Decoupled limbs yield differentiable trajectory outcomes through intermittent contact in locomotion and manipulation

Andrew M. Pace Samuel A. Burden∗

Abstract

When limbs are decoupled, we find that trajectory outcomes in mechanical systems subject to unilateral constraints vary differentiably with respect to initial conditions, even as the contact mode sequence varies.

1 Introduction

Locomotion with legs entails intermittent contact with terrain; manipulation with digits entails intermittent contact with objects. Since legged locomotion is self–manipulation [JK13; Joh+16], mathematical models for intermittent contact between limbs and environments apply equally well to both classes of behaviors. Parsimonious models for the dynamics of intermittent contact are piecewise-defined, with transitions between contact modes summarized by abrupt changes in system velocities. Such models are hybrid dynamical systems whose state evolution is governed by continuous-time flow (generated by a vector field) punctuated by discrete-time reset (specified by a map). Trajectory outcomes are the resulting state of the system after flowing and undergoing necessary resets for a specified period of time. Trajectory outcomes in hybrid systems generally vary discontinuously as the discrete mode sequence varies as in Fig. 1 (left). The point of this paper is to provide sufficient conditions that ensure trajectories in mechanical systems subject to unilateral constraints vary (continuously and) differentiably through intermittent contact, even as the contact mode sequence varies as in Fig. 1 (right). Since scalable algorithms for optimization [Pol97] and learning [SB98] rely on differentiability, conditions ensuring existence of derivatives are of practical importance in robotic locomotion and manipulation.

1.1 Organization

We begin in Sec. 2 by specifying the class of dynamical systems under consideration, namely, mechanical systems subject to unilateral constraints. Sec. 3 imposes conditions on the system dynamics and trajectories that enable us in Sec. 4 to report that trajectories vary differentiably with respect to initial conditions, even as the contact mode sequence varies.

∗Department of Electrical Engineering, University of Washington, Seattle, WA, USA (apace2,sburden@uw.edu). This material is based upon work supported by the U. S. Army Research Laboratory and the U. S. Army Research Office under contract/grant number W911NF-16-1-0158.
1.2 Relation to prior work

The technical content in Sec. 2 and Sec. 3 appeared previously in the literature and is (more–or–less) well–known; we collate the results here to contextualize and streamline our contributions in Sec. 4.

Figure 1: Trajectory outcomes after flowing for a uniform time from the initial conditions away from impacts in mechanical systems subject to unilateral constraints. (left) In general, trajectory outcomes depend discontinuously on initial conditions. In the pictured model for rigid–leg trotting (adapted from [Rem+10]), discontinuities arise when two legs touch down: if the legs impact simultaneously (corresponding to rotation θ(0) = 0), then the post–impact rotational velocity is zero; if the rear leg impacts before the front leg (θ(0) > 0) or vice–versa (θ(0) < 0), then the post–impact rotational velocities are bounded away from zero. (right) When limbs are decoupled (e.g. through viscoelasticity), trajectory outcomes depend continuously on initial conditions. In the pictured model for soft–leg trotting (adapted from [Bur+15a]), trajectory outcomes (solid lines) are continuous and differentiable. These figures were generated using simulations of the depicted models.

2 Mechanical systems subject to unilateral constraints

In this paper, we study the dynamics of a mechanical system with configuration coordinates \( q \in Q = \mathbb{R}^d \) subject to unilateral constraints \( a(q) \geq 0 \) specified by a differentiable function
\( a : Q \to \mathbb{R}^n \) where \( d, n \in \mathbb{N} \) are finite. We are primarily interested in systems with \( n > 1 \) constraints, whence we regard the inequality \( a(q) \geq 0 \) as being enforced componentwise. Given any \( J \subset \{1, \ldots, n\} \), and letting \(|J|\) denote the number of elements in the set \( J \), we let \( a_J : Q \to \mathbb{R}^{|J|} \) denote the function obtained by selecting the component functions of \( a \) indexed by \( J \), and we regard the equality \( a_J(q) = 0 \) as being enforced componentwise. It is well-known (see e.g. [Bal00, Sec. 3] or [Joh+16, Sec. 2.4, 2.5]) that with \( J = \{ j \in \{1, \ldots, n\} : a_j(q) = 0 \} \) the system’s dynamics take the form

\[
M(q)\ddot{q} = f(q, \dot{q}) + c(q, \dot{q})\dot{q} + Da_J(q)(q)\lambda_J(q, \dot{q}), \tag{1a}
\]

\[
\dot{\lambda}_J(q) = \Delta_J(q, \dot{q}), \tag{1b}
\]

where \( M : Q \to \mathbb{R}^{d \times d} \) specifies the mass matrix for the mechanical system in the \( q \) coordinates, \( f : TQ \to \mathbb{R}^d \) is termed the effort map [Bal00] and specifies the internal and applied forces, \( c : TQ \to \mathbb{R}^{d \times d} \) denotes the Coriolis matrix determined\(^2\) by \( M \), \( Da_J : Q \to \mathbb{R}^{|J| \times d} \) denotes the (Jacobian) derivative of the constraint function \( a_J \) with respect to the coordinates, \( \lambda_J : TQ \to \mathbb{R}^{|J|} \) denotes the reaction forces generated in contact mode \( J \) to enforce the constraint \( a_J(q) \geq 0 \),

\[
\lambda_J(q) = \left( Da_J(q)(q)M^{-1}Da_J(q)(q)\right)^{-1}, \tag{2}
\]

\( \Delta_J : TQ \to \mathbb{R}^{d \times d} \) specifies the collision restitution law that instantaneously resets velocities to ensure compatibility with the constraint \( a_J(q) = 0 \),

\[
\dot{\lambda}_J(q) = \Delta_J(q, \dot{q}) = I_d - (1 + \gamma(q, \dot{q}^-))P_J(q)\dot{\lambda}_J(q), \tag{3}
\]

where \( I_d \) is the \((d \times d)\) identity matrix, \( \gamma : TQ \to [0, \infty) \) specifies the coefficient of restitution, \( P_J : Q \to \mathbb{R}^{d \times d} \) is the projection onto the constraint surface,

\[
P_J = M^{-1}Da_J^\top \left( Da_JM^{-1}Da_J^\top \right)^{-1}Da_J, \tag{4}
\]

and \( \dot{\lambda}_J^+ \) (resp. \( \dot{\lambda}_J^- \)) denotes the right– (resp. left–)handed limits of the velocity vector with respect to time.

**Definition 1** (contact modes). The constraint functions \( \{a_j\}_{j=1}^n \) partition the set of admissible configurations \( A = \{ q \in Q : a(q) \geq 0 \} \) into a finite collection\(^3\) \( \{A_J\}_{J \in 2^n} \) of contact modes:

\[
\forall J \in 2^n : A_J = \{ q \in Q : a_j(q) = 0, \forall i \notin J : a_i(q) > 0 \}, \tag{5}
\]

For each \( J \in 2^n \): we let \( TA = \{(q, \dot{q}) \in TQ : q \in A\} \) and \( TA_J = \{(q, \dot{q}) \in TQ : q \in A_J\} \); if \( q \in A_J \) then we say constraints in \( J \) are active at \( q \).

**Remark 1.** In Def. 1 (contact modes), \( J = \{1, \ldots, n\} \) indexes the maximally constrained contact mode and \( J = \emptyset \) indexes the unconstrained contact mode.\(^1\)

\( ^1\) We let \( TQ = \mathbb{R}^d \times \mathbb{R}^d \) denote the tangent bundle of the configuration space \( Q \); an element \((q, \dot{q}) \in TQ\) can be regarded as a pair containing a vector of generalized configurations \( q \in \mathbb{R}^d \) and velocities \( \dot{q} \in \mathbb{R}^d \); we write \( \dot{q} \in T_q Q \).

\( ^2\) For each \( \ell, m \in \{1, \ldots, d\} \) the \((\ell, m)\) entry \( c_{\ell m} \) is determined from the entries of \( M \) by the formula

\[
c_{\ell m} = -\frac{1}{2} \sum_{k=1}^d (D_{\ell k}M_{km} + D_{m k}M_{\ell k} - D_{\ell k}M_{km}) \tag{JK13, Eqn. 30].
\]

\( ^3\) We let \( 2^n = \{J \subset \{1, \ldots, n\}\} \) denote the power set (i.e. the set containing all subsets) of \( \{1, \ldots, n\} \).
3 Assumptions

The point of this paper is to provide conditions that ensure trajectories of (1) vary differentiably as the contact mode sequence\(^4\) varies. Without imposing additional conditions, the seemingly benign equations in (1) admit a range of dynamical phenomena that preclude differentiability. This section contains the conditions that will enable us to obtain differentiable trajectory outcomes in Sec. 4.

3.1 Existence and uniqueness of trajectories

In the present paper, we will assume that appropriate conditions have been imposed to ensure trajectories of (1) exist on a region of interest in time and state.

Assumption 1 (existence and uniqueness). There exists a flow for (1), that is, a function \(\phi : \mathcal{F} \to TA\) where \(\mathcal{F} \subset [0, \infty) \times TA\) is an open subset (in the subspace topology) containing \(\{0\} \times TA\) and for each \((t, (q, \dot{q})) \in \mathcal{F}\) the restriction \(\phi|_{[0,t] \times \{(q,\dot{q})\}} : [0,t] \to TQ\) is the unique left–continuous trajectory for (1).

Remark 2. The problem of ensuring trajectories of (1) exist and are unique has been studied extensively; we refer the reader to [Bal00, Thm. 10] for a specific result, [Bro16, Thm. 5.3] for a setup using constrained complementarity problems, and [Joh+16] for a general discussion of this problem.

3.2 Differentiable vector field and reset map

Since we are concerned with differentiability properties of the flow, we assume the elements in (1) are differentiable.

Assumption 2 (differentiable vector field and reset map). The vector field (1a) and reset map (1b) are continuously differentiable.

Remark 3. If we restricted our attention to the continuous–time dynamics in (1), then Assump. 2 would suffice to provide the local existence and uniqueness of trajectories imposed by Assump. 1; as illustrated by [Bal00, Ex. 2], Assump. 2 is insufficient when the vector field (1a) is coupled to the reset map (1b).

3.3 Decoupled limbs

Since continuity is necessary for differentiability, we must impose a condition that yields continuous outcomes for trajectories of (1). A general condition that is known\(^5\) to provide continuity is that constraint surfaces intersect orthogonally relative to the mass matrix. Formally,

\[
\forall i,j \in \{1, \ldots, n\}, \ i \neq j, \ q \in a_i^{-1}(0) \cap a_j^{-1}(0) : \\
Da_i(q)M(q)^{-1}Da_j(q)^\top = 0. \tag{6}
\]

Physically, this condition implies that any limb or body segments that can undergo impact simultaneously must be inertially decoupled. Although this condition ensures trajectory outcomes are continuous [Bal00, Thm. 20], they generally remain nonsmooth [PB17, Thm. 1]. Thus we introduce a stronger condition that entails decoupling limb forces through a body.

\(^4\)See Def. 4 (contact mode sequence).

\(^5\)We refer to [Bal00, Thm. 20] for a detailed exposition of this result.
Remark 4. In the decoupled structure described in the preceding assumption, the variable 
Assumption 3 (limbs decoupled through body). The configuration decouples into \((n+1)\) segments, hence \(2^n\) possible contact modes, \(q = (q_j)_{j=0}^n \in Q = \prod_{j=0}^n Q_j\) where \(Q_j = \mathbb{R}^{d_j}\) so that:

1. the mass matrix is block diagonal, \(M(q) = \text{diag}(M_j(q_j))_{j=0}^n\), where \(M_j : Q_j \to \mathbb{R}^{(d_j \times d_j)}\);

2. for limb \(j \in \{1, \ldots, n\}\) the constraint \(a_j\) only depends on \(q_j\), \(a_j : Q_j \to \mathbb{R}\), the coefficient of 
   restitution \(\gamma_j\) only depends on the limb states, \(\gamma_j : TQ_j \to \mathbb{R}\), and the effort \(f_j\) only depends 
   on the states of the limb and the body, \(f_j : TQ_0 \times TQ_j \to \mathbb{R}^{d_j}\);

3. the effort \(f_0\) applied to the body depends additively on the states of the limbs and the body, 
   \(f_0 = g_0 + \sum_{j=1}^n g_j\), where for \(j > 0\), \(g_j : TQ_0 \times TQ_j \to \mathbb{R}^{d_0}\), and \(g_0 : TQ_0 \to \mathbb{R}^{d_0}\).

Remark 4. In the decoupled structure described in the preceding assumption, the variable \(q_0 \in Q_0 = \mathbb{R}^{d_0}\) contains the “body” degrees-of-freedom, i.e. all coordinates that cannot undergo impact 
(and are not inertially coupled to those that can). A limb may contain several links and as such have 
several bilateral constraints corresponding to it. For instance in [Ken+16, Fig. 1(middle)], one 
limb contains four rigid bars. Each limb can be coupled through forces with the body, but can only 
influence other limbs indirectly through the body. Note that series compliance [Spr+13; Odh+14] 
and/or backdrivability [Hyu+14; Ken+16] contribute to inertial decoupling, but conditions (1) and 
(2) of Assump. 3 (limbs decoupled through body) require inertial decoupling in all degrees-of-freedom 
between body and limbs.

Remark 5 (discontinuous outcomes in locomotion). The analysis of a sagittal-plane quadruped 
in [Rem+10] provides an instructive example of the behavioral consequences of coupling limbs in 
legged locomotion. As summarized in [Rem+10, Sec 3.1], the model possesses 3 distinct but nearby 
trot gaits, corresponding to whether two legs impact simultaneously or at distinct time instants; 
the simultaneous-impact trot is unstable due to discontinuous dependence of trajectory outcomes 
on initial conditions.

3.4 Differentiable constraint activation/deactivation times

Trajectories of (1) are not continuous functions of time due to intermittent impacts that trigger 
the reset map (1b). However, it has been known for some time\(^6\) that trajectory outcomes can 
nevertheless depend differentiably on initial conditions away from impact times, so long as the 
contact mode sequence is fixed. For this result to hold, the time when constraints activate (or 
deactivate) must depend differentiability on initial conditions. We now develop definitions used 
to state an admissibility condition at the end of the section that yields differentiable time-to-
activation (and time-to-deactivation).

Definition 2 (admissible constraint activation/deactivation). A trajectory initialized at \((q, \dot{q}) \in 
TA_I \subset TQ\) activates constraints \(I \in 2^n\) at time \(t > 0\) if (i) no constraint in \(I\) was active 
immediately before time \(t\) and (ii) all constraints in \(I\) become active at time \(t\); this activation 
is admissible if the constraint velocity\(^7\) for all activated constraints is negative. Formally, with 
\((\rho, \dot{\rho}^-) = \lim_{s \to t^-} \phi(s, (q, \dot{q}))\) denoting the left-handed limit of the trajectory at time \(t\), 
\[
\forall i \in I : D_t [a_i \circ \phi](0, (\rho, \dot{\rho}^-)) = Da_i(\rho)\dot{\rho}^- < 0. 
\]
Similarly, the trajectory deactivates constraints $I \in 2^n$ at time $t > 0$ if (i) all constraints in $I$ were active at time $t$ and (ii) no constraint in $I$ remains active immediately after time $t$; this deactivation time is admissible if, for all deactivated constraints: (i) the constraint velocity or constraint acceleration\footnote{Formally, the second Lie derivative of the constraint along the vector field specified by (1a).} is positive, or (ii) the time derivative of the contact force is negative. Formally, with $(\rho, \dot{\rho}^+) = \lim_{s \to t^+} \phi(s,(q,\dot{q}))$ denoting the right-handed limit of the trajectory at time $t$, for all $i \in I$:

\begin{equation}
(i) \ D_t [a_i \circ \phi] (0,(\rho,\dot{\rho}^+)) > 0 \text{ or } D_t^2 [a_i \circ \phi] (0,(\rho,\dot{\rho}^+)) > 0,
\end{equation}

or (ii) $D_t [\lambda_i \circ \phi] (0,(\rho,\dot{\rho}^+)) < 0$.

**Remark 6.** The conditions for admissible constraint deactivation in case (i) of (8) can only arise at constraint activation times; otherwise the trajectory is continuous, whence active constraint velocities and accelerations are zero.

**Definition 3** (admissible trajectory). The trajectory initialized at $(q, \dot{q})$ is admissible on $[0,t] \subset \mathbb{R}$ if (i) it has a finite number of constraint activation (hence, deactivation) times on $[0,t]$, and (ii) every constraint activation and deactivation is admissible; otherwise the trajectory is inadmissible.

**Definition 4** (contact mode sequence). The contact mode sequence\footnote{This definition differs from the word of [Joh+16, Def. 4] in that a contact mode is included in the sequence only if nonzero time is spent in the mode; this definition is more closely related to the words of [Bur+16, Eqn. 72]}

associated with an admissible trajectory $\phi^{(q,\dot{q})}$ on $[0,t] \subset \mathbb{R}$ that has $m$ activation and/or deactivation times $t_1, \ldots, t_m$ is the unique function $\omega : \{0, \ldots, m\} \to 2^n$ such that there exists a finite sequence of times $\{t_\ell\}_{\ell=0}^{m+1} \subset [0,t]$ for which $0 = t_0 < t_1 < \cdots < t_{m+1} = t$ and

\begin{equation}
\forall \ell \in \{0, \ldots, m\} : \phi((t_\ell, t_{\ell+1}),(q,\dot{q})) \subset TA_{\omega(\ell)}.
\end{equation}

**Remark 7.** In Def. 4 (contact mode sequence), the sequence $\omega$ is easily seen to be unique by the admissibility of the trajectory; indeed, the associated time sequence consists of start, stop, and constraint activation/deactivation times.

**Assumption 4** (admissible trajectories). The trajectory of (1) initialized at $(q, \dot{q})$ is admissible on $[0,t]$ for all $(t, (q, \dot{q})) \in \mathcal{F}$.

### 4 Differentiability through contact

Under Assumptions 1–4 from Sec. 3, previous work has shown that, when the contact mode sequence is fixed, trajectory outcomes vary continuously [Bal00, Thm. 20] and differentiably [AG58] with respect to variations in initial conditions (i.e. initial states and parameters). This enables the use of scalable algorithms for optimal control [Pol97] and reinforcement learning [SB98] to improve the performance of a given behavior (corresponding to the fixed contact mode sequence) using gradient descent. However, these algorithms cannot be relied upon to select among different behaviors (corresponding to different contact mode sequences) since trajectory outcomes are known to depend nonsmoothly on initial conditions [PB17, Thm. 1]. In this section we report that decoupled limbs yield classically differentiable trajectory outcomes even as the contact mode sequence varies, enabling the use of scalable algorithms to select behaviors.
Theorem 1 (differentiability through intermittent contact). Under Assumptions 1–4 from Sec. 3, if \( t \) is not a constraint activation time for \((q, \dot{q})\), then the flow \( \phi : \mathcal{F} \to \text{TA} \) for (1) is continuously differentiable at \((t, (q, \dot{q})) \in \mathcal{F}\).

Remark 8 (proof sketch). We provide an illustration of the result in Fig. 2, and a sketch of the proof strategy in what follows. For the complete proof, see Sec. 6. Given a contact mode sequence \( \omega \) for a trajectory initialized near \((q, \dot{q})\), we construct a continuously differentiable \((C^1)\) function \( \phi_\omega \) defined on an open set containing \((t, (q, \dot{q}))\) by composing the sequence of flow–to–activation and flow–to–deactivation functions specified by \( \omega \). Without loss of generality, we only consider constraint activations.\(^{10}\) Near \((q, \dot{q})\) in Fig. 2, there are two activation sequences, corresponding to whether constraint 1 activates before constraint 2 activates, or vice versa. For each \( I \subset \{1, 2\} \) we let \( \phi_I \) denote the \( C^1 \) flow for (1a)\(^{11}\) and define the \( C^1 \) function \( \Gamma_I(u, (p, \dot{p})) = (u, (p, \Delta_I(p)\dot{p})) \).

By Assump. 4 (admissible trajectories), there exist \( C^1 \) time–to–activation functions \( \tau^2_{\{1\}}, \tau^2_{\emptyset} \) for constraint 2 defined over open neighborhoods of \((p, \dot{p}^-)\) and \((p, \dot{p}^+_{\{1\}})\) and similarly there exists \( C^1 \) time–to–activation functions \( \tau^1_{\{2\}}, \tau^1_{\emptyset} \) for constraint 1 defined over open neighborhoods of \((p, \dot{p}^-)\) and \((p, \dot{p}^+_{\{2\}})\). For each contact mode \( I \subset \{1, 2\} \) and constraint \( j \in \{1, 2\} \) undergoing activation \((j \notin I)\), we let \( \varphi^j_I \) denote the flow–to–activation,

\[
\varphi^j_I(u, (p, \dot{p})) = (u - \tau^j_I(p, \dot{p}), \phi_I(u - \tau^j_I(p, \dot{p})), (p, \dot{p}));
\]

since \( \varphi^j_I \) is obtained via composition from \( C^1 \) functions, it is a \( C^1 \) function. For \( \omega_1 = (\emptyset, \{1\}, \{2\}) \), the function \( \phi_{\omega_1} \) is given by the composition

\[
\phi_{\omega_1} = \phi_{\{1, 2\}} \circ \Gamma_{\{2\}} \circ \varphi^2_{\{1\}} \circ \Gamma_{\{1\}} \circ \varphi^1_{\emptyset};
\]

and similarly there exists \( C^1 \) functions.

Since both \( \phi_{\omega_1} \) and \( \phi_{\omega_2} \) are obtained via composition from \( C^1 \) functions, they are \( C^1 \) functions. The generalization of this procedure to arbitrary contact mode sequences is given in Sec. 6. As illustrated in Fig. 2, the trajectory outcome near \( \phi(t, (q, \dot{q})) \in \text{TA}_{\{1, 2\}} \) is differentiable with respect to the initial condition near \((q, \dot{q}) \in \text{TA}_\emptyset\), even as the contact mode sequence changes from \( \omega_1 \) to \( \omega_2 \). Formally, we can show that \( D\phi_{\omega_1}(t, (q, \dot{q})) = D\phi_{\omega_2}(t, (q, \dot{q})) \) by computing these derivatives via the Chain Rule; this entails taking products of matrices with the general form\(^{12}\)

\[
D\Gamma_I(u, (p, \dot{p})) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & I_d & 0 \\ 0 & D_p(\Delta_I(p, \dot{p})\dot{p}) & D_\dot{p}(\Delta_I(p, \dot{p})\dot{p}) \end{bmatrix},
\]

and

\[
D\varphi^j_I(u, (p, \dot{p})) = \begin{bmatrix} 1 & \frac{1}{Dh_j(p, \dot{p})F_I(p, \dot{p})}Dh_j(p, \dot{p}) \\ 0 & I_{2d} - \frac{1}{Dh_j(p, \dot{p})F_I(p, \dot{p})}F_I(p, \dot{p})Dh_j(p, \dot{p}) \end{bmatrix}.
\]

\(^{10}\)Admissible constraint deactivations do not alter the flow to first order since the state and vector field are continuous during these transitions.

\(^{11}\)These flows are guaranteed to exist over an open subset of \( \mathbb{R} \times TQ \) containing \( \{0\} \times A_I \) by Assump. 2 (differentiable vector field and reset map).

\(^{12}\)For the definition of \( h_j \), see (18); for the definition of \( F_I \), see (38).
\[ (q, \dot{q}) \in T\mathcal{A}_{\emptyset} \subset TQ \] flows via (1a) to a point \((\rho, \dot{\rho}^-) \in T\mathcal{A}_{\emptyset}\) where both constraint functions \(a_1, a_2\) are zero, instantaneously resets velocity via (1b) to \(\dot{\rho}^+ = \Delta_{\{1,2\}}(\rho, \dot{\rho}^-)\), then flows via (1a) to \(\phi(t, (q, \dot{q})) \in T\mathcal{A}_{\{1,2\}} \subset TQ\). Nearby trajectories undergo activation and deactivation at distinct times: trajectories initialized in the red region activate constraint 1 and then flow through contact mode \(T\mathcal{A}_{\{1\}}\) before activating constraint 2—their contact mode sequence is \(\omega_1 = (\emptyset, \{1\}, \{1,2\})\)—while trajectories initialized in the blue region activate 2 and flow through \(T\mathcal{A}_{\{1,2\}}\) before deactivating 1—their contact mode sequence is \(\omega_2 = (\emptyset, \{2\}, \{1,2\})\). Differentiability of trajectory outcomes is illustrated by the fact that red outcomes lie along the same submanifold as blue.

5 Discussion

We conclude by discussing implications and routes to generalizing the theoretical results reported above.

5.1 Implications for optimization and learning

Optimization and learning algorithms have emerged in recent years as powerful tools for synthesis of dynamic and dexterous robot behaviors [Mom+05b; Tod11; Kui+15; Lev+16; Kum+16]. Since scalable algorithms leverage derivatives of trajectory outcomes, their applicability to the dynamics in (1) has previously (i) been confined to a fixed contact mode sequence [Mom+05b; Mom+05a] or (ii) relied on approximations or relaxations of the dynamics [Tod11; Kui+15; Lev+16; Kum+16]. Neither of these approaches is entirely satisfying: (i) prevents the algorithm from automatically selecting the behavior (corresponding to the contact mode sequence) in addition to extremizing its performance; (ii) implies the model under consideration is no longer a mechanical system subject to unilateral constraints. The results we report in Sec. 4 provide an analytical and computational framework within which derivative-based algorithms can be rigorously and directly applied to the dynamics of mechanical systems subject to unilateral constraints (1) to select between permutations of constraint (de)activations.

5.2 Decoupled limbs

Assump. 3 (limbs decoupled through body) can be interpreted physically as asserting that robot segments that can undergo impact simultaneously (i.e. limbs) must be decoupled through another segment not undergoing impact (i.e. the body). Crucially, this condition is required to ensure
trajectory outcomes vary continuously with respect to initial conditions [Bal00, Thm. 20]; since continuity is a precondition for differentiability, this condition is equally necessary for the result reported in Thm. 1 (differentiability through intermittent contact). We note that this condition is violated by conventional robots constructed from rigid serial chains and non–backdrivable actuators [Mur+94]. In contrast, design methodologies that incorporate direct–drive actuators [Hyu+14; Ken+16] or series compliance [Spr+13; Odh+14] tend to produce robot locomotors and manipulators with limbs that are (approximately) decoupled. How approximately the limbs are decoupled is the determining factor on whether Assump. 3 (limbs decoupled through body) holds, and hence whether the trajectories are differentiable with respect to initial conditions away from (de)activations.

5.3 Grazing contact

Def. 2 (admissible constraint activation/deactivation) precludes grazing trajectories, i.e. those that activate constraints with zero constraint velocity, or deactivate constraints with zero instantaneous rate of change in contact force. The key technical challenge entailed by allowing constraint activation (resp. deactivation) we termed inadmissible lies in the fact that the time–to–activation (resp. time–to–deactivation) function is not differentiable. This fact has been shown by others [DB+08, Ex. 2.7], and is straightforward to see in an example. Indeed, consider the trajectory of a point mass moving vertically in a uniform gravitational field subject to a maximum height (i.e. ceiling) constraint. The grazing trajectory is a parabola, whence the time–to–activation function involves a square root of the initial position.

5.4 Zeno phenomena

Def. 2 (admissible constraint activation/deactivation) precludes Zeno trajectories, i.e. those that undergo an infinite number of constraint activations (hence, deactivations) in a finite time interval. The key technical challenge entailed by allowing Zeno lies in the fact that evaluating the flow requires composing an infinite number of flow–and–reset functions. Composing a finite number of smooth functions yields a smooth function, but the same is not generally true for infinite compositions. Thus although it is possible to show that the infinite composition results in a differentiable flow in simple examples like the rocking block [Hou63] and bouncing ball [Bal00, Sec. 6.1], we cannot at present draw any general conclusions regarding differentiability of the flow along Zeno trajectories.

5.5 Friction

Friction is a microscopic phenomenon that eludes first–principles understanding [GM01]. Phenomenological models of friction are macroscopic approximations; one popular model\textsuperscript{13} posits a transition from sticking to sliding when the ratio of normal to tangential force drops below a parameterized threshold. The system’s flow is discontinuous at this threshold, as some trajectories slide away from their stuck neighbors. Even if such transitions are avoided, the introduction of simple friction models into mechanical systems subject to unilateral constraints is known to produce pathologies including nonexistence and nonuniqueness of trajectories [Ste00].

\textsuperscript{13}Usually attributed to Coulomb, but also due to Antomons [GM01].
5.6 Non–Euclidean configuration spaces

We restricted the configuration space to $Q = \mathbb{R}^d$ starting in Sec. 2 to simplify the exposition and lessen the notational overhead. Nevertheless, the preceding results apply to configuration spaces that are complete Riemannian manifolds.\textsuperscript{14}

5.7 Contact–dependent effort

The dynamics in (1) vary with the contact mode $J \subset \{1, \ldots, n\}$ due to intermittent activation of unilateral constraints $a_J(q) \geq 0$, but the (so–called [Bal00]) effort map $f$ was not allowed to vary with the contact mode. Contact–dependent effort can easily introduce nonexistence or nonuniqueness. Indeed, consider a planar system with $q \in \mathbb{R}^2$ undergoing plastic impact with the constraint surface specified by $a(q) = q_1$ subject to contact–dependent effort that satisfies $f_{\emptyset}(q) = (-1, +1)$ if $q_1 > 0$ and $f_{\{1\}}(q) = (+1, -1)$ if $q_1 = 0$. Every trajectory eventually activates the constraint. Once the constraint is active, the trajectory becomes ill–defined.

5.8 Massless limbs

To accommodate massless limbs, one must specify their unconstrained dynamics. If the unconstrained dynamics differ from the constrained dynamics, then in effect one has introduced contact–dependent effort, whence we refer to the preceding section. If the unconstrained dynamics do not differ from the constrained dynamics, then in effect one has introduced bilateral constraints the massless limbs must satisfy, whence we refer to the subsequent section. The constrained dynamics of massless limbs are derived in [BG15].

5.9 Bilateral constraints

The preceding results hold in the presence of bilateral (i.e. equality) constraints so long as they do not couple limbs. Formally, if the bilateral constraints $b(q) = 0$ are specified by a differentiable function $b : Q \to \mathbb{R}^m$, there must exist an assignment $\beta : \{1, \ldots, m\} \to \{1, \ldots, n\}$ such that for all bilateral constraints $k \in \{1, \ldots, m\}$, unilateral constraints $i, j \in \{1, \ldots, n\}, i \neq j$, and configurations $q \in b^{-1}(0) \cap a_i^{-1}(0) \cap a_j^{-1}(0)$:

$$\langle Da_i(q), Da_j(q) \rangle_{M^{-1}} = 0,$$
$$\langle Db_\beta(0), Da_j(q) \rangle_{M^{-1}} = 0. \quad (15)$$

5.10 Non–autonomous dynamics

One may wish to allow the continuous and/or discrete dynamics in (1) to vary with time or an external input. Some common cases can easily be handled. If the dynamics are time–varying, but time could be incorporated as a state variable so that the preceding assumptions hold for the augmented system determined by $\tilde{q} = (t, q) \in \tilde{Q} = \mathbb{R} \times Q$, $\tilde{M}(\tilde{q}) = \text{diag}(1, M(q))$, $\tilde{f}(\tilde{q}, \dot{\tilde{q}}) = (0, f(t, q, \dot{q}))$, (16)

\textsuperscript{14}Since the preceding results are not stated in coordinate–invariant terms, they are formally applicable only after passing to coordinates.
then the preceding results apply directly to the augmented system; a similar observation holds when the value of an external input is determined by time and state in such a way that the closed-loop system (possibly augmented as above to remove the time dependence) satisfied the preceding assumptions.

6 Appendix: Proof of Thm. 1 (differentiability through intermittent contact)

Theorem 1 (differentiability through intermittent contact). Under Assumptions 1–4 from Sec. 3, if \( t \) is not a constraint activation time for \((q, \dot{q})\), then the flow \( \phi : \mathcal{F} \rightarrow TA \) for (1) is continuously differentiable at \((t, (q, \dot{q})) \in \mathcal{F}\).

Proof. We begin with an apology to the reader. The notation used in this proof is nonstandard; it is our hope that though it is nonstandard the notation clarifies the steps more than it confuses the reader.

Before beginning with the proof we introduce some notation:

1. \( x[i] \) denotes the \( i \)th entry into variable \( x \);
2. \( q \) is the vector containing all limb positions. \( q = [q[i]]_{i=0}^n \in Q = \Pi_{i=0}^n Q_i \);
3. similarly \( \dot{q} \) is the vector containing all limb velocities. \( \dot{q} = [\dot{q}[i]]_{i=0}^n \cdot (q, \dot{q}) \in TQ \);
4. \( a_i : Q \rightarrow \mathbb{R} \) and \( h_i : TQ \rightarrow \mathbb{R} \) where
   \[
   \forall q \in Q \quad a_i(q) = a_i(q_i),
   \]
   \[
   \forall (q, \dot{q}) \in TQ \quad h_i(q, \dot{q}) = a_i(q_i),
   \]
   the logical extensions of \( a_i \) to the corresponding domains;
5. let \( \Box_J : TQ \rightarrow \mathbb{R}^{d \times d} \) where \( \Box_J(q, \dot{q}) = D_q(\Delta_J(q, \dot{q}) \dot{q}) \), the derivative of the post-impact velocity with respect to position;
6. let \( \Diamond_J : TQ \rightarrow \mathbb{R}^{d \times d} \) where \( \Diamond_J(q, \dot{q}) = D_q(\Delta_J(q, \dot{q}) \dot{q}) \), the derivative of the post-impact velocity with respect to position;\(^{15}\)
7. \[
   \begin{bmatrix}
   q[i] \\
   \dot{q}[i]
   \end{bmatrix}
   _{i=0}^n =
   \begin{bmatrix}
   q[0]^T, q[1]^T, \cdots, q[n]^T, \dot{q}[0]^T, \cdots, \dot{q}[n]^T
   \end{bmatrix}
   ^T
   \]
   is the deinterleaving of the position and velocity components of the individual limbs into a vector where the first half corresponds to position components and the later half corresponds to velocity values.

What follows are some helpful identities based upon the above notation and the given assumptions.

1. Given orthogonality of constraints:\(^{16}\)

\(^{15}\)Given the coefficient of restitution \( \gamma \) is dependent upon \( \dot{q} \), \( \Diamond_J(q, \dot{q}) \) might differ from \( \Delta_J(q, \dot{q}) \).

\(^{16}\)Properties (a)-(c) are included here for completeness and (d)-(e) may also be seen more succinctly using the limb decoupling assumption.
2. Given limb decoupling:

(a) the reset map has a block diagonal form with \( \Delta_j^j : TQ_j \to \mathbb{R}^{d_j \times d_j} \), the reset map for limb \( j \) with \( J \) constraints active:

\[
\Delta_j(q[j],\dot{q}[j]) = \text{diag} \left( \Delta_j^j(q[j],\dot{q}[j]) \right)_{j=0}^n,
\]

where

\[
\Delta_j^j(q[j],\dot{q}[j]) = I_{d_j} - (1 + \gamma_j(q[j],\dot{q}[j])) M_j(q[j])^{-1} D_{qj}^T(q[j]) (D_{qj}(q[j]) M(q[j])^{-1} D_{qj}^T(q[j])) D_{qj}(q[j]);
\]

(b) the velocity of a given limb is not affected by a reset if the constraint corresponding to that limb is not active:

\[
\Delta_j^k(q[k],\dot{q}[k]) = I_{d_k} \text{ if } k \notin J;
\]

(c) the reset map for constraint mode \( J \) is equal to the product of the reset maps for each active constraint:

\[
\prod_{j \in J} \Delta_j(q,\dot{q}) = \Delta_J(q,\dot{q});
\]

(d) \( \Box_j(q,\dot{q}) \) has a block diagonal structure with \( \Box_j^j : TQ_j \to \mathbb{R}^{d_j \times d_j} \):

\[
\Box_j(q,\dot{q}) = \text{diag} \left( \Box_j^j(q[j],\dot{q}[j]) \right)_{j=0}^n,
\]

where

\[
\Box_j^j(q[j],\dot{q}[j]) = D_{qj} \left( \Delta_j^j(q[j],\dot{q}[j]) \dot{q}[j] \right);
\]

(e) if a given limb is not in the active constraint set, the block corresponding to the limb in \( \Box_j \) is zero:

\[
\Box_j^k(q[k],\dot{q}[k]) = 0 \text{ if } k \notin J.
\]

(f) \( \Box_j(q,\dot{q}) \) is the summation of \( \Box_{(j)} \) for each active constraint:

\[
\sum_{j \in J} \Box_{(j)}(q,\dot{q}) = \Box_j(q,\dot{q}).
\]

2. Given limb decoupling:

(a) the acceleration of each limb is only dependent upon the given limb’s and the body’s current position and velocity; \( \alpha_J : TQ_J \to \mathbb{R}^d \):

\[
\alpha_J(q,\dot{q})[j] = \begin{cases} 
M_j^{-1}(q[j]) \left( f_j(q[0],\dot{q}[0],q[j],\dot{q}[j]) + c_j(q[j],\dot{q}[j])\dot{q} \right) & \text{if } j \notin J \text{ and } j \neq 0 \\
M_j^{-1}(q[j]) \left( f_j(q[0],\dot{q}[0],q[j],\dot{q}[j]) + c_j(q[j],\dot{q}[j])\dot{q} + D_{qj}(q[j])^T \lambda_j(q[j],\dot{q}[j]) \right) & \text{if } j \in J \\
M_0^{-1}(q[0]) \left( f_0(q,\dot{q}) + c_0(q[0],\dot{q}[0])\dot{q}[0] \right) & \text{if } j = 0;
\end{cases}
\]

(b) \( \diamond_J(q,\dot{q}) \) has a block diagonal form with \( \diamond_j^j : TQ_j \to \mathbb{R}^{d_j \times d_j} \):

\[
\diamond_j^j(q[j],\dot{q}[j]) = D_{qj} \Delta_j^j(q[j],\dot{q}[j]) \dot{q}[j]
\]

\[
D_q(\Delta_J(q,\dot{q})\dot{q}) = D_q \left( \text{diag} \left[ \Delta_j^j(q[j],\dot{q}[j]) \right]_{j=0}^n \right),
\]

\[
= \text{diag} \left[ D_{qj} \Delta_j^j(q[j],\dot{q}[j]) \dot{q}[j] \right]_{j=0}^n
\]

\[
= \text{diag} \left[ \diamond_j^j(q[j],\dot{q}[j]) \right]_{j=0}^n;
\]
(c) If a given limb is not in the active constraint set, the corresponding block in \( \Diamond_J \) is the identity:
\[
\Diamond^k_J(q[k], \dot{q}[k]) = I_d_k \quad \text{if } k \notin J;
\]
(32)

(d) \( \Diamond_J(q, \dot{q}) \) is the product of \( \Diamond_{\{j\}} \) for each active constraint:
\[
\prod_{j \in J} \Diamond_{\{j\}}(q, \dot{q}) = \Diamond_J(q, \dot{q}).
\]
(33)

We now proceed with the proof.

1. We repeat some of the notations found in the proof of [PB17, Thm. 1] here.

   (a) For any given perturbation, there is a finite set of selection functions corresponding to a sequence of (de)activating constraints.

   (b) These selection functions will be indexed by a pair of functions \((\omega, \eta)\) where:
   \[
   \omega : \{0, \ldots, m\} \rightarrow 2^n \text{ is a contact mode sequence, i.e. } \omega \in \Omega; \quad \eta : \{0, \ldots, m - 1\} \rightarrow \{1, \ldots, n\} \text{ indexes constraints that undergo admissible activation or deactivation.}
   \]

   (c) Let \( \mu : \{0, \ldots, m\} \rightarrow 2^n \) be defined as
   \[
   \mu(k) = \bigcup_{i=0}^{k-1} \{\eta(i)\},
   \]
   where we adopt the convention that \( \bigcup_{i=0}^{-1} \{i\} = \emptyset \); note that \( \mu \) is uniquely determined by \( \eta \). As in [PB17, Thm. 1], we suppress notation indicating dependence on \( \omega \) and \( \eta \) until (59).

   (d) Let \( (\rho, \dot{\rho}^-) = \lim_{u \uparrow s} \phi(u, (q, \dot{q})) \). For all \( k \in \{0, \ldots, m\} \), define \( \dot{\rho}_k = \Delta_{\mu(k)}(\rho)\dot{\rho}^- \), once again using the convention \( \bigcup_{i=0}^{-1} \{i\} = \emptyset \).

2. Since assumptions 1–4 from Sec. 3 satisfy the hypotheses of [PB17, Thm. 1], \( \phi \) is piecewise-differentiable.

3. Let \( K_a \) be the set of constraints undergoing activation and \( K_d \) be the set of constraints undergoing deactivation.\(^\text{18}\)

4. Assume, without loss of generality, the trajectory begins in the unconstrained mode \( \emptyset \).\(^\text{19}\)

5. Let \( R_J \) denote the reset map into constraint mode \( J \); \( R_J : TQ \rightarrow TQ_J \),
\[
\forall (q, \dot{q}) \in TQ : \quad R_J(q, \dot{q}) = \begin{bmatrix} q \\ \Delta_J(q, \dot{q}) \dot{q} \end{bmatrix}.
\]
(34)

6. Let \( DR_J \) denote the (Jacobian) derivative of \( R_J \) with respect to \( (q, \dot{q}) \).
\[
\forall (q, \dot{q}) \in TQ : \quad DR_J(q, \dot{q}) = \begin{bmatrix} I_d & 0 \\ 0 & \Diamond_J(q, \dot{q}) \end{bmatrix}.
\]
(35)

7. Let \( \bar{R}_J^L \) denote the reset map from constraint mode \( J \) into constraint mode \( J \setminus L \); \( \bar{R}_J^L : TQ_J \rightarrow TQ_{J \setminus L} \),
\[
\forall (q, \dot{q}) \in TQ_J : \quad \bar{R}_J^L(q, \dot{q}) = \begin{bmatrix} q \\ \dot{q} \end{bmatrix}.
\]
(36)

\(^\text{17}\)Assump. 3 (limbs decoupled through body) is stronger than the orthogonality of constraints assumption.

\(^\text{18}\)Activating constraints may instantaneously deactivate, e.g. a bean bag hitting a ceiling.

\(^\text{19}\)This does not imply \( K_d = \emptyset \).
8. Let $\hat{R}_t: T\Omega \rightarrow T\Omega$,

$$\forall (q, \dot{q}) \in T\Omega : \quad \hat{R}_t(q, \dot{q}) = \begin{cases} \frac{\partial R_{(\eta(\ell))}}{\partial (q, \dot{q})} & \text{if } \eta(\ell) \in K_a \\ \frac{\partial R_{(\eta(\ell))}}{\partial (q, \dot{q})} & \text{if } \eta(\ell) \in K_d. \end{cases} \quad (37)$$

9. Let $F_j$ denote the vector field in constraint mode $J$. $F_j: TQ_j \rightarrow \mathbb{R}^{2d}$,

$$\forall (q, \dot{q}) \in TQ_j : \quad F_j(q, \dot{q}) = \begin{bmatrix} \dot{q} \\ \alpha_j(q, \dot{q}) \end{bmatrix}, \quad (38)$$

where $\alpha_j(q, \dot{q})$ is defined in (27).

10. Let

$$S_t = \frac{1}{Dh_t(\rho, \dot{\rho}t)F_t(\rho, \dot{\rho}t)} \left( F_{t+1}(\rho, \dot{\rho}(t+1)) - D\hat{R}_t(\rho, \dot{\rho}_t)F_t(\rho, \dot{\rho}_t) \right) Dh_t(\rho, \dot{\rho}_t), \quad (39)$$

where $F_t = F_{\omega(t)}$, and $Dh_t = Dh_{\eta(t)}$; $S_t \in \mathbb{R}^{2d \times 2d}$.

11. The saltation matrix for a given word $\omega$ at $(\rho, \dot{\rho})$ is

$$\Xi^\eta_{\omega} = \prod_{\ell=0}^{\vert K_a \vert + \vert K_d \vert - 1} \left( D\hat{R}_{(\eta(t)) \Omega (\eta(t))}(\rho, \dot{\rho}_t) + S_t \right) \quad (40)$$

where $S_t$ is defined in (39) [Bur+16, Eq. 66], [Iva98, Eq. 2.5].

12. Given that the vector field associated with a constraint undergoing deactivation is continuous, the corresponding saltation matrix is $I_{2d}$. That is $S_t = 0$ and $D\hat{R}_t(\rho, \dot{\rho}(t-1)) = I_{2d}$ when $\eta(\ell)$ is a deactivation; $\eta(\ell) \in K_d$. In what follows, the calculations are performed only for activating constraints.\textsuperscript{20}

13. The inner product $Dh_t(\rho, \dot{\rho}_t)F_t(\rho, \dot{\rho}_t)$ in the computation of $S_t$ is independent of the word $\omega$.

$$Dh_t(\rho, \dot{\rho}_t)F_t(\rho, \dot{\rho}_t) = Da_{\eta(t)}(\rho)\dot{\rho}_t = Da_{\eta(t)}(\rho[\eta(\ell)])\dot{\rho}[\eta(\ell)]. \quad (41)$$

14. The reset map into contact mode $\omega(\ell) \cup \{\eta(\ell)\}$ from contact mode $\omega(\ell)$ is the same as the reset map into contact mode $\{\eta(\ell)\}$ from contact mode $\omega(\ell)$.\textsuperscript{21}

\[
\forall (q, \dot{q}) \in TQ_{\omega(t)} : \quad R_{\omega(t) \cup \{\eta(\ell)\}}(q, \dot{q}_t) = \begin{bmatrix} \Delta_{\omega(t) \cup \{\eta(\ell)\}}(q, \dot{q}_t) \dot{q}_t \\ \Delta_{\{\eta(\ell)\}}(q, \dot{q}_t) \dot{q}_t \end{bmatrix} \quad (42)
\]

\[
= \begin{bmatrix} \Delta_{\{\eta(\ell)\}}(q, \dot{q}_t) \dot{q}_t \\ R_{\{\eta(\ell)\}}(q, \dot{q}_t) \end{bmatrix} \quad (43)
\]

\[
(44)
\]

\textsuperscript{20}This exclusion does not apply to the case of deactivations caused by an activation, e.g. a bouncing ball or a bean bag hitting the ceiling.

\textsuperscript{21}It is important to note that it is not always the case $\omega(\ell + 1) = \omega(\ell) \cup \{\eta(\ell)\}$ as in the case of instantaneous constraint deactivation dependent upon a constraint activation. In this case $\omega(\ell + 1) = \omega(\ell)$ and $\eta(\ell) \neq \emptyset$. 
15. From the chain rule for total derivatives [Lee12, Prop C.3] and Assump. 3 (limbs decoupled through body), the first order approximation of the reset map into constraint mode \( J \) is the same as the product of the reset maps into constraint mode \( \{ j \} \in J \) at a given point \((q, \dot{q})\).

\[
DR_J(q, \dot{q}) = D \prod_{j \in J} R_{\{j\}}(q, \dot{q}) = \left( \prod_{j \in J} DR_{\{j\}} \right)(q, \dot{q}).
\] (45)

16. Given (45) and identities (33) and (31),

\[
DR_J(q, \dot{q}) = \left[ \sum_{j \in J} I_d \square_{\{j\}}(q) \prod_{j \in J} \lozenge_{\{j\}}(q, \dot{q}) \right].
\] (46)

17. The saltation matrix equation (40) can then be written as

\[
\Xi^n_\omega = \prod_{\ell=0}^{[K_a]+|K_d|-1} \left( D \hat{R}_\ell(\rho, \dot{\rho}) + S_\ell \right).
\] (47)

18. By computing the acceleration of each limb using (27) and \( \lozenge_{\eta(\ell)} \) has a block diagonal structure given by (31), clearly

\[
\alpha_{\omega(\ell+1)}(\rho, \dot{\rho}_{(\ell+1)}) - \lozenge_{\eta(\ell)}(\rho, \dot{\rho}) \alpha_{\omega(\ell)}(\rho, \dot{\rho})
\]

\[
= \begin{cases} 
\alpha_{\eta(\ell)}(\rho, \Delta_{\eta(\ell)}(\rho, \dot{\rho})) \lozenge_{\eta(\ell)}(\rho, \dot{\rho}) \alpha_{\theta(\ell)}(\rho, \dot{\rho}) & \text{if } \omega(\ell + 1) = \omega(\ell) \cup \{\eta(\ell)\} \\
\alpha_{\theta(\ell)}(\rho, \Delta_{\theta(\ell)}(\rho, \dot{\rho})) \lozenge_{\theta(\ell)}(\rho, \dot{\rho}) \alpha_{\omega(\ell)}(\rho, \dot{\rho}) & \text{if } \omega(\ell + 1) = \omega(\ell) \cup \{\eta(\ell)\} 
\end{cases}.
\] (48)

19. From (45), the vector field difference in the calculation \( S_\ell \) for only an activation reduces to

\[
F_{(\ell+1)}(\rho, \dot{\rho}_{(\ell+1)}) - DR_{\omega(\ell) \cup \{\eta(\ell)\}}(\rho, \dot{\rho}_\ell) F_\ell(\rho, \dot{\rho}_\ell)
\]

\[
= F_{\ell+1}(\rho, \dot{\rho}_{(\ell+1)}) - DR_{\ell}(\rho, \dot{\rho}_\ell) F_\ell(\rho, \dot{\rho}_\ell)
\]

\[
= \left[ \begin{array}{c}
\hat{\rho}_{(\ell+1)}[j] \\
\alpha_{\omega(\ell+1)}(\rho, \dot{\rho}_{(\ell+1)})[j]
\end{array} \right] - \left[ \begin{array}{cc}
I_d & 0 \\
\square_{\eta(\ell)}(\rho, \dot{\rho}_\ell) & \lozenge_{\eta(\ell)}(\rho, \dot{\rho}_\ell)
\end{array} \right] \left[ \begin{array}{c}
\hat{\rho}_\ell[j] \\
\alpha_{\omega(\ell)}(\rho, \dot{\rho}_\ell)[j]
\end{array} \right] = \prod_{j=0}^{n-1}.
\] (49)
20. The saltation matrix from (47) can be further simplified using the independence of the inner product in $S_{\ell}$ (41), along with the flow differences (51) and (52) to

$$
\Xi_{\omega}^j = \prod_{\ell=0}^{|K_{\omega}|+|K_d|-1} \left( DR_{\ell}(\rho, \hat{\rho}) + \tilde{S}_{\ell} \right),
$$

where

$$
\tilde{S}_{\ell} = \frac{1}{Da_{\eta(\ell)}(\rho[\eta(\ell)])} \left( F_{\ell+1}(\rho, \hat{\rho}) - DR_{\ell}(\rho, \hat{\rho}) F_{\theta}(\rho, \hat{\rho}) \right) Dh_{\eta(\ell)}(\rho, \hat{\rho}).
$$

21. Given the constraints are only dependent upon position, clearly

$$
\tilde{S}_{j} DR_{(i)}(\rho, \hat{\rho}) = \tilde{S}_{j}
$$

for all $i, j \in \{0, \ldots, |K| - 1\}$. 

The equality in the last step for the $j = \eta(\ell)$ case can be seen from the block diagonal structure of $\Box_{\eta(\ell)}$ and (48). Thus, for the case of only an activation,

$$
F_{(e+1)}(\rho, \hat{\rho}_{(e+1)}) - DR_{\omega(\ell) \cup \eta(\ell)}(\rho, \hat{\rho}) F_{\ell}(\rho, \hat{\rho}) = F_{\eta(\ell)}(\rho, \hat{\rho}_{\eta(\ell)}) - DR_{\eta(\ell)}(\rho, \hat{\rho}_{\eta(\ell)}) F_{\theta}(\rho, \hat{\rho}_{\eta(\ell)}).
$$

Clearly, it can be shown by algebraic manipulation similar to (50), the equality

$$
F_{e+1}(\rho, \hat{\rho}_{(e+1)}) - DR_{\omega(\ell) \cup \eta(\ell)}(\rho, \hat{\rho}) F_{\ell}(\rho, \hat{\rho}) = F_{\theta}(\rho, \hat{\rho}) - DR_{\eta(\ell)}(\rho, \hat{\rho}_{\eta(\ell)}) F_{\theta}(\rho, \hat{\rho}_{\eta(\ell)})
$$

holds for the case of an activation instantly causing a deactivation.
22. Next we show that
\[ DR_{\{j\}}(\rho, \dot{\rho}) \tilde{S}_i = \tilde{S}_i \]  
(56)
for \( j \neq i \). Given the block structure of the corresponding matrices, we make the following observations:

(a) only the columns associated with the indices for \( q_i \) are nonzero in \( \tilde{S}_i \);

(b) only the rows associated with \( q_0 \) and \( q_i \) are nonzero in \( \tilde{S}_i \);

(c) since \( j \neq i \), \( \tilde{\square}_{\{j\}}(\rho, \dot{\rho}) = 0 \) and \( \tilde{\diamond}_{\{j\}}(\rho, \dot{\rho}) = I_d \).

The nonzero elements of \( S^i \) are thus multiplied by an identity like matrix.

23. Given (55) and (56), the saltation matrix (53) contains the matrix product \( \tilde{S}_\ell \tilde{S}_g \), where \( \ell > k \) and \( k, \ell \in \{0, \ldots, |K| - 1\} \). Within this matrix product, lies the inner product
\[ Dh_\ell(\rho, \dot{\rho}) (F_{\omega(k+1)\omega(k)}(\rho, \dot{\rho}) - DR_k(\rho, \dot{\rho})F_0(\rho, \dot{\rho})) = Da_\ell(\rho[\ell])\dot{\rho}[\ell] - Da_\ell(\rho)\dot{\rho}[\ell] = 0. \]  
(57)
Hence
\[ \tilde{S}_\ell \tilde{S}_g = 0. \]  
(58)

24. Given (55), (56), and (58), the saltation matrix (53) can be written as
\[ \Xi^\eta_\omega(\rho, \dot{\rho}) = DR_{K_a}(\rho, \dot{\rho}) + \sum_{k \in K_a} \tilde{S}_k. \]  
(59)

25. The Bouligand-derivative [Sch12, Chpt. 3] of \( \phi_t(q, \dot{q}) \) in direction \( (v, \dot{v}) \in TQ \) is given by
\[ D\phi_t(q, \dot{q}; v, \dot{v}) = D\phi_{t-s}(\rho, \dot{\rho})\Xi^\eta_\omega(\rho, \dot{\rho}) D\phi_s(q, \dot{q}) \begin{bmatrix} v \\ \dot{v} \end{bmatrix}, \]  
(60)
where \( s \in \mathbb{R} \) is the time of simultaneous activation and/or deactivation of constraints, and \( \eta, \omega \) are determined by \( (v, \dot{v}) \) [Bur+16, Eq. 65].

26. As the saltation matrix calculation (59) is independent of the word \( \omega \), (60) can be rewritten as
\[ D\phi_t(q, \dot{q}; v, \dot{v}) = D\phi_{t-s}(\rho, \dot{\rho}) \left( DR_{K_a}(\rho, \dot{\rho}) + \sum_{k \in K_a} \tilde{S}_k \right) D\phi_s(q, \dot{q}) \begin{bmatrix} v \\ \dot{v} \end{bmatrix}. \]  
(61)
Then \( D\phi_t(q, \dot{q}; \cdot) \) is a linear function and the flow is classically differentiable [Sch12, Chpt. 3].
