THE FAILURE OF RUELLE’S PROPERTY FOR ENTIRE FUNCTIONS

VOLKER MAYER AND ANNA ZDUNIK

Abstract. We exhibit an analytic family of hyperbolic, even disjoint type, entire functions for which the hyperbolic dimension does not vary analytically. Additionally we answer several questions in thermodynamic formalism of entire functions such as the existence of a hyperbolic entire function without conformal measure that is supported on the radial Julia set.

1. Introduction

Ruelle [37], answering a conjecture of Sullivan, has shown that the Hausdorff dimension of the Julia set of hyperbolic rational functions depends analytically on the map. An alternative approach to this result is contained in the monograph [43]. Since then, Ruelle’s result has been generalized in many ways. For example, Anderson and Rocha [2] extended Ruelle’s result, which also covered the case of analytic quasiconformal deformations of cocompact Fuchsian groups, to convex co-compact Kleinian groups. There is a version for Henon maps in $\mathbb{C}^2$ by Verjovsky and Wu [42], for rational semi-groups by Sumi and Urbański [39] and also one for hyperbolic surface diffeomorphisms by Pollicott [30]. More related to the present work are [41, 26, 28]. These papers contain analyticity results for dynamics of transcendental, entire or meromorphic, functions in the deterministic and even in the random case.

Contrary to that, we provide here the first example of an analytic family of entire hyperbolic functions for which the Ruelle’s property breaks down.

Theorem 1.1. There exists a holomorphic family of entire functions

$$F_\lambda = \lambda F, \quad \lambda \in \mathbb{C} \setminus \{0\},$$

such that the functions $F_\lambda, \lambda \in (0, 1]$, are all in the same hyperbolic component of the parameter space but the function

$$\lambda \mapsto \text{HypDim}(F_\lambda) = \text{Hdim}(J_r(F_\lambda))$$

is not analytic, where the hyperbolic dimension $\text{HypDim}(F)$ is the Hausdorff dimension of the radial (or conical) limit set $J_r(F)$ of $F$.

For limit sets of Kleinian and Fuchsian groups such a break down of Ruelle’s property was observed. Astala and Zinsmeister [3] were the first who observed that. They gave an example of an analytic family of infinitely generated quasifuchsian groups for which Ruelle’s analyticity result does not hold. Bishop [13] subsequently extended their result and gave a criterion for the failure of analyticity for a class of infinitely generated quasifuchsian groups. More recently, Huo and Wu [19] established an analogous result for deformations of Fuchsian groups of the second kind.

The common tool in all analyticity results is Bowen’s formula (see [16] for the original version) which expresses the dimension in terms of the zero of a pressure function. One should have in mind that this formula really determines the hyperbolic dimension. In many cases, such as for hyperbolic rational functions, the hyperbolic dimension coincides with the Hausdorff dimension of the Julia set. In transcendental dynamics however the situation is different: in general, there is a definite gap between these two dimensions (see [38] and [40]) and a typical phenomenon in the case of entire functions is that the dimension of the Julia set itself is often maximal, i.e. equal to 2. This was first observed by McMullen [29] and Barański’s [6] has shown that all entire functions of finite order and of class $\mathcal{B}$, in particular all the entire functions of the present paper, have this property. The intriguing thing then is how the hyperbolic dimension behaves.

For the family of entire functions we consider, the whole thermodynamic formalism is valid and there exists a transition parameter $\Theta \geq 1$ such that the transfer operator with parameter $t$ is divergent if $t < \Theta$ and convergent, even a bounded operator, if $t > \Theta$. See Section 4 for the definition and properties of the transfer operator. All these facts are contained in [27] and, using this paper, we have precise estimates for the transfer operator and of the transition parameter in terms of the fractal geometry at infinity of the tract of the functions. Using them, we are able to construct entire functions for which the transfer operator at its transition parameter $t = \Theta$ is convergent. We do this in fact first by constructing a model function and then carry all the properties over to an entire function using Rempe’s approximation result in [34].

It turns out that our approach also answers several other open questions. The first result answers positively the question in Remark 3.7 in [8] (see Section 11 for the precise definitions of the notions in the following results such as topological pressure and conformal measure).

**Theorem 1.2.** For every $1 < \Theta < 2$ there exists a disjoint type entire function $f \in \mathcal{B}$ whose transfer operator has transition parameter $\Theta$, such that the transfer operator is convergent at $\Theta$ and such that the topological pressure at $t = \Theta$ is strictly negative. Consequently, the topological pressure of $f$ has no zero.

We also can complete the picture concerning the behavior of the hyperbolic dimension. For an entire function $f$ having a tract of sufficiently nice
geometry it is known that $\text{HypDim}(f) \geq \Theta \geq 1$ where this time $\Theta$ is a transition parameter of $f$ restricted to this tract (see [24]). Moreover, when $\Theta = 1$ then $\text{HypDim}(f) > 1$ (this strict inequality has previously been obtained in full generality in [9]). The functions in the present paper show that strict inequality between the hyperbolic dimension and the transition parameter is no longer true as soon as $\Theta > 1$.

**Theorem 1.3.** For every $1 < \Theta < 2$ there exists a disjoint type entire function $f \in \mathcal{B}$ with a single quasidisk tract and whose hyperbolic dimension attains the minimal possible value $\text{HypDim}(f) = \Theta$.

Finally, the functions of Theorem 1.3 also explain that hyperbolic, even disjoint type, entire functions can behave like the very flexible, since locally defined, irregular conformal iterated function systems (see [23]).

**Theorem 1.4.** For every $1 < \Theta < 2$ there exists a disjoint type entire function $f \in \mathcal{B}$ such that $\text{HypDim}(f) = \Theta$ and such that $f$ does not have a conformal measure supported on its radial Julia set.

2. Preliminaries

For every $r > 0$, let $D_r := \mathbb{D}(0, r)$ be the open disk centered at the origin with radius $r$ and let $D_r^* = \mathbb{C} \setminus D_r$ be the complement of its closure.

Let $f : \mathbb{C} \to \mathbb{C}$ be an entire function and let $S(f)$ be the closure of the set of critical values and finite asymptotic values of $f$. The different type of singularities of an entire function, in fact Iversen’s classification, are all very well explained in [11]. We consider functions of the Eremenko–Lyubich class $\mathcal{B}$ which consists of entire functions for which $S(f)$ is a bounded set.

If $f \in \mathcal{B}$, then there exists $r > 0$ such that $S(f) \subset D_r$. Then $f^{-1}(D_r^*)$ consists of mutually disjoint unbounded Jordan domains $\Omega$ with real analytic boundaries such that $f : \Omega \to D_r^*$ is a covering map (see [17]). In terms of the classification of singularities, this means that $f$ has only logarithmic singularities over infinity. These connected components of $f^{-1}(D_r^*)$ are called tracts and the restriction of $f$ to any of these tracts $\Omega$ has the special form

$$f|_{\Omega} = \exp \circ \tau$$

where $\varphi = \tau^{-1} : \mathcal{H}_{\log r} \to \Omega$

is a conformal map fixing infinity and where

$$\mathcal{H}_s = \{ z \in \mathbb{C} , \Re z > s \} , \quad s \geq 0.$$  

When $s = 0$, then we also write $\mathcal{H}$ for $\mathcal{H}_0$. Still for every $s \geq 0$ we use the notation $\Omega_s = \varphi(\mathcal{H}_s)$ so that, in particular,

$$\Omega = \Omega_{\log r} = \varphi(\mathcal{H}_{\log r}) \quad \text{and} \quad \Omega_0 = \varphi(\mathcal{H}_0) = \varphi(\mathcal{H}).$$

In this work we construct entire functions of class $\mathcal{B}$ having just one particular tract $\Omega$.

An entire function $f : \mathbb{C} \to \mathbb{C}$ is called hyperbolic if there is a compact set $K$ such that

$$f(K) \subset \text{Int}(K)$$
and \( f : f^{-1}(C \setminus K) \to C \setminus K \) is a covering map. Clearly such a function belongs to class \( \mathcal{B} \). According to Theorem 1.3 in [35], an entire function \( f \) is hyperbolic if and only if the postsingular set

\[
P(f) := \bigcup_{n \geq 0} f^n(S(f))
\]

is a compact subset of the Fatou set of \( f \). Here and in the sequel, \( \mathcal{J}_f \) stands for the Julia set of \( f \) defined in the usual way (see for example the survey [10]).

\textit{Disjoint type} functions are particular hyperbolic functions. This notion first implicitly appeared in [5] and means that the compact set \( K \) in the definition of a hyperbolic function can be taken to be connected. In this case, the Fatou set of \( f \) is connected. For example, if \( f \in \mathcal{B} \) and if there exists \( \mathcal{D} \) a simply connected bounded domain such that

\[
S(f) \subset \mathcal{D} \quad \text{and} \quad f^{-1}(C \setminus \overline{\mathcal{D}}) \cap \mathcal{D} = \emptyset
\]

then \( f \) is of disjoint type. A particular case for the domain \( \mathcal{D} \) is a disk centered at the origin.

We construct and study particular model functions. The following is the simplest possible definition, see Bishop [14, 15] for the general version.

**Definition 2.1.** A model is a holomorphic map

\[
f = e^{\tau} : \Omega \to \mathbb{D}^*_r = \{ |z| > r \}
\]

where \( \Omega \) is a simply connected unbounded domain, called tract, where \( r \geq 1 \) and where \( \tau : \Omega \to \mathcal{H}_{\log r} \) is a conformal map fixing infinity:

\[
\tau(z) \to \infty \quad \text{if} \quad z \to \infty.
\]

A model \( f : \Omega \to \mathbb{D}^*_r \) is of disjoint type if \( \overline{\Omega} \subset \mathbb{D}^*_r \) and, in this case, the Julia set is

\[
\mathcal{J}_f = \{ z \in \Omega ; \quad f^n(z) \in \Omega , \ n \geq 1 \}.
\]

This is consistent with the above definitions for entire functions.

Concerning the radial Julia set, there are several definitions in the literature (see [26, 32]). It is explained in Remark 4.1 of [26] that these definitions lead to different sets whose difference is dynamically insignificant. In particular they have same Hausdorff dimension. Since we deal only with hyperbolic, in fact disjoint type, entire or model functions, the following definition fits best to our context:

\[
\mathcal{J}_r(f) = \{ z \in \mathcal{J}(f) : \liminf_{n \to \infty} |f^n(z)| < \infty \}.
\]

The \textit{hyperbolic dimension} of \( f \) is the Hausdorff dimension of this set:

\[
\text{HypDim}(f) = Hdim(\mathcal{J}_r(f)).
\]

We will consider analytic family of maps of the form \( f_\lambda = \lambda f, \lambda \in \mathbb{C}^* \), where \( f \in \mathcal{B} \) is a given entire function.
Definition 2.2. The functions \( f_{\lambda_1}, f_{\lambda_2} \) belong to the same hyperbolic component of the parameter space of \((f_{\lambda}), \lambda\) if there exists a simply connected domain \( V \subset \mathbb{C}^* \) that contains \( \lambda_1, \lambda_2 \) and such that

1. all the functions \( f_{\lambda}, \lambda \in V \), are hyperbolic and
2. the functions \( f_{\lambda}, \lambda \in V \), are J-stable in the sense of holomorphic motions: there exists a base point \( \lambda_0 \in V \) and a holomorphic motion \((\varphi_{\lambda})_{\lambda \in V}\) identifying the Julia sets \( \varphi_{\lambda}(J_{\lambda_0}) = J_{\lambda} \) and conjugating the dynamics on the Julia sets, i.e., \( \varphi_{\lambda} \circ f_{\lambda_0} = f_{\lambda} \circ \varphi_{\lambda}, \lambda \in V. \)

See [21] for the notion of holomorphic motions and of J-stability in the setting of analytic families of rational functions.

3. Models with snowflake tract

The restriction of an entire function to a logarithmic tract is an example of a model function. The approach here goes the opposite way. We first construct explicit model functions and then use the uniform approximation described in detail in the paper of L. Rempe [34] in order to get entire functions having the same required properties. This will be done in Section 7 and, in order to be able to perform this approximation, we have to work right now with an extended half plane defined as follows.

Let \( \sigma(t) = -14 \log |t| - 7 \) for \( |t| > 1 \) and extend this function to a symmetric with respect to the origin and \( C^\infty \)-smooth function \( \sigma : \mathbb{R} \to (-\infty, 0] \) such that

\[
\sigma(0) = 0 \quad \text{and} \quad -7 \leq \Re(\sigma(t)) \leq 0 \quad \text{for} \quad |t| \leq 1.
\]

Consider then

\[
(3.1) \quad \hat{\mathcal{H}} = \{ z = x + iy, \ x > \sigma(y) \} \supset \mathcal{H} = \mathcal{H}_0.
\]

This domain is a regularized version of the domain used in [34]. Let \( h : \hat{\mathcal{H}} \to \mathcal{H} \) be the conformal map fixing the origin and infinity and such that \( h'(\infty) = 1 \) (see Appendix 12 for the existence of \( h'(\infty) \)). Notice that the symmetry of the curve \( \sigma \) implies that \( \overline{h(z)} = h(\overline{z}), \ z \in \hat{\mathcal{H}}. \)

Let \( \varphi = \tau^{-1} : \hat{\mathcal{H}} \to \hat{\Omega} \) be also a conformal map fixing the origin and infinity. Set \( \psi = \varphi \circ h^{-1} \) so that we have the following diagram

\[
\begin{array}{ccc}
\hat{\mathcal{H}} & \xrightarrow{\varphi} & \hat{\Omega} \\
\downarrow h & & \\
\mathcal{H} \supset \mathcal{H}_{\log r} & \xrightarrow{\varphi} & \Omega
\end{array}
\]

where \( r \geq e^2 \) will be defined in [34.11]. So, \( \Omega \) is the image of \( \mathcal{H}_{\log r} \) under the restriction of \( \varphi \) to \( \mathcal{H}_{\log r} \). Since we will always have \( 2\pi i \in \partial \hat{\Omega}, \) we can make
the additional normalization $\psi(i) = 2\pi i$ so that, all in all, the conformal map $\varphi : \hat{\mathcal{H}} \to \hat{\Omega}$ is normalized by

$$
\varphi(0) = 0, \varphi(\infty) = \infty \quad \text{and} \quad \varphi(h^{-1}(i)) = 2\pi i.
$$

From the particular form of $\hat{\mathcal{H}}$ follows that $h$ behaves almost like the identity near infinity. We have collected all required properties of this map in Appendix 12.

The models and their properties rely on a particular construction of the extended tracts $\hat{\Omega}$ that we describe now. It is based on a modification of a standard snowflake arc $\gamma$ attached at the endpoints $2\pi i$ and $4\pi i$ and with the $4^n$ intervals of the $n$-th approximation of length $l_n$ defined as follows. Let

$$
1 < \rho_{\min} < \frac{1}{3} < \frac{1}{e} < \rho_{\max} < \frac{1}{2},
$$

let $\rho_n \in [\rho_{\min}, \rho_{\max}]$, $n \geq 1$, and define then inductively $l_n = \rho_n l_{n-1}$, $n \geq 1$, with $l_0 = 2\pi$. If $\rho_n = \frac{1}{3}$ for all $n \geq 1$ then $\gamma$ is a standard snowflake arc with dimension $\Theta = \frac{\log 4}{\log 3}$. The domain $\hat{\Omega}$ is the connected component of the complement of the quasicircle

$$
\Gamma = \{0\} \cup \bigcup_{n \in \mathbb{Z}} 2^n(-\gamma \cup \gamma)
$$

such that $10 \in \hat{\Omega}$. By construction, $0, 2\pi i \in \Gamma = \partial \hat{\Omega}$.

Now, with $\tau = \varphi^{-1}$ as introduced above and since $\Omega = \varphi(\mathcal{H}_{\log \rho}) \subset \varphi(\hat{\mathcal{H}}) = \hat{\Omega}$, we get the associated model map

$$
f = e^\tau : \Omega \to \mathbb{D}_r^*.
$$

By construction, $f$ is defined on the larger domain $\hat{\Omega}$. On the other hand, this function is not of disjoint type. In order to remedy this it suffices to translate the domain $\Omega$ and curve $\Gamma$ so that, after translation, $\Omega \cap \mathbb{D}_r = \emptyset$.

Such a disjoint type model is given by

$$
f(z) = f(z - T), \quad z - T \in \hat{\Omega}.
$$

where the precise value of $T$ will be fixed in Section 7.

In general, $\Theta = \Theta_f$ will be the transition parameter of the transfer operator as introduced in [27] but each time we deal with one of the following examples we will have $\Theta = \Theta_f = \frac{\log 4}{\log 3}$.

**Example 3.1.** Let $\alpha > 1$ and choose the numbers $\rho_n$ such that

$$
\frac{1}{C_f} \leq n^\alpha 4^n l_n^\Theta \leq C_f, \quad n \geq 1,
$$

for some constant $C_f > 1$. 

Example 3.2. Let $N > 1$ and let $\alpha > 1$. Set

$$\rho_n = \frac{1}{e^n} \quad \text{for} \quad 1 \leq n \leq N$$

and let $\rho_n \in [\rho_{\min}, \frac{1}{3}]$ such that (3.7) holds for some constant $C_f > 1$.

Clearly, the domains coming from Example 3.2 are special cases of those in Example 3.1.

Standard references on quasiconformal mappings are [1, 20, 4]. An important feature is that a $K$–quasiconformal map $\varphi : \mathbb{C} \to \mathbb{C}$ is $K'$–quasisymmetric which means that

$$|\varphi(z_1) - \varphi(z_2)| \leq K' |\varphi(z_1) - \varphi(z_3)| \quad \text{for every} \quad |z_1 - z_2| \leq |z_1 - z_3|.$$ 

Moreover, $\varphi$ has good Hölder continuity properties: there are constants $0 < c_1 < c_2$ such that

$$(3.8) \quad c_1 |z_1 - z_2|^K \leq |\varphi(z_1) - \varphi(z_2)| \leq c_2 |z_1 - z_2|^{1/K} \quad \text{for all} \quad z_1, z_2 \in \mathbb{D}(0, 2)$$

and, if $\varphi(0) = 0$, then

$$(3.9) \quad \mathbb{D}(0, c_1 R^{1/K}) \subset \varphi(\mathbb{D}(0, R)) \subset \mathbb{D}(0, c_2 R^K) \quad \text{for all} \quad R > 1.$$ 

The first inequality (3.8) is mainly Mori’s Theorem, for a precise version see Theorem II.4.3 in [20]. One can find inequality (3.9) in [22, Theorem 3.2].

All these constants do depend quantitatively on each other. In particular, if we deal with a family of uniformly quasiconformal mappings of the plane, meaning that they are all $K$–quasiconformal for some fixed constant $K$, and if the maps are normalized, for example by the requirement that (3.2) holds, then the quasisymmetric and the Hölder constants are also uniform.

A quasicircle is the image of a circle or line by a quasiconformal map of the plane. We only consider unbounded quasicircles. Such a curve $\Gamma$ is characterized by the important Ahlfors 3–point condition: there exists $c > 0$ such that

$$|z_1 - z_2| \leq c |z_1 - z_3| \quad \text{for all} \quad z_1, z_3 \in \Gamma \quad \text{and} \quad z_2 \in \Gamma(z_1, z_3)$$

where $\Gamma(z_1, z_3)$ is the subarc of $\Gamma$ with endpoints $z_1, z_3$. It is a well known fact that all the curves defined in (3.4) satisfy this condition uniformly and have uniform quasisymmetric parametrization (for a proof, see for example Lemma 3.1 in [36]):

Fact 3.3. There are constants $c, K'$ depending on $\rho_{\max}$ only such that for all choices of $\rho_n \in [\rho_{\min}, \rho_{\max}]$ the curve $\Gamma$ defined in (3.4) satisfies the Ahlfors 3–point condition with constant $c$ and the natural parametrization of $\Gamma$ is a $K'$–quasisymmetry.

Inhere we call natural parametrization the map $g : \mathbb{R} \to \Gamma$ defined as follows. If $m \geq 0$ and if $\gamma_m$ is the $m$-th approximation of $\gamma$ then $\gamma_m$ is the union
of $4^m$ intervals $I_{m,l} = [a_{m,l}, a_{m,l+1}]$, $l = 0, ..., 4^m - 1$, and we can define $g: [i/2, i] \to \gamma$ as the continuous extension of the map defined by

$$a_{m,l} = g\left(\frac{i}{2}(1 + l/4^m)\right) \quad \text{for every} \quad m \geq 0 \text{ and } 0 \leq l \leq 4^m \, .$$

The natural parametrization of $\Gamma$ will be the unique extension to $i\mathbb{R}$ of this map that satisfies the two relations $g \circ 2 = 2 \circ g$ and $g(-z) = -g(z)$, $z \in i\mathbb{R}$.

The quasicircles $\Gamma$ given by the Examples (3.1) and (3.2) admit uniformly quasiconformal reflections which allows to show that the corresponding conformal maps $\varphi: \hat{\mathcal{H}} \to \hat{\Omega}$ have normalized and uniformly quasiconformal extension to the plane. Also, there are several extensions, such as the one based on the Beurling-Ahlfors extension [12], of a quasisymmetric parametrization of a quasicircle to a quasiconformal map of the plane with control of the constant. Consequently, the family of natural parameterizations of the curves $\Gamma$ extend to a family of normalized and uniformly quasiconformal mappings of the plane.

As a first direct consequence of these properties along with the normalisation (3.2) we have the following:

**Remark 3.4.** The family of all conformal maps $\varphi: \hat{\mathcal{H}} \to \hat{\Omega}$ (as well as $\psi: \mathcal{H} \to \hat{\Omega}$) corresponding to all possible choices of $\rho_n \in [\rho_{\min}, \rho_{\max}]$, $n \geq 1$, is a normal family and each limit of a convergent sequence of these maps is again a non-constant conformal map.

Indeed, the maps $\varphi$ are normalized by (3.2) and they have uniformly quasiconformal extension to the plane. The statement in Remark 3.4 is thus a standard fact for families of normalized uniformly quasiconformal maps and, consequently, Remark 3.4 not only applies to the conformal maps $\varphi, \psi$ but also to their quasiconformal extensions whose convergent subsequences converge uniformly on every compact subset of the plane.

The normality behavior of these maps allows to precise that the conformal map $\psi$ reflects the self-similarity of the curve $\Gamma$:

**Lemma 3.5.** If $i\mu = \psi^{-1}(2\psi(i)) = \psi^{-1}(4\pi i)$ then $\psi \circ \mu = 2 \circ \psi$

and there exists $1 < \mu_{\min} \leq \mu_{\max} < \infty$ such that for every choice of $\rho_n \in [\rho_{\min}, \rho_{\max}]$, $n \geq 1$, we have $\mu_{\min} \leq \mu \leq \mu_{\max}$.

**Proof.** Since, by construction, $2\hat{\Omega} = \hat{\Omega}$ the map $\psi^{-1} \circ 2 \circ \psi$ is a conformal self-map of $\mathcal{H}$ fixing the origin and infinity which immediately implies the validity of the functional relation for some real $\mu > 1$.

Set $\mu_{\min} = \inf \mu$. If $\mu_{\min} = 1$ then, for every $k \geq 1$, there exists $\rho_n \in [\rho_{\min}, \rho_{\max}]$, $n \geq 1$, such that the associated conformal map $\psi_k$ satisfies the above functional relation with number $\mu_k \in ]1, 1 + \frac{1}{k}[$. We may assume that $\psi_k$ is a converging sequence. Let $\psi$ be the non-constant limit conformal map of this sequence. Then $\mu = \frac{1}{4}\psi^{-1}(2\psi(i)) > 1$ since $\psi^{-1}(\psi(i)) = i$. Finiteness of $\mu_{\max} = \sup \mu$ can be shown by a similar normal family argument. \qed
A second direct consequence of Remark 3.4 is that the number \( r \geq e^2 \) in the definition of the tract \( \Omega \) can be defined such that
\[
\Omega = \varphi(H_{\log r}) \subset \mathbb{D}_4^\ast
\]
for all conformal maps \( \varphi \) of this Section. We always assume that this is the case.

We use several standard notations such as the symbols \( A \preceq B \) and \( A \asymp B \), which mean that the ratio \( A/B \) is bounded above respectively bounded above and below by constants that do not depend on the particular choice of the numbers \( \rho_n \), some of them will depend on \( \rho_{\min}, \rho_{\max} \) and parameters like \( r \) above. But these are fixed and the same for all models of this paper. In other words, all constants will be uniform for the family of quasidisks \( \Omega \), of conformal maps \( \varphi \) and of models \( f \) we consider.

Throughout the text when we refer to all models of Section 3, then this refers to the models from Example 3.1 and Example 3.2 with fixed numbers \( \rho_{\min}, \rho_{\max} \) according to (3.3).

4. Estimating the Transfer Operator

The paper [27] contains a complete treatment of the thermodynamic formalism of disjoint type models and functions. We now collect some properties of the central tool of this theory, the transfer operator. In order to do so, we consider a model \( f = e^\tau : \Omega \to \mathbb{D}_r^\ast \). Typically, \( f \) is one of the examples of the previous section but it can also be the restriction of a convenient entire function to its logarithmic tract.

In the sequel we will work with a particular Riemannian, in fact the cylindrical, metric \( |dz|/|z| \). The derivative of a holomorphic function \( h \) calculated with respect to this metric at a point \( z \) such that \( h(z) \neq 0 \) is denoted by \( |h'(z)|_1 \) and is given by the formula
\[
|h'(z)|_1 = |h'(z)||z|/|h(z)|.
\]
Given a real number \( t \geq 0 \), we define the transfer operator \( \mathcal{L}_t \) by the usual formula:
\[
\mathcal{L}_t g(w) := \sum_{f(z)=w} |f'(z)|_1^{-t} g(z) \quad \text{for every } w \in \mathbb{D}_r^\ast
\]
where \( g \) is any function in \( C_b(\overline{\Omega}) \), the vector space of all continuous bounded functions defined on \( \Omega \). The norm on this space, making it a Banach space, will be the usual sup-norm \( \| \cdot \|_\infty \). Note that if \( w \in \mathbb{D}_r^\ast \), then \( f^{-1}(w) \subset \Omega \) and, by the disjoint type assumption, \( \Omega \subset \mathbb{D}_r^\ast \). Thus \( |f'(z)|_1 \) is well defined for all \( z \in f^{-1}(w) \) and, in consequence, \( \mathcal{L}_t g(w) \) is well defined for all \( w \in \mathbb{D}_r^\ast \) provided the series is convergent. Since we work with quasidisk tracts the whole scope of [27] applies and we know in particular that there is a number \( \Theta = \Theta_f \in [1,2] \), called transition parameter, such that the series defining \( \mathcal{L}_t \) is convergent if \( t > \Theta \) and diverges if \( t < \Theta \).
**Definition 4.1.** The function $f$ is of convergence type if the series defining $L_t$ converges for $t = \Theta$.

The reader should have in mind the following fact (which is a very particular case of Theorem 4.1 in [27]):

**Theorem 4.2.** Let $f$ be a model or an entire function of class $\mathcal{B}$ having one (or finitely many) quasidisk tracts. Assume that $f$ is of disjoint type. Let $t > 0$ and suppose that there exists $w_0 \in \mathbb{D}^*_r$ such that $L_t 1(w_0) < \infty$. Then the series defining $L_t 1$ is uniformly convergent meaning that $L_t$ is a bounded operator of the space $\mathcal{C}_b(\bar{\Omega})$.

**4.1. Integral means.** The transition parameter $\Theta$ is precisely determined by the geometry of the boundary of the tract $\Omega$ near infinity. For this one considers rescalings of the conformal map $\varphi$ given by

$$\varphi_T := \frac{1}{|\varphi(T)|} \varphi \circ T, \quad T \geq 1.$$  

The map $\varphi_T$ is defined on $T^{-1} \hat{\mathcal{H}}$. In particular, all the maps $\varphi_T, T \geq 1$, are defined on the half space $\mathcal{H}$.

By self-similarity of the tracts and in view of Lemma 3.5 it suffices to consider only values $T = \mu^n, n \geq 0$. Considering now integral means of the rescalings of $\varphi$ we get the required information about the geometry of the boundary of the tract $\Omega$ near infinity:

$$\beta_\infty(t) = \limsup_{n \to \infty} \frac{\log \int_{\mu^{-1} \leq |y| \leq 1} |\varphi_{\mu^n} (\mu^{-n} + iy)|^t dy}{n \log \mu}, \quad t \geq 0.$$  

Since the tract $\Omega$ is a quasidisk, there exists a unique zero of the function $t \mapsto \beta_\infty(t) - t + 1$ which is the transition parameter of the transfer operator (see Proposition 5.6 and Theorem 4.4 in [27]) and, for all our examples, is the dimension of the snowflake curves $\Theta = \log 4 / \log 3$. In terms of [27], this means that the models or entire functions we deal with in the present paper have negative spectrum and their disjoint type versions are in the class $\mathcal{D}$ so that the whole scope of [27] applies.

**4.2. The transfer operator of the models.** We now come back to the models introduced in Section 3 and give precise estimates for the transfer operator of these models. The first step, which expresses $L_t 1(w)$ as an integral, follows Section 4 of [27] and so we can allow us to present only the essential steps.

Let $f$ be one of the models introduced in Section 3. Let $w \in \mathbb{D}^*_r$ and set $x = \log |w| > \log r \geq 2$. Fix also

$$j \geq 1 \quad \text{maximal such that} \quad \mu^{j-1} \leq x.$$  

For \( z \in f^{-1}(w) \in \Omega \) we have \( |f'(z)|_1 = \frac{\varphi'(\xi)}{\varphi(\xi)} \) where \( \xi = \varphi^{-1}(z) \). Hence,

\[
\mathcal{L}_t \varphi(w) = \sum_{\xi \in \exp^{-1}(w)} \left| \frac{\varphi'(\xi)}{\varphi(\xi)} \right|^t = \sum_{\xi \in \exp^{-1}(w)} \left| (\log \varphi)'(\xi) \right|^t
\]

and thus, using bounded distortion,

\[
\mathcal{L}_t \varphi(w) \asymp \int_{\mathbb{R}} \left| (\log \varphi)'(x + iy) \right|^t \, dy
\]

where \( I_m = [-\mu^{-m}, -\mu^{m-1}] \cup [\mu^{m-1}, \mu^m] \). The first term can be estimated as follows. By quasisymmetry of \( \varphi \), since \( \varphi(0) = 0 \) and since \( |y| \leq \mu^j \times x \) we have

\[
|\varphi(x + iy)| \asymp \text{diam} \left( \varphi(\mathbb{D}(x + iy, \frac{x}{2})) \right).
\]

On the other hand, \( \text{diam}(\varphi(\mathbb{D}(x+iy, \frac{x}{2}))) \asymp |\varphi(x+iy)|x \) because of bounded distortion. Consequently,

\[
\int_{-\mu^j \leq y \leq \mu^j} \left| \frac{\varphi'(x + iy)}{\varphi(x + iy)} \right|^t \, dy \asymp x^{1-t}.
\]

The integrals over \( I_{n+j} \) can be estimated using the rescalings \( \varphi_T \) introduced in (4.3) with \( T = \mu^{n+j} \) where, we recall, \( j \) comes from (4.3). Again quasisymmetry of \( \varphi \) and the fact that \( \varphi(0) = 0 \) show that \( |\varphi(x+iy)| \asymp |\varphi(\mu^{n+j})|, y \in I_{n+j} \). It thus follows from a simple change of variable combined with bounded distortion that

\[
\int_{I_{n+j}} \left| \frac{\varphi'(x + iy)}{\varphi(x + iy)} \right|^t \, dy \asymp \int_{I_0} \left| \frac{\varphi'(\mu^{n+j}(\mu^{-n-j}x + iu))}{\varphi(\mu^{n+j})} \right|^t \mu^{n+j} \, du
\]

\[
\asymp \int_{I_0} \left| \frac{\varphi'(\mu^{n+j}(\mu^{-n} + iu))}{\varphi(\mu^{n+j})} \right|^t \mu^{n+j} \, du.
\]

Since \( \varphi'_T = \frac{T}{|\varphi(T)|} \varphi' \circ T \) we get, taking \( T = \mu^{n+j} \),

\[
\int_{I_{n+j}} \left| \frac{\varphi'(x + iy)}{\varphi(x + iy)} \right|^t \, dy \asymp (\mu^{n+j})^{1-t} \int_{I_0} \left| \varphi'_{\mu^{n+j}}(\mu^{-n} + iy) \right|^t \, dy.
\]

Let \( r_n = r_n(x) = (n + j + \mu^j)\mu^{-(n+j)} \asymp \mu^{-(n+j)} \text{dist}(x + iy, \partial \mathcal{H}) \), \( y \in I_{j+n} \). An elementary calculation shows that

\[
(4.6) \quad \mu^{-n} \leq r_n \lesssim n\mu^{-n}, \quad n \geq 1.
\]

Choose a maximal number of points \( y_{n,k} \) in \( \mu^{-n} + iI_0 \) such that

\[
\text{sign}(\Im(y_{n,k})) = \text{sign}(k)
\]
and such that two consecutive points have distance $r_n$. Then,

$$
\int_{I_n+j} \left| \frac{\varphi'}{\varphi}(x + iy) \right|^t dy \asymp (\mu^{n+j})^{1-t} \sum_k |\varphi'_{\mu^{n+j}}(y_{n,k})|^t r_n
$$

$$
\asymp (n + j + x)^{1-t} \sum_k \left( |\varphi'_{\mu^{n+j}}(y_{n,k})| r_n \right)^t.
$$

Finally, it is convenient to replace $\varphi$ by $\psi = \varphi \circ h^{-1}$. We have

$$
\varphi_{\mu^m} = \frac{1}{|\varphi(\mu^m)|} \varphi \circ \mu^m = \frac{2^m}{|\varphi(\mu^m)|} \left( \frac{1}{2^m} \psi \circ \mu^m \right) (\mu^{-m} \circ h \circ \mu^m).
$$

The first factor is approximately equal to 1 since $\varphi$ is a quasisymmetry with $\varphi(0) = 0$, since $\mu^m \asymp |h^{-1}(i \mu^m)|$ and since $\varphi(h^{-1}(i \mu^m)) = \psi(i \mu^m) = 2^m \psi(i) = 2^m 2\pi i$ by Lemma 3.5. The same lemma implies that the second term equals $\psi$ and for the last factor we introduce $h_m = \mu^{-m} \circ h \circ \mu^m$.

It follows from Proposition 12.2 in Appendix 12 that $|h_m'| \asymp 1$. Therefore,

$$
(4.7) \quad |\varphi'_{\mu^m}| \asymp |\psi' \circ h_m|
$$

and, injecting this in the above expression, we get

$$
\int_{I_n+j} \left| \frac{\varphi'}{\varphi}(x + iy) \right|^t dy \asymp (n + j + x)^{1-t} \sum_k \left( |\psi'_{h_{n+j}}(y_{n,k})| r_n \right)^t.
$$

Set $z_{n,k} = h_{n+j}(y_{n,k})$. We will see in Lemma 4.4 below that $\text{dist}(z_{n,k}, \partial H) \asymp r_n$. We get all in all

$$
(4.8) \quad \mathcal{L}_t \mathbb{I}(w) \asymp x^{1-t} \left[ 1 + \sum_{n \geq 1} \left\{ \left( 1 + \frac{n + j}{x} \right)^{1-t} \sum_k (|\psi'_{h_{n+j}}(y_{n,k})| r_n)^t \right\} \right]
$$

for all $w \in D^*_t$. The factor $|\psi'_{h_{n+j}}(y_{n,k})| r_n$ has obvious geometric meaning. Indeed, assume that $Q_{n,k} \subset H$ is a rectangle containing $z_{n,k}$, and such that

$$
(4.9) \quad \text{diam}(Q_{n,k}) \asymp r_n \quad \text{and} \quad \text{dist}(Q_{n,k}, \partial H) \asymp r_n.
$$

Set

$$
(4.10) \quad \mathcal{W}_{n,k} = \psi(Q_{n,k}).
$$

Then the following statement immediately follows from bounded distortion and (4.8).

**Proposition 4.3.** With the previous notations we have

$$
\mathcal{L}_t \mathbb{I}(w) \asymp (\log |w|)^{1-t} \left[ 1 + \sum_{n \geq 1} \left\{ \left( 1 + \frac{n + j}{x} \right)^{1-t} \sum_k (\text{diam} \mathcal{W}_{n,k})^t \right\} \right]
$$

for all $w \in D^*_t$ and with comparability constants uniform for all models of Section 3 but depending on the multiplicative constants in (4.9).
In order to exploit this we have to define properly the rectangles $Q_{n,k}$. We first need a technical result.

**Lemma 4.4.** There exists $\kappa \geq 1$, independent of $n$ and $k$ such that the following properties hold:

1. For all $(n,k)$, 
   $$ \frac{r_n}{\kappa} \leq \Re (z_{n,k}) \leq \kappa r_n. $$

2. $\kappa r_{n+1} > \frac{x}{\kappa}$ for every $n \geq 1$ and $x > \log r \geq 2$.

3. $|z_{n,k+1} - z_{n,k}| \leq \kappa r_n$ for every $n \geq 1$ and $k > 0$ and the analogue statement also holds if $k < 0$.

4. Let $L = L_1$ be a common bilipschitz constant for the maps $h_m$, $m \geq 1$ (see Proposition 12.2 in Appendix 12). Then
   $$ \frac{1}{L \mu_{\text{max}}} \leq |\Im z_{n,k}| \leq L \text{ for all } (n,k). $$

Given (4), it is appropriate to define the values 

$$ s_{\text{imag}} = \frac{1}{L \mu_{\text{max}}} \text{ and } S_{\text{imag}} = L. $$

**Proof.** For every $m \geq 1$, the map $h_m : \mu^{-m} \mathcal{H} \to \mu^{-m} \mathcal{H} = \mathcal{H}$ is conformal and thus a hyperbolic isometry. This implies that, for every $\xi \in \mu^{-m} \mathcal{H}$,

$$ \text{dist}(\xi, \partial \mu^{-m} \mathcal{H}) |h'(m)(\xi)| \asymp \text{dist}(h_m(\xi), \partial \mathcal{H}) = \Re (h_m(\xi)). $$

Taking $\xi = y_{n,k}$ and $m = n + j$ we get

$$ \Re (z_{n,k}) \asymp \text{dist}(y_{n,k}, \partial \mu^{-m-j} \mathcal{H}) |h'_{n+j}(y_{n,k})| \asymp r_n $$

since, by Proposition 12.2 $|h'_{n+j}(y_{n,k})| \asymp 1$. This shows Item (1).

Item (2) follows from the estimate

$$ \frac{r_n}{r_{n+1}} = \frac{(n+j+\mu^j)\mu^{-(n+j)}}{(n+1+j+\mu^j)\mu^{-(n+1+j)}} = \mu \left( 1 - \frac{1}{n+1+j+\mu^j} \right) \leq \mu \leq \mu_{\text{max}} $$

with $\mu_{\text{max}}$ from Lemma 3.5.

Since the maps $h_m$ are bilipschitz uniformly with $m$, we have the following: if $k_1$, $k_2$ have same sign then

$$ |z_{n,k_1} - z_{n,k_2}| \asymp |y_{n,k_1} - y_{n,k_2}| = |k_1 - k_2| r_n $$

In particular, $|z_{n,k+1} - z_{n,k}| \asymp |y_{n,k+1} - y_{n,k}| = r_n$ which shows Item (3).

Finally, Item (4) follows from Lemma 12.3. \qed

Let $\kappa \geq 1$ be given by Lemma 4.4. This number being fixed, we can now define the rectangles $Q_{n,k}$ around $z_{n,k}$ as follows:

$$ Q_{n,k} = \left\{ \frac{r_n}{\kappa} \leq \Re (\xi) \leq \kappa r_n, |\Im (\xi - z_{n,k})| \leq \kappa r_n \right\} \cap \left\{ s_{\text{imag}} \leq |\Im (\xi)| \leq S_{\text{imag}} \right\}. $$

Notice that (4.9) is satisfied since $z_{n,k} \in Q_{n,k}$ by Item (1) and Item (4) of Lemma 4.4.
Lemma 4.5. Let $\kappa \geq 1$ be given by Lemma 4.4 and let $Q_{n,k}$ be defined as above. Then:

1. \( \bigcup_{n,k} Q_{n,k} \subset U_{\text{ext}} = \left\{ 0 < \Re(\xi) < S_{\text{real}}, \frac{s_{\text{imag}}}{2} < |\Im(\xi)| < 2S_{\text{imag}} \right\} \)

   where 
   
   \[ S_{\text{real}} = 2\kappa \left( 1 + \frac{1}{\log \mu_{\min}} \right). \]

2. There exist $\delta_{\text{real}} > 0$ and $\mu_{\min}^{-1} < \delta_{\text{imag}}^{-} < \delta_{\text{imag}}^{+} < 1$ such that 
   \[ \bigcup_{n,k} Q_{n,k} \supset U_{\text{int}} = \left\{ 0 < \Re(\xi) < \delta_{\text{real}}, \delta_{\text{imag}}^{-} < |\Im(\xi)| < \delta_{\text{imag}}^{+} \right\}. \]

3. The collection \( \{Q_{n,k}\} \) has bounded overlap: there exist $B \geq 1$ such that for every \( (n_0,k_0) \) there exist at most $B$ indices \( (n,k) \) such that 
   \[ Q_{n,k} \cap Q_{n_0,k_0} \neq \emptyset. \]

Again, all the involved constants are uniform. In particular, the sets $U_{\text{int}}$ and $U_{\text{ext}}$ do not depend on the model $f$.

Proof. An elementary calculation shows that $\sup_{a \geq 1} \frac{a}{\mu^a} \leq \frac{1}{\log \mu} \leq \frac{1}{\log \mu_{\min}}$. Combined with the definition of $r_n$ and of $S_{\text{real}}$ we get for every $\xi \in \bigcup_{n,k} Q_{n,k}$ that $\Re(\xi) < S_{\text{real}}$. Item (1) follows since the assertion concerning the imaginary part is obvious given the definition of the sets $Q_{n,k}$.

The second item can be shown as follows. Fix arbitrarily $\delta_{\text{imag}}^{-}, \delta_{\text{imag}}^{+}$ such that $\mu_{\min}^{-1} < \delta_{\text{imag}}^{-} < \delta_{\text{imag}}^{+} < 1$. By the definition of the points $y_{n,k}$ there exists $k_1, k_2 > 0$ such that $|\Im(y_{n,k_1})| < \mu_{\min}^{-1} + r_n$ and $|\Im(y_{n,k_2})| > 1 - r_n$. The bilipschitz property in Lemma 4.4 implies thus that 

\[ |\Im(z_{n,k_1})| \leq L_n(\mu_{\min}^{-1} + r_n) \leq L_n(\mu_{\min}^{-1} + r_n) \quad \text{and} \quad |\Im(z_{n,k_2})| \geq \frac{1}{L_n}(1 - r_n). \]

Notice that $(L_m)_m$ is a decreasing sequence with limit 1. On the other hand, $r_n \to 0$ and thus there exists $n_{\min}$, which does not depend on the model $f$, such that 

\[ L_n(\mu_{\min}^{-1} + r_n) < \delta_{\text{imag}}^{-} \quad \text{and} \quad \frac{1}{L_n}(1 - r_n) > \delta_{\text{imag}}^{+} \quad \text{for every} \quad n \geq n_{\min}. \]

If we combine this with the definition of the sets $Q_{n,k}$ and Item (3) of Lemma 4.4 then this gives 

\[ V_n = \left\{ \frac{r_n}{\kappa} < \Re(\xi) < \kappa r_n, \delta_{\text{imag}}^{-} < |\Im(\xi)| < \delta_{\text{imag}}^{+} \right\} \subset \bigcup_{n,k} Q_{n,k} \]

for all $n \geq n_{\min}$. Given (2) of Lemma 4.4, the set 

\[ \bigcup_{n \geq n_{\min}} V_n \]

covers $U_{\text{int}}$ if we set $\delta_{\text{real}} = \kappa r_{n_{\min}}$. 

We are left to show that the collection \( \{Q_{n,k}\} \) has bounded overlap. To start with, suppose that \( n < m \) and \((n, k), (m, l)\) are such that \( Q_{n,k} \cap Q_{m,l} \neq \emptyset \). Then necessarily \( \kappa r_m \geq \frac{r_n}{K} \). But

\[
\frac{r_n}{r_m} = \frac{(n + j + \mu^j)\mu^{-n-j}}{(m + j + \mu^j)\mu^{-m-j}} = \mu^{m-n} \frac{n + (j + \mu^j)}{m + (j + \mu^j)} \geq \mu^{m-n} \frac{n}{m}.
\]

Put \( \Delta = m - n \geq 1 \). Clearly \( \frac{n}{m} = \frac{n}{n+\Delta} = \frac{1}{1+\Delta/n} \geq \frac{1}{1+\Delta} \geq \frac{1}{2\Delta} \) so that we get altogether the condition

\[
\kappa^2 \geq \frac{1}{2} \frac{\mu \Delta}{\Delta} \geq \frac{1}{2} \frac{\mu \Delta_{\min}}{\Delta}
\]

which shows that there is a constant \( B_1 = B_1(\kappa) \) such that \( \Delta = m - n \leq B_1 \).

Now, let \( \xi \in \mathcal{H} \), fix \( n \) and consider \( k \) such that \( \xi \in Q_{n,k} \). Then

\[
|\xi - z_{n,k}| \leq \text{diam}(Q_{n,k}) \leq \left( \kappa - \frac{1}{\kappa} \right) r_n + 2\kappa r_n = \left( 3\kappa - \frac{1}{\kappa} \right) r_n.
\]

It follows from (4.11) that this can happen for at most

\[
B_2 = 2\left( 3\kappa - \frac{1}{\kappa} \right) L
\]

indices \( k \) where \( L \) is the bilipschitz constant involved in (4.11).

In conclusion, \( \xi \in Q_{n,k} \) can happen for at most \( B_1 \) different indices \( n \) and, for every fixed \( n \geq 1 \), there are at most \( B_2 \) indices \( k \) such that \( Q_{n,k} \) contains \( \xi \). Therefore, the collection \( \{Q_{n,k}\} \) has bounded overlap with constant \( B = B_1B_2 \).  

\[\square\]

5. Whitney decompositions

In order to estimate the transfer operator via the sets \((W_{n,k})\) we will compare them to Whitney decompositions that reflect the geometry of the snowflake curve.

Whitney coverings are standard. Here we use a slight modification of the usual notion. The following definition applies to more general open sets \( V \) but in this paper we will take \( V = \psi(U) \) where \( U \) is one of the sets \( U_{\text{int}}, U_{\text{ext}} \) of Lemma 4.5 and where \( \Upsilon = \psi(\partial U \cap i\mathbb{R}) \subset \partial V \cap \partial \hat{\Omega} = \partial V \cap \Gamma \).

**Definition 5.1.** A collection \((W_{m,l})\) of sets is a Whitney covering of \( V \) with respect to \( \Upsilon \subset \partial V \) if the following holds:

1. \( V \subset \bigcup W_{m,l} \) and \( V \cap W_{m,l} \neq \emptyset \) for all \((m, l)\).
2. The sets \( W_{m,l} \) have bounded overlap: there exists \( B \geq 1 \) such that for every \((m_0, l_0)\) there exist at most \( B \) indices \((m, l)\) such that

\[
W_{m,l} \cap W_{m_0,l_0} \neq \emptyset.
\]
3. The sets \( W_{m,l} \) are closures of simply connected domains, they are round and of diameter comparable to the distance to the boundary: there exists a \( a > 0 \) such that every \((m, l)\) there exists a disk

\[
diam(W_{m,l}) \leq \frac{a}{\kappa}
\]

where \( \kappa \) is the bilipschitz constant of \( \psi \).
\( D(z_{m,l}, r_{m,l}) \) such that
\[
D(z_{m,l}, r_{m,l}) \subset W_{m,l} \subset D(z_{m,l}, r_{m,l}/a)
\]
and
\[
\text{adiam}(W_{m,l}) \leq \text{dist}(W_{m,l}, \Upsilon) \leq \frac{1}{a} \text{diam}(W_{m,l}).
\]

**Fact 5.2.** The Whitney covering property is a conformal, even quasiconformal, invariant since quasiconformal mappings are quasi-isometries for the quasi-hyperbolic distance (see [18]). In particular, if \((W_{m,l})\) is a Whitney covering of \(V\) with respect to \(\Upsilon\) then \((\psi^{-1}(W_{m,l}))\) is a Whitney covering of \(U\) with respect to \(\psi^{-1}(\Upsilon)\) and the converse is also true.

5.1. **Geometric Whitney covering.** Consider now \(g\) a quasiconformal map of the plane such that \(g(\mathcal{H}) = \hat{\Omega}\) and such that \(g\) reflects the geometry of the snowflake curve \(\Gamma\). It is a quasiconformal extension of the natural parametrization of \(\Gamma\) as explained in Section 3 and it satisfies the relation (3.10). We use this map to produce coverings of the sets \(V_{\text{int}} = \psi(U_{\text{int}})\) and of \(V_{\text{ext}} = \psi(U_{\text{ext}})\).

In the following, \(V\) is one of the sets \(V_{\text{int}}, V_{\text{ext}}\) and we recall from Lemma 4.5 that \(U_{\text{int}}, U_{\text{ext}}\) do not depend on the model, hence on \(\Gamma\).

Consider a standard decomposition of \(\mathcal{H}\) given by
\[
Q_{m,l} = \left\{ 4^{-m+1} \leq \Re \xi \leq 4^{-m}, \quad l 4^{-m} \leq \Im \xi \leq (l + 1)4^{-m} \right\}
\]
and set
\[
W_{m,l} = g(Q_{m,l}), \quad m, l \in \mathbb{Z}.
\]
By Fact 5.2, the collection of all \((W_{m,l})\) such that \(W_{m,l} \cap V \neq \emptyset\) is a Whitney covering of \(V\) with respect to \(\Upsilon = \psi(\partial U \cap i\mathbb{R})\). This covering reflects the geometry of the snowflake, as explained in Lemma 6.1 below. As always, the constants in this result do not depend on the particular snowflake chosen out of the family described in Section 3.

**Lemma 5.3.** For every set \(W_{m,l}\) of this Whitney covering of \(V\) with respect to \(\Upsilon\) we have \(\text{diam} W_{m,l} \asymp l_m\), there exists \(K \geq 1\) such that
\[
4^{-mK} \leq \text{diam} W_{m,l} \leq 4^{-m/K}
\]
and, for some \(m_0 \geq 1\), the number of sets \(W_{m,l}\) of level \(m \geq m_0\) is
\[
\# \{l, \ W_{m,l} \cap V \neq \emptyset \} \asymp 4^m
\]
where the involved equivalence constants do only depend on the set \(V = V_{\text{int}}\) or \(V = V_{\text{ext}}\) respectively.

**Proof.** The relation \(\text{diam} W_{m,l} \asymp l_m\) follows from the fact that the quasiconformal map \(g\) is quasisymmetric and (5.1) is a consequence of the Hölder continuity (3.8). The statement concerning the number of sets of a given level \(m\) is clear and the involved constants are independent of the model since the sets \(U_{\text{int}}, U_{\text{ext}}\) do not depend on them. \(\square\)
5.2. Conformal Whitney covering. The covering \( \mathcal{W}_{n,k} = \psi(Q_{n,k}) \) has been introduced in (4.10).

Lemma 5.4. The sets \( \mathcal{W}_{n,k} \), \( (n,k) \) such that \( Q_{n,k} \cap \mathcal{U}_{\text{int}} \neq \emptyset \), are a Whitney covering of \( \mathcal{V}_{\text{int}} = \psi(\mathcal{U}_{\text{int}}) \) with respect to \( \mathcal{T}_{\text{int}} = \psi(\partial \mathcal{U}_{\text{int}} \cap i\mathbb{R}) \). In addition, there exists \( K \geq 1 \) such that

\[
(5.3) \quad r_n^K \leq \text{diam} \mathcal{W}_{n,k} \leq r_n^{1/K}.
\]

Proof. By Fact 5.2, it suffices to verify that \( (Q_{n,k}) \) is a Whitney covering with respect to \( \partial \mathcal{U}_{\text{int}} \cap i\mathbb{R} \). But this we already checked in Section 4 (see (4.9) and Lemma 4.5).

It remains to justify the inequalities in (5.3). But they follow from \( \text{diam} Q_{n,k} \asymp r_n \) and, again, from the Hölder property (3.8). \( \square \)

5.3. Comparing the coverings. In view of estimating the series in Proposition 4.3 we now compare the geometric and conformal Whitney coverings.

Lemma 5.5. There exists a constant \( B_* \) such that for every \( (n,k) \) (or \( (m,l) \)) there are at most \( B_* \) indices \( (m,l) \) (respectively \( (n,k) \)) such that

\[
(5.4) \quad \mathcal{W}_{n,k} \cap \mathcal{W}_{m,l} \neq \emptyset.
\]

Proof. First of all, there exists \( a > 0 \) such that every set \( \mathcal{W}_{n,k} \) and \( \mathcal{W}_{m,l} \) contains respectively a ball \( B_{n,k}, B_{m,l} \) of radius \( a \text{diam} \mathcal{W}_{n,k}, a \text{diam} \mathcal{W}_{m,l} \)

Again, this constant \( a \) is independent of the model of Section 3 since, by uniform quasiconformality, the sets \( \mathcal{W}_{n,k}, \mathcal{W}_{m,l} \) are uniformly round meaning precisely that they satisfy the roundness condition in Item (3) of Definition 5.1 for some fixed constant \( a > 0 \).

Both coverings being Whitney, (5.4) implies \( \text{diam} \mathcal{W}_{n,k} \asymp \text{diam} \mathcal{W}_{m,l} \). Therefore, there exists \( A > 1 \) such that, whenever (5.4) holds,

\[
B_{n,k} \subset \mathcal{W}_{n,k} \subset \mathbb{D}(w_{m,l}, A \text{diam} \mathcal{W}_{m,l})
\]

where \( w_{m,l} \in \mathcal{W}_{m,l} \) is any arbitrary point. The conclusion comes now from the bounded overlap property combined with a volume comparison argument. Clearly in this argument we can exchange the role of the two coverings and thus the proof is complete. \( \square \)

We also have to compare the levels \( n \) and \( m \) for sets \( \mathcal{W}_{n,k} \) and \( \mathcal{W}_{m,l} \) that intersect. This is not possible for general domains but here we deal with quasidisks and have good Hölder estimates.

Lemma 5.6. There exists a constant \( b > 0 \), still independent of the model, such that for every \( (n,k) \) and \( (m,l) \) for which (5.4) holds we have

\[
b n \leq m \leq \frac{1}{b} n.
\]

Proof. Assume \( (n,k) \) and \( (m,l) \) are such that (5.4) holds. Then \( \text{diam} \mathcal{W}_{n,k} \asymp \text{diam} \mathcal{W}_{m,l} \). It follows from Lemma 5.3 and from (5.3) that

\[
4^{-mK} \leq r_n^{b^{-1}} \quad \text{and} \quad r_n^K \leq 4^{-\frac{1}{b}}.
\]
Concerning \( r_n \), we use now the estimate (4.6). Combined with the previous one gives
\[
4^{-mK} \lesssim n^{\frac{1}{K}} \mu^{-\frac{n}{K}} \leq n^{\frac{1}{K}} \mu_{\max}^{-\frac{n}{K}} \quad \text{and} \quad \mu_{\min}^{-nK} \leq \mu^{-nK} \lesssim 4^{-\frac{n}{K}}
\]
from which the affirmation easily follows.

6. Models of convergence type

Let \( f \) be a model of Section 3 with tract \( \Omega = \varphi(\mathcal{H}_{\log r}) \) given by Example 3.1. We recall that then
\[
I_m^{\Theta} \asymp 4^{-m} \frac{1}{m^\alpha}, \quad m \geq 1 \quad \alpha > 1,
\]
where the involved multiplicative constant \( C_f \) does depend on the model \( f \).

**Theorem 6.1.** The transfer operator \( L_t \) of such a model \( f \) is of convergence type (with \( \Theta = \log 4/\log 3 \)) and there exists \( M = M_f \geq 1 \) such that
\[
L_t \mathbb{I}(w) \leq M'(\log |w|)^{1-t}
\]
for every \( w \in \mathbb{D}_r^\ast \) and every \( t \geq \Theta \).

**Remark 6.2.** As explained in Section 8 of [27], Theorem 6.1 implies that for these models the full thermodynamic formalism holds for all \( t \geq \Theta \) so also in the particular case when \( t = \Theta \) equals the transition parameter.

**Proof of Theorem 6.1.** From Proposition 4.3 we have a precise estimate of \( L_t \) which implies
\[
L_t \mathbb{I}(w) \lesssim (\log |w|)^{1-t} \left[ 1 + \sum_{n \geq 1} \sum_k (\text{diam } W_{n,k})^t \right]
\]
since \( t > 1 \). Take \( U = U_{\text{ext}} \) and remember from Lemma 4.5 that \( U \) contains all the sets \( Q_{n,k} \), hence \( \bigcup_{n,k} W_{n,k} \subset V_{\text{ext}} = \psi(U_{\text{ext}}) \). Set \( \mathcal{I} = \{(m,l) : W_{m,l} \cap V_{\text{ext}} \neq \emptyset\} \) so that \( \{W_{m,l}, (m,l) \in \mathcal{I}\} \) is a Whitney covering of \( V_{\text{ext}} \) with respect to \( Y = \psi(\partial U \cap i\mathbb{R}) \). In particular, for every \( (n,k) \) there exists \( (m,l) \in \mathcal{I} \) such that
\[
W_{n,k} \cap W_{m,l} \neq \emptyset \quad \text{and} \quad \text{diam } W_{n,k} \leq C \text{diam } W_{m,l}
\]
for some uniform constant \( C \). It thus follows now from Lemma 5.5 that
\[
\sum_{n \geq 1} \sum_k (\text{diam } W_{n,k})^t \leq B^d \sum_{(m,l) \in \mathcal{I}} (\text{diam } W_{m,l})^t.
\]
We have \( \text{diam } W_{m,l} \asymp l_m \) (Lemma 5.3) which, along with (5.2) of Lemma 5.3 and (6.1), implies that for every \( t \geq \Theta \)
\[
L_t \mathbb{I}(w) \lesssim (\log |w|)^{1-t} \sum_{m \geq 1} 4^m \left( C_f 4^{-m} \frac{1}{m^\alpha} \right)^{t/\Theta} \leq C_{f^t} \Theta M'(\log |w|)^{1-t}
\]
where \( M' = \sum_{m \geq 1} \frac{1}{m^\alpha} < \infty. \)
It remains to show that $L_t \mathbb{I}(w) = \infty$ for $t < \Theta$ and for some $|w| > r \geq e^2$. We first provide an appropriate lower bound for the transfer operator starting again from Proposition 4.3. The expression there gives, for every $w \in D_r \ast$ and still with $x = \log |w|$,

$$L_t \mathbb{I}(w) \geq (\log |w|)^{1-t} \sum_{n \geq 1} \left\{ \left(1 + \frac{n + j}{x}\right)^{1-t} \sum_k (\text{diam } W_{n,k})^t \right\}.$$ 

Since

$$1 + \frac{n + j}{x} \leq 1 + n + \frac{j}{\mu^{j-1}} \leq 1 + n + \frac{\mu}{\log \mu}$$

we have

$$L_t \mathbb{I}(w) \geq x^{1-t} \sum_{n \geq 1} \left\{ \left(1 + \frac{\mu}{\log \mu} + n\right)^{1-t} \sum_k (\text{diam } W_{n,k})^t \right\}.$$ 

Let $0 < t < \Theta$ and let $\varepsilon > 0$ such that $t' = t + \varepsilon < \Theta$. By (5.3) and (4.6)

$$\text{diam } W_{n,k} \lesssim r_n^{1/K} \lesssim n^{1/K} \mu^{-n/K}$$

and thus

$$c_t = \inf_{n \geq 1} \left(1 + \frac{\mu}{\log \mu} + n\right)^{1-t} (\text{diam } W_{n,k})^{-\varepsilon} \geq \min_{n \geq 1} \mu^{-\varepsilon} \left(1 + \frac{\mu}{\log \mu} + n\right)^{1-t} > 0.$$ 

Injecting this in the lower estimate of $L_t \mathbb{I}$ gives

$$L_t \mathbb{I}(w) \geq c_t x^{1-t} \sum_{n \geq 1} \sum_k (\text{diam } W_{n,k})^{t'}.$$ 

In view of Lemma 4.5, the sets $W_{n,k}$ cover $\mathcal{V}_{\text{int}} = \psi(U_{\text{int}})$. The same arguments that lead to (6.2) gives

$$\sum_{n \geq 1} \sum_k \left(\text{diam } W_{n,k}\right)^{t'} \geq \frac{1}{B \cdot C^v} \sum_{(m,l) \in \mathcal{I}} \left(\text{diam } W_{m,l}\right)^{t'}$$

where, this time, $\mathcal{I}$ is the set of all the $(n,k)$ such that $W_{m,l} \cap \mathcal{V}_{\text{int}} \neq \emptyset$. Consequently,

$$L_t \mathbb{I}(w) \geq c_t x^{1-t} \sum_{(m,l) \in \mathcal{I}} \left(\text{diam } W_{m,l}\right)^{t'}.$$ 

There exists $m_{\text{min}}$ such that for every $m \geq m_{\text{min}}$ the number $\# \{l : (m,l) \in \mathcal{I}\}$ is comparable to $4^m$ (5.2) of Lemma 5.3 this time applied with $\mathcal{V} = \mathcal{V}_{\text{int}}$. On the other hand, $\text{diam } W_{m,l} \asymp l_m$ and, by (6.1), $l_m \geq C_f^{-1} 4^{-m} m^{-1}$. Since $t' < \Theta$ it follows that $L_t \mathbb{I}(w)$ is divergent. □
Up to now we have considered particular model functions and have good estimates for their transfer operator. But we really need global entire functions having similar properties. Such functions will be obtained with the help of an approximation result of model functions by entire functions. There are several approximation results, the most general being the quasiconformal approximations by Bishop \[15, 14\]. We will use Rempe’s uniform approximation \[34\] which is more restrictive but very precise. It extends models that are defined on the enlarged tract \(\hat{\Omega} \supset \Omega\). Here is a version of his result.

**Theorem 7.1** (Uniform approximation). Let \(\varphi = \tau^{-1} = \hat{\mathcal{H}} \to \hat{\Omega}\) be a conformal map fixing infinity and let \(f = e^\tau : \Omega \to \mathbb{C}\). Let \(C : \mathbb{R} \to \hat{\mathcal{H}}\) be defined by \(C(t) = \varphi(it - 13 \log_+ |t| + 1)\). Let \(\hat{\Omega}\) be the component of \(\mathbb{C} \setminus \mathcal{C}\) that is contained in \(\hat{\Omega}\) and let \(\hat{\mathcal{H}} = \tau(\hat{\Omega})\). So, \(\hat{\mathcal{H}} \subset \hat{\mathcal{H}}\) and \(\hat{\Omega} \subset \hat{\Omega}\). Put

\[
h(z) = \frac{1}{2\pi i} \int_C \frac{f(\xi)}{\xi - z} \, d\xi, \quad z \notin C.
\]

Then this formula defines a holomorphic function for \(z \notin C\) and the function \(F\) defined as

\[
F(z) = \begin{cases} f(z) + h(z) & \text{when } z \in \hat{\Omega} \\ h(z) & \text{when } z \notin \hat{\Omega} \end{cases}
\]

extends to an entire function \(F\) in the class \(B\). Moreover, the function \(h\) satisfies the estimate

\[
|h(z)| \leq \frac{C}{|z|_+}
\]

where \(C\) is some constant and where \(|z|_+ = \max(|z|, 1)\).

7.1. **Universality of estimates.** We shall use the above approximation for varying model functions \(f\), and then pass from the estimates for the model to the estimates for the actual function \(F\). It is essential for further estimates to examine the error term \(h\), i.e the universality of the constant \(C\) appearing in the inequality (7.2). In order to check this universality it is sufficient to go carefully through very precise estimates provided in \[34\].

Indeed, the domain \(\hat{\mathcal{H}}\) is exactly the one considered in Remark 2 of Section 4 in \[34\]. This domain is called "initial configuration”. So, in the case under consideration the "initial configuration” is fixed.

In Corollary 4.5 in \[34\] the required estimate for the error function \(h\) appears:

\[
|h(z)| < M_5, \quad |h(z)| \leq \max(|z_0|_+ + \text{dist}(z_0, \partial \hat{\Omega})) \frac{M_6}{|z|_+}
\]

for all \(z \in \mathbb{C} \setminus \mathcal{C}\). The function \(F\) is in class \(B\) since

\[
S(F) \subset \overline{D}_{2M_5}.
\]
Here, the constants $M_5$ and $M_6$ depend only on the initial configuration, which is fixed. We may assume that $M_5 \geq r \geq e^2$. The point $z_0$ which appears in (7.3) is defined as

$$z_0 = \varphi(1).$$

It follows directly from the normal family property of the family of maps $\varphi$ as explained in Remark 3.4 that

$$|h(z)| \leq \frac{M_0}{|z|_+}, \quad z \in \mathbb{C} \setminus C$$

for all our examples. In particular, we have the statement of Remark 4.6 in [34]:

$$|F| \leq M_0 \text{ outside } \hat{\Omega} \text{ and } |F| \leq |f| + M_0 \text{ in } \hat{\Omega}.$$  

7.1.1. **Disjoint type.** The above estimates allow us to fix the translation constant $T$ in (3.6) such that all the models $f$ and also the shifted approximation functions defined by

$$F(z) = F(z-T), \quad z \in \mathbb{C},$$

are of disjoint type. In the following we will always assume that $T$ is chosen such that the following result holds whereas $\eta$ will be fixed in (7.9).

**Lemma 7.2.** For $\eta \geq 2M_0$, set $T = 4\eta$. Then, for all models $f$ of Section 3 and every entire function $F$ associated to $f$ by the above construction,

$$\Omega_g := g^{-1}(\mathbb{D}^*_\eta) \subset \mathbb{D}^*_2$$

for $g = f$ and for $g = F$. Consequently,

$$J_f \subset \mathbb{D}^*_2 \quad \text{and} \quad J_F \subset \mathbb{D}^*_2.$$  

**Proof.** Let $\eta \geq 2M_0$ and $T = 4\eta$. Then, by construction of $\hat{\Omega}$,

$$f^{-1}(\mathbb{D}^*_\eta/2) \subset \hat{\Omega} + T = \varphi(\hat{\mathcal{H}}) + T \subset \mathbb{D}^*_2$$

for all models $f$. In particular $\Omega_f = f^{-1}(\mathbb{D}^*_\eta) \subset \mathbb{D}^*_2$.

Concerning $F$, if $z \in \Omega_F$ then, $|F(z)| = |F(z-T)| > \eta \geq 2M_0$ and thus the second inequality in (7.6) applies and gives

$$|f(z)| = |f(z-T)| > \eta - M_0 \geq \eta/2.$$  

This shows that $z \in f^{-1}(\mathbb{D}^*_\eta/2) \subset \mathbb{D}^*_2$. The proof is complete. \qed
7.2. Comparing the transfer operators of the model function $f$ and of the approximating entire function $F$. Let $f : \Omega \to \mathbb{C}$ be again one of our model functions and let $F$ be the approximating entire map in class $B$ produced by the above construction.

**Lemma 7.3.** There exists $R_0 \geq 4M_0$ such that for all $z \in \Omega \cap D_R^*$,

$$\frac{1}{2} \leq \frac{|F(z)|}{|f(z)|} \leq 2 \quad \text{and} \quad \frac{1}{2} \leq \frac{|F'(z)|}{|f'(z)|} \leq 2.$$  \hfill (7.7)

Consequently,

$$\frac{1}{4} \leq \frac{|F'(z)|}{|f'(z)|} \leq 4, \quad z \in \Omega \cap D_R^*.$$  \hfill (7.8)

Here, $R_0$ depends only on the constant $M_0$ from the estimate $\mathbf{(7.5)}$.

**Proof.** The estimate $\mathbf{(7.5)}$ implies

$$\left| h(z) \right| \leq 1/4 \quad \text{for} \quad \left| z \right| \geq 4M_0, \quad z \notin \mathcal{C}. \quad \text{\hfill (7.7)}$$

Since $f : \Omega = \Omega_\log r \to D_r^*$, for $z \in \Omega$ we have $|f(z)| > r \geq c^2$. Consequently,

$$\frac{|F(z)|}{|f(z)|} = \left| 1 + h(z) \right| \in \left[ \frac{15}{16}, \frac{17}{16} \right], \quad z \in \Omega \cap D_{4M_0}^*.$$  \hfill (7.9)

Passing to the derivatives, if $\Phi := h \circ \varphi$ then

$$F' = f' + h' = f' + \Phi' \circ \varphi^{-1} \circ (\varphi^{-1})'$$

and, as $f = \exp \circ \varphi^{-1}$, $f' = f \cdot (\varphi^{-1})'$. So,

$$\frac{|F'|}{|f'|} = \left| 1 + \frac{\Phi' \circ \varphi^{-1}}{f} \right| \quad \text{on} \quad \Omega.$$  \hfill (7.10)

Since $|f(z)| > 2$ in $\Omega$, the required estimate relies on the estimate of $\Phi'$. In order to estimate it, let $z \in \Omega$ and put $\xi = \varphi^{-1}(z) \in \mathcal{H}_\log r \subset \mathcal{H}_2$. Then $D_\xi := D(\xi, 1) \subset \mathcal{H}_1 \subset \varphi^{-1}(\Omega)$. This allows to make the estimate

$$|\Phi'(\xi)| = \left| \frac{1}{2\pi i} \int_{\partial D_\xi} \frac{\Phi(v)}{(v-\xi)^2} dv \right| \leq \sup_{\hat{z} \in \varphi(\partial D_\xi)} |h(z)| \quad \text{on} \quad \Omega.$$  \hfill (7.11)

In order to use the estimate $\mathbf{(7.5)}$ for the function $h$ we need to estimate $\inf_{\hat{z} \in \varphi(\partial D_\xi)} |\hat{z}|$. But this can be done by using twice the Hölder continuity property $\mathbf{(6.9)}$. It shows that $|\xi| \geq (|z|/c_2)^{1/K}$ and also that

$$|\varphi(\hat{z})| \geq c_1 |\hat{z}|^{1/K} \geq c_1 \left( (|z|/c_2)^{1/K} - 1 \right)^{1/K} \quad \text{for every} \quad \hat{z} \in \partial D_\xi.$$  \hfill (7.12)

Choose now $R_0 \geq 4M_0$ such that $c_1 ((R_0/c_2)^{1/K} - 1)^{1/K} \geq 4M_0$. Then, if $z \in D_{R_0}^*$, the corresponding $\inf_{\hat{z} \in \varphi(\partial D_\xi)} |\hat{z}| \geq 4M_0$ which enables us to conclude using $\mathbf{(7.7)}$:

$$|\Phi'(\xi)| \leq \sup_{\hat{z} \in \varphi(\partial D_\xi)} |h(\hat{z})| \leq 1/4 \quad \text{for every} \quad z \in \Omega \cap D_{R_0}^*.$$  \hfill (7.13)
which shows the required estimate of the ratio \(|F'(z)|/|f'(z)|\). The estimate for the ratio \(|F'(z)|_1/|f'(z)|_1\) follows directly, since \(|f'|_1(z) = |f'(z)| \cdot \frac{|z|}{|f(z)|}\) (and the analogous formula for \(F\)).

Assume in the following that \(R_0 \geq 4M_0\) is such that Lemma 7.3 holds and let
\[
\eta = 3 \max \left\{ M_0, \exp \left( \frac{(R_0/c_1)^K}{c} \right) \right\}.
\]
Then Lemma 7.2 applies. Also
\[
f^{-1}(D_{\eta/3}^*) \subset D_{R_0}^* \subset D_{4M_0}^*.
\]

The transfer operator has been defined in (4.2). Since we now deal with several functions we write \(L_{t,g}\) for the transfer operator of a function \(g\). We first compare the operators of an initial model \(f\) and its approximation \(F\).

**Proposition 7.4.** There exists a constant \(K \geq 1\) such that the following holds. Let \(f\) be a model as defined in Section 3, \(F\) an approximating entire function of \(f\) given by Theorem 7.1. Then
\[
\frac{1}{K} t \leq L_{t,f} \mathbb{I}(w) \leq K t \quad \text{for all } w \in D_{\eta}^*
\]
and the same holds if \(f, F\) are replaced by their disjoint type versions \(f, F\).

We thus get first examples of entire functions for which the full thermodynamic formalism holds in the particular case where \(t = \Theta\).

**Corollary 7.5.** The transition parameter \(\Theta\) is the same for the model \(f\) and for the approximating entire function \(F\). Moreover, \(F\) is also of convergence type and Theorem 6.1 as well as Remark 6.2 hence the full thermodynamic formalism, meaning that all the results in Section 8 of \([27]\), is also valid for the disjoint type entire function \(F\) for all \(t \geq \Theta\).

**Proof of Proposition 7.4.** Lemma 7.3 shows that the values of the derivatives of \(f\) and \(F\) are comparable at a given point \(z\). But, in the formulas defining the operators \(L_{t,f}\) and \(L_{t,F}\) the summation runs over preimages of a given point \(w\) under \(f\) and \(F\), respectively. So, in order to compare \(L_{t,f}(w)\) and \(L_{t,F}(w)\), the preimages of \(w\) under \(f\) and \(F\) will be “paired” and the derivatives of \(f\) and \(F\) on these paired preimages will be compared.

Let \(w \in D_{\eta}^*\). Then all preimages of \(w\) under the model map \(f\) are in \(\Omega_{\log \eta} = \varphi(\mathcal{H}_{\log \eta})\) and
\[
\sum_{z \in f^{-1}(w)} |f'(z)|^{-t} = \sum_{\xi \in \exp^{-1}(w)} \left( \frac{|\varphi'(\xi)|}{|\varphi(\xi)|} \right)^t.
\]

Take the circle \(\sigma\) centered at \(w\), with radius 1, and for each \(\xi \in \exp^{-1}(w)\) let \(\gamma_\xi\) be the preimage of \(\sigma\) under \(\exp\), surrounding \(\xi\). Finally, put \(\tilde{\gamma}_\xi = \varphi(\gamma_\xi)\).
Notice that the domain bounded by \( \tilde{\gamma}_t \) contains exactly one preimage of \( w \) under the map \( f_t \); this is the point \( z = \varphi(\xi) \).

On each curve \( \tilde{\gamma}_t \) we have that \( |f(z) - w| = 1 \), while

\[
|(|F(z) - w| - (f(z) - w)| = |h(z)| < \frac{M_0}{|z|}
\]

where \( M_0 \) comes from (7.5). From (7.10) we know that \( |z| > 4M_0 \) since \( w \in \mathbb{D}_{\eta} \subset \mathbb{D}_{\eta/3} \). Hence, the right hand inequality of (7.11) is strictly less than 1. This allows to conclude via Rouché’s Theorem that \( F \) has exactly one preimage in the region bounded by \( \tilde{\gamma}_t \). Denoting this preimage by \( \tilde{z} \), we need to compare \( |f'(z)|_1 \) and \( |F'(\tilde{z})|_1 \). But this directly follows from Koebe’s Distortion Theorem and Lemma 7.3, and the constant \( K \) in Proposition 7.4 is exactly a Koebe constant times an absolute one. This gives the first part of the required estimate, i.e.

\[
\frac{\mathcal{L}_{t,F}(w)}{\mathcal{L}_{t,F}(w)} \leq K^t
\]

The second part of the estimate can be obtained in a similar way: Let \( w \in \mathbb{D}_{\eta} \). Since \( \eta \geq 2M_0 > M_0 + 2 \), the disk \( \mathbb{D}(w,2) \) does not contain singular values of \( F \), and \( F^{-1}(\mathbb{D}(w,1)) \) is a countable union of Jordan domains \( \mathcal{D}_I \) each of them being mapped bijectively and with bounded distortion onto \( \mathbb{D}(w,1) \).

If \( z \in \mathcal{D}_I \) then \( |F(z)| \geq |w| - 1 > \eta - 1 \geq 2M_0 \). It thus follows from (7.6) that \( z \in \tilde{\Omega} \) and thus all the domains \( \mathcal{D}_I \subset \tilde{\Omega} \). Moreover, still using (7.6),

\[
|f(z)| \geq |F(z)| - M_0 > \eta - 1 - M_0 \geq \frac{2}{3}\eta - 1 \geq \frac{7}{2}
\]

since \( \eta \geq 3M_0 \geq 6 \). This allows to apply (7.10) and thus to get \( |z| \geq 4M_0 \).

On the curve \( \gamma_I \) bounding \( \mathcal{D}_I \) we have \( |F(z) - w| = 1 \), while

\[
|(|F(z) - w| - (f(z) - w)| = |h(z)| < \frac{M_0}{|z|} \leq \frac{M_0}{4M_0} = 1/4.
\]

Again, Rouche’s theorem implies that \( f \) has exactly one preimage of \( w \) in each domain \( \mathcal{D}_I \). Applying again Koebe’s Distortion Theorem and Lemma 7.3 we obtain the desired inequality:

\[
\frac{\mathcal{L}_{t,F}(w)}{\mathcal{L}_{t,F}(w)} \geq \frac{1}{K^t}.
\]

Let us finally consider the disjoint type functions \( f, F \). If \( z, \tilde{z} \) is a pair of preimages under \( f, F \) then, clearly, \( z = z + T, \tilde{z} = \tilde{z} + T \) is a pair of preimages of \( f \) and \( F \) respectively and we have

\[
\frac{|f'(z)|_1}{|F'(\tilde{z})|_1} = \frac{|f'(z)|_1}{|F'(\tilde{z})|_1} \left| \frac{z - \tilde{z} - T}{\tilde{z}} \right| \times \frac{|f'(z)|_1}{|F'(\tilde{z})|_1} \left| \frac{z - T}{\tilde{z}} \right|
\]

with involved multiplicative constants independent of the functions, of the point \( w \in \mathbb{D}_\eta \) and of the pair of preimages. This clearly completes the proof of Proposition 7.4. \( \square \)
There is also a relation between the transfer operator of the functions and their disjoint type version.

**Lemma 7.6.** Let $A = 1 + \frac{T}{\eta^4}$. Then

$$\frac{1}{A^t}L_{t,f}(w) \leq L_{t,f}(w) \leq A^tL_{t,f}(w) \quad \text{on} \quad \mathbb{D}_*^r.$$

**Proof.** This follows from an elementary estimation based on (3.11) and on (7.12)

$$|f'(z)|_1 = |f'(z - T)|_1 \frac{|z|}{|z - T|}, \quad z \in \Omega_t = f^{-1}(\mathbb{D}_*^r).$$

\[\square\]

### 8. Topological pressure and Bowen’s Formula

Let $f$ be a disjoint type model or entire function and consider again $L_t = L_{t,f}$ its transfer operator. By Theorem 8.1 of [27] the limit

$$P(t) = P_f(t) = \lim_{n \to \infty} \frac{1}{n} \log L_{t^n}(w)$$

exists and, by bounded distortion, it does not depend on $w \in \mathbb{D}_*^r$ (for $r$ sufficiently large). This limit is called topological pressure and for a convergence type function the pressure $P(\Theta)$ is finite. The basic properties is that $t \mapsto P(t)$ is a convex and strictly decreasing function on $(\Theta, \infty)$ with $P(t) = \infty$ if $t < \Theta$, $P(t)$ is finite if $t > \Theta$ and $\lim_{t \to \infty} P(t) = -\infty$. Consequently, the map $t \mapsto P(t)$ has a unique zero $h > \Theta$ provided there exists $t > \Theta$ such that $P(t) > 0$.

We refer to [24] for the notion of Hölder tract. All what is needed here is that the tracts of our examples have this property since they are quasidisks.

**Proposition 8.1.** Assume that the disjoint type entire function $f$ has only one logarithmic tract, assume that this tract is Hölder. Then

$$HypDim(f) = \inf \{t > 0, \ P(t) < 0\}.$$  

**Proof.** Consider first the case that $P(t) > 0$ for some $t > \Theta$ in which case the pressure has a unique zero $h > \Theta$. The assumptions on $f$ imply that [27] applies to them and, in this case, the statement in Proposition 8.1 is exactly the Bowen’s Formula in [27] which states that

$$HypDim(f) = h > \Theta.$$  

It remains to consider the case where $P(t) \leq 0$ for $t > \Theta$ and, clearly, $P(t) = \infty$ for $t < \Theta$. We then have to show that

$$HypDim(f) = \Theta.$$  

The Hölder tract assumption along with [24] gives $HypDim(f) \geq \Theta$ no matter how $P$ behaves. For the other inequality, let us first recall that the thermodynamic formalism of [27] applies to $f$ for every parameter $t > \Theta$. In particular, there exists $e^{P(t)}$–conformal measure which allows to employ
Lemma 8.1 in [25]. This Lemma gives the required estimate since it shows that $\text{HypDim}(f) \leq t$ whenever $P(t) \leq 0$. □

9. Convergence type entire functions with positive pressure

For the models of the previous section the topological pressure, introduced in (8.1), is finite for every $t \geq \Theta$ but certainly we may have $P(\Theta) < 0$. Here we consider the disjoint type versions of the models given by Example 3,2 and show that they have positive pressure for $t = \Theta$ and even for slightly larger values of $t$ provided the number $N$ in Example 3,2 has been chosen sufficiently large. We then also show that this property is true for the disjoint type approximating entire functions.

We recall that the models of Example 3,2 are special cases of those of Example 3,1. Therefore, they are of convergence type with $\Theta = \log 4 / \log 3$ and Theorem 6.1 applies.

Proposition 9.1. Let $f$ be a model of Example 3,2 and let $\Theta = \log 4 / \log 3$. Then there exists $t > \Theta$ such that

$$P_g(t) > 0$$

provided $N$ is sufficiently large where $g = f$, the disjoint type version of $f$, and also if $g = F$, the disjoint type version of the entire function $F$ approximating $f$.

Proof. First, we establish an auxiliary estimate for the initial model function $f$. We shall prove that, choosing sufficiently large $N$ in the model in Example 3,2, one can find $S > \eta$ such that

$$(9.1) \quad \mathcal{L}_{t,f}(\mathbb{D}_{S^*})(w) \geq 2A^t \quad \text{for every} \quad \eta \leq |w| \leq S$$

and for some $t > \Theta$, where $S^* = S - T$ and with $A$ from Lemma 7.6.

In order to establish (9.1), let $N \geq 1$ be maximal such that $2^N \leq S$, and let $M$ be determined by the inequality $2^{M-1} < T \leq 2^M$. Consider any $w \in \mathbb{D}_S \cap \mathbb{D}^*_\eta$ and set $x = \log |w| \in [\log \eta, \log S]$ where $\eta$ is given by (7.9). Let $j \geq 0$ be again the maximal integer such that $\mu^{j-1} \leq x$. Notice that

$$(9.2) \quad j \leq \log(\log S) \sim \log N.$$  

We have to estimate $\mathcal{L}_t(\mathbb{D}_{S^*})(w)$ and, in order to do so, we first describe the preimages $z \in f^{-1}(w)$ that are in the disk $\mathbb{D}_{S^*}$. We have $z = \varphi(\xi) = \psi(h(\xi))$ where $\xi = x + iy$ and where $y \in I_{n+j}$ for some $n \geq 0$. Selfsimilarity of $\psi$ (Lemma 3.5) yields

$$z = 2^{n+j} \psi \left( \mu^{-(n+j)} h(\xi) \right).$$

On the other hand, $|h(\xi)| \asymp |\xi| \asymp \mu^{n+j}$ since $h'(\infty) = 1$ (see Proposition 12.2, and thus $|\psi(\mu^{-(n+j)} h(\xi))| \leq 1$ and $|z| \leq 2^{n+j}$. Denote by $c$ the constant in the last inequality, meaning that it becomes $|z| \leq c 2^{n+j}$. Then, by the choice of $N$, we see that $z \in \mathbb{D}_{S^*}$ if $c 2^{n+j} < 2^N - 2^M$. This is the case
if \( n < N - j + (\log(1 - 2^{M - N}) - \log c) / \log 2 \) and since we will take \( N \) large, it thus suffices to have \( n \leq N/2 \).

Given this discussion on the preimages of \( w \), we get out of the expression of \( \mathcal{L}_t \) in Proposition \ref{prop:failure_of_ruelle_property_for_entire_functions} that

\[
\mathcal{L}_{t,f}(\mathbb{D}_{S'})(w) \geq x^{1-t} \sum_{n=1}^{[N/2]} \left\{ \left( 1 + \frac{n + j}{x} \right)^{1-t} \sum_k (\text{diam } W_{n,k})^t \right\}
\]

\[
\geq N^{1-t} \sum_{n=1}^{[N/2]} \left\{ (1 + N)^{1-t} \sum_k (\text{diam } W_{n,k})^t \right\}
\]

\[
\geq N^{2(1-t)} \sum_{n=1}^{[N/2]} \sum_k (\text{diam } W_{n,k})^t.
\]

The sets \( W_{n,k} \) can now be replaced by the covering \((W_{m,l})\) precisely like we did in the proof of Theorem \ref{thm:failure_of_ruelle_property_for_entire_functions}. More precisely, we use \((6.3)\) with the difference that we deal here with a finite sum:

\[
B_* C^t \sum_{n=1}^{[N/2]} \sum_k (\text{diam } W_{n,k})^t \geq \sum_{(m,l) \in I_{\text{finite}}} (\text{diam } W_{m,l})^t
\]

and we must specify the new set of indices \( I_{\text{finite}} \) over which the summation goes. In order to do so, we recall first that the sets \( W_{n,k} \) cover \( V_{int} = \psi(U_{int}) \). Therefore, if \((m,l)\) is such that \( W_{m,l} \cap V_{int} \neq \emptyset \) then there exists \((n,k)\) such that \( W_{m,l} \cap W_{n,k} \neq \emptyset \) and then, by Lemma \ref{lem:failure_of_ruelle_property_for_entire_functions_3} \( n \leq m/b \). We can thus take

\[
I_{\text{finite}} = \{(m,l) \in I_{\text{finite}} \mid (m,l) \cap V_{int} \neq \emptyset \text{ and } m_0 \leq m \leq b[N/2]\}
\]

where \( m_0 \) comes from Lemma \ref{lem:failure_of_ruelle_property_for_entire_functions_3}

By \((5.2)\) of Lemma \ref{lem:failure_of_ruelle_property_for_entire_functions_3} for every \( m \geq m_0 \) the number of indices \((m,l)\) in \( I_{\text{finite}} \) is comparable to \( 4^m \). Also, \( \text{diam } W_{m,l} \asymp l_m \) and for the models of Example \ref{ex:failure_of_ruelle_property_for_entire_functions} we have \( l_m = (\frac{1}{e})^m \) if \( 1 \leq m \leq N \). Consequently, if \( N \) is large enough, we get all in all

\[
(9.3) \quad \mathcal{L}_{t,f}(\mathbb{D}_{S'})(w) \geq N^{2(1-t)} \sum_{m=m_0}^{b[N/2]} 4^m \left( \frac{1}{e} \right)^{mt} \times N^{2(1-t)} \left( \frac{4}{e^t} \right)^{bN/2}
\]

which is arbitrarily large provided we take \( \Theta < t < \log 4 / \log e = \log 4 \) and provided that \( N \) is sufficiently large.

Coming now to the associated disjoint type model \( f \), and using Lemma \ref{lem:failure_of_ruelle_property_for_entire_functions_4} we can translate the estimate \((9.1)\) to the case of \( f \) as follows:

\[
(9.4) \quad \mathcal{L}_{t,f}(\mathbb{D}_{S})(w) \geq 2 \quad \text{for every} \quad \eta \leq |w| \leq S
\]

Indeed, if \( w \in \mathbb{D}_{S}^0 \cap \mathbb{D}_{S} \) and if \( f(z) = w \) then \( f(z) = w \) where \( z = z + T \). Moreover, if \( z \in \mathbb{D}_{S'} \) then \( z \in \mathbb{D}_{S} \). Combining now \((9.1)\) with the estimate in Lemma \ref{lem:failure_of_ruelle_property_for_entire_functions_5} we obtain directly the required \((9.4)\).
But now, since \( f \) is of disjoint type, and, in particular \( f^{-1}(\mathbb{D}_g^*) \subset \mathbb{D}_g^* \) (9.4) allows us to conclude inductively:

\[
\mathcal{L}_{t,F}(w) \geq \mathcal{L}_{t,F}(\mathbb{I}_{DS} \mathcal{L}_{t,F}(\mathbb{I}_{DS} \ldots \mathcal{L}_{t,F}(\mathbb{I}_{DS}))) (w) \geq 2^n \quad \text{for every} \quad n \geq 1.
\]

Therefore, \( P_t(t) > 0 \).

It remains to verify that the entire function \( F \) also has positive pressure. Proposition 7.4 compares the operators of \( f \) and \( F \) but with transfer operators applied to the constant function \( \mathbb{I} \) and we have to replace it by \( \mathbb{I}_{DS} \). So let \( w \in \mathbb{D}_S \cap \mathbb{D}_g^* \), consider a pair of preimages \( z, \tilde{z} \) of \( w \) under \( f, F \) respectively defined exactly like in the proof of Proposition 7.4. Then \( z = z + T, \tilde{z} = \tilde{z} + T \) are corresponding preimages of \( w \) under \( f, F \) respectively. It is explained in this proof that, given \( z \in f^{-1}(w) \), there exists a unique \( \tilde{z} = \tilde{z}(z) \in F^{-1}(w) \) which is in the region bounded by \( \varphi(\gamma_\xi) \). An elementary estimation shows that \( diam(\gamma_\xi) \leq \frac{2}{n} \). Since \( \varphi \) fixes the origin and is uniformly quasisymmetric, it follows that there exists a constant \( K \geq 1 \) such that

\[
\tilde{z}(z) = \varphi(\gamma_\xi) \subset \varphi(\mathbb{D}_{|\xi|+\frac{2}{n}}) \subset \mathbb{D}_K|\varphi(\xi)| = \mathbb{D}_K^*|z|.
\]

If again \( S' = S - T \) then

\[
F^{-1}(w) \cap \mathbb{D}_{S'} \supset \{ \tilde{z} = \tilde{z}(z), \ |z| < S'/K \quad \text{and} \quad f(z) = w \}.
\]

Since Lemma 7.6 in fact (7.12), is also valid for \( F, F \) instead of \( f, f \), we get

\[
\mathcal{L}_{t,F}(\mathbb{I}_{DS})(w) \geq A^{-t} \mathcal{L}_{t,F}(\mathbb{I}_{DS})(w) \geq A^{-t} \sum_{\tilde{z}(z), f(z) = w} |F'(\tilde{z})|^{-t} \geq \mathcal{L}_{t,F}(\mathbb{I}_{DS'/K})(w), \ w \in \mathbb{D}_S \setminus \mathbb{D}_g^*,
\]

the last inequality resulting from the proof of Proposition 7.4. In conclusion, in order to get (9.1) for the function \( F \) it suffices to adjust the number \( N \) so large such that \( \mathcal{L}_{t,F}(\mathbb{I}_{DS'/K}) \) is sufficiently large on \( \mathbb{D}_S \setminus \mathbb{D}_g^* \) which is possible because of (9.3).

\[\square\]

10. Proof of Theorem 1.1

Let \( f \) be a model such that the associated disjoint type entire function \( F \) has positive pressure (Proposition 9.4). Consider the analytic family of entire functions:

\[
F_\lambda = \lambda F, \quad \lambda \in \mathbb{C}^*.
\]

**Proposition 10.1.** The functions \( F_\lambda, 0 < \lambda \leq 1 \) do all belong to the same hyperbolic component of the parameter space of \( (F_\lambda)_\lambda \).

**Proof.** By Lemma 7.2 the tract \( \Omega_1 \) of \( F_1 \) satisfies \( \Omega_1 = F_1^{-1}(\mathbb{D}_g^*) \subset \mathbb{D}_g^* \). Clearly, for every \( \lambda \in \mathbb{D} \setminus \{0\}, \Omega_\lambda = F_\lambda^{-1}(\mathbb{D}_g^*) \subset \Omega_1 \) and thus \( \Omega_\lambda \subset \mathbb{D}_g^* \). Therefore, all the functions \( F_\lambda, \lambda \in \mathbb{D} \setminus \{0\} \), are of disjoint type and thus hyperbolic.
It remains to find a simply connected domain \( V \subset \mathbb{C} \setminus \{0\} \) that contains \((0,1]\) along with a holomorphic motion \((\varphi_\lambda)_{\lambda} \in V\), that identifies the Julia sets and conjugates the dynamics of \(F_1\) and \(F_\lambda\). But this has been shown in Section 3 of the paper [33] by Rempe.

**Proposition 10.2.** There exists \(0 < l_0 < 1\) such that 
\[
P_{F_\lambda}(\Theta) < 0
\]
for every \(0 < |\lambda| \leq l_0\).

**Proof.** Again by Lemma 7.2 \(F_\lambda^{-1}(D^*_{\eta}) \subset D^*_{2\eta}, \lambda \in \mathbb{D} \setminus \{0\}\). In particular, \(J_{F_\lambda} \subset D^*_{2\eta}\) for all these parameters and it suffices to study the transfer operator on \(D^*_{\eta}\).

Notice that \(L_{t,F_1}I(w) = L_{t,F}I(w/\lambda)\) for every \(w \in \mathbb{D}^*_{\eta}\). On the other hand, Proposition 7.4 and Lemma 7.6 imply for the operator of the generating function \(F = F_1\)
\[
L_{t,F}I \leq K^t L_{t,f}I \leq (AK)^t L_{t,f}I
\]
still on \(D^*_{\eta}\). Moreover, we have Theorem 6.1 which implies, for every \(t \geq \Theta\),
\[
L_{t,f}I(w) \leq M^t(\log |w|)^{1-t}, \quad w \in \mathbb{D}^*_{\eta}.
\]
Combining all these relations and taking \(t = \Theta\) we get
\[
L_{\Theta,F_\lambda}I(w) = L_{\Theta,F}I(w/\lambda) \leq (AKM)^t \left(\log(\eta/l_0)\right)^{1-t}
\]
for every \(w \in \mathbb{D}^*_{\eta}\) and every \(0 < |\lambda| \leq l_0\). It suffices now to choose \(l_0\) small enough in order to conclude this proof since \(t = \Theta = \log 4/\log 3 > 1\).

**Proof of Theorem 11.1.** Given Proposition 10.1 it remains to show that the hyperbolic dimension does not vary analytically. We know from Proposition 9.1 that \(P_{F_1}(t) > 0\) for some \(t > \Theta = \log 4/\log 3\). In this case, the Bowen’s Formula in Proposition 8.1 shows that
\[
\text{HypDim}(F_1) > \Theta.
\]
On the other hand, \(P_{F_\lambda}(t) < 0\) for all \(\lambda \in (0,l_0]\) where \(l_0\) comes from Proposition 10.2. Again Proposition 8.1 shows then that
\[
\text{HypDim}(F_\lambda) = \Theta \quad \text{for every} \quad 0 < \lambda \leq l_0.
\]
Consequently, \(\lambda \mapsto \text{HypDim}(F_\lambda)\) is not an analytic function.

**11. Irregular hyperbolic functions in Class \(\mathcal{B}\)**

In this section we proof Theorem 1.2, 1.3 and 1.4. First of all, all our examples share the particular value \(\Theta = \log 4/\log 3\). But clearly the snowflake construction can be modified in order to get functions with the same behavior and with \(\Theta\) any value in \([1,2]\). The only modification is the choice of the
numbers $\rho_n \in [\rho_{\min}, \rho_{\max}]$ where then $\rho_{\min}, \rho_{\max}$ have to be fixed such that (3.3) is replaced by

$$\frac{1}{4} < \rho_{\min} < \left(\frac{1}{2}\right)^{2/\Theta} < \rho_{\max} < \frac{1}{2}.$$ 

So, we can restrict the discussion here to the particular value $\Theta = \log 4 / \log 3$.

We directly get from Proposition 10.2 functions that fulfill the requirements of Theorem 1.2. Combining it with the Bowen’s Formula of Proposition 8.1, Theorem 1.3 also follows. The remaining point is to show the affirmation concerning the conformal measure in Theorem 1.4.

In view of establishing it we need some preliminary considerations on the choice of the Riemannian metric and to clarify the notion of conformal measure. Up to now we have used the cylindrical metric in order to evaluate the derivatives (see (4.1)). This choice is related to the logarithmic coordinates in [17] and it allows to get a bounded transfer operator as defined in (4.2). However, it is sometimes more convenient to make a different choice. For example, employing the spherical metric allowed the authors in [7] to get the most general Bowen’s Formula.

Consider a general Riemannian metric $d\rho(z) = \rho(z)|dz|$ on $\mathbb{C}$, denoted by $|f'|_\rho = |f'|_{\rho}\frac{\rho(z)}{z}$ the derivative with respect to it and let us have in mind the particular choices

$$d\rho_{cyl}(z) = \frac{|dz|}{|z|} \quad \text{and} \quad d\rho_{sph}(z) = \frac{|dz|}{1 + |z|^2}.$$ 

The cylindrical metric as written has a singularity at the origin, a problem that we can neglect since we work far away from it especially in the case of disjoint type functions.

**Definition 11.1.** Let $f$ be an entire function. A finite measure $\nu$ is said to be $t$–conformal with respect to the metric $\rho$ if for every Borel set $A \subset \mathbb{C}$ such that $f|_A$ is injective we have

$$\nu(f(A)) = \int_A |f'|_\rho^t d\nu.$$ 

As defined, such a measure is sometimes also called geometric conformal measure since such a measure is commonly used to analyse the geometry of the Julia set.

The topological pressure with respect to the cylindrical metric has been defined in (8.1). If $L_{\rho,t}$ denotes the operator defined by Formula (4.2) but with $|f'|_\rho$ replaced by $|f'|$ and if we inject this operator in (8.1) then this defines the topological pressure with respect to the metric $\rho$:

$$P_{\rho}(t) = P_{\rho,f}(t) = \lim_{n \to \infty} \frac{1}{n} \log L_{\rho,t}^n(w), \quad w \in \mathbb{D}_{\rho}.$$ 

A priori, the transition parameter $\Theta_{\rho} = \inf\{t > 0 : P_{\rho}(t) < \infty\}$ can depend on the metric. In the case of the cylindrical or spherical metric we also
write $P_{cyl}, \Theta_{cyl}$ respectively $P_{sph}, \Theta_{sph}$. Recall that for our examples $\Theta_{cyl} = \log 4/\log 3$ and, right from the definition of the pressures, it is clear that

$$P_{sph}(t) \leq P_{cyl}(t)$$

hence $\Theta_{sph} \leq \Theta_{cyl}$. Given these notations, we can now show the following result which contains Theorem 1.4.

**Theorem 11.2.** For every $1 < \Theta < 2$ there exists a disjoint type entire function $f \in \mathcal{B}$ with transition parameter $\Theta$, with $HypDim(f) = \Theta$ and which does not have a spherical nor cylindrical conformal measure supported on its radial Julia set.

**Proof.** Again, we treat the case $\Theta = \Theta_{cyl} = \log 4/\log 3$. Let $f = F_{0}$ be the disjoint type entire function from Proposition 10.2. This function has negative cylindrical pressure at $\Theta_{cyl}$ and thus

$$P_{sph}(\Theta_{cyl}) \leq P_{cyl}(\Theta_{cyl}) < 0.$$

Bowen’s Formula (Proposition 8.1) implies then that $\Theta_{cyl} = HypDim(f)$. We also dispose in the same Bowen’s Formula with respect to the spherical metric ([9]) so that

$$\Theta_{cyl} = HypDim(f) = \inf\{t > 0, \ P_{sph}(t) < 0\}.$$\n
Combined with (11.1) and with the continuity of $t \mapsto P_{sph}(t)$ on $]\Theta_{sph}, \infty[$ we get that

$$\Theta_{cyl} = \Theta_{sph}$$

and thus $P_{sph}(t) < 0$ for $t \geq \Theta_{sph}$ and $P_{sph}(t) = \infty$ if $t < \Theta_{sph}$.

Now, assume that this map $f$ has a spherical $t$–conformal measure supported on $J_{r}(f)$ for some $t > 0$. Then necessarily $t \geq \Theta_{sph}$ and $P_{sph}(t) = 0$ by Theorem A in [8]. But this is not possible as we have seen just above and thus such a conformal measure cannot exist.

The analogue for the cylindrical conformal measure also follows. Indeed, assume that $\nu$ is a cylindrical $t$–conformal measure supported on $J_{r}(f)$ for some $t > 0$. Then

$$dm = \left(\frac{|z|}{1 + |z|^{2}}\right)^{t} d\nu$$

would define a finite spherical $t$–conformal measure supported on $J_{r}(f)$. But such a measure cannot exist if $P_{sph}(t) < 0$ (see Proposition 3.3 in [8]). □

12. **Appendix**

Throughout the paper we used good bilipschitz properties of $h$ and of the rescaled functions $h_{m} = \mu^{m} \circ h \circ \mu^{-m}$. They follow from the fact that $h'$ has continuous extension to the boundary and this follows from the smoothness of the boundary of $\mathcal{H}$. Indeed, the relation between continuous extension of the derivative of a conformal map to the boundary and the geometry of the boundary is the object of Section 3 in Pommerenke’s book [31]. The relevant fact for our application is that the derivative of a conformal map from the
unit disk $\mathbb{D}$ onto the inner domain of a Jordan curve $C \subset \mathbb{C}$ has continuous extension to the boundary if $C$ is Dini-smooth (see Theorem 3.5 in [31]). This means that $C$ admits a parametrization $\alpha : \mathbb{S}^1 = \{|z| = 1\} \to C$ whose derivative $\alpha'$ is Dini-continuous:

$$\int_0^{\pi} t^{-1} \omega(t, \alpha', \mathbb{S}^1) \, dt < \infty$$

where the modulus of continuity $\omega$ of $\alpha'$ on a set $A$ is defined by

$$\omega(t, \alpha', A) = \sup \left\{ |\alpha'(\xi_1) - \alpha'(\xi_2)| : |\xi_1 - \xi_2| \leq t, \xi_1, \xi_2 \in A \right\}.$$  

The domain $\hat{H}$ and a boundary parametrization $\gamma$ has been defined in (3.1). In fact, $\partial \hat{H} = \{ \sigma(y) + iy : y \in \mathbb{R} \}$. Since $\sigma$ is $C^\infty$–smooth we only have to check what happens near infinity. In order to do so, consider $\alpha : I = [-1/2, 1/2] \to \mathbb{R}$ defined by $\alpha(0) = 0$ and

$$\alpha(t) = \frac{1}{\sigma(1/t) + i/t}, \quad 0 < |t| \leq 1/2.$$

**Lemma 12.1.** The domain $\hat{H}$ is Dini-smooth.

**Proof.** The function $\alpha \in C^1$ with $\alpha'(0) = -i$ and

$$\alpha'(t) = \frac{i - 14t}{(14t \log |t| - 7t + i)^2}, \quad 0 < |t| \leq 1/2.$$  

Given this derivative, a direct calculation gives for the modulus of continuity $\omega(t, \alpha', I) = O(t \log 1/t)$ which shows that $\int_0^{1/2} \frac{\omega(t, \alpha', I)}{t} \, dt < \infty$. □

Theorem 3.5 in [31] therefore applies and gives that the derivative of $\tilde{h}$ defined by $\tilde{h}(z) = 1/h(1/z)$ has continuous extension to the boundary of the inverse of the domain $\hat{H}$. In particular $\tilde{h}'(0)$ exists and in fact $\tilde{h}'(0) = 1$ because this corresponds to the normalization $h'(\infty) = 1$ that we assumed in Section 3.

Remember that we introduced the rescaled maps

$$h_m = \mu^{-m} \circ h \circ \mu^m : \hat{H}_m \to \hat{H}$$

in Section 4.2.

**Proposition 12.2.** $|h'| \asymp 1$ and $|h'_m| \asymp 1$ uniformly in $m$ and $h : \hat{H} \to \hat{H}$ and the maps $h_m : \hat{H}_m \to \hat{H}$ are uniformly bilipschitz. Moreover, when restricted to $\hat{H}_m \cap \{ |z| \geq \mu^{-2} \}$, then the bilipschitz constant $L_m$ of the maps $h_l, l \geq m$, satisfies $L_m \to 1$ as $m \to \infty$. Finally,

$$h_m \to \text{Id}_{\hat{H}} \quad \text{as} \ m \to \infty.$$  

**Proof.** The assertion on the derivatives holds since we checked that the domain $\hat{H}$ is Dini-smooth (Lemma 12.1) which then allows to apply Theorem 3.5 in [31]. From this we also get the bilipschitz property since the domains $\hat{H}$ and $\hat{H}_m$ have sufficiently good convexity properties and $L_m \to 1$ results from $h'(\infty) = 1$. 

Concerning the last statement, consider \( h_m^{-1} : \mathcal{H} \to \mathcal{H} \) and let \( g = \lim_{j \to \infty} h_m^{-1} : \mathcal{H} \to \mathcal{H} \) be the limit of a convergent subsequence. Then \( |g'| = 1 \) in \( \mathcal{H} \) and so \( g \) is non-constant, hence a conformal self map of \( \mathcal{H} \). Again since \( |g'| = 1 \) in \( \mathcal{H} \) and since \( h_m(0) = 0 \) for every \( m \geq 1 \), \( g \) is the identity map. □

Lemma 12.3.

\[
\frac{|y|}{L_m} \leq |\Im(h_m(r + iy))| \leq L_m|y| \quad \text{for all} \quad y \in \mathbb{R} \quad \text{and} \quad r > 0.
\]

Proof. Remember that \( \overline{h(z)} = h(\overline{z}) \), \( z \in \mathcal{H} \). This symmetry implies that \( h([0, \infty)) = [0, \infty) \) and thus Lemma 12.3 follows directly from the fact that \( h_m \) is \( L_m \)-bilipschitz. □
