suppose that $u_1, u_2, \ldots, u_{N_0} \in \mathcal{H}_d(M, P)$ is linearly independent. Then by Proposition 10.9 and reverse Poincaré inequality (Lemma 6.14) there exists $C_R > 0$ and $m > m_0$ such that for all $f \in L^2_{\text{loc}}(M, \mu)$, we have harmonic functions $v_1, v_2, \ldots, v_l$ satisfying

\begin{equation}
\int_{B(p, \Omega^m)} v_i v_j \ d\mu = V(p, \Omega^m) \delta_{i,j}, \tag{10.26}
\end{equation}

\begin{equation}
\int_{B(p, \Omega^{m+1})} v_i^2 \ d\mu \leq 2C_R \Omega^{4d+25} V(p, \Omega^m), \tag{10.27}
\end{equation}

and

\begin{equation}
\int_{B(p, 2\Omega^m)} \nabla P v_i^2 \ d\mu \leq C_R \Omega^{2m} \int_{B(p, 4\Omega^m)} v_i^2 \ d\mu \leq 2\Omega^{4d+25-2m} V(p, \Omega^m). \tag{10.28}
\end{equation}

Note that (10.26), (10.27), (10.28) and $\Omega > 4$ implies that $v_1, v_2, \ldots, v_l$ satisfy (10.3), (10.3)

\begin{equation}
\int_{B(p, \Omega^m)} v_i^2 + (2\Omega^m)^2 |\nabla P v_i|^2 \ d\mu \leq (8C_R + 2)\Omega^{4d+25} V(p, r) \tag{10.29}
\end{equation}

for all $i = 1, \ldots, l$. Note that (10.25), (10.26), (10.29) along with Proposition 10.8 implies the desired contradiction. Therefore $\dim \mathcal{H}_d(M, P) < N_0 < \infty$. \hfill $\Box$

Remark 10.10. Similar to [53], we can replace the volume doubling hypotheses $(V D)_{\text{loc}}$, $(V D)_{\infty}$ of Theorem 10.7 by a weakly polynomial growth assumption on the volume growth.

10.2. Directions for future work

We end with a few directions for future work. One of the features of our work is that it provides an unified approach to Gaussian estimates for discrete time Markov chains on both discrete and continuous spaces. Recently, there has been considerable interest in analysis and probability on fractals and fractal-like manifolds and graphs. For many natural family of fractals the heat kernel satisfies sub-Gaussian estimates of the form

$$p_t(x, y) \asymp \frac{C_1}{V(x, t^{1/\beta})} \exp \left( -C_2 \left( \frac{d(x, y)^\beta}{t} \right)^{1/(\beta-1)} \right)$$

for all $t > 0$ and for all $x, y \in M$ and $\beta > 1$ is a parameter (See [11, Theorem 1.5(e)] for an early example). Here $\asymp$ means that both inequalities $\leq$ and $\geq$ hold with different values of constants $C_1, C_2$. Similar to the characterizations of Gaussian estimates in [32, 69, 76, 27, 42] there exists various characterizations for sub-Gaussian estimates both in the setting of diffusions on local Dirichlet spaces [8] and for discrete time Markov chains on graphs [7, 9, 37, 38]. As in the case of Gaussian
estimates, it is desirable to obtain characterizations of sub-Gaussian estimates that are stable under quasi-isometries. This was achieved using a condition called cutoff-Sobolev inequality first introduced by Barlow and Bass [7] (See also [8]). Our work naturally raises an analogous question for sub-Gaussian estimates on Markov chains.

**Problem 10.11.** Characterize sub-Gaussian estimates for discrete time Markov chains on quasi-geodesic metric measure spaces using geometric conditions that are stable with respect to quasi-isometries.

Another direction for future work is to clarify the applications to mixing times in the finite diameter case as mentioned in Remark 8.5(b).

As mentioned in the introduction, we state the problem concerning the stability of the elliptic Harnack inequality.

**Problem 10.12.** Is elliptic Harnack inequality stable under quasi-isometries? If so, characterize the elliptic-Harnack inequality by geometric properties that are stable under quasi-isometries.

We refer the reader to [12, 6] for partial progress and conjectures aimed at solving the above problem.
APPENDIX A

Interpolation Theorems

In this appendix, we state Riesz-Thorin and Marcinkiewicz interpolation theorems and refer the reader to the literature for a proof.

Let $T : (X, \| \cdot \|_X) \to (Y, \| \cdot \|_Y)$ be a linear operator between normed linear spaces. We denote the operator norm by

$$\|T\|_{X \to Y} = \sup_{x \in X, x \neq 0} \frac{\|Tx\|_Y}{\|x\|_X} = \sup_{x \in X, \|x\|_X = 1} \|Tx\|_Y.$$ 

If $\|T\|_{X \to Y} < \infty$, we say the operator $T$ is bounded. It is well known that $T$ is bounded if and only if $T$ is continuous. We abbreviate $\|T\|_{L^p \to L^q}$ as $\|T\|_{p \to q}$.

**Theorem A.1** (Riesz-Thorin interpolation theorem). Assume that $(X, \Sigma, \mu)$ is a $\sigma$-finite measure space. Suppose $1 \leq p_0, p_1 \leq \infty$, $1 \leq q_0, q_1 \leq \infty$. Let $T : L^{p_0} + L^{p_1} \to L^{q_0} + L^{q_1}$, be a linear operator such that $T : L^{p_0} \to L^{q_0}$ and $L^{p_1} \to L^{q_1}$ are bounded. Then

$$\|T\|_{p_0 \to q_0} \leq \|T\|_{1 \to q_0}^{1 - \theta} \|T\|_{p_1 \to q_1}^\theta$$

for all $\theta \in (0, 1)$ where $1/p_0 := (1 - \theta)/p_0 + \theta/p_1$ and $1/q_0 := (1 - \theta)/q_0 + \theta/q_1$.

We refer the reader to [75] for a proof of Stein’s interpolation theorem which in turn implies Theorem A.1.

Consider a $\sigma$-finite measure space $(X, \Sigma, \mu)$. The distribution function of $f$ is defined by

$$\lambda_f(t) = \mu \{ x \in X : |f(x)| > t \}$$

We denote weak $L^p$ space by $L^{p,w}$. For a measurable function $f$ and $1 \leq p < \infty$, we define its $L^{p,w}$ norm by

$$\|f\|_{p,w} = \left( \sup_{t > 0} t^p \lambda_f(t) \right)^{1/p}.$$ 

We say a measurable function $f \in L^{p,w}$ if $\|f\|_{p,w} < \infty$. Note that $L^{p,w}$ is not a true norm, since $\|\cdot\|_{p,w}$ does not satisfy triangle inequality. If $f \in L^p$, then $\|f\|_p \leq \|f\|_{p,w}$. Therefore $L^p \subset L^{p,w}$. It is easy to check that $L^p \neq L^{p,w}$ in general.

**Theorem A.2** (Marcinkiewicz interpolation theorem). Let $1 \leq p_0 \leq q_0 < \infty$, $1 \leq p_1 \leq q_1 < \infty$ with $q_0 \neq q_1$. Let $T$ be a linear operator from $L^p_1 + L^p_2$ to the space of measurable functions. If $T$ satisfies

$$\|Tf\|_{q_i,w} \leq B_i \|f\|_{p_i}, \text{ for all } f \in L^{p_i}, \quad i = 0, 1$$

then

$$\|T\|_{p_0 \to q_0} \leq C_{p_0,p_1,q_0,q_1,\theta} B_0^{-\theta} B_1^\theta$$

for all $\theta \in (0, 1)$, where $1/p_0 := (1 - \theta)/p_0 + \theta/p_1$, $1/q_0 := (1 - \theta)/q_0 + \theta/q_1$ and $C_{p_0,p_1,q_0,q_1,\theta} < \infty$ depends only on $p_0, p_1, q_0, q_1, \theta$. 

137
We refer the reader to [2, Theorem 2.58] for a proof of Theorem A.2.
APPENDIX B

Examples

Here we collect various examples discussed earlier and supplement them with more examples, comments and pictures.

Example B.1 (Euclidean space with radial weights). We expand upon the ball walk described in Example 4.4 for specific metric measure spaces. If a weighted Riemannian manifold satisfies two-sided Gaussian estimates for its canonical diffusion, one might naively expect the same to hold for the ball walk. However this is not true in general because the measure \( \mu' \) of Example 4.4 is not necessarily comparable to \( \mu \). The measure \( \mu' \) might fail to satisfy either \((VD)_\infty \) or \((P)_\infty \). Recall the example \((M, d, \mu) = (\mathbb{R}^n, \|\cdot\|_2, \mu_\alpha)\) from Example 3.21, where \( \mu_\alpha = (1 + |x|)^{\alpha/2} \, dx \).

Note that if \( \alpha > 0 \) there is a drift away from the origin and if \( \alpha < 0 \) there is a drift towards the origin. If \( \mu = \mu_\alpha \) one can verify that \( \mu' = \mu'_\alpha \) is comparable to \( \mu^{2\alpha} \). Therefore the ballwalk accentuates the drift towards or away from the origin (See Figure 1). In light of the above observation along with Table 1, Theorem 1.4 and Proposition 3.20, if \( n \geq 2 \) and \( \alpha \in (-n, -n/2] \), then the canonical diffusion on \((\mathbb{R}^n, \|\cdot\|_2, \mu_\alpha)\) satisfies Gaussian estimates but the ball walk fails to satisfy Gaussian estimates because \((\mathbb{R}^n, \|\cdot\|_2, \mu'_\alpha)\) does not satisfy \((VD)_\infty \). In the case \( n = 1 \) and \( \alpha \in [1/2, 1) \), the canonical diffusion on \((\mathbb{R}, \|\cdot\|_2, \mu_\alpha)\) satisfies Gaussian estimates but the ball walk fails to satisfy Gaussian estimates because \((\mathbb{R}, \|\cdot\|_2, \mu'_\alpha)\) does not satisfy \((P)_\infty \).

Even when both diffusion and ball walk satisfy Gaussian estimates for the transition kernels with respect to the invariant measures, the long term behavior might be different. For example, if \( n \geq 3 \) and if \( 2 - n < \alpha \leq (2 - n)/2 \) then both

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{example.png}
\caption{Density of \( \mu_\alpha \) and \( \mu'_\alpha \) for the case \( \alpha = 0.6 \) (left) and \( \alpha = -0.6 \) (right) in \( \mathbb{R} \). Here \( \mu'_\alpha \) is normalized to have density 1 at origin.}
\end{figure}
diffusion and ball walk on \((\mathbb{R}^n, d, \mu_\alpha)\) satisfy Gaussian estimates for the transition kernels with respect to the invariant measures. However in this case the ball walk is recurrent but the diffusion is transient.

For \(n \in \mathbb{N}^*\), the the ball walk on \((\mathbb{R}^n, d, \mu_\alpha)\) is positive recurrent chain \(\alpha < -n/2\), null recurrent for \(-n/2 \leq \alpha \leq (2-n)/2\) and transient if \(\alpha > (2-n)/2\) (See [59, Proposition 10.1.1] and Proposition 10.3). However the canonical diffusion on \((\mathbb{R}^n, d, \mu_\alpha)\) is positive recurrent chain \(\alpha < -n\), null recurrent for \(-n \leq \alpha \leq 2 - n\) and transient if \(\alpha > 2 - n\).

**Example B.2 (Complexes).** Consider the Euclidean 2-complex in \(\mathbb{R}^3\) formed by the hyperplanes \(H_{i,n} = \{(x_1, x_2, x_3) : x_i = n\}\) where \(i = 1, 2, 3\) and \(n \in \mathbb{Z}\). The metric is described by the intrinsic metric and the measure is the two dimensional surface measure. Dirichlet forms on such Riemannian complexes have been studied in [66]. This example satisfies both Poincaré inequality \((P)_h\) for all \(h > 0\) and Volume doubling \((VD)_\infty\). The geometry of the balls depend on the center (See Figure 2).

The above example can also be viewed as a *Cayley complex* [43, p. 77] corresponding to the presentation

\[
\mathbb{Z}^3 = \langle a_1, a_2, a_3 \mid a_1a_2a_1^{-1}a_2^{-1}, a_2a_3a_2^{-1}a_3^{-1}, a_3a_1a_3^{-1}a_1^{-1}\rangle.
\]

More generally, consider a finitely generated and finitely presented group \(G = \langle S \mid R \rangle\). Note that the 1-skeleton of the Cayley complex is the Cayley graph of \(\langle S \mid R \rangle\) and the 2-cells (faces) are in bijection with \(G \times \mathbb{R}\). We equip each 2-cell with the the usual Euclidean metric on the regular \(n\)-gon with edges of length 1 and we endow the space with the measure obtained by equipping each two-cell with its Lebesgue measure. It is easy to verify that the Cayley complex is quasi-isometric to the Cayley graph of \(G\) with the quasi-isometry given by the natural embedding of the Cayley graph in the Cayley complex. By the stability of \((VD)_\infty\) and \((P)_h\) under quasi-isometries, we have that ball walk on Cayley complexes of nilpotent groups (such groups are finitely generated and finitely presented) satisfy two sided Gaussian bounds.

**Figure 2.** Two balls (in intrinsic metric) with same radius but different centers in the Cayley complex of \(\mathbb{Z}^3\).

In Figure 3 we consider the 1-complex \(\{(x, y) \in \mathbb{R}^2 : x \in \mathbb{Z} \text{ or } y \in \mathbb{Z}\}\) equipped with intrinsic metric. Note that the geometry of the balls depend both on the location of the center and the radius.
Next, we consider an example from [35, Example 3.14].

**Example B.3 (Model manifolds/Surfaces of revolution).** Given a smooth function \( \psi : (0, \infty) \to (0, \infty) \), denote by \( M_\psi \) a model manifold. Here by model manifold, we mean \( \mathbb{R}^N \) equipped with the Riemannian metric in polar coordinates \((r, \theta) \in (0, +\infty) \times S^{N-1}\) by

\[
d s^2 = d r^2 + \psi(r)^2 d \theta^2,
\]

where \( d \theta^2 \) is the standard metric on \( S^{N-1} \) and \( \psi \) is a smooth positive function on \((0, +\infty)\). The necessary and sufficient conditions under which \( d s^2 \) can be smoothly extended to a metric on the entire space \( \mathbb{R}^N \) is given by

\[
\psi(0) = 0, \quad \psi'(0) = 1, \quad \text{and} \quad \psi''(0) = 0
\]

(see [35, equation (4.12)]). Therefore we may choose \( \psi(r) = r^\alpha \) where \( \alpha \in \mathbb{R} \) for all \( r \geq 1 \) and extend it smoothly satisfying the above conditions.

It is known that that \( M_\psi \) with \( \psi(r) = r^\alpha \) for \( r \geq 1 \) satisfies parabolic Harnack inequality if and only if \( -1/(N-1) < \alpha \leq 1 \). The Riemannian measure (in polar coordinates) is given by \( d \mu = \psi(r)^{N-1} \, dr \, d\theta \). One can check that the reversible measure \( \mu' \) for the ball walk satisfies \( d\mu' = V(x, 1) \, d\mu \approx \psi(r)^{2(N-1)} \, dr \, d\theta \) for the case \( \alpha < 0 \) and \( d\mu' = V(x, 1) \, d\mu \approx d\mu \) for the case \( \alpha \geq 0 \) (see [35, p. 856]). Therefore the ball walk on the model manifold \( M_\psi \) with \( \psi(r) = r^\alpha \) for \( r \geq 1 \) satisfies the parabolic Harnack inequality and two-sided Gaussian estimates if and only if \( -1/2(N-1) < \alpha \leq 1 \). Using Lemma 2.12, it is easy to verify that \( M_\psi \) with \( \psi(r) = r^\alpha \) for \( r \geq 1 \) equipped with the measure \( \mu' \) fails to satisfy \((VD)_\infty\) if \( \alpha \leq -1/2(N-1) \). Therefore for the case \(-1/(N-1) < \alpha \leq -1/2(N-1)\), the model manifold \( M_\psi \) defined above satisfies two sided Gaussian estimates for diffusion but fails to satisfy two sided Gaussian estimates for the ball walk.

These model manifolds can also be considered as surfaces of revolution formed by the graph of the function \( \psi \) (see [34, Section 5.1]). Similar to Example B.1, the
ball walk and diffusions may exhibit different behaviors in terms of null recurrence, 
positive recurrence and transience depending on $\alpha$ and $N$.

**Example B.4 (Bodies of revolution).** Another related class of examples given 
in [34, Section 5.2] are bodies of revolution. Let $f : [0, \infty) \to [0, \infty)$ be a concave 
function with $f(0) = 0$. Then the body of revolution in $\mathbb{R}^n$ (with $n > 1$) defined by 
$$M := \{(u, t) \in \mathbb{R}^n : u \in \mathbb{R}^{n-1}, t \geq 0, \|u\|_2 \leq f(t)\}$$
where $\|\cdot\|_2$ above denotes the Euclidean norm in $\mathbb{R}^{n-1}$ (See figure 4). Note that

![Figure 4](image-url) The body of revolution corresponding to $f$ in $\mathbb{R}^3$. This 
figure shows two balls of the same radius.

since $f$ is concave, $M$ is a convex subset of $\mathbb{R}^n$. By the results of [58], we have 
that $M$ satisfies two-sided Gaussian estimates for the heat kernel corresponding to 
the Neumann Laplacian. Hence by Theorem 1.1 the Neumann Laplacian satisfies 
Poincaré inequality in $M$ and satisfies volume doubling. If we set $f(x) = x^\alpha$ for 
some $\alpha \in (0, 1)$ and by Proposition 3.20 and Theorem 1.4 the ball walk on $M$ 
satisfies two-sided Gaussian bounds. Hence by Proposition 10.3 the corresponding 
ball walk on $M \subset \mathbb{R}^n$ with $f(x) = x^\alpha$ is transient if and only if $\alpha(n - 1) > 1$.
