Aspergillus niger, one of the most common and important fungal species, is ubiquitous in various environments. A. niger isolates possess a large number of cryptic biosynthetic gene clusters (BGCs) and produce various biomolecules as secondary metabolites with a broad spectrum of application fields covering agriculture, food, and pharmaceutical industry. By extensive literature search, this review with a comprehensive summary on biological and chemical aspects of A. niger strains including their sources, BGCs, and secondary metabolites as well as biological properties and biosynthetic pathways is presented. Future perspectives on the discovery of more A. niger-derived functional biomolecules are also provided in this review.

Keywords: Aspergillus niger, secondary metabolite, bioactivity, biosynthesis, application

INTRODUCTION

Aspergillus, one sizeable genus belonging to Aspergillaceae family, comprises as many as 492 species registered on the database of the National Center for Biotechnology Information (NCBI) to date. Its section Nigri is an important group of species, and the A. niger aggregate represents its most complicated taxonomic subgroup with eight morphologically indistinguishable taxa (Perrone et al., 2011). Owing to superior adaptability and survivability, A. niger is ubiquitous in nature, including in terrestrial soil (Xie et al., 2006), ocean (Li et al., 2016; Uchoa et al., 2017), the Arctic (Singh et al., 2011), and space. It also occupies a wide spectrum of habitats in plants and animals such as herb (Shreelalitha and Sridhar, 2015; Manganyi et al., 2018), shrub (Kaur et al., 2015; Liu et al., 2016), tree (Soltani and Moghaddam, 2014; Wang et al., 2019), lichen (Elissawy et al., 2019), shrimp (Liu et al., 2013; Fang et al., 2016), and marine sponge (Takano et al., 2001; Hiort et al., 2004). A. niger strain grows well in various media with different carbon sources, including glucose, bran, maltose, xylan, xylose, sorbitol, and lactose (Toghueo et al., 2018). However, its metabolism is remarkably affected by culture conditions, such as medium composition and fermentation mode.

The genome features of strain L14 are summarized in a polycyclic graph (Figure 1), which consists of in-paralog pair, GC skew, widely, SM biosynthetic gene cluster (BGC), ncRNA, repeat, strand coding sequence (CDS) annotation, and scaffold. There are some in-paralog pairs between different scaffolds, and SM BGCs and CDS distributed widely in genome. As shown in Table 1, genome sizes of WT A. niger strains range from 33.8 to 36.1 Mb. Their G + C% and gene numbers are closely similar, while the numbers of scaffolds are different owing to various sequencing and assembling manners. The antibiotics and Secondary Metabolite Analysis Shell (antiSMASH) results indicated that each WT A. niger strain harbors at least 20 cryptic SM BGCs, including PKS, NRPS, NRPS-like, and their hybrids (Figure 2 and Supplementary Table S1) (Blin et al., 2019). These BGCs involving in indole and terpene biosynthesis are ubiquitous and have great potential to synthesize therapeutical agents and pesticides, such as AbT1, azanigerone A, fusarin, ferrichrome, nidulanin A, melanin, TAN-1612, yanuthone D, and aflavarin (Supplementary Table S2).
It is a matter of controversy that some A. niger isolates are renowned for biosynthesis of valuable natural products of nutritional, agrochemical, and pharmaceutical interest, while others are reputed to cause the "black mold" disease (Hayden et al., 1994; Ozer and Koycu, 2006) and produce a plethora of mycotoxins (Sanchez et al., 2012). A. niger possesses a bulk warehouse of prolific genes, which involve in regulation of primary and secondary metabolisms (Pel et al., 2007). A genome-scale metabolic network for A. niger has been established on account of its high efficiency in rational metabolic design and systems biology studies, such as strain improvement and process optimization (Sun et al., 2007; Lu...
TABLE 1 | General genomic features of 12 Aspergillus niger strains from NCBI database.

Yu et al. Secondary Metabolites From Aspergillus niger

et al., 2017). Numerous A. niger strains have been applied in many fields for a long time. For instance, citric acid as one of incredible organic acids in food industry had been produced on a large scale by A. niger 100 years ago (Cairns et al., 2018; Li et al., 2020). It is important that A. niger is one of the excellent producers of valuable proteases, which had been widely used as detergents and food ingredients and additives, such as acetylserine, amylase, fucosidase, glucose oxidase, glucosidase, mannanase, phospholipase, phytase, prolyl endopeptidase, triacylglycerol lipase, trehalase, and xylanase. In addition, numerous chemical studies have indicated that A. niger is one of the rich sources of bioactive SMs, with great potential application in agriculture and medicine. Moreover, endoxylanase isozymes of A. niger have great potential transforming lignocellulose in pulp and paper industry as industrial bleaching aids (Duarte and Costaferreira, 1994). Furthermore, A. niger is also able to deal with the phenolic contaminants in waste water of fermentation broth from industry (Duarte and Costaferreira, 1994). Since genetic engineering is inefficient for fully exploiting in the filamentous fungi industry, a CRISPR (clustered regularly interspaced short palindromic repeats–Cas9 system had been developed (Nødvig et al., 2015; Nødvig et al., 2018). Based on these genome-editing toolbox, gene inactivation and knockout, gene insertion, base editing, promoter replacement, and regulation of gene expression in A. niger have come true. In the future, more important may be focused on traceless gene editing, multiple gene editing and fine regulation of gene expression in A. niger.

SECONDARY METABOLITES FROM ASPERGILLUS NIGER

By extensive search on the database of Dictionary of Natural Products (DNP), as many as 166 A. niger–derived secondary metabolites (1–166) were detected till 2020. On the basis of chemical structures, these chemicals are grouped into five types: pyranone, alkaloid, cyclopentapeptide, polyketide, and sterol and, respectively, introduced as follows. (More detailed information about these substances is provided in the Supplementary Materials (Supplementary Table S3).)

Pyranones γ-Naphthylpyrdarone Monomers

Pyranone derivatives are the most isolated SMs from A. niger, including γ-naphthylpyrdarones (1–31), α-pyranones (32–56), and γ-pyranones (57–60). A. niger–derived naphthylpyrdarones are sorted into two classifications: monomers and dimers, with linear and angular naphtho-γ-pyrones. Fonsecin (1) is one of the most frequently isolated γ-naphthylpyrdarone produced by several A. niger strains from various sources, including terrestrial soil (Sakurai et al., 2002), marine (Leutou et al., 2016; Zhou et al., 2016), and plants (Bouras et al., 2005; Fernand et al., 2017; Akinfala et al., 2020). Biological tests suggested that compound 1 possesses dose-dependent inhibitory effect on the interleukin-4 (IL-4) signal transduction and stronger radical scavenging activity against 2,2-diphenyl-1-picrylhydrazyl (DPPH) than ascorbic acid (Sakurai et al., 2002; Leutou et al., 2016). Two analogs TMC-256A1 (3) and TMC-256C1 (8) also effectively inhibited the IL-4 driven luciferase (Sakurai et al., 2002). However, fonsecin B (2) and ningeraasperone A (4) exhibited weak bioactivity against luciferase and DPPH. 
γ-Naphthylpyradone Dimers

A. niger-derived dimeric naphthylpyradones (10–31) consist of two monomers with linear and/or angular structures. It is interesting that most of these bis-naphtho-γ-pyrones were produced by symbiotic A. niger strains. Chemical investigation of eight A. niger strains led to isolation of the same SM aurasperone A (10) (Tanaka et al., 1966; Tanaka et al., 1972; Akiyama et al., 2003; Zhang et al., 2007b; Fang et al., 2016; Li et al., 2016; Wang et al., 2018; Padhi et al., 2020), which possessed a broad spectrum of bioactivities including moderate cytotoxicity (Fang et al., 2016; Padhi et al., 2020), strong antimicrobial effect (Lu et al., 2014; Padhi et al., 2020), and xanthine oxidase (XO) inhibitory and anti-hyperuricosuric activity (Song et al., 2004). Aurasperone B (15) had potent radical scavenging activity against DPPH with an IC₅₀ value of 0.01 μM (Leutou et al., 2016). Marine strain SCSIO Jcs6F30 was a prolific producer of asperpyrone-type bis-naphtho-γ-pyrones (BNPs) 10, 13–16, 18, 20–22, 24, and 27, among which compounds 13, 16, and 20 exhibited remarkable inhibitory effects on COX-2 (Fang et al., 2016). In addition to nigerasperone A (4), two dimeric naphthylpyradones nigersperones B (29) and C (19) were obtained from strain EN-13 and shown to exhibit a moderate radical scavenging effect on DPPH (Zhang et al., 2007b). Bioassay-guided fractionation of the crude extract of strain AKRN associated with Entandrophragma congoense afforded a new antibacterial naphtho-γ-pyrene dimer 2-hydroxydihydronigerone (30) (Happi et al., 2015).

One possible pathway for biosynthesis of γ-naphthylpyradone derivatives had been first proposed by Obermaier and Muller (2019). As shown in Figure 3, one acetyl-CoA and six malonyl-CoA clusters were used as substrates for the biosynthesis of compounds 1–3 and 8 by successive catalytic reactions in a nonreducing PKS (nrPKS) system. Two of these monomers further dimerized at various carbon positions (C-6, C-7, C-9, or C-10) and resulted in the formation of dimers 16, 21, 27, and 28. Lately, one nrPKS gene D8.t287 responsible for the biosynthesis of the initial precursor heptaketone was identified and characterized by target gene knockout experiment and UPLC-MS analysis (Hua et al., 2020). However, the role of the gene AunB or BfoB is not confirmed so far.

α-Pyrones

A. niger-derived α-pyrones contain 14 monocyclic compounds (32–40, 50), 7 dicyclics (41–47, 51), three tricyclics (48, 49, and 56), and four tetracyclics (52–55). Chemical analysis of an endophytic A. niger strain colonizing in liverwort Heteroscyphus tener (Steph.) Schiffn resulted in isolation of three new amide campyrones A–C (38–40) together with compounds 33 and 34 (Talontsi et al., 2013; Li et al., 2015). One possible biosynthetic pathway proposed by Reber and Burdge (2018) suggested that compounds 38–40 were, respectively, formed by one malonyl-CoA and three N-acetyl aliphatic amino acids including L-valine, L-leucine, and L-isoleucine (Figure 4), along with two congener asnipyrones A (42) and B (46) and nigerapyrones A-H (35–37, 43–45, 48–49) were first discovered from a mangrove plant-derived strain MA-132 (Liu et al., 2011).
Unfortunately, none of these compounds showed potent cytotoxic or antimicrobial activities. Nafuredin (50) and bicoumanigrin (52) were new α-pyranone analogs produced by marine sponge-derived A. niger strains; the former exhibited a powerful and selective inhibitory effect on NFRD (NADH-fumarate reductase) (Takano et al., 2001; Ui et al., 2001) and the latter 3,3′-bicoumarin had moderate cytotoxicity against leukemia and carcinoma cell lines (Hiort et al., 2004). Three 8,8′-bicoumarins, orlandin (53), kotanin (54), and 7-desmethyl-kotanin (55) were produced by a number of A. niger strains from various sources, and 53 showed potent inhibitory activity against wheat coleoptile growth at 1 mM but not toxic to day-old cockerels (Cutler et al., 1979; Ovenden et al., 2004; Sorensen et al., 2009; Jomori et al., 2020). Biosynthetically, one acetyl-CoA and four malonyl-CoAs comprised one coumarin through several successive reactions catalyzed by PKSs, followed by formation of compounds 52–55 through dimerization (Figure 5) (Huttel et al., 2003; Huttel and Muller, 2007; Girol et al., 2012). In this pathway, PKS gene ktnS was responsible for origination of dimeric coumarins 52–55, gene ktnB encode O-methyltransferase, and gene ktnC encode CYP450 monoxygenase, manipulating the dimerization of 52–55.

γ-Pyranones
To the best of our knowledge, only four γ-pyranone derivatives (57–60) had been detected in SM of A. niger. Among these substances, kojic acid (57) is the most common product with weak antimicrobial property (Liu et al., 2011; Happi et al., 2015; Padhi et al., 2020). In addition to carbonarone A (59) and tensidol B (60), one new benzyl γ-pyranone nigerpyrone (58) was discovered from a mutant strain FGSC A1279 ΔgcnE and was found to have potent and selective activity against Candida parapsilosis (Wang et al., 2018; Padhi et al., 2020).

Alkaloids
Pyroles
Pyranonigrin derivatives (61–69) are a family characterized by pyrano [2,3-b] pyrrole skeleton, and their biosynthesis are manipulated by the pyn gene cluster in A. niger (Riko et al., 2014; Yamamoto et al., 2015). Chemical investigation of one marine sponge-derived strain afforded four pyranonigrins B-D (61, 62, 64) and Ab (63), which 63 showed a strong inhibitory effect on the growth of neonate larvae of the plant pest insect Spodoptera littoralis (Hiort et al., 2004). Pyranonigrins A (65), S (66), and E (67) were important agents with potent radical scavenging activity toward DPPH and superoxide (Miyake et al., 2007; Riko et al., 2014). One possible biosynthetic pathway of pyranonigrin E (67) had been first proposed by Yamamoto et al. (2015) and coworker in 2015, in which the start units contained one acetyl-CoA, six malonyl-CoAs, and one L-Ser (Figure 6), under the action of gene pynA (PKS-NRPS hybrid synthase), pynI (encode thioesterase), pynC (encode methyltransferase), pynG (encode flavin-dependent oxidase), pynD (encode CYP450), and pynH (encode aspartyl protease). After non-enzymatic reaction, two pyranonigrin E (67) units could be dimerized to form pyranonigrin F (69). One soil-derived A. niger strain was found to produce a new dichlorinated pyrrole pyoluteorin (70), which obviously induced cell cycle arrest and apoptosis in human triple-negative breast cancer cells MDA-MB-231 (Ding et al., 2020). Two benzyl furopyroles tensidols A (71) and B (72) from strain...
FKI-2342 were potentiatos of antifungal miconazole activity (Fukuda et al., 2006) and lately corrected as compounds 59 and 60 (Henrikson et al., 2011).

Pyridones

*Aspergillus niger*-derived pyridone derivatives (73–82) have one benzyl group and possess antimicrobial and cytotoxic properties (chatr 4). Two new α-pyridones aspernigrins A (73) and Bα (74) were isolated from one *A. niger* strain of marine sponge *Axinella damicornis* and showed moderate cytotoxicity and a potent neuroprotective effect, respectively, (Hiort et al., 2004). When cultivated in fermentation medium containing suberoylanilide hydroxamic acid (SAHA) and p-fluoro SAHA, strain ATCC 1015 was discovered to produce three antifungal γ-pyridones, nygerones A (78), B (75), and p-fluoro nygerone B (77) (Henrikson et al., 2009; Henrikson et al., 2011). In addition to three γ-naphthylpyridones (1, 3, and 5) and one cyclic peptide (111), three 2-benzyl-γ-pyridones aspernigrins B-D (80–82) were obtained from the marine strain SCSIO Jcsw6F30, and 81 was found to have potent inhibitory activity toward HIV-1 SF162-infected TZM-bl cells (Zhou et al., 2016).

Other Alkaloids

Three fatty amines fumonisins B2 (83), B1 (84), and B4 (85) from stains FGSC A1279 and IBT 28144 were carcinogenic (Nielsen et al., 2009; Sorensen et al., 2009; Li et al., 2019). The *aza* gene cluster in strain ATC C1015 was found to be responsible for biosynthesis of azanigroene D (86) (Zabala et al., 2012). In addition to pyoluteorin (70), phenazine-1-carboxylic acid (87) was produced by the soil *A. niger* strain (Ding et al., 2020). Two new piperazines nigragillin (88) and nigerazine B (89) were purified from strain ATCC 11414, and their biosynthesis were regulated by the naphthopyrone precursor BGC *alb* gene cluster (Chiang et al., 2011). Endophytic strain IFB-E003–derived aspernigerin (90) displayed a potent effect on the tumor cell lines nasopharyngeal epidermoid KB, cervical carcinoma Hela, and colorectal carcinoma SW1116 (Shen et al., 2006).

Amides

Till the end of 2020, only six amides (91–96) had been isolated and characterized from *A. niger* strains. Fractionation of crude extract of marine strain BRF-074A afforded one furan ester derivative (91), one cerebroside chrysoside D (93), and two spiro amides pseurotins A (95) and D (96), among which 91 exerted a cytotoxic effect on HCT-116 cell line (Uchoa et al., 2017). When cultivated on wheat bran, strains CFR-W-105 and MTCC-5166 were discovered to produce nigerloxin (92) with free radical DPPH scavenging activity and inhibitory effect on lipooxygenase-1 (LOX-1) and rat lens aldose reductase (RLAR) (Rao et al., 2002; Chakradhar et al., 2009). Ergosterimide (94) was a new natural Diels–Alder adduct of ergosteroid and maleimide produced by the strain EN-13 from marine alga (Zhang et al., 2007a).

Cyclopeptides

All peptides of *A. niger* are cyclic and consist of ten dipeptides (97–106), eight pentapeptides (107–114), and three bis(dipeptide)s (115–117). In addition to α-pyranones 32–34, 38, and 40, four diketopiperazines (97, 99, 115, and 116) were isolated from an endophytic strain of liverwort *Heteroscyphus tener* (Steph.). Schiffrin, and compounds 115 and 116 showed weak activity against the human ovarian carcinoma cancer cell line A2780 (Li et al., 2015). However, 115 exhibited significant selective cytotoxicity to human leukemia murine colon 38 and human colon H116 and CX1 cell lines (Varoglu et al., 1997; Varoglu and Crews, 2000). One strain BRF-074A from Northeast Brazilian coast was a prolific producer of cyclopeptides (101–107, 114) (Uchoa et al., 2017). Phytochemical analysis of an uncoded marine strain afforded a new diketopiperazine dimer (117) and nine monomers (98–106) (Ovenden et al., 2004; Zhang et al., 2010; Uchoa et al., 2017). Compounds 98 and 99 had been reported to regulate plant growth (Kimura et al., 1996; Kimura et al., 2001), and 101 had selectively potential cytotoxicity (Graz et al., 2000). Eight malformin analogs (107–114) were a group of SMs containing structural skeleton of cyclo-D-cysteinyld-cysteinyl-L-amino acid-D-amino acid-L-amino acid (Kim et al., 1993). Malformin A (107) demonstrated antibacterial (Suda and Curtis, 1966; Liu et al., 2013) and...
anticancer activities (Wang et al., 2015), while malformin C (114) exhibited a broad spectrum of biological properties including anti-HIV-1 (Zhou et al., 2016), cytotoxic (Jomori et al., 2020), anticancer (Wang et al., 2015), and antibacterial (Suda and Curtis, 1966; Liu et al., 2013).

Polyketides

Polyketides (118–155) are the largest group of SMs produced by A. niger. Citric acid (118) and itaconic acid (119) have been large-scale products in food and pharmaceutical industry for decades (Andersen et al., 2011; Li et al., 2012). Some other valuable chemicals with low molecular weight are also produced by A. niger, such as 2-phenylethanol (128) (Etschmann et al., 2015), p-hydroxyphenylacetic acid (129) (Happi et al., 2015), gallic acid (130) (Saeed et al., 2020), benzoic acid derivative (131) (Zabala et al., 2012), and asperyellone (147) (Jefferson, 1967; Chidananda et al., 2008). In comparison with 119, the biological activity of hexylitaconic acid (120) dramatically attenuated (Varoglu et al., 1997; Varoglu and Crews, 2000). By overexpression of transcriptional regulator pBARAGA-CaaR of BGC caa in glucose minimal medium, strain ATC C1015 successfully produced three acyltetronic acid derivatives carlosic acid (123), carlosic acid methyl ester (124), and agglomerin F (125) (Yang et al., 2014). Chemical analysis of two strains KB1001 and F97S11 afforded fifteen meroterpenoid derivatives (132–146), in which biosynthesis was deduced to be manipulated by the yan gene cluster in strain KB1001 (Figure 7) (Bugni et al., 2000; Holm et al., 2014). Furthermore, yan gene cluster consisted of gene yanA [encode 6-methylsalicylic acid synthase (6-MSAS)] together with eight additional genes yanB (encode decarboxylase), yanC (encode CYP450), yanD (encode dehydrogenase), yanE (unknown), yanF (encode oxidase), yanI (encode O-mevalon tirsferase), yanH (encode CYP450), and yanG (encode prenyl transferase).

Asperyellone (147) was the common product of strains NRRL-3 and CFTRI 1105 (Jefferson, 1967; Chidananda et al., 2008) and exhibited inhibitory effect on lipoxigenase and human platelet aggregation (Rao et al., 2002), UVB protection (Santhakumaran et al., 2019), and antifungal activity (Ayer et al., 1996). In addition

![Proposed biosynthetic pathway of yanuthones.](image-url)
to γ-pyridone (86), five highly oxygenated pyranoquinones (86, 149, and 151–154) were detected in SMs of strain T1 by activation of the aza gene cluster (Zabala et al., 2012) (Figure 8). In biosynthesis of pyranoquinones, genes azaE (encode ketoreductase), azaF (encode acylCoA ligase), azaG (encode FAD-dependent oxygenase), azaH (encode salicylate monooxygenase), azaI (encode CYP450), azaJ (encode dehydrogenase), and azaL (encode FAD-dependent oxygenase) play important roles. Funalenone (150), one phenalene derivative, was obtained from strain ATCC 11414 whether the albA gene was auxotrophic or not (Chiang et al., 2011). Meanwhile, funalenone (150) was also found in A. niger mutant ΔgcnE (strain FGSC A1279 lacking epigenetic regulator gcnE) (Wang et al., 2018). Two tetracycline analogs BMS-192548 (157) and TAN-1612 (158) were, respectively, obtained from strains WB2346 and ATCC C1015 and shown to be acyclic binding inhibitors of neuropeptide Y receptors (Kodukula et al., 1995; Shu et al., 1995; Li et al., 2011).

**Sterols**

As the by-product of manufacture of citric acid, 14-dehydroergosterol (159) and its benzoate (160) were the first steroids isolated from A. niger (Barton and Bruun, 1951) and possessed anti-inflammatory and cytotoxic properties (Ano et al., 2017). Strain MA-132–derived nigerasterol A (161) and B (162) had potent antiproliferative activity against human promyelocytic leukemia (HL60) and human lung carcinoma (A549), with IC50 values of 0.11 and 0.43 μM, respectively (Liu et al., 2013). In addition to ergosterimide (94), four steroid derivatives (163–166) were discovered from the endophytic strain EN-13 associated with marine brown alga (Zhang et al., 2007a).

**CONCLUSION AND FUTURE PROSPECTS**

A. niger strains are ubiquitous in nature and occupy a wide spectrum of habitats in animal and plant environments, and they are economically important both as harmful or beneficial microorganisms. Numerous chemical studies suggest that A. niger is one of the prolific sources of functional biomolecules, including organic acids, vitamins, pesticides, valuable proteases, and therapeutic agents, which have potential...
application in various fields including agriculture, food industry, and medicine. However, the number of new bioactive compounds from *A. niger* has been decreasing for the past 5 years. This deteriorating trend will result in a negative impact on discovery and development of new *A. niger*-derived valuable substances, such as new drug leads. Therefore, more efforts should be made to explore more sources for isolation of new *A. niger* strains and to awaken their silent BGCs to manufacture novel functional biomolecules using new strategies, such as one strain A.

Moreover, functional genomics should allow for an in-depth understanding of the underlying biosynthetic logic of *A. niger*-derived SMs (He et al., 2018). In order to accelerate development of valuable products from *A. niger*, construction and breeding of robust strains as well as optimization of their cultivation and fermentation processes should be intensively conducted at various levels (Zou et al., 2015; Xu et al., 2019).

**AUTHOR CONTRIBUTIONS**

RY made a draft of this review; JL and YW searched and collected all references; HW helped in critical assessing this manuscript; and HZ conceived and revised this review.

**FUNDING**

Financial supports from the National Key R&D Program of China (2018YFC0311004), the National Natural Science Foundation of China (41776139) and the Fundamental Research Fund for the Provincial Universities of Zhejiang (RF-C2019002) were greatly appreciated.
