On the algebraic invariant curves of plane polynomial differential systems

Tsygvintsev Alexei

Abstract

We consider a plane polynomial vector field $P(x, y)dx + Q(x, y)dy$ of degree $m > 1$. To each algebraic invariant curve of such a field we associate a compact Riemann surface with the meromorphic differential $\omega = dx/P = dy/Q$. The asymptotic estimate of the degree of an arbitrary algebraic invariant curve is found. In the smooth case this estimate was already found by D. Cerveau and A. Lins Neto [2] in a different way.

Introduction

The study of plane polynomial vector fields goes back at least to Poincaré [12]. Recall that the second half of Hilbert’s 16th problem [8] asks for an upper bound on the number of limit cycles of real plane polynomial vector fields. Notice, that the class of invariant curves of the given planar system involves the class of its limit cycles. Of course, every limit cycle is also an invariant curve.

This paper is devoted to one aspect of this problem: to study algebraic invariant curves i.e. defined by an algebraic equation $f(x, y) = 0$, where $f \in \mathbb{C}[x, y]$ is an arbitrary polynomial. The real part of the above curve which turns out to be a limit cycle, is called the algebraic limit cycle. Up to now only several cases of algebraic limit cycles are known, especially for quadratic plane systems [3]. It has been shown by Darboux [4] that if a given planar polynomial system of degree $m$ has more than $2 + [m(m+1)]/2$ algebraic invariant curves, then it admits a rational first integral.

In this paper we apply a new method connecting the problem of existence of algebraic invariant curves of plane polynomial vector fields of the form $P(x, y)dx + Q(x, y)dy$ with the contemporary theory of Riemann surfaces. To each algebraic invariant curve of such a field we associate a compact Riemann surface $C$ and a meromorphic differential $\omega = dx/P = dy/Q$.

Using this approach, in Section 5 we find the asymptotic estimate of the degree of an arbitrary algebraic invariant curve (Theorem 6). In the particular case we obtain the estimate for a degree of a nodal algebraic invariant curves, then it admits a rational first integral.

In this paper we apply a new method connecting the problem of existence of algebraic invariant curves of plane polynomial vector fields of the form $P(x, y)dx + Q(x, y)dy$ with the contemporary theory of Riemann surfaces. To each algebraic invariant curve of such a field we associate a compact Riemann surface $C$ and a meromorphic differential $\omega = dx/P = dy/Q$.

Using this approach, in Section 5 we find the asymptotic estimate of the degree of an arbitrary algebraic invariant curve (Corollary 3). It is shown too that an arbitrary smooth algebraic invariant curve has a degree less than $m + 2$ (Theorem 2) and that for an arbitrary algebraic invariant curve its genus is a linear function of the degree (Theorem 5). These results were already obtained (in a completely different way) in papers [1], [2].

1. The Darboux divisor and points at infinity.

Consider the system of differential equations

$$\dot{x} = P(x, y), \quad \dot{y} = Q(x, y), \quad (x, y) \in \mathbb{C}^2$$

(1)

where $P, Q$ are polynomials of degree $m > 1$. We suppose that $P$ and $Q$ have not a common nonconstant polynomial factor and $P = \sum_{i=1}^{m} P_i$, $Q = \sum_{i=1}^{m} Q_i$, where $P_i, Q_i$ are homogeneous polynomials of degrees $i = 0, \ldots, m$.

Let $C = \{(x, y) \in \mathbb{C}^2 : f(x, y) = 0\}$ be an invariant curve of (1). Without loss of generality we may suppose that $f \in \mathbb{C}[x, y]$ is irreducible. Then $\dot{f} = \left(\frac{\partial f}{\partial x} + Q \frac{\partial f}{\partial y}\right)_{f=0} \equiv 0$. As the ideal $< f >$ is radical, then $\dot{f} \in < f >$ and hence $\dot{f} = kf$, for some $k \in \mathbb{C}[x, y]$.

Definition 1 The polynomial $f(x, y) \in \mathbb{C}[x, y]$ is called an algebraic partial integral of the system (1) if there exists a polynomial $k \in \mathbb{C}[x, y]$ such that

$$P \frac{\partial f}{\partial x} + Q \frac{\partial f}{\partial y} = kf.$$  

(2)
The polynomial $k$ is called *cofactor* and has the following form $k = \sum_{i=1}^{m-1} k_i$, where $k_i$ are homogeneous polynomials of degrees $i = 0, \ldots, m-1$.

If $k \equiv 0$ then $f(x, y) = \text{const}$ is a first integral of the system (1).

**Remark 1** It is easy to see that if $f(x, y)$ is reducible, i.e. $f = f_1^{m_1} \cdots f_l^{m_l}$, where $f_k \in \mathbb{C}[x, y]$, $k = 1, \ldots, l$, then polynomials $f_k$ are again partial integrals of the system (1).

The polynomial $f$ is a sum of its homogeneous parts $f = \sum_{i}^{n} f_i$, where $f_i$ are homogeneous polynomials of degrees $i = 0, \ldots, n$ and $n = \deg(f)$.

Consider the homogeneous polynomial $R_{m+1}(x, y)$ of degree $m + 1$ defined by

$$R_{m+1}(x, y) = xQ_m(x, y) - yP_m(x, y),$$

where $P_m$ and $Q_m$ are higher homogeneous parts of the polynomials $P$ and $Q$ respectively. Let us suppose that $R_{m+1}$ does not vanish identically, then it has $m + 1$ zeros $D_i = [x_i : y_i] \in \mathbb{CP}^1$, $i = 1, \ldots, m + 1$. By the suitable rotation of variables $x, y$ we can obtain $x_i y_j \neq 0$, $i = 1, \ldots, m + 1$. Hence, without loss of generality: $D_i = (1, z_i)$, $z_i \in \mathbb{C}^2$, $z_i \neq 0$, $i = 1, \ldots, m + 1$.

**Definition 2** The formal sum of points $D = \sum_{i=1}^{m+1} D_i$ is called the *Darboux divisor* of the differential system (1).

Notice that the important role of the points $D_i$ for polynomial vector fields first was observed by Darboux in 1878.

Let

$$V(x, y) = P(x, y)\frac{\partial}{\partial x} + Q(x, y)\frac{\partial}{\partial y},$$

be the polynomial vector field on $\mathbb{C}^2$ corresponding to the system (1). Through the non-linear change of variables

$$u = \frac{1}{x}, \quad v = \frac{y}{x}, \quad x \neq 0, \quad (u, v) \in \mathbb{C}^2,$$

and multiplying the induced vector field by $u^{m-1}$ we obtain [6], [5]

$$\tilde{V}(u, v) = A(u, v)\frac{\partial}{\partial u} + B(u, v)\frac{\partial}{\partial v},$$

$$A(u, v) = -u^{m+1}P \left( \frac{1}{u}, \frac{v}{u} \right),$$

$$B(u, v) = u^{m} \left[ Q \left( \frac{1}{u}, \frac{v}{u} \right) - vP \left( \frac{1}{u}, \frac{v}{u} \right) \right],$$

where $\tilde{V}(u, v)$ represents the vector field of (1) near the line at infinity $L_\infty = \{ u = 0 \}$. The point $(0, v_0)$ where $\tilde{V}(0, v_0) = (0, 0)$ is the singular point of $\tilde{V}(u, v)$. It is easy to see that $R_{m+1}(1, v_0) = 0$ and we obtain

**Proposition 1** The points $D_i = (1, z_i) \in D, i = 1, \ldots, m + 1$ are the singular points at infinity of the system (1).

The equation (2) turns into

$$A(u, v)\frac{\partial F}{\partial u} + B(u, v)\frac{\partial F}{\partial v} = K(u, v)F,$$

where $F(u, v) = u^n f \left( \frac{1}{u}, \frac{v}{u} \right) = f_n(1, v) + u f_{n-1}(1, v) + \cdots = 0$ represents the curve $C$ near $L_\infty$ and

$$K(u, v) = u^{m-1}k \left( \frac{1}{u}, \frac{v}{u} \right) - u^{m}nP \left( \frac{1}{u}, \frac{v}{u} \right).$$
Let us show now that the Darboux divisor $D$ contains all possible points at infinity of any algebraic invariant curve of the system (1).

Denote by $L_\infty = \{[x_i : y_i : 0] : (x, y) \subset \mathbb{CP}^1\} \subset \mathbb{CP}^2$ the line at infinity. Let $I_f$ be a set of points at infinity of the algebraic curve $C$ which corresponds to the equation $f(x, y) = 0$, where $f(x, y)$ is an algebraic partial integral of the system (1).

**Theorem 1.** $I_f \subset D$.

**Proof.** By considering the right and left hand homogeneous parts of (2) we find

$$P_m \frac{\partial f_n}{\partial x} + Q_m \frac{\partial f_n}{\partial y} = k_{m-1}f_n,$$

where $f_n$ is the highest order term of the polynomial $f = \sum_{i=a}^n f_i$ and $k_{m-1}$ is the highest order term of the cofactor $k = \sum_{i=1}^{m-1} k_i$.

To show $I_f \subset D$ we need to prove that if $f_n(x_0, y_0) = 0$ then $(x_0, y_0) \in D$ or

$$R_{m+1}(x_0, y_0) = 0,$$

where the polynomial $R_{m+1}$ is defined by (3).

Consider the linear change of variables $(x, y) \rightarrow (u, v)$: $x = x_0 + u$, $y = y_0 + v$. The polynomial $f_n(x, y)$ turns into the polynomial $F(u, v) = f_n(x_0 + u, y_0 + v)$ which has the following Taylor expansion

$$F(u, v) = \sum_{i=r}^n F_i(u, v),$$

where $F_i$ are homogeneous polynomials of degrees $i = r, \ldots, n$, $r \geq 1$ and

$$F_i = \frac{1}{(n-i)!} \left( x_0 \frac{\partial}{\partial u} + y_0 \frac{\partial}{\partial v} \right)^{n-i} f_n(u, v).$$

Thus, for the lower order term $F_r$ of the sum (6) we have $F_r \not\equiv \text{const}$ and the following identity is fulfilled

$$x_0 \frac{\partial F_r}{\partial u} + y_0 \frac{\partial F_r}{\partial v} = 0.$$

The equation (4) takes the form

$$((c_1 + N_1(u, v)) \frac{\partial}{\partial u} + (c_2 + N_2(u, v)) \frac{\partial}{\partial v}) (F_r + \cdots + F_n) = 0,$$

where

$$c_1 = P_m(x_0, y_0) - \frac{x_0}{n} k_{m-1}(x_0, y_0), \quad c_2 = Q_m(x_0, y_0) - \frac{y_0}{n} k_{m-1}(x_0, y_0),$$

are constants and $N_1(u, v)$, $N_2(u, v)$ are polynomials such that $N_1(0, 0) = N_2(0, 0) = 0$.

The two cases should be considered.

1) $c_1 = c_2 = 0$. Then from relations (9) it follows that the equality (5) is fulfilled.

Hence $(x_0, y_0, 0) \in D$.

2) $(c_1, c_2) \neq (0, 0)$. Then one can show from (8) that $c_1 \frac{\partial F_r}{\partial u} + c_2 \frac{\partial F_r}{\partial v} = 0$. Using (7) we see that vectors $(c_1, c_2)$ and $(x_0, y_0)$ are colinear i.e.

$$\det \begin{pmatrix} c_1 & x_0 \\ c_2 & y_0 \end{pmatrix} = 0,$$

which gives again the equality (5). Q.E.D.
Corollary 1. Let $D = D_1, \ldots, D_{m+1}$ be a Darboux divisor of the system (1) and $l_i = a_ix + b_iy, a_i, b_i \in \mathbb{C}$, $i = 1, \ldots, m+1$ be a set of linear forms such that $l_i(D_i) = 0$, $i = 1, \ldots, m+1$. Then there exists nonnegative integers $n_1, \ldots, n_{m+1}$, $\sum n_i = n$ that
\[
f_n(x, y) = \prod_{i=1}^{m+1} l_i^{n_i}(x, y) .
\] (10)

Notice, that the same expression for $f_n$ was introduced first by Jablonskii [9] in the case $m = 2$, see also [10].

2. The smooth case.

Let $C \subset \mathbb{CP}^2$ be an algebraic smooth curve of $\deg(C) = n$ satisfying the equation $f(x, y) = 0$ where $f(x, y)$ is an irreducible algebraic partial integral of the system (1). Without loss of generality we suppose that
\[
f(x, y) = y^n + a_1(x)y^{n-1} + \cdots + a_n(x), \quad a_i(x) \in \mathbb{C}[x], \quad i = 1, \ldots, n.
\]
Consider the holomorphic mapping $\phi : C \to \mathbb{CP}^1$ defined by $\phi(x, y) = x$.

Let $\nu = \nu_\phi(P)$ be a multiplicity of $\phi$ at the point $P \in C$. Consider the ramification divisor $R = \sum_{P \in C} (\nu_\phi(P) - 1)P \subset \text{Div}(C)$.

We break $R$ into two divisors $R = R_1 + R_2$, where
\[
R_1 = \sum_{P \in C \cap L_\infty} (\nu_\phi(P) - 1)P
\]
contains branching points of $\phi$ at infinity and
\[
R_2 = \sum_{P \in C / L_\infty} (\nu_\phi(P) - 1)P
\]
contains all finite branching points.

Lemma 1. Let $C = \{f(x, y) = 0\} \subset \mathbb{CP}^2$ be a nonsingular algebraic curve of $\deg(C) = n$ where $f(x, y)$ is a partial first integral of the system (1). Then
\[
\deg(R_1) \leq n - 1.
\]

This statement is proved by noting that $f = f_n + \cdots + f_0$, $\deg f_k = k$ and $f_n = \prod_{i=1}^{m} L_i^{n_i}(x, y)$ where $\sum_{i=1}^{m} n_i = n$, $m \leq n$, $L_i(x, y)$ are linear homogeneous polynomials.

Lemma 2. $\deg(R_2) = n^2 - n + 1 - \deg(R_1)$. (11)

Proof. Denote $g = \text{genus}(C)$, $n = \deg(C)$, then by the genus-degree formula for a nonsingular curve $C$ we have $g = \frac{(n-1)(n-2)}{2}$.

By the Riemann-Hurwitz formula we obtain $g = \frac{\deg(R)}{2} - n + 1$. Comparing these two expressions for $g$ we find (11), Q.E.D.

Now let us study the divisor $R_2$.

If $K = (x_0, y_0) \in R_2$ then $\frac{\partial f}{\partial y}(K) = 0$ by the definition of a branching point. With help of (2) we obtain
\[
P(K) \frac{\partial f}{\partial x}(K) + Q(K) \frac{\partial f}{\partial y}(K) = 0.
\] (12)

4
Lemma 3. If the curve $C$ is nonsingular, $\deg(C) = n$, then
$$\deg(R_2) \leq mn,$$
where $m > 1$ is the degree of the system (1).

Proof. Since $K$ is a smooth point the relation (12) holds
$$\left(f, \frac{\partial f}{\partial y}\right)_K \leq \left(f, P\right)_K, \quad K \in R_2,$$
where $(g, l)_X$ denotes the intersection number of the curves $g(x, y) = 0$ and $l(x, y) = 0$ at the point $X \in g \cap l$. One can easily verify that $\deg(R_2) = \sum_{P \in R_2} \left(f, \frac{\partial f}{\partial y}\right)_P$. Thus, by Bézout theorem $\deg(R_2) \leq mn$. Q.E.D.

Theorem 2. Let us assume that the system (1) admits a smooth algebraic invariant curve $C \subset \mathbb{CP}^2$ defined by the equation $f(x, y) = 0$, $\deg(f) = n$. Then
$$n \leq m + 1$$
where $m > 1$ is the degree of the system (1).

The statement of the theorem follows immediately from the above three lemmas. The Theorem 2 was obtained for the first time in [2] using a different method. By J. Moulin-Ollagnier it was shown that the same result can be obtained in the theory of the Koszul complexes of polynomial vector fields.

3. The Weierstrass polynomials.

Let $X = (x_0, y_0) \in \mathbb{C}^2$ be a finite singular point of the curve $C = \{(x, y) \in \mathbb{C}^2 : f(x, y) = 0\}$ i.e. the point $X$ at which $\frac{\partial f}{\partial x}(X) = \frac{\partial f}{\partial y}(X) = 0$. Without loss of generality we suppose $X = (0, 0)$.

In order to clarify the local structure of $C$ near $X$, we shall need the help of the Weierstrass polynomials [7n7].

Let $\mathbb{C}\{x\}$ ($\mathbb{C}\{x, y\}$) represent the ring of holomorphic functions defined in some neighborhood of $0 \in \mathbb{C}$ ($(0, 0) \in \mathbb{C}^2$).

Definition 3. $w \in \mathbb{C}\{x, y\}$ is said to be a Weierstrass polynomial with respect to $y$, if
$$w = y^d + c_1(x)y^{d-1} + \cdots + c_d(x), \quad c_j(x) \in \mathbb{C}\{x\}, \quad c_j(0) = 0, \quad j = 1, \ldots, d.$$

Let us assume that $C$ is irreducible and its affine equation is
$$f(x, y) = y^n + a_1(x)y^{n-1} + \cdots + a_n(x) = 0.$$

Theorem 3. The polynomial $f(x, y)$ can be expressed as
$$f = uf_1f_2 \cdots f_p,$$
where $f_i(x, y) = y^{d_i} + c_{i1}(x)y^{d_i-1} + \cdots + c_{id_i}(x)$, $i = 1, \ldots, p$, are irreducible Weierstrass polynomials and $u(x, y)$ is a unit of $\mathbb{C}\{x, y\}$, i.e. $u(0, 0) \neq 0$.

There exists the open discs $\Delta_i = \{\tau \in \mathbb{C} : |\tau| < \rho_i\}$, $i = 1, \ldots, p$, such that each equation $f_i(x, y) = 0$, $i = 1, \ldots, p$ defines holomorphic mapping $q_i : \Delta_i \to C$ as follows
$$\tau \to (\tau^{d_i}, g_i(\tau)), \quad \text{where} \quad g_i(\tau) = \sum_{k=1}^{\infty} c_{i,k} \tau^k \in \mathbb{C}\{\tau\}, \quad i = 1, \ldots, p. \quad (13)$$
Thus, with topological point of view, the algebraic curve $C$ can be obtained near the singular point $X = (0, 0)$ from several open discs by identifying them together at their centers. This is the concept of normalization [7].

**Theorem 4.** Let $C = \{(x, y) \in \mathbb{C}^2 : f(x, y) = 0\}$ be an algebraic invariant curve of the system (1) and $X = (x_0, y_0)$ be a singular point of $C$. Then $X$ is an equilibrium point of the system (1).

**Proof.** Let us assume that $X = (x_0, y_0)$ is not an equilibrium point of the system (1). Then it has the unique solution passing through this point

$$x = x_0 + P(x_0, y_0)t + \sum_{i=2}^{\infty} a_i t^i, \quad y = y_0 + Q(x_0, y_0)t + \sum_{i=2}^{\infty} b_i t^i, \quad a_i, b_i \in \mathbb{C}$$

(14)

where $t \in \Delta = \{t \in \mathbb{C} : |t| < \rho\}$ for any small $\rho \in \mathbb{R}$.

On the other hand $X$ is the singular point of $C$ and according to the Theorem 3 the system (1) has no less than $p > 0$ different solutions passing through $X$ and locally expressed by (13). Thus, we obtain $p = 1$ and the solution (14) is the parametrization of the curve $C$ near the singular point $X$. By our assumption $X$ is not an equilibrium point of (1) i.e. $P(x_0, y_0) \neq 0$ or $Q(x_0, y_0) \neq 0$. Hence, looking at (14), $X$ is the smooth point of $C$. We obtain the contradiction. Q.E.D.

**Corollary 2.** The number of finite singular points of an arbitrary algebraic invariant curve of the system (1) is not more than $m^2$. Furthermore, if $\frac{P(x, y)}{Q(x, y)} \neq \frac{x}{y}$, then

$$|\text{Sing}(C)| \leq m^2 + m + 1.$$

Indeed, if $\frac{P(x, y)}{Q(x, y)} \neq \frac{x}{y}$ then the polynomial (3) is not equal zero identically and according to Corollary 1 the curve $C$ cannot have more than $m + 1$ singular points at infinity.

4. The genus of $C$.

Let $C$ be an algebraic invariant curve of the system (1) defined by the equation $f(x, y) = 0$. Denote by $\text{Sing}(C)$ the set of its singular points. There exists the compact Riemann surface $\tilde{C}$ with a surjective continuous map $\pi : \tilde{C} \to C$ such that $\pi : \tilde{C}/\pi^{-1}(\text{Sing}(C)) \to C/\text{Sing}(C)$ is a holomorphic bijection. The aim of this section is to calculate the genus of $\tilde{C}$ which is also called the genus of the curve $C$. Consider the following meromorphic differential on $C$

$$\omega = \frac{dx}{P} = \frac{dy}{Q}.$$ (15)

Let $\omega$ be its divisor then according to the Poincaré-Hopf formula

$$2g - 2 = \deg(\omega).$$ (16)

On the other hand, by Noether’s formula [8n11]

$$g = \frac{(n - 1)(n - 2)}{2} - \sum_{X \in \text{Sing}(C)} \delta(X),$$ (17)

where the numbers $\delta(X)$ are given by

$$\delta(X) = \left(f, \frac{\partial f}{\partial y}\right)_X + |\pi^{-1}(X)| - \nu_\phi(X).$$

Here $(,)_X$ is the intersection number and $\nu_\phi(X)$ is the multiplicity of the map $\phi : (x, y) \to x$ at the point $(x, y) \in \text{Sing}(C)$.
It is easy to see that $\omega$ has no zeros in the affine part of $C$. Let now $X = (x_0, y_0) \in \mathbb{C}^2$ be the singular point of the curve $C$. Without loss of generality we put $X = (0, 0)$. According to Theorem 3 we can factor $f(x, y)$ into the product of irreducible factors

$$f = u_1 \cdots u_r, $$

where $u(0, 0) \neq 0$ and $u_i, i = 1, \ldots, r$ are Weierstrass polynomials. Notice, that $|\pi^{-1}(X)| = r$. Then locally $C$ can be represented as follows

$$C = C_1 + \cdots + C_r,$$

where $C_i = \{(x, y) \in \mathbb{C}^2 : |x| < \rho, |y| < \epsilon, f(x, y) = 0\}, \quad i = 1, \ldots, r$ are irreducible local analytic curve components of $C$ and $\rho, \epsilon$ are sufficiently small real numbers.

The parametrization of $C_i, i = 1, \ldots, r$ near $X = (0, 0)$ is given by

$$x = \tau^{d_i}, \quad y = \sum_{k=1}^{\infty} c_{ik} \tau^k, \quad c_{ik} \in \mathbb{C}, \quad d_i = \text{deg}(u_i). \quad (18)$$

Putting (18) into (15) and using Theorem 4 one can show that the differential $\omega$ has in the point $X$ a pole of the multiplicity at least one. So, for the affine part of the curve $C$ we have the following estimate

$$\text{deg}(\omega) |_{C \cap \mathbb{C}^2} \leq - \sum_{X \in \text{Sing}(C) \cap \mathbb{C}^2} |\pi^{-1}(X)|. \quad (19)$$

Now let us consider the points at infinity. Substituting $x = 1/u, y = v/u$ into $f(x, y) = 0$ and multiplying both sides of the resulting expression by $u^n$, we obtain the equation

$$F(u, v) = f_n(1, v) + uf_{n-1}(1, v) + \cdots + f_0u^n = 0, \quad f_0 = \text{const} \neq 0,$$

which represents the algebraic curve curve $C$ near the line at infinity $L_{\infty} = \{u = 0\}$. We can write $f_n(1, v)$ as follows

$$f_n(1, v) = \prod_{i=1}^{q}(v - v_i)^{n_i}, \quad n_i = 0, 1, \ldots, \quad q \leq n, \quad \sum n_i = n, \quad (20)$$

where the points $(0, v_i) \in C \cap L_{\infty}, i = 1, \ldots, k$.

Now we break (20) into the product of three factors

$$f_n(1, v) = L_1 L_2 L_3.$$ 

Here $L_1 = \prod_{i=1}^{r}(v - v_i), r \leq n$ contains all simple factors of (17). Near the points $(0, v_i), i = 1, \ldots, r$ the curve $C$ has the parametrization of the form

$$u = \tau(a_{0i} + a_1 \tau + O(\tau)), \quad v = v_{i1} + \tau(p(b_{0i} + b_1 \tau + O(\tau)), \quad (21)$$

where $\tau \in \mathbb{C}$ is a local parameter, $a, b \in \mathbb{C}, a_{0i} \neq 0$ and $p$ is a positive integer.

$$L_2 = \prod_{i=1}^{k}(v - v_{2i})^{m_i}, k \leq n \text{ contains factors of multiplicity } m_i > 1 \text{ such that the corresponding points } (0, v_{2i}) \text{ satisfy the condition } \frac{\partial F}{\partial u}(0, v_{2i}) \neq 0. \quad (22)$$

At last, the factor $L_3 = \prod_{i=1}^{s}(v - v_{3i})^{l_i}, s \leq n$ includes the multipliers of (20) for which $l_i > 1$ and $\frac{\partial F}{\partial u}(0, v_{3i}) = 0$. 

7
These points are singular and according to Theorem 4 near the point \((v_3i, 0)\) we have \(p_i > 1\) local components of \(C\) each of them can be parametrized as
\[
u = \tau^k_j (g_{0ij} + g_{1ij} \tau + O(\tau)), \quad v = v_3i + \tau^d_j, \quad g_{0ij} \neq 0, \quad j = 1, \ldots, p_i. \tag{23}
\]
where \(d_{ij}, k_{ij}\) are positive integers and \(\sum_{j=1}^{p_i} k_{ij} \leq l_i\).

In addition we have
\[
\begin{align*}
r + \sum_{i=1}^{k} m_i + \sum_{i=1}^{s} l_i &= n \quad \text{and} \quad C \cap L_\infty = V_1 \cup V_2 \cup V_3, \quad V_i = \{L_i = 0\}, \quad i = 1, 2, 3.
\end{align*}
\]

From (15) with use of (21), (22), (23) one can show that the following estimates hold
\[
\begin{align*}
\deg(\omega)|_{V_1} &\leq r(m - 2), \quad \deg(\omega)|_{V_2} \leq (m - 1) \sum_{i=1}^{k} m_i - k, \\
\deg(\omega)|_{V_3} &\leq (m - 1) \sum_{i=1}^{s} l_i - \sum_{X \in \Sing(C) \cap L_\infty} | \pi^{-1}(X) |.
\end{align*}
\]

Summing we obtain
\[
\deg(\omega)|_{C \cap L_\infty} \leq n(m - 1) - \sum_{X \in \Sing(C) \cap L_\infty} | \pi^{-1}(X) | - k - r.
\]

Since \(\deg(\omega) = \deg(\omega)|_{C \cap L_\infty} (\omega) + \deg(\omega)|_{C \cap C^2} (\omega)\) in view of (16), (19) we have

**Theorem 5.** For an arbitrary algebraic invariant curve of the system (1) the following estimate for the genus \(g\) holds
\[
2g - 2 \leq n(m - 1) - \sum_{X \in \Sing(C)} | \pi^{-1}(X) |. \tag{24}
\]

This result seems to be a consequence of the formula 1 of the paper [2].

**5. The algebraic invariant curves with nodes.**

Let \(C\) be an algebraic invariant curve of the system (1) with the defining polynomial \(f(x, y)\).

**Lemma 4.** \(|\Sing(C)| \leq m^2 + \frac{n}{2}\).

This is a simple consequence of Corollary 2 and the notation, that \(C\) has at most \(n/2\) singular points at infinity.

**Theorem 6.** Let there exists the integer \(K\) such that \(\forall X \in \Sing(C)\) we have \(\left(f, \frac{\partial f}{\partial y}\right)_X \leq K\), then the following estimate for the degree of the curve \(C\) holds
\[
n \leq \frac{4 + 2m + K + ((4 + 2m + K)^2 + 16Km^2)^{1/2}}{4}, \tag{25}
\]
where \(m\) is the degree of the system (1).

**Proof.** With using of (17), (24) one can show that
\[
n(n - 3) - \sum_{X \in \Sing(C)} \left(f, \frac{\partial f}{\partial y}\right)_X \leq n(m - 1). \tag{26}
\]

By our assumption: \(\left(f, \frac{\partial f}{\partial y}\right)_X \leq K\). According to Lemma 4 we obtain immediately
\[
\sum_{X \in \Sing(C)} \left(f, \frac{\partial f}{\partial y}\right)_X \leq K(m^2 + \frac{n}{2}). \tag{27}
\]

8
Puting (27) into (26) we arrive at Theorem 6.

**Corollary 3.** Let us suppose that all singular points of the algebraic invariant curve $C$ are nodes, then

$$n \leq 2(m+1).$$

(28)

Indeed, as a node is an ordinary double point then $K = 1$ and we can use the estimate (25) which gives (28). It is interesting to compare this result with Theorem 3 of the paper [2].

**Acknowledgement.**

The author would be grateful to L. Gavrilov for his attention to the paper and many useful comments.
