Abstract

Background

Major cost of bioethanol is attributed to enzymes employed in biomass hydrolysis. Lignocellulolytic enzymes are predominantly produced from the hyper cellulolytic mutant filamentous fungus *Trichoderma reesei* RUT-C30. Several decades of research have failed to provide an industrial grade organism producing higher titers of an effective synergistic biomass hydrolyzing enzyme cocktail. *Penicillium janthinellum* NCIM1366 was reported as a cellulase hyper producer and a potential alternative to *T. reesei*, but a comparison of their hydrolytic performance was seldom attempted.

Results

Hydrolysis of acid or alkali pretreated rice straw using cellulase enzyme preparations from *P. janthinellum* and *T. reesei* indicated 37 and 43 % higher glucose release respectively with *P. janthinellum* enzymes. A comparison of these fungi with respect to their secreted enzymes indicated that the crude enzyme preparation from *P. janthinellum* showed 28 % higher overall cellulase activity. It also had an exceptional 10-fold higher beta-glucosidase activity compared to that of *T. reesei*, leading to a lower cellobiose accumulation and thus alleviating the feedback inhibition. *P. janthinellum* secreted more number of proteins to the extracellular medium whose total concentration was 1.8 fold higher than *T. reesei*. Secretome analyses of the two fungi revealed more number of CAZymes and a higher relative abundance of cellulases upon cellulose induction in the fungus.

Conclusions

The results revealed the ability *P. janthinellum* for efficient biomass degradation through hyper cellulase production, and it outperformed the established industrial cellulase producer *T. reesei* in the hydrolysis experiments. A higher level of induction, larger number of secreted CAZymes and a high relative proportion of BGL to cellulases could be the possible reasons for its performance advantage in biomass hydrolysis.

Background

Lignocellulosic biomass is mainly composed of three polymers - cellulose, which is the most abundant component and comprise about 35-50 % of plant dry weight, 20-35 % hemicellulose and 5-30 % lignin[1]. Degradation of lignocelluloses is generally carried out by a set of enzymes including ligninases, hemicellulases, cellulases and other accessory enzymes and their relative proportions and quantities can determine the efficiency of hydrolysis [2]. The major cost involved in bioethanol production from lignocellulosic biomass is contributed by the hydrolysis step, owing to the cost of production of these enzymes [3]. Thus, reducing the cost of enzymes is critical for making the process economical. The major sources of lignocellulose degrading enzymes are filamentous fungi, mainly the genera *Trichoderma*, *Aspergillus* and *Penicillium* [4]. With cellulose being the major component, cellulases play an important role in the degradation process. Cellulases are mainly divided into three major groups based on their mode of action on cellulose 1) endoglucanases, which randomly cleave internal β-1, 4 linkages in cellulose chain generating free ends 2) cellobiohydrolases, which act in a processive manner on either reducing or non-reducing ends of the cellulose chain, releasing cellobiose as the major product and 3) beta glucosidases that hydrolyze cellobiose into glucose [5].

Among the filamentous fungi, *Trichoderma reesei* is the most studied cellulase producer and considered as the model organism for cellulase research. It was originally isolated from the Solomon Islands during the Second World War, and the isolate was named *T. reesei* QM6a as part of the culture collection at the US Army Quarter Master Research and Development Center at Natick, Massachusetts. Attempts to improve the cellulase production from *T. reesei* QM6a by several generations of mutagenesis resulted in an enzyme hyper-secreting mutant named as *T. reesei* RUT-C30 [6]. Currently, *T. reesei* RUT-C30 is the predominantly used industrial cellulase producer, because of its ability to produce a high titer of cellulosases and a gene regulation mechanism that is highly adapted for cellulose utilization [7]. Nevertheless, the cost of cellulases is still a major concern, with only a handful of companies commercially manufacturing biomass hydrolysis enzymes, and transportation and storage of the enzyme itself adding significantly to the cost [8]. Availability of an alternate cellulase source that is better than *T. reesei* would be highly advantageous to the 2G-Ethanol industry, especially in countries where commercial production of efficient biomass hydrolyzing cellulases are not available. *Penicillium janthinellum* NCIM1366 is a mutant produced from its wild type *Penicillium janthinellum* NCIM1171 [9] and it is known to be a hyper producer of cellulases. But a comparative study of this organism with the model cellulase producer *T. reesei* RUT-C30 has
not been performed. In this paper, the cellulase production and hydrolysis efficiency of *P. janthinellum* NCIM1366 was compared with *T. reesei* RUT-C30. Secretome analyses performed using Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS) revealed higher number of CAZymes in *P. janthinellum* compared to *T. reesei*, and a higher relative abundance of cellulases upon induction using cellulose, which may explain the higher activity and better biomass hydrolytic performance of enzyme preparation from the fungus.

**Results**

1. **Cellulases from *Janthinellum* perform better than *T. reesei* cellulases in the hydrolysis of rice straw.**

Both the dilute acid and dilute alkali pretreated rice straw were hydrolyzed better by *P. janthinellum* cellulases compared to enzymes from *T. reesei*, indicated by a significantly higher glucose release (Fig. 1). At 24h, glucose release by *T. reesei* and *P. janthinellum* cellulases from acid pretreated rice straw were 12.94 ± 0.8 mg/ml and 17.69 ± 0.47 mg/ml respectively, the latter showing a 37% higher glucose release. Similar results were observed for alkali pretreated rice straw, where *P. janthinellum* enzyme released 27.24 ± 0.22 mg/ml of glucose which was 43% higher than the *T. reesei* cellulase. Also, the glucose release for both the acid and alkali pretreated biomasses was higher with *P. janthinellum* cellulase at all the measured time points.

2. **Janthinellum produces higher enzyme titers compared to *T. reesei***

To know how each of the major components of cellulolytic system contribute to the hydrolytic efficiency of *P. janthinellum* cellulase cocktail, standard cellulase assays were performed, on the enzymes produced by the fungi. Extracellular enzyme production in this case was carried out using the same medium and under identical conditions of growth. Secreted enzymes from both fungi were analyzed for the total cellulase, endo-glucanase and beta-glucosidase activities. Both *T. reesei* and *P. janthinellum* showed maximum cellulase activity on the 10th day, but the FPase activity of *P. janthinellum* (0.83 FPU/ml) was 28% higher than that of *T. reesei* (0.65 FPU/ml) (Fig 2A). Peak endoglucanase activity of 18.17 IU/ml was shown by *P. janthinellum* on the 10th day, whereas *T. reesei* showed an almost identical activity (17.1 IU/ml), but at 6th day (Fig 2B). However, the endo glucanase activity levels were not sustained at further time points, probably indicating a feedback inhibition through glucose accumulation. *P. janthinellum* on the contrary, had a lower initial endo glucanase activity (12.8 IU/ml) which steadily increased to 18.17 IU/ml on 10th day and showed an ascending trend. The largest difference in enzyme activity between the two fungi was observed in the case of beta glucosidase (BGL) activity. Highest BGL activity in the case of *T. reesei* was 10.15 IU/ml. *P. janthinellum* also showed the highest BGL activity (95.42 IU/ml) on the 10th day (Fig 2C). Also, the fungus produced 24.88 IU/ml activity on the 2nd day, where *T. reesei* could elaborate only 1.68 IU/ml. These results are remarkable as the beta-glucosidase activity at peak levels by the two fungi is different by an almost 10-fold margin. Also, it becomes evident that the expression of BGL sets in early in the *P. janthinellum* which would allow it to hydrolyze cellulose faster and prevent cellobiose accumulation, which in turn may help to overcome an early setting in of feedback inhibition. The results were also confirmed by a Zymogram analysis which showed a prominent BGL activity band in *P. janthinellum*, whereas the *T. reesei* BGL band was barely visible (Fig 2D).

3. **Janthinellum shows lesser cellobiose accumulation in the hydrolysis medium which is indicative of its better beta-glucosidase activity**

Cellobiose, the intermediate product of enzymatic cellulose hydrolysis, is produced through action of exoglucanases and is the substrate for cellobiose/beta-glucosidase. Cellobiose accumulation can lead to product inhibition of upstream enzymes (endoglucanases and cellobiohydrolases) thus slowing down the whole hydrolytic process [10,11]. *T. reesei* is known to have limited cellobiose/beta glucosidase (BGL) activity, and while it may be advantageous for the organism in tight regulation of cellulose metabolism while growing on natural substrates, it is a disadvantage for the biomass hydrolyzing enzyme cocktails produced using the fungus and often the *T. reesei* enzymes lack of BGL activity is compensated by addition of BGL enzyme from other organisms. In this study, it was observed that the cellobiose accumulation in the hydrolysis mixtures was higher for the *T. reesei* enzyme compared to *P. janthinellum*, indicating an incomplete digestion due to the inherent low BGL activity of the former (Fig 3). For acid pretreated rice straw, there was little or no cellobiose accumulation observed during the 24h of hydrolysis, in the case of *P. janthinellum* enzyme, while about 5 mg/ml cellobiose was observed consistently from 4th hour onwards in the case of *T. reesei*. In alkali pretreated rice straw hydrolysis, the cellobiose concentration increased from 2.42 mg/ml in 4h to 7.45 mg/ml in 24h for *T. reesei* while the maximum cellobiose accumulation in the case of *P. janthinellum* was only 0.76mg/ml at 12h after which it again decreased. This
indicated the efficient removal of cellobiose, from the reaction medium by *P. janthinellum* enzyme, which could be accounted for by the almost 10-fold higher beta-glucosidase activity in the fungus. The results are an indicative of an optimum enzyme cocktail from a single fungus that outperforms the conventional cellulase producer.

4. *janthinellum* secretes higher amount of proteins compared to *T. reesei*

Cellulose is a large polymer and utilization of it requires secretion of enzyme by microorganisms to process it outside the cell, so that the simple sugars derived from its breakdown can be taken inside. The total secreted protein concentration in presence of cellulose is indicative of the efficiency of the fungus in utilizing the polymer, as efficient cellulose digestion typically requires a milieu of different enzyme activities, in addition to cellulases. *T. reesei* showed a maximum protein secretion of 0.28 mg/ml on the 6th day of growth, whereas *P. janthinellum* secreted the maximum protein on 10th day of growth which was ~1.8 times higher than *T. reesei* (Fig 4A). At all the time points tested, extracellular protein concentration was higher in *P. janthinellum*. SDS PAGE of the extracellular fractions from both fungi under un-induced (glucose grown) and induced (cellulose grown) conditions indicated significant elevation in secreted proteins upon cellulose induction (Fig 4B). It was also observed that visibly, a greater number of extracellular proteins were secreted by *P. janthinellum*.

5. Comparative secretome analysis of cellulose induced cultures confirm secretion of a relatively larger number of CAZymes and lignocellulose active enzymes by *janthinellum*

The observed cellulase activity and hydrolysis activity are contributed by the extracellular enzymes in both organisms. As both cultures showed maximum filter paper activity on 10th day of inoculation in cellulose medium, it was speculated that the maximum repertoire of enzymes are secreted at that time point. For comparison glucose was selected as the non-inducing carbon source. The secreted proteins from both cultures, either grown with glucose as carbon source or upon induction with cellulose on the 10th day of growth, were identified and quantitatively analyzed by Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS) analysis. Supplementary Tables S1 and S2 lists all the proteins, their Uniprot accession number, molecular weights, number of unique peptides, normalized abundance in glucose and cellulose grown cultures and fold change of upon induction for both *T. reesei* RUT-C30 and *P. janthinellum* NCIM1366 cultures respectively. Our analysis detected a total of 53 proteins from *T. reesei* and 85 proteins from *P. janthinellum* in the 10th day secretome. The distribution of proteins according to their biological function is shown in Figure 5. Among them, 27 proteins from *T. reesei* (51 %) and 29 proteins from *P. janthinellum* (34 %) were predicted to have an N terminal signal peptide using SignalP5.0 server. The identification of proteins without a signal peptide in the secretome could be indicative of the presence of cell lysis, cell death, or secretion through unconventional mechanisms [12]. Figure 6 shows the top 10 highly expressed proteins, as measured by the normalized abundance of their peptides in cellulose induced cultures, compared to the control (grown in glucose). Most of the highly expressed proteins from both organisms were directly involved in the lignocellulose degradation.

Since it appeared from the forgoing studies that the reason for better overall cellulolytic activity and hydrolytic efficiency of *P. janthinellum* could be its secretion of a larger number of proteins, most of which are known to be involved in lignocellulose hydrolysis, it was speculated that the organism could elaborate more cellulolytic enzymes and/or accessory proteins compared to the industrial workhorse - *T. reesei*. An analysis of the CAZymes in the total secretomes was performed to understand their distribution in the extracellular proteins of both fungi. Among the 53 secreted proteins detected in *T. reesei*, 20 were identified as CAZymes (Figure 5A) and the number of CAZymes identified in the 85 identified secreted proteins of *P. janthinellum* were 27 (Figure 5B). The distribution of proteins among different CAZy families and the distribution of glycosyl hydrolase (GH) family proteins in both the fungi are shown in Figure 7. CAZymes from *P. janthinellum* were mostly GH family proteins except one in GT family. The CAZymes from *T. reesei* RUT-C30 were distributed to more CAZy families which included GH (Glycoside Hydrolases), CE (Carbohydrate Esterases), AA (Auxiliary Activities) and CBM (Carbohydrate Binding Module). In the case of GH family proteins, *P. janthinellum* secretome had almost double the number of different Glycoside Hydrolases compared to *T. reesei*. GH family proteins from *P. janthinellum* spanned over 12 GH subfamilies while for *T. reesei* it was 11 GH subfamilies. GH subfamilies 5, 6, 7 and 11 were detected in both secretomes while GH subfamilies 3, 4, 16, 17, 30 and 72 were detected only in *T. reesei* and GH subfamilies 2, 15, 27, 28, 36, 43, 55 and 75, were detected only in *P. janthinellum*.

Table 1 shows the list of CAZymes identified from the secretomes of *P. janthinellum* and *T. reesei*. Among the CAZymes detected, a total of 17 enzymes which are directly involved in cellulose hydrolysis were detected, of which 3 were common to both fungi, which
were cellobiohydrolase1 (CBH1) (Uniprot accession: P62694, A0A088DLG0), cellobiohydrolase2 (CBH2) (P07987, F1CHI2) and endoglucanase 1 (EG-1) (A0A024SNB7, A0A0F7TSC9). The two cellobiohydrolases showed higher abundance in \textit{P. janthinellum} and the endoglucanase showed higher abundance in \textit{T. reesei}. Apart from the EG-1, two other endoglucanases, EG-II (P07982) and EG-V (A0A024S5P6), are identified from \textit{T. reesei}. In \textit{P. janthinellum}, 10 cellobiohydrolases and 2 endoglucanases were identified from the common cellulosomes. However, it may be noted that multiple peptide tags may be matching the same \textit{P. janthinellum} NCIM 1366 gene sequence in reality, which may not be captured on analyzing against the genome (s) of other \textit{Penicillium} species’ genomes as is the case here. While \textit{P. janthinellum} exhibited 10 times the BGL activity of \textit{T. reesei}, no beta-glucosidases were identified in both the fungi. There was therefore no way to confirm if the higher BGL activity obtained experimentally for \textit{P. janthinellum} corresponded to a higher amount of the corresponding protein in the secretome. It was previously observed that the BGL proteins had high specific activities and minute quantities can give high hydrolytic efficiencies, even though their proteins were undetectable by conventional means.

There were 9 enzymes involved hemicellulose degradation identified from the secretome of \textit{T. reesei}, while 6 were identified in \textit{P. janthinellum} of which, 2 were common with \textit{T. reesei}. Chitin degrading enzymes were also identified from both secretomes but pectin degrading enzymes were identified only in \textit{P. janthinellum}. Accessory activities known to aid cellulose hydrolysis in \textit{T. reesei}, Swollenin (A0A024RZP7) and Lytic Polysaccharide Monoxygenase (AOA024SM10) were identified in the secretome of \textit{T. reesei}, while these activities were not detected in \textit{P. janthinellum}. In general, the relative abundance of most of the CAZymes were high in \textit{P. janthinellum} compared to \textit{T. reesei} and one of the cellobiohydrolases (A0A1Q5UFZ3) from GH7 family showed a very high relative abundance of 2.3 million. Though \textit{P. janthinellum} did not show the accessory enzymes / activities in its secretome, it does not necessarily mean that the fungus lacks them, and further confirmations from the genome analysis is awaited.

**Discussion**

Lignocellulose degrading enzymes are critical in biomass conversion to biofuels and filamentous fungi are typically used for the production of these enzymes because of their ability to synthesize and secrete a wide array of plant cell wall degrading enzymes [13]. \textit{T. reesei} RUT-C30 is the most widely used fungus for cellulase production, in the past several decades, and efforts for improving its enzyme production are still at large [14,15]. \textit{P. janthinellum} NCIM 1366 is a mutant strain developed at the National Chemical Laboratory, Pune, India through classical mutagenesis and which exhibited enhanced cellulase production compared to the parent strain NCIM 1171 [9]. The extracellular enzyme preparation from the strain was found in this study to be more efficient than the \textit{T. reesei} enzyme in the hydrolysis of pretreated rice straw. The cellulase system of the fungus is relatively unexplored and the present study aimed to study the cellulases from \textit{P. janthinellum} and compare it with established cellulase hyper producer \textit{Trichoderma reesei} RUT-C30.

Experiments were designed to assess the efficiencies of both cellulase preparations for the hydrolysis of rice straw, pretreated using the most common methods of dilute acid or dilute alkali treatment at high temperature. The enzyme from \textit{P. janthinellum} hydrolyzed the pretreated biomass better, indicated by the higher glucose release. Interestingly, the glucose release from acid and alkali pretreated biomasses was respectively 37 % and 43 % higher compared to \textit{T. reesei}. The results were surprising for a “new” cellulase producer to outperform the established industrial producer. Hence the extracellular enzyme preparations from both fungi were analyzed for their major component activities. These included endoglucanases (EGs), cellobiohydrolases (CBHs), and beta-glucosidases (BGLs), which act in synergism to hydrolyze cellulose[16]. Since the parameters like media composition, pH, carbon source used etc., can influence the quantity and variety of the cellulase components produced by fungi [17], the basic mineral salts medium of Mandels and Weber [18] with cellulose as the sole carbon source was used for both the organisms to obtain un-biased data. The results showed higher activity for all the three major components with peak activity on 10\textsuperscript{th} day of incubation. Among the enzymes, the largest difference in activity was observed for beta glucosidase (BGL), which was 10 fold higher in \textit{P. janthinellum}. It is already recognized that the extracellular enzymes of \textit{T. reesei} strains are limited in BGL activity for effective biomass hydrolysis [19]. Thus it may be speculated that the higher BGL activity may be one of the significant factors which can contribute to the higher hydrolytic efficiency shown by \textit{P. janthinellum} cellulase. This was also supported by the fact that the hydrolysis using \textit{T. reesei} cellulase accumulated higher concentration of cellobiose in the medium, indicative of an incomplete hydrolysis. Thus, unlike \textit{T. reesei} enzyme which has to be supplemented with external BGL for hydrolysis reaction [20], \textit{P. janthinellum} enzyme preparations may be used without the need for any blending or with minimal addition of synergistic BGL preparation (s). In addition to the major cellulases, the
total extracellular proteins were also 1.8 times higher for *P. janthinellum* and the qualitative analysis by SDS-PAGE showed more number of proteins in the gel complementing this finding.

Proteomic approaches have been widely used in filamentous fungi for the identification of both intracellular and extracellular proteins [21]. The genome of *T. reesei* QM6a, which is the parent strain of RUT-C30 was first sequenced in 2008 giving insight into its CAZyme system [22]. *T. reesei* is known to encode at least 10 cellulases, 16 hemicellulases and a total of around 400 CAZymes in its genome. But the composition of secretome varies depending on the carbon source used, culture conditions or experimental parameters. The first proteome analysis of *T. reesei* RUT-C30 identified a total of 22 proteins using lactose as carbon source [23]. Another study, using different carbon sources identified 230 extracellular proteins and 90 CAZymes [24]. In the present study using a minimal mineral salt medium under identical conditions, a total of 53 proteins were identified from *T. reesei* secretome, while *P. janthinellum* secreted 85 different proteins. As expected, most of the proteins identified from both the fungi were related to biomass degradation. More number of CAZymes was identified from *P. janthinellum* secretome. CAZymes from *T. reesei* included 2 cellobiohydrolases, 3 endoglucanases, 9 hemicellulases and the accessory activities - Swollenin and Lytic Polysaccharide monooxygenase (LPMO). CAZymes from *P. janthinellum* were grouped into 12 cellobiohydrolases, 3 endoglucanases, and 6 hemicellulases. No beta glucosidases were identified from both secretomes to support the extremely higher beta glucosidase activity shown by *P. janthinellum*. However, the number of cellobiohydrolases and their relative abundance was very high in *P. janthinellum*.

The proteins identified from the secretome may not be a complete representation of all the CAZymes secreted by the organism, as the study used only a single time point and pure cellulose as sole carbon source. The highest differentially expressed protein from *T. reesei* was the GH7 family endoglucanase EG-1, which showed 183567-fold increase in expression upon cellulose induction. However, CBH1 is known to be the major secreted protein of *T. reesei* on cellulose induction [25]. The difference in this study might be a result of the culture conditions and/or the time point of analysis. It could also result from the processing of samples where the insoluble cellulose fraction, which could bind the enzyme, was removed to obtain the supernatant used for analyses. The normalized fold difference shown by the most highly expressed protein from *P. janthinellum* was almost 2 million, and this was a cellobiohydrolase from GH7 family. While *T. reesei* secreted a wider variety of enzymes involved in lignocellulose hydrolysis, it was the *P. janthinellum* that secreted more glycosyl hydrolases and especially very high level of exoglucanases. The study provides preliminary information on the presence of all major cellulolytic and hemicellulolytic activities in the fungus and a very high induction in presence of cellulose, which could account for its enhanced hydrolytic performance.

**Conclusions**

Here, we provide the first ever secretome analysis of *Penicillium janthinellum* NCIM1366 and its comparison with the established cellulase hyper producing industrial strain - *Trichoderma reesei* RUT-C30. The analyses have highlighted the better hydrolytic efficiency, enzyme activity, protein production and secretion efficiency of *P. janthinellum*, which indicates its potential as future industrial cellulase producer. Further exploration and a deeper understanding on the reasons of its better cellulase production warrants genome and transcriptome level studies on the fungus which is progressing and we aim to reveal soon. Further targeted genetic improvements is expected to improve its performance even more, providing a worthy alternative for *T. reesei*, or complement it in the cellulase applications for biomass conversion.

**Methods**

**a. Microorganism and growth medium**

*Penicillium janthinellum* NCIM1366 was kindly provided by National Culture Collection of Industrial Microorganisms (NCIM), CSIR-National Chemical Laboratory, Pune, India and *Trichoderma reesei* RUT-C30 culture was a kind gift from Prof George Szakacs, Technical University of Budapest. The cultures were grown and maintained in Potato Dextrose Agar (PDA) slant. For enzyme production, spores were collected from 20-day old PDA slants of *P. janthinellum* NCIM1366 and 5-day old slants of *T. reesei* RUT-C30.

**b. Enzyme Production, Comparison of hydrolytic efficiencies and Cellobiose accumulation**

For enzymatic hydrolysis, cellulase enzyme production was carried out under submerged fermentation using optimized media for both organisms. Both media were modified from the original Mandels and Weber [18] medium, optimized for growth and cellulase production of the respective organisms. The enzyme production medium for *P. janthinellum* contained (in g/L): KH$_2$PO$_4$ (2.0),
CaCl$_2$.2H$_2$O (0.3), Urea (0.3), MgSO$_4$.7H$_2$O (0.3), (NH4)$_2$SO$_4$ (1.4), Peptone (0.75), Yeast extract (0.25), Tween-80 (0.5) and Trace elements: FeSO$_4$.7H$_2$O (0.005), MnSO$_4$.H$_2$O (0.0016), ZnSO$_4$.7H$_2$O (0.0014) and CoCl$_2$.6H$_2$O (0.002) with the pH of medium adjusted to 5.5. Cellulose (1% w/v) and wheat bran (2.5% w/v) were used as carbon sources and a spore suspension containing $1 \times 10^5$ spores/ml was used in inoculum at 1% (v/v) level. For T. reesei, the production medium contained (in g/L): KH$_2$PO$_4$ (2.0), (NH$_4$)$_2$HPO$_4$ (2.1), Yeast extract (2), NaCl (0.5), CaCl$_2$.2H$_2$O (0.3), Urea (0.3), MgSO$_4$.7H$_2$O (0.3), Tween 80 (0.5) and Trace elements: FeSO$_4$.7H$_2$O (0.005), MnSO$_4$.H$_2$O (0.0016), ZnSO$_4$.7H$_2$O (0.0014) and CoCl$_2$.6H$_2$O (0.002) with pH of the medium adjusted to 7.2. The carbon sources used were 0.1% Lactose, 2% cellulose and 1.5% Wheat bran and the medium was inoculated at 1% (v/v) level with a $1 \times 10^6$ spores/ml spore suspension. Cultivation was carried out at 30 ± 2°C and 200 rpm agitation. The extracellular crude enzyme from both cultures was collected after 10 days of incubation, and was assayed for total cellulase activity. Enzyme activity was expressed in Filter Paper Units (FPU).

Rice straw, pretreated using either dilute acid or alkali, was used for hydrolysis studies. For acid pretreatment, rice straw (20% w/v) was mixed with 10% w/w of H$_2$SO$_4$ and was pretreated for 1h at 120 ± 2°C. The biomass was cooled to room temperature and a slurry was made by adding 2× volume of water. The pH of the slurry was adjusted to 6.0 by adding 10N NaOH. Solid-liquid separation was performed using a nylon sieve and the biomass was washed twice with tap water. The biomass was used directly after correction of moisture or air dried at room temperature and stored until used. For alkali pretreatment, 20% w/w NaOH was mixed and pretreated at 120 ± 2°C for 1h. Water (2× volume) was added and the pH of the pretreated slurry was adjusted to 6 by adding 10N H$_2$SO$_4$. The biomass was then processed as described above.

The hydrolysis reaction was carried out in a volume of 20 ml in screw capped glass conical flasks with the following conditions: 10% w/w of dry biomass, 10 FPUs/g enzyme loading and 0.05% w/w surfactant (Tweem 80) loading. 0.5% v/v of a commercial Penicillin/Streptomycin mixture (Himedia, India) was added to prevent any bacterial contamination. The hydrolysis reaction was carried out at 50°C for 24 h and samples were collected at 0, 4, 8, 12 and 24 hours of hydrolysis. The amount of glucose and cellulbiose in the samples was determined using the HPLC as described previously [26].

c. Comparison of total cellulase activity, endoglucanase activity, and beta-glucosidase activity

Both organisms were cultivated in the basic Mandels and Weber [18] medium (Composition in g/L: KH$_2$PO$_4$ (2.0), CaCl$_2$.2H$_2$O (0.3), urea (0.3), MgSO$_4$.7H$_2$O (0.3), (NH4)$_2$SO$_4$ (1.4), Peptone (0.75), yeast extract (0.25), Tween-80 (0.5) and Trace elements (g/L): FeSO$_4$.7H$_2$O (0.005), MnSO$_4$.H$_2$O (0.0016), ZnSO$_4$.7H$_2$O (0.0014) and CoCl$_2$.6H$_2$O (0.002) with pH of the medium adjusted to 5.0. Cellulose (1% w/v) was used as the sole carbon source. The inoculum size used was 1% v/v of a 1×10$^6$ spores/ml suspension for both the cultures. Cultivation was carried out at 30 ± 2°C and 200 rpm agitation. Samples were collected from 2nd day onwards, every 48h. Total cellulase activity (Filter Paper Activity) and endoglucanase (CMCase) activity was determined by the IUPAC method [27] and beta-glucosidase activity was determined as described by Rajasree et al [28].

Zymogram analysis of extracellular proteins

Native Poly-Acrylamide Gel Electrophoresis (PAGE) of the extracellular enzyme and Methyl umbelliferyl β-D-glucopyranoside (MUG) staining was performed as described by Rajasree et al. [28].

d. Comparison of extracellular protein production and secretome analysis

Both organisms were grown in basic Mandels and Weber [18] medium with either Glucose or cellulose at 1% (w/v) level as sole carbon sources, as described above. Samples were collected at 48h intervals starting from 2nd day. Total secreted proteins present in the samples were estimated by the Bradford method [29] with BSA as standard. SDS-PAGE was carried out as described by Laemmli [30], using 12% and 5% acrylamide for the resolving and the stacking gels, respectively. Proteins were visualized by staining with Coomassie Brilliant Blue R-250.

For secretome analyses, extracellular proteins were collected by centrifugation for 10 min at 4°C and 13400g after 10 days of incubation. The supernatants were further clarified by filtration through 1μm Glass microfiber filter. The collected proteins were dialyzed against 50 mM ammonium bicarbonate buffer and concentrations were normalized. Samples were digested using trypsin following the standard protocol [31]. The proteomic profiling was performed in duplicates by Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS) at the Mass Spectrometry & Proteomics Core facility of Rajiv Gandhi Centre for Biotechnology, Trivandrum, India. The protein samples were subjected to in-solution trypsin digestion using sequence grade Trypsin (Sigma Aldrich,
India). The LC/MS/MS analyses of the tryptic peptides were performed in a SYNAPT G2 High Definition Mass Spectrometer (Waters, UK), connected to a NanoACQUTY UPLC® chromatographic system (Waters, UK) for the separation of the peptides. The LC-MS/MS acquired raw data was analyzed by Progenesis QI for Proteomics V3.0 (NonLinear Dynamics, Waters, UK) for protein identification using the protein database of Trichoderma reesei and Penicillium downloaded from UniProt repository. Prediction of the presence of secretion signal motifs was achieved using SignalP 5.0 [32].

f. Identification of CAZymes from secretome data

Annotation of CAZy (Carbohydrate Active Enzymes) family of proteins and as per CAZy database [33] was done through dbCAN2 meta server [34].

Declarations

- **Ethics approval**: This article does not contain any studies with human participants or animals performed by any of the authors.
- **Consent to publish**: RKS, the corresponding author, declare on behalf of all authors that we do not have data pertaining to individuals.
- **Availability of data and materials**: All essential data generated or analyzed during this study are included in this published article and its supplementary information files. More elaborate datasets generated during and/or analysed during the current study available from the corresponding author on reasonable request.
- **Competing interests**: The authors declare that they have no competing interests.
- **Funding**: Primary funding of the work is from the contingencies of ASR, MC, PKV and part of the funding from grants for projects BT/PR20695/BBE/117/211/2016 (DBT, Govt. of India) and MLP 0035: 33/2018/MD-FTT&FTC-ANB (CSIR, Govt. of India).
- **Author's Contributions**: ASR - Performed most of the experimental work and protein studies, MC, PKV and AA did data analyses and categorization, RKP did initiated the original studies on cellulase production from Pj and Tr and established protocols, DVG originally isolated the Pj culture, did classical mutations and also corrected manuscript, MS and AA did biomass pretreatment and hydrolysis of biomass, AP was involved in experiment planning and manuscript corrections, RKS conceptualized the work, planned experiments and work distribution, did data interpretation and graphing, drafted manuscript and performed corrections and coordinated the entire work.
- **Acknowledgements**: Included above as separate section

Acknowledgements

ASR, MC, PKV and MS are thankful to the Council of Scientific and Industrial Research (CSIR), Govt. of India for the Junior /Senior research fellowships for Ph.D. This study was partially funded by Department of Biotechnology Govt. of India (BT/PR20695/BBE/117/211/2016) and CSIR (MLP 0035: 33/2018/MD-FTT&FTC-ANB). We thank Prof. George Szakacs, Technical University of Budapest for the Trichoderma reesei RUT-C30 strain.

Glucose release on enzymatic hydrolysis of pretreated rice straw by cellulases from T. reesei RUT C30 and P. janthinellum NCIM 1366. A) acid pretreated rice straw and B) alkali pretreated rice straw using cellulases.
Figure 2

Extracellular cellulase production by T. reesei and P. janthinellum in Mandels and Weber medium with cellulose as sole carbon source
A) Total cellulase as Filter Paper Units, B) Endoglucanase 
C) Beta-glucosidase (BGL) D) Zymogram analysis showing BGL activity as MUG fluorescence
E) Native PAGE showing protein profile of T. reesei and P. janthinellum secreted enzymes
Figure 3

Cellobiose accumulation during hydrolysis of biomass using T. reesei or P. janthinellum enzymes A) Acid pretreated rice straw B) Alkali pretreated rice straw

Figure 4

Extracellular protein production by T. reesei and P. janthinellum in response to induction by cellulose A) Extracellular protein concentrations in T. reesei (Tr) and P. janthinellum (Pj) at different time points when cultivated in glucose and in cellulose B) SDS-PAGE showing differences in protein production by the two fungi. Lane Information - 1) Page Ruler® pre-stained protein ladder, 2) Tr grown in glucose 3) Tr. grown in cellulose as sole C source 4) Pj grown in glucose 5) Pj. grown in cellulose as sole C source.
Figure 5

Functional categories of proteins secreted on cellulose induction by *P. janthinellum* and *T. reesei* Legend: A) *P. janthinellum* B) *T. reesei*
Figure 6
Most highly expressed proteins in the secretome of *P. janthinellum* and *T. reesei*, on cellulose induction Legend A) *P. janthinellum* B) *T. reesei*
Figure 7

Distribution of secreted proteins of the fungi in different CAZyme families, and the glycosyl hydrolase family representation in the secretome A) secreted protein distribution in CAZyme families B) distribution of glycosyl hydrolases in subfamilies. Inner circle – T. reesei, Outer circle – P. janthinellum
