(Dated: May 1, 2012)

Considering the possibility to build an e⁺e⁻ collider at the energies around the Z⁰-boson resonance with a planned luminosity so high as \( \mathcal{L} \propto 10^{34} \sim 10^{36} \text{cm}^{-2}\text{s}^{-1} \) (super Z-factory), we make a detailed discussion on the \((c\bar{b})\)-quarkonium production through \( e^+ + e^- \rightarrow (c\bar{b})[n] + b + \bar{c} \) within the framework of non-relativistic QCD. Here \([n]\) stands for the Fock-states \([|c\bar{b}]_1^{S_0}|S_0\rangle\), \([|(c\bar{b})S_0^1]\rangle\), \([|(c\bar{b})S_0^3]\rangle\), \([|(c\bar{b})S_1^1]\rangle\), \([|(c\bar{b})S_1^3]\rangle\), \([|(c\bar{b})S_1^5]\rangle\) and \([|(c\bar{b})S_1^7]\rangle \) (with \( J = (1, 2, 3) \)) respectively. To simplify the hard-scattering amplitude as much as possible and to derive analytic expressions for the purpose of future events simulation, we adopt the “improved trace technology” to do our calculation, which deals with the hard scattering amplitude directly at the amplitude level other than the conventional way at the squared-amplitude level. Total cross-section uncertainties caused by the quark masses are predicted by taking \( m_c = 1.50 \pm 0.30 \text{GeV} \) and \( m_b = 4.90 \pm 0.40 \text{GeV} \). If all higher \((c\bar{b})\)-quarkonium states decay to the ground state \( B_c \) \([|(c\bar{b})S_0^1]\rangle\) with 100% efficiency, we obtain \( \sigma_{e^+ + e^- \rightarrow B_c + b + \bar{c}} = 5.190 \pm 0.219 \text{pb} \), which shows that about \( 10^{11} \sim 10^{12} B_c \) events per operation year can be accumulated in the super Z-factory. If taking the collider energy runs slightly off the Z⁰-peak, i.e. \( \sqrt{s} = 1.00 \pm 0.05 \text{TeVe} \), the total cross-section shall be lowered by about one-order from its peak value. Such a super Z-factory shall provide another useful platform to study the properties of \( B_c \) meson, or even the properties of its excited \( P \)-wave states, in addition to its production at the hadronic colliders Tevatron and LHC.

I. INTRODUCTION

Recently, a Chinese group has raised the proposal of constructing a high luminosity \( e^+e^- \) collider in China, the so-called super Z-factory [1], which is similar to the Gigaz program suggested by the Internal Linear Collider Collaboration [2,3] but with a even higher luminosity. As for this newly purposed super Z-factory, a \( e^+e^- \) collider shall run at the energies around the mass of Z⁰-boson resonance and with a high luminosity up to \( \mathcal{L} \propto 10^{34} \sim 10^{36} \text{cm}^{-2}\text{s}^{-1} \). Many interesting topics can be studied in this super Z-factory: the properties of Z⁰-boson and the precision tests of the electro-weak sector of the standard model, the properties of the heavy mesons or baryons, \( \tau \) physics, the physics beyond the standard model and etc.

The \( B_c \) meson has aroused people’s great interests since its discovery by CDF collaboration [4, 5]. The \( B_c \) meson is a doubly heavy quark-antiquark bound state and carries flavors explicitly. Systematic studies of its production properties at the hadronic colliders Tevatron and LHC have been done in the literature, e.g. Refs. [6–12]. In particular, a computer program BCVEGPY for the hadronic production of the \( B_c \) meson has been completed and developed in Refs. [13, 14], which can be conveniently implemented into PYTHIA [15] for simulating \( B_c \) events. Very recently, a first observation of the decay channel \( B_c^+ \rightarrow J/\Psi\pi^+\pi^-\pi^0 \) with the help of BCVEGPY by LHCb group has been finished [16]. At the hadronic colliders, there is much pollution from the hadronic background and many produced \( B_c \) events shall be cut off by the trigger condition [17, 18]. So, some alternative measurements would be helpful for a comprehensive study.

Comparing to the hadronic colliders as the Tevatron and LHC, a \( e^+e^- \) collider has three general features as cleanliness, democracy and holism [19], which are helpful and have some advantages to perform more precise measurements for certain processes. To seek the \( B_c \) events at a \( e^+e^- \) collider has already been tried by the LEP-I experiment, however no \( B_c \) events have been found there. If the luminosity of a \( e^+e^- \) collider is raised up to \( \mathcal{L} \propto 10^{33} \sim 10^{36} \text{cm}^{-2}\text{s}^{-1} \) and its colliding energy is confined to be around the Z⁰-peak, it will raise the production rate up to several orders. This is reasonable, since as estimated in Ref. [3], more than \( 10^{9} \sim 10^{11} \) Z⁰-boson resonance can be produced for Gigaz with \( \mathcal{L} \propto 10^{34} \text{cm}^{-2}\text{s}^{-1} \). Moreover, Refs. [20–22] have shown that sizable \( B_c \) events can be produced through the Z⁰-boson decays. Then, as a rough combination, one can estimate that such a super Z-factory will open new opportunities for studying the \( B_c \) meson properties. And to be useful reference, it is interesting to present a more sound estimation.

Under the non-relativistic QCD (NRQCD) framework [26], a doubly heavy meson is considered as an expansion of Fock states, and the probability of finding each Fock state in the expansion is proportional to a definite power of \( v \), where \( v \) is the relative velocity and \( v^2 \) is around \( 0.1 \sim 0.3 \) for heavy quarkonium. We have studied the production of \((c\bar{c})\)- and \((b\bar{b})\)- quarkonium with a photon or via initial state radiation at the Z⁰-peak in the super Z-factory [27]. It is interesting to see whether there

---

*wuxg@cqu.edu.cn*
has enough $B_c$ events produced at such a high luminosity $e^+e^-$ collider, which can be produced through the process $e^+e^- \rightarrow \gamma^*/Z^0 \rightarrow (c\bar{b})[n]+b+c$, where $[n]$ stands for the $(c\bar{b})$-quarkonium Fock states. Excited $(c\bar{b})$-quarkonium states, such as the color-singlet $P$-wave states and the color-octet $S$-wave states, may directly or indirectly decay to the ground state with almost 100% possibility via electromagnetic or hadronic interactions. Then, as a full estimation of the $B_c$-meson production, we shall discuss the off-shell $(c\bar{b})$-quarkonium states simultaneously; i.e., $|(c\bar{b})\bar{1}[\bar{S}_0]⟩$, $|\bar{(c\bar{b})}\bar{1}[\bar{S}_0]⟩$, $|(c\bar{b})\bar{1}[\bar{S}_1]⟩$, $|\bar{(c\bar{b})}\bar{1}[\bar{S}_1]⟩$, $|(c\bar{b})\bar{1}[\bar{P}_1]⟩$, and $|\bar{(c\bar{b})}\bar{1}[\bar{P}_1]⟩$ (with $J = (1, 2, 3)$). Here the thickened subscript of $(c\bar{b})$-quarkonium denotes the color index, 1 for color-singlet and 8 for color-octet; the relevant angular momentum quantum numbers are shown in the parentheses accordingly.

Because of the emergence of massive-fermion lines, the analytical expression for the squared amplitude becomes too complex and lengthy for more (massive) particles in the final states and for more higher-order $Fock$ states to be generated. For example, to derive the amplitudes for the $P$-wave states, one also needs to get the derivative of the amplitudes over the relative momentum of the constituent quarks. It has been found that to do the numerical calculation using the conventional squared-amplitude technology becomes time-consuming for these complex processes, since the cross-terms increases with the increment of Feynman diagrams, $|M|^2 = \sum_{ij} M_i M_j^*$, where $i$ stands for the number of Feynman diagrams for the process. One important way to solve this is to deal with the process directly at the amplitude level. For the purpose, the “improved trace technology” is suggested and developed in the literature [12, 21–23]. After generating proper phase-space points, one first calculate the numerical value for the amplitudes, and then sum these values algebraically and square it to get the squared amplitude, $|M|^2 = \sum_i |M_i|^2$; through such way, numerical simulation efficiency can be greatly improved in comparison to the usual squared amplitude technology [1]. Moreover, under the approach, many simplifications can be done at the amplitude level due to the fermion-line symmetries and the specific properties of each heavy-quarkonium Fock states, then, we can even written down the analytic expressions for the amplitude.

The “Improved trace technology” has been adopted to derive a simplified and compact analytical expressions for the on-shell $Z^0$-boson decay process, $Z^0 \rightarrow (c\bar{b})[n]+b+c$ [21, 23]. At the present, we will adopt the same method for dealing with the $(c\bar{b})$-quarkonium production through the full production process, $e^+e^- \rightarrow \gamma^*/Z^0 \rightarrow (c\bar{b})[n]+b+c$. The intermediate $Z^0$-boson may or may not be on-shell, and if it is off-shell, some new Lorentz structures must be introduced to ensure a gauge-invariant result. In a sense, this paper provides an extension of the “improved trace technology” on how to deal with the off-shell particles.

The remaining parts of the paper are organized as follows. In Sec.II, we present the formulation for dealing with the process of $e^+e^- \rightarrow Z^0/\gamma^* \rightarrow (c\bar{b})[n]+b+c$, where improved trace technology are adopted to simplify the hard scattering amplitude. In Sec.III, we give the numerical results. Sec.IV is reserved for a summary. All necessary expressions are put in the Appendices.

II. FORMULATION AND CALCULATION TECHNIQUES

As shown in Fig.1, there are four Feynman diagrams for the process $e^+(p_1) + e^-(p_1) \rightarrow Z^0/\gamma^* \rightarrow (c\bar{b})[n]+b+c$, where $[n]$ stands for the $(c\bar{b})$-quarkonium Fock-states: $|(c\bar{b})\bar{1}[\bar{S}_0]⟩$, $|\bar{(c\bar{b})}\bar{1}[\bar{S}_0]⟩$, $|(c\bar{b})\bar{1}[\bar{S}_1]⟩$, $|\bar{(c\bar{b})}\bar{1}[\bar{S}_1]⟩$, $|(c\bar{b})\bar{1}[\bar{P}_1]⟩$, and $|\bar{(c\bar{b})}\bar{1}[\bar{P}_1]⟩$ (with $J = (1, 2, 3)$) respectively. Here as a comparison, the production channel via a virtual photon, which is small around the $Z^0$ peak, is also presented.

According to NRQCD factorization formulae [29], the inclusive transition probability of the perturbative state $(c\bar{b})[n]$ into the bound states, $\sigma(e^+e^- \rightarrow (c\bar{b})[n]+b+c)$ stands for the short-distance cross-section; i.e.

$$\sigma = \sum_n \frac{d\sigma(e^+e^- \rightarrow (c\bar{b})[n]+b+c)}{d\Phi_3} (O^H(n)), \quad (1)$$

where the matrix element $\langle O^H(n) \rangle$ is proportional to the inclusive transition probability of the perturbative state $(c\bar{b})[n]$ into the bound states. $\frac{d\sigma(e^+e^- \rightarrow (c\bar{b})[n]+b+c)}{d\Phi_3}$ stands for the short-distance cross-section; i.e.

$$\frac{d\sigma(e^+e^- \rightarrow (c\bar{b})[n]+b+c)}{d\Phi_3} = \frac{1}{4\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2}} \sum_i |M|^2 d\Phi_3. \quad (2)$$

FIG. 1. Feynman diagrams for the process $e^+ + e^- \rightarrow \gamma^*/Z^0 \rightarrow (c\bar{b})[n]+b+c$, where $[n]$ stands for the Fock states: $|(c\bar{b})\bar{1}[\bar{S}_0]⟩$, $|\bar{(c\bar{b})}\bar{1}[\bar{S}_0]⟩$, $|(c\bar{b})\bar{1}[\bar{S}_1]⟩$, $|\bar{(c\bar{b})}\bar{1}[\bar{S}_1]⟩$, $|(c\bar{b})\bar{1}[\bar{P}_1]⟩$, and $|\bar{(c\bar{b})}\bar{1}[\bar{P}_1]⟩$ (with $J = (1, 2, 3)$) respectively.
The spin-indices spectively. For the quarkonium production through an energy scan. The shape of the cross-section varia-
and
C ansatz with an energy-dependent total width. While, for
outgoing quark and antiquark respectively. The over-
ten as, VEGAS program [31].

The scattering amplitude for the process can be writ-
ten as,

\[ iM = C \times L_{rr}^\mu D_{\mu\nu} H_{s\bar{s}'}^{\nu}, \]

where

\[ L_{rr}^\mu = \bar{v}_r(p_2) \Gamma^\nu u_r(p_1) \]

and

\[ H_{s\bar{s}'}^{\nu} = \bar{u}_s(q_2) \sum_{n=1}^{4} A_n^{\nu} v_{s'}(q_1). \]

The spin-indices \( r, r', s \) and \( s' \) stand for the spin projections of the initial electron and positron, and the outgoing quark and antiquark respectively. The over-
all parameter \( C = C_o \) or \( C_s \) is for the production of the color-singlet or the color-octet quarkonium state re-
spectively. For the quarkonium production through \( Z^0 \)-boson propagator: \( C_s = \frac{4e^2 g_0^2}{3\sqrt{3} \sin^2 \theta_w \cos^2 \theta_w} \delta_{ij} \) and \( C_o = \frac{e^2 g_0^2}{\sin^2 \theta_w \cos^2 \theta_w} \times (\sqrt{T^a T^b T^a T^b})_{ij} \) for the color-octet \( (c\bar{b}) \)-quarkonium state); the vertex \( \Gamma^\nu = \frac{\gamma^\nu (1 - 4 \sin^2 \theta_w - \gamma^5)}{4} \) and the propagator \( D_{\mu\nu} = \frac{\exp(ig_{\mu\nu} + k_i k_r/k)}{k^2 - m_Z^2 + \imag \epsilon i}, \) where \( \Gamma_z \) stands for the total decay width of \( Z^0 \) boson. If \( e^+e^- \) collider runs at the energies above the \( Z^0 \) mass, it will constitute an energy scan. The shape of the cross-section variation around the \( Z^0 \) peak is described by a Breit-Wigner ansatz with an energy-dependent total width. While, for the quarkonium production through photon propagator: \( C_s = \frac{4}{3\sqrt{3}} e^2 g_0^2 \delta_{ij} \) and \( C_o = e^2 g_0^2 (\sqrt{T^a T^b T^a T^b})_{ij} \); the vertex \( \Gamma^\nu = \frac{\gamma^\nu}{4} \) and the propagator \( D_{\mu\nu} = \frac{\exp(ig_{\mu\nu})}{4g_{\mu\nu}} \). The gamma matrices \( A_n^{\nu} \) with \( n = 1, \cdots, 4 \) can be read off from the four Feynman diagrams in Fig. 1, whose explicit expres-
sions can be directly found in Refs. [22 23 3].

\[ L_{rr'}^{\mu}, \text{and} \ H_{s\bar{s}'}^{\nu}, \text{contain explicit strings of Dirac } \gamma \text{-matrices sandwiched by two fermion spinors, which can be done under the conventional trace technology. However it is hard to write down the squared amplitudes for these massive processes, which is too complex and lengthy. Here, to simplify the analytic results and to make it more compact, we adopt the “improved trace technology” [12 21 23]. It is noted that under suitable transformations, this approach is also useful for deriving the polarized cross-sections, which is helpful for a polarized } e^+e^- \text{ collider.} \]

As an explanation for the “improved trace technology”, we first arrange the amplitude \( H_{s\bar{s}'}^{\nu} \) into four orthogonal sub-amplitudes \( H_{s\bar{s}'}^{\nu} \) according to the spins of the outgoing quark \( q \) with spin \( s \) and antiquark \( \bar{q} \) with spin \( s' \), then transform these sub-amplitudes into a trace form by properly dealing with the massive spinors with the help of an arbitrary light-like momentum \( k_0 \) and an arbitrary space-like momentum \( k_1 \), which satisfies \( k_0^2 = -1 \) and \( k_0 \cdot k_1 = 0 \). The final results are independent of \( k_0 \) and \( k_1 \), which provides a way to check the rightness of the derived results. And one can choose them to be those that will maximally simplify the amplitude. And then we do the trace of the Dirac \( \gamma \)-matrix strings at the amplitude level, which shall result in explicit series over some independent Lorentz-structures. The amplitude \( L_{rr'}^{\mu} \) can be done in a similar way. Detailed process of the amplitude can be found in Refs. [22 23], so to short the paper, we only list all the differences for the present processes. However, because at the present \( Z^0 \) may or may not be on-shell, one should use these on-shell expressions carefully with suitable transformations.

As for \( H_{s\bar{s}'}^{\nu}, \) it can be rearranged as the following four spin combinations

\[ H_1^{\nu} = \frac{H_{s\bar{s}'}^{\nu} + H_{s\bar{s}'}^{\nu}}{2} \]

\[ H_2^{\nu} = H_{s\bar{s}'}^{\nu} - \frac{H_{s\bar{s}'}^{\nu}}{2} \]

\[ H_3^{\nu} = \frac{H_{s\bar{s}'}^{\nu} - H_{s\bar{s}'}^{\nu}}{2} \]

\[ H_4^{\nu} = \frac{H_{s\bar{s}'}^{\nu} + H_{s\bar{s}'}^{\nu}}{2} \]

The production through the photon propagator is simi-
lar to the case of the \( Z^0 \)-boson propagator, which can be directly read from its vector part. So we shall only con-
centrate our attention on the case of the \( Z^0 \)-boson propagator \( \mathcal{H}_1 \). \( H_{1,2,3,4}^{\nu} \) can be expressed over the independent Lorentz-structures. For example, for the production of \(|(c\bar{b})\rangle |(1 \bar{S}_0)\rangle \)-quarkonium, we have

\[ H_{1,2,3,4}^{\nu} = A_1^{(1 \bar{S}_0)} \frac{k_{1\nu}}{m_Z} + A_2^{(1 \bar{S}_0)} \frac{k_{2\nu}}{m_Z} + A_3^{(1 \bar{S}_0)} \frac{k_{3\nu}}{m_Z} + A_4^{(1 \bar{S}_0)} \frac{k_{4\nu}}{m_Z} \]

\[ + \frac{1}{m_Z^2} \epsilon_{\nu, k, q_2, q_3}, \]

---

2 As for the case of \( Z^0 \) propagator, from the correspondence be-
 tween \( A_1^{\nu} \) and \( A_4^{\nu} \), one only needs to replace \( \phi(k) \) in the am-
plitudes of Refs. [22 23] by \( \gamma^\nu \). And the case of photon propagator can be easily derived by changing the corresponding vertex.

3 A generator BEEC for dealing with the heavy quarkonium produc-
tion at a \( e^+e^- \) collider within the PYTHIA environment [13] is in preparation, where both cases with the photon and the \( Z^0 \)-boson propagators are included [32].
where $\varepsilon(\nu, k, q_2, q_3) = \varepsilon^{\nu \beta \rho \sigma} k_\beta q_2 \varepsilon_{\rho \sigma}$. Comparing the Lorentz expansions of $H_\nu^{[S_0]}$ with those of $M_\nu^{[S_0]}$ in Refs. 22, 23, we obtain the same expansion coefficients for the corresponding Lorentz structures. More explicitly, by multiplying both side of Eq. (10) with the on-shell $Z^0$-boson polarization vector $\varepsilon_\nu(k)$, which satisfies $k \cdot \varepsilon(k) = 0$, we can obtain exactly the same matrix elements i.e. $\varepsilon_\nu(k)H_\nu^{[S_0]}|_{k\cdot\varepsilon=0} = M_\nu^{[S_0]}$. However, when the $Z^0$-boson is not on-shell, $\left(A_3^{[S_0]}k^\nu/m_Z\right)$ must be kept in $H_\nu^{[S_0]}$. And to be a consistent analysis for the present case, we need to take these new terms into consideration. For convenience, we present all the new Lorentz structures for all the mentioned Fock states together with their non-zero coefficients in Appendix B.

As for the leptonic vector $L_\mu^\nu$, it is simpler and can be directly expressed as

$$L_\mu^\nu = C_1^\nu \frac{p_1^\mu}{m_Z} + C_2^\nu \frac{p_2^\mu}{m_Z} + C_3^\nu \frac{q_3^\mu}{m_Z} + C_4^\nu \frac{m_Z}{m_Z} \varepsilon(\mu, p_1, p_2, q_3),$$

(11)

where all the non-zero coefficients $C_n^\nu$ are presented in Appendix C.

To be a cross check, we also use the squared amplitude approach to deal with the process, which however can be rewritten as the following more convenient form

$$|M|^2 = \frac{1}{3} C^2 \times \langle D_{\alpha \beta} L^{\alpha \beta} \rangle \cdot \langle D^{\rho \sigma} H_{\rho \sigma} \rangle.$$  

(12)

The leptonic tensor

$$L^{\alpha \beta} = -4g^{\alpha \beta} p_1 \cdot p_2 + 4p_1^\beta p_2^\alpha + 4p_1^\alpha p_2^\beta,$$

(13)

where small mass terms involving $m_e$ are neglected. The result for the phase-space integration over $\langle D^{\rho \sigma} H_{\rho \sigma} \rangle$ is equal to the decay width of $Z^0 \to (\bar{c}b)[n] + b + \bar{e}$ times a factor $1 /[ (k^2 - m_Z^2)^2 + m_Z^2 T^2 ]$. Numerically, we obtain the same results for these two approaches.

III. NUMERICAL RESULTS

The basic input parameters are chosen as the following values: $m_Z = 91.1876$ GeV, $\Gamma_Z = 2.4952$ GeV, $\sin^2 \theta_w = 0.23119$ and $\alpha_s(m_Z) = 0.1176$. We adopt the leading-order $\alpha_s$ running, and take the normalization scale to be $2m_c$, which leads to $\alpha_s(2m_c) = 0.212$. The color-singlet matrix elements can be directly related to the wave functions at the origin for the $S$-wave states or with the first derivative of the wave functions at the origin for the $P$-wave states. The $S$-wave color-octet ones are suppressed to the corresponding ones by a factor $\Delta_s^2(v)$ with $\Delta_s(v) \sim v^2$ 17, 22, 54. In the leading order approximation, the color-octet or color-singlet matrix element appears in the amplitude as a linear factor. The uncertainties in the production from the matrix elements can be figured out straightforwardly, so throughout the paper, we will fix the values of the radial wave function at the origin and the first derivative of the radial wave function at the origin to be $|R_3(0)|^2 = 1.642$ GeV$^3$ and $|R_2(0)|^2 = 0.201$ GeV$^2$ 35 which are derived under the Buchmüller-Tye-potential model 36.

To calculate the hard-scattering amplitude for the short-distance cross-section $d\sigma/d\eta$, the equations: $q_3^2 = m_3^2$ and $q_3^2 = M^2$ ($M$ is the $(\bar{c}b)$-quarkonium mass, $q_3 = q_c + q_b$ with $q_c$ and $q_b$ are momenta of the constituent quarks) must be satisfied simultaneously, and only when these equations are satisfied can the gauge invariance of the amplitude be guaranteed. In this paper, we proceed the numerical calculation by taking $m_c = 1.50$ GeV and $m_b = 4.90$ GeV as their center values 4. The mass of the quarkonium bound-state is the sum of the two heavy quark masses; i.e. $M = m_c + m_b = 6.40$ GeV. We will discuss the theoretical uncertainties caused by the $c$- and $b$- quark masses by varying $m_c = 1.50 \pm 0.30$ GeV and $m_b = 4.90 \pm 0.40$ GeV.

Firstly, we calculate the total cross-section for the $e^+e^-$ collider energy at the $Z^0$ peak, i.e. $E = m_Z$. We obtain

$$\sigma_{|(\psi_{\bar{b}b})^{[S_0]}]} = 1.800 \text{ pb},$$

(14)

$$\sigma_{|(\psi_{\bar{b}b})^{[S_1]}]} = 2.575 \text{ pb},$$

(15)

$$\sigma_{|(\psi_{\bar{b}b})^{[P_1]}]} = 0.190 \text{ pb},$$

(16)

$$\sigma_{|(\psi_{\bar{b}b})^{[D_3]}]} = 0.115 \text{ pb},$$

(17)

$$\sigma_{|(\psi_{\bar{b}b})^{[P_2]}]} = 0.232 \text{ pb},$$

(18)

$$\sigma_{|(\psi_{\bar{b}b})^{[P_3]}]} = 0.256 \text{ pb}.$$  

(19)

\footnote{There values are consistent with the so called 1S mass 37, i.e. half of the $J/\Psi$-mass for charm quark and half of the $\Upsilon(1S)$ for bottom quark. And they are also consistent with the bound-state parameters under the potential-model calculations 35, 36.}
states can be added up to the ground state. It is found that the total cross-sections of all the Fock states \((|\bar{b}\rangle_1^{[1]S_0}|, |\bar{b}\rangle_1^{[3]P_1}|, |\bar{b}\rangle_1^{[3]P_2}|, |\bar{b}\rangle_1^{[3]S_1}|\) and \(|\bar{b}\rangle_1^{[3]P_0}|\) respectively.

\[
\begin{align*}
E_{\text{cm}} & | 95\% & m_{\bar{b}} & | 97\% & m_{\bar{b}} & | m_{\bar{b}} & | 103\% & m_{\bar{b}} & | 105\% & m_{\bar{b}} \\
\sigma_{\text{tot}} \text{(pb)} & | 0.341 & 0.860 & | 5.190 & 0.930 & | 3.84 \\
\end{align*}
\]

TABLE I. Total cross-section of the process \(e^+ + e^- \rightarrow (\bar{b})[n] + b + \bar{c}\) with varying \(m_{\bar{b}}\), where \(m_b\) is fixed to be 4.90 GeV.

\[
\begin{align*}
\sigma_{\text{(b)}_1^{[1]S_0}|} & = 0.225 \times v^4 \text{ pb}, \\
\sigma_{\text{(b)}_1^{[3]S_1}|} & = 0.322 \times v^4 \text{ pb}.
\end{align*}
\]

It is found that the total cross-sections of all the P-wave states can be added up to \(\sim 20\%\) of that of the ground state \(B_c(|\bar{b}\rangle_1^{[1]S_0})\). So the P-wave \((\bar{b})\)-quarkonium states should be taken into consideration, especially for the future high luminosity e⁺e⁻ colliders. Two color-octet S-wave states shall only provide \(\sim 1\%\) contribution to the ground state.

As a reference, we present the total cross section \(\sigma(e^+ + e^- \rightarrow \gamma^*/Z^0 \rightarrow (\bar{b})[n] + b + \bar{c})\) versus the \(e^+e^-\) collision energy \(E\) in Fig. 2, where contributions from the mentioned Fock states \(|\bar{b}\rangle_1^{[1]S_0}|, |\bar{b}\rangle_1^{[3]P_1}|, |\bar{b}\rangle_1^{[3]P_2}|\) and \(|\bar{b}\rangle_1^{[3]S_1}|\) have been summed up. We take \(v^2 = 0.2\) for the color-octet states. For small \(e^+e^-\) collision energy \((E \lesssim 60\text{ GeV})\), we have

\[
\sigma_{\gamma^*/Z^0 \rightarrow (\bar{b})[n]} > \sigma_{e^+e^- \rightarrow Z^0 \rightarrow (\bar{b})[n]}.
\]

One may observe a small peak around 20 GeV, which is caused by the production channel through \(\gamma^*/\)-propagator and has already been observed by Ref. [21]. When the collider energy runs from \(\sim 10\text{ GeV}\) to 100 GeV, it is found that the total cross-section at the energy around \(Z^0\)-peak raises up to four orders than that of 10 GeV due to the \(Z^0\)-resonance effects. Moreover, as shown by Table II if taking the collision energy \(E = (1\pm 3\%) m_{\bar{b}}\), the total cross-section shall be lowered to \(\sim (15\% \pm 17\%)\) of its peak value; and if taking the collision energy \(E = (1\pm 5\%) m_{\bar{b}}\), the total cross-section shall be lowered to \(\sim 7\%\) of its peak value. Moreover, we present the \((\bar{b})\)-quarkonium transverse momentum \((p_t)\) and rapidity \((y)\) distributions in Fig. 3.

Secondly, we discuss the theoretical uncertainties caused by the \(c\) and \(b\) quarks by varying \(m_c = 1.50\pm 0.30\) GeV and \(m_b = 4.90\pm 0.40\) GeV. There are other uncertainty sources include the matrix elements, the renormalization scale \(\mu_R\) and etc. There are overall factors, their uncertainties can be easily estimated when their values are known, so we shall not discuss them there. The cross-section for the \((\bar{b})\)-quarkonium production through \(e^+e^-\) annihilation with varying \(m_c\) and \(m_b\) are presented in Tabs. III. III. It can be found that the total cross-section is more sensitive to \(m_c\) than that of \(m_b\). And the total cross-section of the P-wave states are more sensitive to quark masses than the S-wave states. By adding the uncertainties in quadrature, we obtain

\[
\begin{align*}
\sigma_{\text{(b)}_1^{[1]S_0}|} & = 1.800^{+1.764}_{-0.760} \text{ pb}, \\
\sigma_{\text{(b)}_1^{[3]S_1}|} & = 2.570^{+2.872}_{-1.179} \text{ pb}.
\end{align*}
\]
Furthermore, to show the corresponding uncertainties have been summed up. The uncertainties are drawn by a |
\(|c\rangle = 1\)
\(P_1\rangle\) and \(|c\rangle = 1\)
\(P_2\rangle\) have been summed up.

\[
\sigma_{(|c\rangle = 1\)P_1\rangle} = 0.190^{+0.381}_{-0.111}\text{ pb}, \quad (24)
\]
\[
\sigma_{(|c\rangle = 3\)P_0\rangle} = 0.115^{+0.166}_{-0.060}\text{ pb}, \quad (25)
\]
\[
\sigma_{(|c\rangle = 1\)P_2\rangle} = 0.232^{+0.426}_{-0.131}\text{ pb}, \quad (26)
\]
\[
\sigma_{(|c\rangle = 1\)P_2\rangle} = 0.256^{+0.589}_{-0.159}\text{ pb}, \quad (27)
\]
\[
\sigma_{(|c\rangle = 1\)P_2\rangle} = 0.225^{+0.221}_{-0.096} x v^4\text{ pb}, \quad (28)
\]
\[
\sigma_{(|c\rangle = 1\)P_2\rangle} = 0.322^{+0.359}_{-0.147} x v^4\text{ pb}. \quad (29)
\]

If assuming the higher excited states decay to the ground state \(B_c(|c\rangle = 1\)S_0\rangle\)) with 100% efficiency, then we obtain the total cross-section for \(B_c\), i.e.

\[
\sigma_{e^+e^-\rightarrow B_c + b+\bar{c}} = 5.190^{+6.222}_{-2.415}\text{ pb}. \quad (30)
\]

Furthermore, to show the corresponding uncertainties more clearly, we present the uncertainties of \(p_t\) - and \(y\)- differential distributions for the \((c\bar{b})\)-quarkonium production in Fig.4, where the Fock states \(|c\bar{b}\rangle = 1\)S_0\rangle\), \(|c\bar{b}\rangle = 1\)S_1\rangle\), \(|c\bar{b}\rangle = 1\)P_1\rangle\) and \(|c\bar{b}\rangle = 1\)P_2\rangle\) states have been summed up. The uncertainties are drawn by a shaded band, where the center solid line is for \(m_c = 1.5\) GeV and \(m_b = 4.9\) GeV, the upper edge of the band is for \(m_c = 1.2\) GeV and \(m_b = 5.3\) GeV, and the lower edge of the band is for \(m_c = 1.8\) GeV and \(m_b = 4.5\) GeV.

Experimentally, there is no detector which can cover all the kinematics of the events, so only some of the \(B_c\) events can be observed. That is, the \(B_c\) events with small \(p_t\) and/or a large rapidity \(y\) cannot be detected, so they cannot be utilized for experimental studies. As a final remark, it would be helpful to know how the differential cross-sections change with different \(p_t\) - or \(y\)-cuts. In Fig.5, we present the \((c\bar{b})\)-quarkonium \(p_t\)-distributions for all the considered Fock states with a particular rapidity cut \((y_{cut}\rangle\), where the solid, the dashed, the dotted, the dash-dot and the dash-dot-dot lines are for \(y_{cut} = 0, 0.5, 1.0, 1.5\) and 2.0 respectively. In Fig.6, we present the \((c\bar{b})\)-quarkonium \(y\)-distributions for all the considered Fock states with a particular transverse momentum cut \((p_{tcut}\rangle\), where the solid, the dashed, the dotted and the dash-dot lines are for \(p_{tcut} = 0, 5, 20, 35\) GeV respectively. To analyze the quantitative difference of the differential distributions with regard to the parameters \(p_{tcut}\) and \(y_{cut}\), we introduce a ratio for the integrated total cross-section:

\[
R_{p_{tcut}} = \left( \frac{\sigma_{y_{cut}}}{\sigma_{0}} \right)_{p_{tcut}}, \quad (31)
\]
TABLE IV. $R_{pcut}$ versus the parameters $p_{cut}$ and the $y_{cut}$.

| $p_{cut}$ | 0 GeV | 5 GeV | 20 GeV |
|-----------|-------|-------|--------|
| $y_{cut}$ | 0.5   | 1.0   | 1.5    |
|           | 0.5   | 1.0   | 1.5    |
| $R_{pcut}$ | 0.382 | 0.710 | 0.897  |
|           | 0.391 | 0.725 | 0.913  |
|           | 0.520 | 0.913 | 1.00   |

where $\sigma_{y_{cut}}$ and $\sigma_0$ are the total cross-section with and without $y_{cut}$ respectively. In the definition of $R_{pcut}$, contributions from all the considered Fock states have been summed up. The values of the ratio $R_{pcut}$ that correspond to different values of $p_{cut}$ and $y_{cut}$ are presented in Tab. (IV). It is found that when under the same $p_{cut}$, $R_{pcut}$ increases with the increment of $y_{cut}$, and when under the same $y_{cut}$, $R_{pcut}$ also increases with $p_{cut}$. This shows that the rapidity distribution of the $(c\bar{b})$-quarkonium shrinks with the increment of $p_{cut}$; e.g. when $p_{cut} = 20$ GeV, $|y| \lesssim 1.5$.

**IV. SUMMARY**

In the present paper, we have studied the $(c\bar{b})$-quarkonium production through $e^+e^-$ annihilation in leading order, but with the $\nu^2$-expansion up to $\nu^4$. The production of the $(c\bar{b})$-quarkonium in Fock states $|{(c\bar{b})1^1 S_0}\rangle$, $|{(c\bar{b})1^3 S_1}\rangle$, $|{(c\bar{b})1^1 P_1}\rangle$, $|{(c\bar{b})1^3 P_2}\rangle$, $|{(c\bar{b})3^1 S_0}\rangle$, $|{(c\bar{b})3^3 S_1}\rangle$ have been studied. Higher Fock states such as the $P$-wave states will also provide sizable contributions to the total cross-section of the $B_c$ meson. If assuming the higher excited states decay to the ground state $B_c (|(c\bar{b})1^1 S_0\rangle$) with 100% efficiency via electromagnetic or hadronic interactions, then we will obtain $\sigma_{e^+e^- \rightarrow B_c + b+\bar{c}} = 5.190 ^{+2.222}_{-2.419}$ pb.

According to our present calculation, one would expect to accumulate $10^5 \sim 10^7 B_c$ events in one operational year for the super Z-factory with a high luminosity $L \propto 10^{34} \sim 10^{36} \text{cm}^{-2}\text{s}^{-1}$. If taking the $e^+e^-$ collision energy to run slightly off the $Z^0$-peak; i.e. $\sqrt{s} = 0.95 m_Z$ or 1.05$m_Z$, the total production cross-section will be lowered by about one-order from its peak value. However one can estimate $10^4 - 10^6 B_c$ events to be produced under such condition, which is still sizable. Then, in addition to the hadronic colliders Tevatron and LHC, the super Z-factory will provide another good platform for studying the $B_c$-meson properties.

**Appendix A: Linear polarization vector and tensor**

We set the $z$-axis to be along the incoming beam. The momentum of the $(c\bar{b})$-quarkonium $q_i^0 = (q_i^0, q_i^1 \sin \theta \cos \phi, q_i^1 \sin \theta \sin \phi, \sqrt{(q_i^0)^2 - M^2})$, where $|q_i^0| = \sqrt{(q_i^0)^2 - M^2}$, $M$ is the quarkonium mass, $\theta$ and $\phi$ are polar and azimuthal angles respectively. The expressions of the polarization vector can be written as

$$
\epsilon_x(q_3) = (0, \cos \theta \cos \phi, \cos \theta \sin \phi, -\sin \theta),
$$

$$
\epsilon_y(q_3) = (0, -\sin \phi, \cos \phi, 0),
$$

$$
\epsilon_z(q_3) = \frac{1}{M}(|q_3^0|, q_3^0 \sin \theta \cos \phi, q_3^0 \sin \theta \sin \phi, q_3^0 \cos \theta).
$$

As required, the polarization vector satisfies the following relation

$$
\epsilon_i \cdot q_3 = 0, \quad \epsilon_i \cdot \epsilon_j = -\delta_{ij}, \quad (i, j = x, y, z).
$$

(A1)

The polarization tensor $\epsilon_{ij}^{\alpha\beta}(q_3)$ for $(3P_2)$-quarkonium state can be constructed in terms of $\epsilon_x(q_3), \epsilon_y(q_3)$ and $\epsilon_z(q_3)$ as

$$
\epsilon_{ij}^{\alpha\beta} = \frac{1}{\sqrt{3}}(\epsilon_x^{\alpha\beta} + \epsilon_y^{\alpha\beta}) \quad (i, j = x, y, z).
$$

(A2)

**Appendix B: New lorentz structures and their coefficients for $e^+ + e^- \rightarrow Z^0 \rightarrow (c\bar{b})[n] + b+\bar{c}$**

In the present section, we present the new lorentz structures and their non-zero coefficients for the process $e^+e^-(p_1) \rightarrow Z^0/\gamma^* \rightarrow (c\bar{b})[n](q_3) + b(q_2) + \bar{c}(q_1)$, where $n$ stands for $|(c\bar{b})1^1 S_0\rangle, |(c\bar{b})1^3 S_1\rangle, |(c\bar{b})1^1 P_1\rangle, |(c\bar{b})1^3 P_2\rangle, |(c\bar{b})3^1 S_0\rangle, |(c\bar{b})3^3 S_1\rangle$. All these new Lorentz structures have no correspondence to the Lorentz structures introduced from the process $Z^0(k) \rightarrow (c\bar{b})[n](q_3) + b(q_2) + \bar{c}(q_1)$. Below, the note, the following parameters, $r_1, r_2, r_3, T_0, T_\omega$, and so on, have the same meaning as those of Refs. [22, 23], and we shall not present them here for short.

1. Spin-singlet S-wave state: $|(c\bar{b})1^1 S_0\rangle$

There is only one new Lorentz structure for $|(c\bar{b})1^1 S_0\rangle$,

$$
B_3 = \frac{k^\nu}{m_Z},
$$

(B1)

whose coefficients $A_1^{1,2,3}a^4$ are
\[ A_1 = \frac{m z^{7/2} L_1}{\sqrt{r_1}} (d_4 r_1 (3 r_1 - r_2) r_3 + d_1 (3 r_3 r_1^2 + (-r_2 r_3 + u - 2x) r_1 - r_2 u) \\
+ (d_2 (r_1 (3 r_1 + r_2) + u - 2y) + d_3 (r_1 (r_1 + r_2) + 3 u - 2y)) r_3 + d_4 (r_1 + r_2) u) \\
A_2 = \frac{4 m z^{7/2} L_2}{\sqrt{r_1}} ((d_3 + d_4) T_c - d_2 T_b) (r_1 (3 r_1 - r_2) r_3 + (3 r_1 + r_2) u) + d_1 T_b (3 r_3 r_1^2 - (r_2 r_3 \\
- 3 u + 2x) r_1 + r_2 u) + 2 r_3 (d_2 T_b - d_3 T_c) y \\
A_3^t = \frac{m z^{9/2} N_0}{\sqrt{r_1 L_2}} (d_1 T_b (u (2y - 1) + 2 r_3 (x + 2y - 1)) + d_2 T_b (u - 2 (-r_2 r_3 y + r_1 r_3 (x + y - 1) \\
+ u (x + y))) + T_c (2 d_4 (r_1 r_3 + u) (2r_1 r_3 + u) + d_3 (u (2y - 1) + 2 r_3 (x + 2y - 1)))) \\
A_4^t = \frac{-1}{4 \sqrt{r_2} L_1} (m z^{9/2} N_0 (2 d_4 (r_1^4 + 2 r_3 r_1^2 + 3 u r_1^2 + r_3^2 r_1 + u (u - r_2^2)) - d_3 (-4 r_3^2 \\
+ 2 (r_2 r_1^2 - (r_2^2 + x - 1) r_1 + r_2 u) r_3 + u - 2 u y) + d_2 (2 r_1^4 + (-r_2^2 + u + x \\
y + y - 1) r_1^2 + r_2 (u + x + 2y - 1) r_1 + r_3^2 y - u (x + y))) + d_1 (6 r_3 r_1^3 \\
- 2(3 u + 3 x + 2 y - 1) r_1^2 - 2 r_3 r_2 r_1^2 + 2 r_2 (u - x - 2 y + 1) r_1 + u (2y - 1)))) \\
\]

2. Spin-triplet S-wave state: \(|(c\bar{b})^3[S_1]\)

There are three new Lorentz structure for \(|(c\bar{b})^3[S_1]\),
\[ B_1 = \frac{1}{m_2} k \cdot (\epsilon(q_3) k)^2, \quad B_2 = \frac{1}{m_2} q_2 \cdot (\epsilon(q_3) k)^2, \quad B_3 = \frac{i}{m_2} \epsilon(k, q_3, q_2, \epsilon(q_3) k)^2, \]
whose coefficients \(A_1^{1,2,3,4'} (j = 1, 2, 3)\) are
\[ A_1^t = 8 d_1 L_1 m z^{7/2} r_1 \sqrt{r_1} T_b, \]
\[ A_2^t = 4 L_1 m z^{7/2} r_3^{3/2} [(d_2 - d_1) T_b - (d_3 + d_4) T_c], \]
\[ A_3^t = -2 L_1 m z^{7/2} \sqrt{r_3} (d_3 - d_4), \]
\[ A_4^t = 2 d_1 L m z^{7/2} r_1 \sqrt{r_3}, \]
\[ A_2^t = -L_2 m z^{7/2} r_3^{3/2} [(3 d_1 - d_2 + d_3 + d_4) r_1 \\
-(d_1 - d_3 + d_3 - d_4) r_2], \]
\[ A_3^t = \frac{8 L_2 m z^{7/2} r_3^{3/2}}{\sqrt{r_1}} (d_2 T_b + d_3 T_c), \]
\[ A_4^t = \frac{d_3 m z^{9/2} N_0 \sqrt{r_3}}{2 L_2} (r_1 r_3 + u), \]

3. Spin-singlet P-wave state: \(|(c\bar{b})^1[P_1]\)

There are three new Lorentz structure for \(|(c\bar{b})^3[S_1]\), whose coefficients \(A_1^{1,2,3,4'} (j = 1, 2, 3)\) are
\[ A_1^t = \frac{m z^{5/2} L_1}{r_2 \sqrt{r_3}} (2 d_1 r_1 r_3 r_2 - 2 ((d_1 + d_2 + d_2 - d_3) r_1 (3 r_1 + r_2) r_3 + (d_1 + d_2 - 3 d_3) u) r_3 \\
+d_1 (3 r_3 r_1^2 + u r_1 - 2 x r_1 - r_2 u)) r_2 + 4 (d_2 + d_2 - d_3) r_3 y r_2 + d_1 (r_2 - r_1) r_3), \]
\[ A_2^t = \frac{1}{2 r_1 r_2 \sqrt{r_3}} (m z^{5/2} L_1 (-d_1 r_1 r_3 r_2^2 + d_4 r_3 r_2^2 + d_2 r_3^2 r_2 - 3 r_3^2 r_2 - 8 (d_2 + d_3) r_1 r_3 y r_2 \\
+ 4 d_4 r_1 (3 r_3 r_1^2 + (u - 2x) r_1 - r_2 u - r_2 r_3 r_1) r_2 + r_1 (-4 d_1 r_3 r_1^2 \\
+ 4 (d_4 + (3 r_1 + r_2) + (d_2 + d_3) r_3) y r_2 + r_3 (4 (d_2 + d_3) r_1 r_2^2 \\
- 2 (d_2 + d_3 + d_4) r_1^2 + d_1 + d_4) r_2), \]
\[ \]
\[ A_3^t = \frac{m z^{9/2} N_0}{2 L_1} ((d_1 - d_2) (r_1 - r_2) + (d_2 - d_1) (r_1 - r_2)) \]
\[ A_4^t = \frac{m z^{9/2} N_0}{2 L_1} ((d_2 - d_3) (r_1 - r_2) + (d_2 - d_1) (r_1 - r_2)), \]
\[ \]
\[ A_b = \frac{-m z^{9/2} N_0 \sqrt{r_3}}{4 L_2} (d_2 - d_3 + 2 d_4 (r_3^2 + u) \\
+ 2 (d_2 (r_1 r_3 - x - y)) + d_3 (r_2 r_3 + y)), \]
\[ A_3^t = \frac{2 m z^{9/2} N_0 \sqrt{r_3}}{L_2} (d_1 T_b + d_3 T_c), \]
\[ A_4^t = \frac{-2 d_1 m z^{9/2} N_0 \sqrt{r_3} T_b}{L_1} (r_1^2 - r_2 r_1 + u), \]
\[ A_2^t = \frac{m z^{9/2} N_0 \sqrt{r_3}}{L_1} (d_2 - d_3 + 2 d_4 (r_3^2 + u) \\
+ 2 (d_2 (r_1 r_3 - x - y)) + d_3 (r_2 r_3 + y)), \]
\[ A_3^t = \frac{2 m z^{9/2} N_0 \sqrt{r_3}}{L_2} (d_1 T_b + d_3 T_c), \]
\[ A_4^t = \frac{-2 d_1 m z^{9/2} N_0 \sqrt{r_3} T_b}{L_1} (r_1^2 - r_2 r_1 + u), \]
\[ A_2^t = \frac{m z^{9/2} N_0 \sqrt{r_3}}{L_1} (d_2 - d_3 + 2 d_4 (r_3^2 + u) \\
+ 2 (d_2 (r_1 r_3 - x - y)) + d_3 (r_2 r_3 + y)), \]
\[ A_3^t = \frac{2 m z^{9/2} N_0 \sqrt{r_3}}{L_2} (d_1 T_b + d_3 T_c), \]
\[ A_4^t = \frac{-2 d_1 m z^{9/2} N_0 \sqrt{r_3} T_b}{L_1} (r_1^2 - r_2 r_1 + u), \]
\[ A^1_3 = -\frac{4L_1 m_{\tilde{Z}}^{5/2}}{r_1 r_2 \sqrt{r_3}}(d_2 T_b + d_3 T_c), \quad (B20) \]

\[ A^2_3 = \frac{4m_{\tilde{Z}}^{5/2} L_2}{r_z \sqrt{r_3}}(d_1 (r_2^2 - r_1^2) T_b + 2 r_2 (3r_3 r_1^2 + 3u_r + r_2 u - 2r_3 y)
- r_2 r_3 r_1) - d_{11} T_b(3r_3 r_1^2 + 3u_r - 2x_r + u - r_2 r_3 r_1)), \quad (B21) \]

\[ A^3_2 = \frac{1}{r_1 r_2 \sqrt{r_3}}(2L_2 m_{\tilde{Z}}^{5/2}(d_1 (r_2 r_3 T_b(r_1 - r_2)^2 - d_2 r_2 T_b(r_1 - r_2)^2 + d_3 r_3 T_c(r_1 - r_2)^2) + d_4 r_3 T_c(r_1 - r_2)^2)) \]

\[ + 2d_11 r_1 r_2 T_b(2r_3 r_1 r_3(x + u)(2x - 1)) + 4(d_21 + d_22) r_1 (r_1 - r_2) r_2 r_3 T_b y + 4(d_21 + d_22) r_1 r_2 x
+ 2d_{11} r_1 r_2 T_b(-2uy + u - 2r_1 r_3(x + y - 1)) + 2d_{22} r_1 r_2 T_b(u - 22(2r_2 r_3 y + r_1 r_3(x + y - 1))) \]

\[ A^3_3 = -\frac{m_{\tilde{Z}}^{5/2} N_0 \sqrt{r_3}}{4r_1 r_2 L_2}(-d_2 r_1 + d_1 (r_1 - r_2) + d_3 r_3) \quad (B26) \]

\[ A^4_2 = \frac{m_{\tilde{Z}}^{7/2} N_0}{8L_1 r_1 r_2 \sqrt{r_3}}(-d_4 d_1 r_1 r_2 r_3 r_1^3 + 2d_{11} r_2(-u + 2r_1 (r_3 + (3r_1 + r_2))(u - x) + 3)
+ 2(u - 2r_1 r_3) y r_1 + 2r_2(d_32 u + 2r_3 (r_2 r_1^2 - r_2^2 + x - 1)r_1 + r_2 u) - 2(2r_3^2 + u) y
+ d_21(u + 2(r_3 r_1^2 - r_2 r_3 r_1^2 + r_3 (u + x - 1)r_1 + r_3^2 y - u(x + y)) + d_22(u + 2r_3 r_1^2)
- r_2 r_3 r_1^2 + r_3 (u + x - 1)r_1 + r_3^2 r_1^2 - u(x + y)) + d_1 (r_1 - r_2) r_3 (r_1^2 - 2r_1 r_2 + u)), \quad (B27) \]

\[ A^4_3 = \frac{m_{\tilde{Z}}^{7/2} N_0}{8L_1 r_1 r_2 \sqrt{r_3}}(-2d_4 (r_1 - r_2) r_3 (r_1^2 + r_2^2 + u) - 8d_{41} r_1 r_2 (2r_1^4 + 2r_2 r_1^2 + 3u r_1^2 + r_2^3 r_1 + u(u
- r_1^2)) + 2d_{21} r_1 r_2 r_3 (2r_2 x - r_3) + 2d_{32} r_1 r_2 r_3 (r_3 - 2r_2 x) - d_4 (r_1 - r_2) r_3 (r_1 - r_2) + 2x
+ 2y - 1) + 4d_{31} r_1 r_2 (u + 2r_3 (r_2 r_1^2 - r_2^2 + x - 1)r_1 + r_2 u) - 2(2r_3^2 + u) y - d_2 r_3 (3r_3 r_1^2
+ (-2x - 2y + 1)r_1 - r_2 + 2r_2 (x + y)) + d_3 (2r_3 y - 2r_3 y r_1 + r_2 (2r_3^2 - 1) + r_3 y)\]

\[ - d_{22} r_1 r_2 (2r_3 r_2^2 + u + 2(r_3^2 - r_3 r_2^2 + r_2^2 + 2x - 1)r_1 + r_2 (2r_3^2 - 1) + r_3 y)\]

\[ - 4d_{11} r_1 r_2 (u - 2u - 2r_1 r_3) y + 2r_1 (3r_3 r_1^2 - 2r_2 r_3 + r_3 + (3r_1 + r_2)(u - x))), \quad (B28) \]

\[ A^4_3 = \frac{m_{\tilde{Z}}^{7/2} N_0 \sqrt{r_3}}{r_1 r_2 L_2}(r_1 - r_2)(d_1 T_b + d_3 T_c) \quad (B29) \]

---

4. **Spin-triplet P-wave state: \((|\tilde{c}\bar{b}|^3 P_J)|\)**

There are nine new Lorentz structures for \((|\tilde{c}\bar{b}|^3 P_J)|\), which are
\[ B_1 = \frac{1}{m_z} \varepsilon^j_{\alpha\alpha} k^\nu, \quad B_2 = \frac{1}{m_z^2} k^\alpha k^\beta \varepsilon^j_{\alpha\beta} k^\nu, \quad B_3 = \frac{1}{m_z^3} q_2^\beta \varepsilon^j_{\alpha\beta} k^\nu, \quad B_4 = \frac{1}{m_z^4} q_2^\beta q_2^\gamma \varepsilon^j_{\alpha\beta} k^\nu, \]

\[ B_5 = \frac{i}{m_z} \varepsilon(k, q_2, \beta, \alpha) \varepsilon^j_{\alpha\beta} k^\nu, \quad B_6 = \frac{i}{m_z} \varepsilon(q_2, q_3, \beta, \alpha) \varepsilon^j_{\alpha\beta} k^\nu, \quad B_7 = \frac{i}{m_z} \varepsilon(k, q_3, \beta, \alpha) \varepsilon^j_{\alpha\beta} k^\nu, \]

\[ B_8 = \frac{i}{m_z} \varepsilon(k, q_2, q_3, \alpha) k^\beta \varepsilon^j_{\alpha\beta} k^\nu, \quad B_9 = \frac{i}{m_z} \varepsilon(k, q_2, q_3) q_2^\beta \varepsilon^j_{\alpha\beta} k^\nu, \]

It is noted that \( \varepsilon^{0,2}_{\alpha\beta} \) is the symmetric tensor and \( \varepsilon^1_{\alpha\beta} \) is the anti-symmetric tensor, and the fact that \( \varepsilon^1_{\alpha\alpha} = \varepsilon^{2}_{\alpha\alpha} = 0 \). As the terms involving the following coefficients have no contributions to the square of the amplitude. So practically we can safely set the coefficients before them to be zero:

\[ A_j^i \left( |(\bar{c}\bar{b})_1|^3 P_0 \right) = 0 \quad \text{for } i = (1 - 4), \]

\[ j = (5, 6, 7, 8, 9), \quad (B30) \]

\[ A_j^i \left( |(\bar{c}\bar{b})_1|^3 P_1 \right) = 0 \quad \text{for } i = (1 - 4), \]

\[ j = (1), \quad (B31) \]

The coefficients \( A_j^1, A_j^2, A_j^3 \) and \( A_j^4 \) that are the same for all three \( P \)-waves:

\[ A_1^1 = \frac{2L_1 m_z^{3/2}}{r_1 r_2 \sqrt{3}} \left( 2d_1 r_2 T_b (r_3 - 2 r_1 x) r_1^2 + 2d_2 r_2 T_c (r_3 - 2 r_2 x) r_1^2 + d_4 (3 r_1 + r_2) r_3 T_c \right. \]
\[ \times (r_1 r_3 + u) + d_2 T_b ((3r_1 + r_2) r_3 r_1 r_3 + u) - 2r_1 (r_1 - r_2) x - d_2 T_b ((3r_1 + r_2) r_3 r_1 r_3 + u) \]
\[ + 6r_2 r_1 + (3r_1 + r_2) u - 2r_2 y) + d_3 T_c (2r_1^3 + (3r_1 + r_2) r_1 + r_2 u - 2r_3 y)), \]
\[ (B33) \]

\[ A_1^2 = -16d_1 m_z^{3/2} r_1 \sqrt{3} T_b L_1, \quad (B34) \]

\[ A_1^3 = -8m_z^{5/2} r_3^3 (d_1 T_b - d_2 T_b + (d_31 + d_41) T_c) L_1, \quad (B35) \]

\[ A_1^4 = \frac{m_z^{5/2}}{r_1 r_2} (d_2 - d_3) (r_1 - r_2), \quad (B36) \]

\[ A_2^1 = \frac{m_z^{5/2} L_1}{2r_1 r_2 r_3} ((3d_1 + 3d_2 + 3d_3) r_1^2 + 2(2d_1 - d_2 + 2d_2 + d_3 + 2d_3) r_2 r_1 \]
\[ + (d_1 - d_2 + 2d_3 + 4d_1) r_2^2) r_3 - 8r_1 r_2 (d_21 r_1 + d_32 r_2) x), \]
\[ (B37) \]

\[ A_2^2 = -\frac{m_z^{5/2}}{r_2} \sqrt{3} L_1 (d_1 - d_2), \quad (B38) \]

\[ A_2^3 = -\frac{4m_z^{5/2} L_1}{\sqrt{3}} (d_21 + d_22 + d_32), \quad (B39) \]

\[ A_2^4 = \frac{4m_z^{5/2} L_1}{\sqrt{3}} (d_22 - d_31), \quad (B40) \]

\[ A_2^2 = \frac{L_2 m_z^{5/2}}{2r_1 r_2 \sqrt{3}} \left( 2d_1 r_2 (r_3 - 2 r_1 x) r_1^2 + 2d_2 r_2 (r_3 - 2 r_2 x) r_1^2 + d_4 (3 r_1 + r_2) r_3 (r_1 r_3 + u) \right. \]
\[ + d_1 (3r_1^4 + 7r_2 r_1^3 + (5r_2^4 + u - 2x)r_1^2 + r_2 (r_2^4 + 8u + 2x)r_1 - r_2^2 u) + d_2 (3r_3 r_1^3 \]
\[ + ur_1^2 + r_2 (6u - 2r_2 r_3) r_1 + r_2 u - 2r_2^3 y) + d_3 (3r_3 r_1^3 + 3ur_1^2 + 2r_2 u r_1 \]
\[ - r_2^2 r_1 + r_3^2 u - 2r_2^3 y)), \]
\[ (B41) \]

\[ A_2^2 = -4d_1 m_z^{5/2} r_1 \sqrt{3} L_2, \quad (B42) \]

\[ A_2^3 = -2m_z^{5/2} ((3d_1 - 2d_2 + d_31 + d_41) r_1 - (d_11 - d_22 + d_31 - d_41) r_2) \sqrt{3} L_2, \quad (B43) \]

\[ A_2^5 = -2m_z^{5/2} r_1 r_2 \sqrt{3} (d_22 T_b + d_3 T_c) (r_1 - r_2), \quad (B44) \]
\[ A_8 = \frac{2m_z^{5/2}L_2}{r_1r_2r_3^{3/2}}(((d_1 - d_2)r_1^2 + 4(d_2 - d_{21})r_2r_1 - (d_1 - d_2)r_2^2)r_3T_b + ((d_3 - d_4)r_1^2
-4(d_3 - d_{32})r_2r_1 - (d_3 - d_4)r_2^2)r_3T_c + 8r_1r_2(d_{21}r_1T_b - d_{32}r_2T_c)x), \]  

\[ A_8 = -\frac{4m_z^{5/2}\sqrt{r_3T_bL_2}}{r_2}(d_1 - d_2), \]  

\[ A_8 = \frac{16m_z^{5/2}L_2}{\sqrt{r_3}}((d_{21} + d_{22})T_b - d_{32}T_c), \]  

\[ A_8 = -\frac{16m_z^{5/2}L_2}{\sqrt{r_3}}(d_{22}T_b + d_{31}T_c), \]  

\[ A_9' = \frac{1}{8\sqrt{r_3L_2}}(m_z^{7/2}N_0\frac{2d_4}{r_1r_2}(r_1(2r_1^2 + 5r_2r_1 + r_2^2)r_3^2 + (3r_1 + r_2)ur_3^2 + (r_1 - r_2)u^2)

Appendix C: Lorentz structure coefficients of $L^\mu_{\nu r}$. 

All the non-zero coefficients of $L^\mu_{\nu r}$, 

$$C_2^{-r'} = \frac{-m^2 N_1}{4 \sqrt{2M}} (1 + 4 T_d) p_1 \cdot q_3$$  \hspace{1cm} (C2) 

$$C_1^{-r'} = \frac{-m^2 N_1}{4 \sqrt{2M}} (1 + 4 T_d) p_2 \cdot q_3$$  \hspace{1cm} (C1)
\[ C_3^{rr'} = \frac{m_2 N_f}{4 \sqrt{2} M} (1 + 4T_d) p_1 \cdot p_2 \]  
(C3)

\[ C_4^{rr'} = \frac{-m_2^2 N_f}{4 \sqrt{2} M} (1 + 4T_d) \]  
(C4)

\[ C_1^{rr'} = \frac{m_2 N_f}{8 \sqrt{2} M} (\sqrt{2} - 4(2 - \sqrt{2})T_d) p_2 \cdot q_3 \]  
(C5)

\[ C_2^{rr'} = \frac{m_2 N_f}{8 \sqrt{2} M} (\sqrt{2} - 4(2 - \sqrt{2})T_d) p_1 \cdot q_3 \]  
(C6)

\[ C_3^{rr'} = \frac{m_2 N_f}{8 \sqrt{2} M} (-\sqrt{2} + 4(2 - \sqrt{2})T_d)(p_1 \cdot p_2) \]  
(C7)

\[ C_4^{rr'} = \frac{-m_2^2 N_f}{8 M} (1 + 4T_d - \sqrt{2}) \]  
(C8)

where \( M = \frac{1}{\sqrt{p_1 \cdot p_2}} \) and \( T_d = \frac{1}{2} - \sin^2 \theta_w \). \( N_f \) can be obtained by ensuring \( k_1^\mu = iN_1 \varepsilon^{\mu \nu \rho \sigma} p_{1 \nu} q_{3 \rho} p_{2 \sigma} \) to satisfy \( k_1^2 = -1 \).
