Inexact and primal multilevel FETI-DP methods
a multilevel extension and interplay with BDDC

Bedřich Sousedík

Abstract  We study a framework that allows to solve the coarse problem in the
FETI-DP method approximately. It is based on the saddle-point formulation
of the FETI-DP system with a block-triangular preconditioner. One of the
blocks approximates the coarse problem, for which we use the multilevel BDDC
method as the main tool. This strategy then naturally leads to a version of
multilevel FETI-DP method, and we show that the spectra of the multilevel
FETI-DP and BDDC preconditioned operators are essentially the same. The
theory is illustrated by a set of numerical experiments, and we also present a
few experiments when the coarse solve is approximated by algebraic multigrid.

1 Introduction

The last two decades in the development of iterative substructuring class of the
domain decomposition methods has been marked by a significant progress of
the two most advanced methods: Finite Element Tearing and Interconnecting
- Dual, Primal (FETI-DP) and Balancing Domain Decomposition by Con-
straints (BDDC). The FETI-DP method by Farhat et al. [8,9] was developed
from an earlier version, called FETI (or FETI-1) by Farhat and Roux [10,11].
The methods from the FETI family are dual because they iterate on a system
of Lagrange multipliers that enforce continuity on the interfaces. However, in

the FETI-DP some of the “coarse” variables are treated as primal. The BDDC method was developed by Dohrmann [4,26], as a fully primal counterpart of the FETI-DP, from an earlier BDD method by Mandel [25]. Interestingly, two methods that turned out to be equivalent to BDDC were developed independently by Cros [3] and by Fragakis and Papadrakakis [12], see [29,41] for a proof. The methods are closely related, and the essential role here is played by the coarse problem. The proof that the eigenvalues of the FETI-DP and BDDC are the same except possibly for the multiplicity of eigenvalue equal to one, provided that the coarse components of both methods are the same, was obtained by Mandel et al. [27], and simpler proofs were derived soon afterwards by Li and Widlund [24], and also by Brenner and Sung [2].

Even though both methods were originally developed for elliptic problems, they were later extended to other models see, e.g., the monographs [23,32,44] for an overview. From our current perspective, we find the most important extensions beyond the original two-level algorithms. The possibility for a multilevel extension of the BDDC was already mentioned by Dohrmann [4]. The theory of three-level BDDC was developed by Tu [45,46] and extended into a general multispace BDDC framework (with multilevel BDDC as a particular instance) by Mandel et al. [30]. For further developments of multilevel BDDC see, e.g., [17,33,37,40,42,47,48]. Extensions of the FETI-DP are less straightforward because the inverse of the coarse problem is built directly into the system matrix, and to the best of our knowledge the literature on this topic is limited. For example, a hybrid approach to three-level FETI was proposed by Klawonn and Rheinbach [21], and a recursive application of the FETI-DP was recently proposed by Toivanen et al. [43], see also Horák [13, Chapter 11].

The FETI-DP method is, due to the use of dual variables, suitable in particular for numerical solution of certain classes of coercive variational inequalities such as the contact problems see, e.g., [5,6,14]. However, factorization of the coarse problem may become a computational bottleneck when the number of substructures is large. Our main goal here is to develop a variant of the FETI-DP method that would allow for an approximate solution of the coarse problem using a multilevel strategy, but we do not apply the method recursively as [43]. Instead, we keep the coarse variables primal. Klawonn and Rheinbach [20] studied inexact FETI-DP methods based on the saddle-point formulation of the FETI-DP which allows to move (the approximation of) the inverse of the coarse problem into the preconditioner. We also use the saddle-point formulation, and the preconditioner based on an approximation of the block inverse of the system matrix. However, while [20] applied algebraic multigrid (AMG) to the coarse problem, our main focus here is the multilevel BDDC and also our formulation of the algorithms is different since we do not rely on partial subassembly and a change of variables. This strategy then naturally leads to a version of multilevel FETI-DP method, which we refer to as primal. We show that the spectra of the preconditioned multilevel FETI-DP and BDDC operators are essentially the same, in the same way as in the two-level case, and we present numerical experiments that confirm the theory. We note that an alternative point of view is that our method is a variant of the...
multilevel BDDC that allows to use the dual, FETI-DP formulation on the finite element level.

The paper is organized as follows. In Section 2 we introduce the model problem and substructuring components, in Section 3 we recall the FETI-DP and BDDC methods, in Section 4 we formulate the inexact and multilevel FETI-DP method, in Section 5 we relate it to the multilevel BDDC, and in Section 6 we present results of numerical experiments.

2 Model problem and substructuring components

We introduce a model problem and some standard substructuring concepts. So, let us assume we are interested in solving a system of linear equations

$$Au = f,$$  \hspace{1cm} (1)

where $u \in U$, and $A$ is a symmetric, positive definite matrix obtained by a discretization of an elliptic partial differential equation subject to appropriate boundary conditions in a bounded domain $\Omega \subset \mathbb{R}^d$, $d = 2$ or 3. Let $\Omega$ be decomposed into $N$ nonoverlapping subdomains $\Omega^s$, $s = 1, \ldots, N$, equally called substructures. Let each substructure be obtained as a union of Lagrangian P1 or Q1 finite elements with mesh size $h$, and let $H$ denote the characteristic size of a subdomain. The first step in substructuring is elimination of degrees of freedom interior to each substructure, $u_I \in U_I$, by so-called static condensation, and the problem is reduced to substructure interfaces. To this end, we denote by $W_i$ the space of degrees of freedom on the substructure $i$ interface, by $w_i$ the vector of substructure interface degrees of freedom, and let

$$W = W_1 \times \cdots \times W_N.$$  \hspace{1cm} (2)

Next, we denote by $S^i : W^i \to W^i$ the Schur complement of subdomain $i$ after eliminating the interior degrees of freedom, and by $g^i$ the substructure force vector. Also, we introduce $U_\Gamma$ as the space of the global interface degrees of freedom, and denote by $\hat{W}$ the space of degrees of freedom continuous across the substructure interfaces. Finally, we introduce $R^i : U_\Gamma \to W^i$ as the restriction map (a zero-one matrix) of global to local degrees of freedom. Then, we denote

$$S = \begin{bmatrix} S^1 \\ \vdots \\ S^N \end{bmatrix} \quad w = \begin{bmatrix} w^1 \\ \vdots \\ w^N \end{bmatrix}, \quad g = \begin{bmatrix} g^1 \\ \vdots \\ g^N \end{bmatrix}, \quad R = \begin{bmatrix} R^1 \\ \vdots \\ R^N \end{bmatrix},$$  \hspace{1cm} (2)

where $R$ has a full column rank such that $R^T R^T = I$, and $\hat{W} = \text{range } R$. Then, problem (1) reduced to interfaces may be written as

$$\hat{S} w = f_\Gamma, \quad \hat{S} = R^T S R, \quad f_\Gamma = R^T g.$$  \hspace{1cm} (3)
Next ingredient is the averaging operator $E = R^T D_P$, where $D_P : W \rightarrow W$ is a given weight matrix such that $ER = I$. Also, let $B : W \rightarrow A$ denote the matrix enforcing the condition $w \in \tilde{W}$ by $Bw = 0$, that is range $R = \text{null} B$.

In agreement with the block structure (2), we consider

$$B = \begin{bmatrix} B^1 & \cdots & B^N \end{bmatrix}, \quad B^i : W^i \rightarrow A, \quad \text{range } B = A.$$ 

Let $B_D^T$ denote a generalized inverse of $B$, that is $B_D^T : A \rightarrow W$ and $BB_D^T = IA$.

In computations, the matrix $B_D$ is constructed from $B$ and $D_P$, see [22,27], and, in particular, we will assume that

$$B_D^T B + RE = I.$$ 

The FETI-DP and BDDC methods are characterized by a selection of coarse degrees of freedom (resp. constraints). These can be values at corners or averages over edges or faces. Let $\tilde{W} \subset W$ be the subspace of vectors with continuous coarse degrees of freedom across substructure interface. Specifically, suppose we are given a space $X$ and a matrix $C : W \rightarrow X$, and define

$$\tilde{W} = \{ w \in W : C (I - RE) w = 0 \}, \quad \text{(4)}$$

where each row of $C$ defines one constraint. The values $Cw$ are called local coarse degrees of freedom and by (4) they have zero jumps on adjacent substructures. To represent the global coarse degrees of freedom, we use a space $U_c$ and a matrix $R_c$ with full column rank, such that

$$\tilde{W} = \{ w \in W : \exists u_c \in U_c : Cw = R_c u_c \}.$$ 

Next, let $\Phi$ be a matrix that defines the basis for the coarse problem, given as

$$\Phi = \begin{bmatrix} \phi^1 \\ \vdots \\ \phi^N \end{bmatrix}, \quad C\Phi = R_c.$$ 

Here we use energy minimal coarse basis functions $\Psi$ that minimize energy of the form $x^T \Phi^T S \Phi x$ subject to constraints $Cx = e$ for some vector $e$ given for each basis function as a column of matrix $R_c$. Specifically, the basis functions are found by solving saddle-point problems

$$\begin{bmatrix} S & C^T \\ C & 0 \end{bmatrix} \begin{bmatrix} \Psi \\ \Lambda \end{bmatrix} = \begin{bmatrix} 0 \\ R_c \end{bmatrix}. \quad \text{(5)}$$

In implementation, we use a decomposition of the space $\tilde{W}$, see [27, Lemma 8],

$$\tilde{W} = \overline{W}_R \oplus \overline{W}_\Delta, \quad \text{(6)}$$

where $\overline{W}_R = \text{range } \Phi$ is the primal space, which gives rise to the (global) coarse problem, and $\overline{W}_\Delta = \text{null } C$ is the dual space with coarse degrees of freedom equal to zero, which gives rise to independent subdomain problems.
3 FETI-DP and BDDC methods

3.1 FETI-DP

Problem (3) may be equivalently written as

\[
\min_{w \in \tilde{W}} \max_{\lambda \in \Lambda} \mathcal{L}(w, \lambda),
\]

(7)

where \( \mathcal{L}(w, \lambda) \) is the Lagrangian

\[
\mathcal{L}(w, \lambda) = \frac{1}{2} w^T S w - w^T E^T f_{\Gamma} + w^T B^T \lambda.
\]

Problem (7) is further equivalent to the dual problem \( \max_{\lambda \in \Lambda} \mathcal{F}(\lambda) \), where

\[
\mathcal{F}(\lambda) = \min_{w \in \tilde{W}} \mathcal{L}(w, \lambda)
\]

(8)

is the dual functional.

Next, we use the splitting (6) and introduce Lagrange multipliers \( \mu \) to enforce the zero values of coarse degrees of freedom in \( \tilde{W} \Delta \). Then, functional (8) can be written with minimization over \( \tilde{W} \) instead of \( \tilde{W} \Delta \) as

\[
\mathcal{F}(\lambda) = \min_{w_{\Delta} \in \tilde{W}} \min_{w_{\Pi} \in \tilde{W}_\Pi} \sup_{\mu} \mathcal{L}(w_{\Delta} + w_{\Pi}, \lambda) + w_{\Delta}^T C \mu.
\]

(9)

Writing \( w_{\Pi} = \Phi u_c \), and differentiating with respect to \( w_{\Delta}, \mu, u_c, \lambda \), we get a linear system, with a solution equivalent to solving the dual problem, which is

\[
\begin{bmatrix}
S & C^T & S \Phi & B^T \\
C & 0 & 0 & 0 \\
\Phi^T S & 0 & \Phi^T S \Phi & \Phi^T B^T \\
B & 0 & B \Phi & 0 \\
\end{bmatrix}
\begin{bmatrix}
w_{\Delta} \\
\mu \\
u_c \\
\lambda \\
\end{bmatrix} =
\begin{bmatrix}
E^T f_{\Gamma} \\
0 \\
\Phi^T E^T f_{\Gamma} \\
0 \\
\end{bmatrix}.
\]

(10)

Eliminating \( w_{\Delta} \) and \( \mu \) from the first two equations, we derive the so-called saddle-point FETI-DP formulation, which can be written as

\[
\begin{bmatrix}
S_c & \Psi^T B^T \\
B \Psi - BS_{\Delta}^{-1} B^T \\
\end{bmatrix}
\begin{bmatrix}
u_c \\
\lambda \\
\end{bmatrix} =
\begin{bmatrix}
\Psi^T E^T f_{\Gamma} \\
-BS_{\Delta}^{-1} E^T f_{\Gamma} \\
\end{bmatrix},
\]

(11)

where \( S_{\Delta}^{-1} \) corresponds to independent subdomain solves

\[
S_{\Delta}^{-1} = \begin{bmatrix} I \\ 0 \end{bmatrix}^T \begin{bmatrix} S & C^T \end{bmatrix}^{-1} \begin{bmatrix} I \\ 0 \end{bmatrix},
\]

(12)

so that \( \Psi = (I - S_{\Delta}^{-1} S) \Phi \) are the energy minimizing coarse basis functions, the same as in (5), cf. [27, eqs. (22) and (25)], and \( S_c \) is the coarse matrix

\[
S_c = \Phi^T S \Phi - \begin{bmatrix} S \Phi^{-1} \\ 0 \end{bmatrix}^T \begin{bmatrix} S & C^T \end{bmatrix}^{-1} \begin{bmatrix} S \Phi \\ 0 \end{bmatrix} = \Psi^T S \Psi,
\]

(13)
where the second equality follows from [27, Theorem 3].

We note that eliminating \( u_c \) from (11) yields the original FETI-DP system

\[
B \left( \Psi S_c^{-1} \Psi^T + S_{c,\Delta}^{-1} \right) B^T \lambda = B \left( \Psi S_c^{-1} \Psi^T + S_{c,\Delta}^{-1} \right) E^T f_R.
\]

(14)

The original FETI-DP is the method of preconditioned conjugate gradients applied to (14), used typically with the so-called Dirichlet preconditioner

\[
M_D = B_D S B_D^T.
\]

(15)

3.2 BDDC

The BDDC preconditioner was originally formulated by Dohrmann [4] for problem (1). Formulations for the reduced problem (3) followed in [26, 27]. The BDDC is the method of preconditioned conjugate gradients, in which the (two-level) BDDC preconditioner for problem (3) is given as, cf. [27, Lemma 27],

\[
M_{\hat{S}} = EHE^T,
\]

(16)

where

\[
H = \left[ \begin{array}{cc} \Psi^T & I \\ S_c & 0 \\ 0 & S_{\Delta} \end{array} \right]^{-1} \left[ \begin{array}{cc} \Psi^T \\ I \end{array} \right] = \Psi S_c^{-1} \Psi^T + S_{\Delta}^{-1}.
\]

(17)

The preconditioner formulated for problem (1) includes in addition a pre-processing step with a static condensation of the residual and post-processing step with recovery of the approximate solution corresponding to the subdomain interiors. Both formulations are equivalent, and in particular by [30, Theorem 14], the eigenvalues of the two preconditioned operators are the same except possibly for multiplicity of eigenvalue equal to one.

3.2.1 Multilevel BDDC

In case when the number of subdomains is large, solving the coarse problem becomes a bottleneck. This motivated the introduction of the multilevel extensions [30, 45, 46] that solve the coarse problem only approximately by applying the two-level BDDC recursively. Since we will apply this idea in the FETI-DP framework, we briefly recall the Multilevel BDDC from [30]. The substructuring components will be denoted by an additional subscript \( \ell \) as \( U_1, \tilde{W}_{\Omega_1} \), and \( \Omega_1^s, s = 1, \ldots, N_1 \), etc., and called level 1. Level 1 coarse problem will be called level 2 problem. Because it has an analogous structure as the original problem on level 1, we put \( U_2 = \tilde{W}_{\Omega_1} \), and we introduce the substructuring components for level 2 in the same way as we introduced level 1 components. Generally, in a design of \( L \)-level method, we repeat this process recursively for levels \( \ell = 1, \ldots, L - 1 \). On each decomposition level \( \ell \), we assume that the subdomains \( \Omega_\ell^s, s = 1, \ldots, N_\ell \), have characteristic size \( H_\ell \) and form a conforming triangulation of the domain \( \Omega \). Level \( \ell - 1 \) substructures become level \( \ell \) elements, level \( \ell - 1 \) coarse degrees of freedom become level \( \ell \) degrees
of freedom, and $I_\ell \subset I_{\ell-1}$. The finite element level will be denoted as level 0 and $H_0 = h$. An example of a decomposition is shown in Figure 1.

The shape functions on level $\ell$ are determined by minimization of energy with respect to level $\ell-1$ shape functions, subject to the value of exactly one level $\ell$ degree of freedom being one and others level $\ell$ degrees of freedom being zero. The minimization is done on each level $\ell$ element (level $\ell-1$ substructure) separately, so the values of level $\ell-1$ degrees of freedom are in general discontinuous between level $\ell-1$ substructures, and only the values of level $\ell$ degrees of freedom between neighboring level $\ell$ elements coincide. The hierarchy of the spaces for $L$-level BDDC method can be written as

$$
\hat{W}_1 \subset \tilde{W}_1 = \bigoplus W_\Delta 1, \quad \hat{W}_{\Pi 1} = U_2, \quad U_2 = \ldots = U_L = \bigoplus \tilde{W}_{\Pi L-1} = \bigoplus \tilde{W}_{\Delta L-1}.
$$

The two-level BDDC preconditioner for problem (3) entails finding corrections in the spaces $\hat{W}_{\Delta 1}$ and $\hat{W}_{\Pi 1}$, and the multilevel BDDC for the same problem entails computing corrections in the spaces as above, that is

$$
V_1 = \hat{W}_{\Delta 1}, \quad V_2 = U_{T 2}, \quad V_3 = \hat{W}_{\Delta 2}, \quad \ldots \quad V_{2(L-1)} = \hat{W}_{\Pi L-1}, \quad (18)
$$

such that

$$
\hat{W}_1 = \left( \hat{W}_{\Delta 1} \oplus \hat{W}_{\Pi 1} \right) \subset \hat{V} = \sum_{k=1}^{2(L-1)} V_k \subset W. \quad (19)
$$

The precise formulation of the multilevel BDDC preconditioner can be found in [30, Algorithm 17]. More generally, as an analogy to (16)–(17), we may consider an inexact BDDC preconditioner given as

$$
\tilde{M}_{\tilde{R}} = E\tilde{H}E^T, \quad (20)
$$

where

$$
\tilde{H} = \begin{bmatrix} \Psi^T & M_c & 0 \\ 0 & 0 & S_{\Delta}^{-1} \end{bmatrix} \begin{bmatrix} \Psi^T \\ I \end{bmatrix} = \Psi M_c \Psi^T + S_{\Delta}^{-1}, \quad (21)
$$
and $M_c$ is a preconditioner for the coarse matrix $S_c$. The multilevel BDDC applied to the coarse problem is then a particular example of $M_c$.

Finally, we note that the derivation of the FETI-DP (14) provides an alternative proof to [27, Lemma 27], which states that the preconditioned BDDC and FETI-DP operators can be written, respectively, as

$$M_\tilde{S}S = (EHE^T)(R^T SR),$$
$$M_DF = (BD^2B_D^T)(BHB^T),$$

which is used in the proof of equivalence of the spectra of the two operators.

**Theorem 1** ([27, Theorem 26]) The eigenvalues of the preconditioned operators of the BDDC and FETI-DP methods given, respectively, by (22) and (23) are the same except possibly for the eigenvalues equal to zero and one.

**Proof** See Appendix.

Our next goal is to design a multilevel version of the FETI-DP method, based on formulation (11), and relate its spectrum to that of Multilevel BDDC.

### 4 Inexact and multilevel FETI-DP methods

Since the inverse of the coarse matrix $S_c$ is built into the original FETI-DP operator in (14), its application may become a bottleneck when the number of substructures is large. Therefore, we work with the saddle-point formulation (11) that allows to solve coarse problem inexactly, which is a strategy proposed by Klawonn and Rheinbach [20].

The proposed preconditioner is based on the block inverse

$$\begin{bmatrix} X & Y^T \\ Y & -Z \end{bmatrix}^{-1} = \begin{bmatrix} I - X^{-1}Y^T & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} X^{-1} & 0 \\ 0 & -S_X^{-1} \end{bmatrix} \begin{bmatrix} I & 0 \\ -X^{-1} & I \end{bmatrix} = \begin{bmatrix} I - X^{-1}Y^T & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} X^{-1} & 0 \\ S_X^{-1}YX^{-1} & -S_X^{-1} \end{bmatrix},$$

and $S_X = Z + YX^{-1}Y^T$. For the inverse of matrix in (11), we then get

$$\begin{bmatrix} S_c & \Psi B^T \\ B\Psi - BS_A^{-1}B^T \end{bmatrix}^{-1} = \begin{bmatrix} I - S_c^{-1}\Psi B^T \\ 0 & I \end{bmatrix} \begin{bmatrix} S_c^{-1} & 0 \\ F^{-1}B\Psi S_c^{-1} & -F^{-1} \end{bmatrix},$$

and $F = B (\Psi S_c^{-1}\Psi^T + S_A^{-1}) B^T$ is the same as the FETI-DP matrix in (14). The matrix on the right in (24) then motivates the choice of a preconditioner

$$M_F = \begin{bmatrix} M_c & 0 \\ M_D B\Psi M_c - M_D \end{bmatrix},$$

where $M_D$ is the Dirichlet preconditioner (15), and $M_c$ is the preconditioner for the coarse matrix $S_c$. In general, we may consider any suitable $M_c$ giving
rise to inexact FETI-DP. For example, Klawonn and Rheinbach [20] used algebraic multigrid (AMG). Here, our main focus is on application of multilevel BDDC in place of $M_c$, which we then refer to as primal multilevel FETI-DP method. In implementation, the application of the preconditioner $M_F$ entails one application of both $M_c$ and $M_D$, which may be computed as follows.

**Algorithm 2** The preconditioner $M_F : (r_c, r_\lambda) \mapsto (u_c, \lambda)$ is applied as:

First, apply the preconditioner $M_c$ as $u_c = M_c r_c$, and compute

$$x = B \Psi u_c,$$
$$y = x - r_\lambda.$$

Then, apply the preconditioner $M_D$ as $\lambda = M_D y$, and concatenate the results

$$\begin{bmatrix} u_c \\ \lambda \end{bmatrix}.$$

**Remark 1** Algorithm 2 is closely related to the second algorithm by Klawonn and Rheinbach [20]. However, our formulation of FETI-DP does not use partial subassembly and a change of variables, and we consider multilevel BDDC besides algebraic multigrid as a preconditioner $M_c$ for the coarse matrix $S_c$.

### 5 Analysis of the methods

The saddle-point FETI-DP matrix from (11) preconditioned by $M_F$ from (25) is

$$\begin{bmatrix} M_c S_c & M_c \Psi^T B^T \\ M_D B \Psi (M_c S_c - I) M_D B (\Psi M_c \Psi^T + S_c^{-1}) B^T \end{bmatrix}. \quad (26)$$

First, note that with the exact coarse solve, i.e., setting $M_c = S_c^{-1}$, the matrix in position (1,1) is the identity so the matrix in position (2,1) vanishes, and the matrix in position (2,2) is the same as the preconditioned FETI-DP operator (23). Finally, multiplying the right-hand side of (11) by $M_F$ we may check that solving the second set of equations therein is the same as solving the original FETI-DP problem (14) with the Dirichlet preconditioner $M_D$.

Next, let us observe that the inexact BDDC preconditioner (20) with $\tilde{H}$ from (21) and the entry in position (2,2) of matrix (26) with the Dirichlet preconditioner $M_D$ defined by (15) may be written, respectively, as

$$\tilde{M}_{\tilde{S}} \tilde{S} = \begin{pmatrix} E \tilde{H} E^T \\ R^T S R \end{pmatrix}, \quad (27)$$
$$M_{\tilde{D}} \tilde{F} = \begin{pmatrix} B_D S B_D^T \\ B \tilde{H} B^T \end{pmatrix}. \quad (28)$$

That is (27)–(28) is an analogy to (22)–(23), just with $\tilde{H}$ in place of $H$.

Let us now focus on the primal multilevel FETI-DP method, which combines the dual (FETI-DP type of) approach to the solve in $\tilde{W}_\Delta$ and applies the (primal) multilevel BDDC preconditioner to the coarse solve in $\tilde{W}_H$. 

Assumption 3 We will assume that the spaces $V_k$, $k = 1, \ldots, 2(L-1)$, are constructed so that the associated linear systems are nonsingular, and the multilevel BDDC uses exact solves in these subspaces, so that

$$\tilde{H} S |_{\tilde{V} \subset W} = I.$$  \hfill (29)

For the two-level BDDC method the Assumption 3 holds due to the exact coarse solve, see also [27, Lemma 28]. For multispace and multilevel BDDC see [30, Corollary 4, Remark 5 and Lemma 18].

Then, a variant of Theorem 1 also holds for the two operators (27)–(28).

Lemma 1 Let $\tilde{H}$ be defined as in (21) and so that assumption (29) is satisfied. Then the eigenvalues of the preconditioned operators given by (27) and (28) are the same except possibly for the eigenvalues equal to zero and one.

Proof See Appendix.

Let us now use Lemma 1 to examine the eigenvalues of the preconditioned operator (26). The corresponding eigenvalue problem can be written as

$$M_c S_c u + M_c \Psi^T B^T p = \mu u,$$

$$M_D B \Psi (M_c S_c - I) u + M_D B (\Psi M_c \Psi^T + S_\Delta^{-1}) B^T p = \lambda p.$$  \hfill (30)

We begin by considering possible eigenvalues of $M_c S_c$. There are two possible cases for $M_c S_c u = \mu u$ where $(\mu, u)$ is the corresponding eigenpair: $\mu = 1$ or $\mu \neq 1$. If $\mu = 1$, then $M_c S_c u = u$ and, assuming $\lambda \neq 1$, we get from the first equation $u = 1/(\lambda - 1) M_c \Psi^T B^T p$. Then, the second equation of (30) simplifies to the eigenvalue problem for (28), that is $M_D \tilde{F} p = \lambda p$, which has essentially the same eigenvalues as the multilevel BDDC preconditioned operator $\tilde{M} \tilde{S}$ by Lemma 1. If $\mu \neq 1$, then $M_c S_c u = \mu u$ and, assuming $\lambda \neq \mu$, we get from the first equation $u = 1/(\lambda - \mu) M_c \Psi^T B^T p$. Substituting this into the second equation of (30), we obtain

$$M_D B \left( \frac{\mu - 1}{\lambda - \mu} \Psi M_c \Psi^T + \Psi M_c \Psi^T + S_\Delta^{-1} \right) B^T p = \lambda p,$$

which reduces with $\lambda = 1$ to $M_D B S_\Delta^{-1} B^T p = \lambda p$. Therefore, Theorem 1 for two-level methods translates to the multilevel BDDC and FETI-DP methods.

Theorem 4 The eigenvalues of the preconditioned operators of the multilevel BDDC and primal multilevel FETI-DP methods are the same except possibly for the eigenvalues equal to zero and one.

For further discussion of multilevel BDDC method we refer to [30]. It is well known that the eigenvalues of the operators provide only asymptotic insight into the convergence of GMRES, which is the main iterative method used in the numerical experiments. The bound on the error at every step involves the condition number of the operator eigenvectors see, e.g., [7,35,36], which is difficult to estimate. Nevertheless, the numerical experiments presented in
the next section illustrate that the convergence of GMRES applied to either multilevel FETI-DP or BDDC method is quite comparable to that of the preconditioned conjugate gradients applied to the multilevel BDDC. We also note that if the preconditioned operator is symmetric, positive definite in some inner product then it may be also used in conjugate gradient method [18, 20].

6 Numerical experiments

The methods were implemented in MATLAB. We used the right-preconditioned GMRES method with no restarts and (for multilevel BDDC also) preconditioned conjugate gradients, with relative residual tolerance $10^{-8}$ as the stopping criterion and zero initial guess. To estimate the largest eigenvalues of the preconditioned operators, we used the MATLAB function `eigs`.

First, we present results of numerical experiments for the model problem corresponding to the scalar second-order elliptic problem with zero Dirichlet boundary conditions on a square domain discretized by linear quadrilateral finite elements. The domain was uniformly divided into substructures with fixed $H_\ell/H_{\ell-1}$ ratio on each level $\ell$. Table 1 shows the largest eigenvalues of the preconditioned operators and the iteration counts of the multilevel FETI-DP and BDDC methods set up using corner constraints and varying numbers of levels $L$ and coarsening ratios $H_\ell/H_{\ell-1}$, $\ell = 1, \ldots, L - 1$. Table 2 then shows results for the same set of problems and the two methods set up using corner constraints combined with arithmetic averages over edges. We used right-preconditioned GMRES for the FETI-DP method (11) preconditioned by $M_F$ from (25), in which multilevel BDDC preconditioner was applied as $M_c$, and for the multilevel BDDC method we used also preconditioned conjugate gradients (PCG). In addition, for the FETI-DP formulation, we studied performance of a block-diagonal variant of the preconditioner $M_F$, that is

$$
\begin{bmatrix}
M_c & 0 \\
0 & -M_D
\end{bmatrix},
$$

(31)

which from the theory in [31] may be nearly as efficient. From the tables it can be seen the largest eigenvalues of both multilevel FETI-DP and BDDC preconditioned operators were the same. Also, the iteration counts of GMRES were essentially the same for the two methods, and the same trend can be observed for the PCG method. However, in case of the FETI-DP method with the block-diagonal preconditioner the iteration counts of GMRES are higher in all cases. Since the overhead associated with the application of $M_F$ is small, cf. Algorithm 2, the block-diagonal preconditioner appears to be less suitable.

Figure 2 displays estimates of the largest 150 eigenvalues of the multilevel FETI-DP and BDDC preconditioned operators in the setup with three levels and coarsening ratio $H_2/H_1 = H_1/H_0 = 3$. Specifically, the left panel corresponds to the second row of Table 1 and the right panel to the second row of Table 2. In both panels all eigenvalues match as predicted by the theory.
Table 1  Numbers of GMRES iterations (and GMRES/PCG for BDDC) for the multilevel FETI-DP and BDDC methods, and for the FETI-DP with the block diagonal preconditioner (BD) from (31), with increasing number of levels \( L \) and coarsening ratios \( H/ H_{ℓ−1} \), \( ℓ = 1, \ldots, L − 1 \) with corner constraints. Here \( n_{sub} \) is the number of subdomains on each level, \( n_{dof} \) is the number of degrees of freedom, and \( λ_{max} \) is the largest eigenvalue of the multilevel BDDC and FETI-DP preconditioned operators.

| \( L \) | \( n_{sub} \) | \( n_{dof} \) | \( λ_{max} \) | BD | FETI-DP | BDDC |
|---|---|---|---|---|---|---|
| \( H/ H_{ℓ−1} = 3 \) | | | | | | |
| 2 | 9 | 100 | 1.8781 | 14 | 9 | 10/10 |
| 3/2 | 729/81/9 | 6724 | 5.3709 | 29 | 20 | 21/21 |
| 5/4 | 6561/729/81/9 | 59,536 | 8.8557 | 35 | 27 | 28/29 |
| \( H/ H_{ℓ−1} = 4 \) | | | | | | |
| 2 | 16 | 289 | 2.1797 | 10 | 6 | 12/11 |
| 3/2 | 256/16 | 4225 | 4.1758 | 29 | 18 | 19/19 |
| 4/3 | 4096/256/16 | 66,049 | 7.8472 | 37 | 27 | 28/29 |
| \( H/ H_{ℓ−1} = 6 \) | | | | | | |
| 2 | 36 | 1369 | 2.7982 | 24 | 14 | 15/15 |
| 3/2 | 1296/36 | 47,089 | 6.0284 | 36 | 24 | 25/26 |

Table 2  Numbers of GMRES (and GMRES/PCG for BDDC) iterations for the same problems as in Table 1, but here with corner constraints combined with averages over edges.

| \( L \) | \( n_{sub} \) | \( n_{dof} \) | \( λ_{max} \) | BD | FETI-DP | BDDC |
|---|---|---|---|---|---|---|
| \( H/ H_{ℓ−1} = 3 \) | | | | | | |
| 2 | 9 | 100 | 1.0550 | 8 | 4 | 4/5 |
| 3/2 | 729/81/9 | 6724 | 1.2866 | 11 | 8 | 8/8 |
| 5/4 | 6561/729/81/9 | 59,536 | 2.1212 | 17 | 14 | 14/14 |
| \( H/ H_{ℓ−1} = 4 \) | | | | | | |
| 2 | 16 | 289 | 1.1094 | 7 | 4 | 6/6 |
| 3/2 | 256/16 | 4225 | 1.4779 | 13 | 9 | 9/9 |
| 4/3 | 4096/256/16 | 66,049 | 1.9393 | 17 | 13 | 13/13 |
| \( H/ H_{ℓ−1} = 6 \) | | | | | | |
| 2 | 36 | 1369 | 1.2280 | 13 | 7 | 7/7 |
| 3/2 | 1296/36 | 47,089 | 1.7775 | 17 | 11 | 11/11 |

Table 3  Numbers of GMRES iterations (and GMRES/PCG for BDDC) for the dam problem and the BDDC and FETI-DP methods with varying choices of constraints: corners (c), arithmetic averages over edges (e) and faces (f), and their total numbers on level 1/level 2, and also the largest eigenvalues \( λ_{max} \) of the preconditioned operators. The inexact methods apply algebraic multigrid (AMG) to the coarse problem.

| constraints | inexact methods | three-level methods |
|---|---|---|
| type level 1/level 2 | FETI-DP | BDDC | FETI-DP | BDDC |
| | \( λ_{max} \) | | \( λ_{max} \) | | |
| c | 11,970/99 | 65/75 | 89/56 | 66/95 | 73/87 |
| c+e | 21,180/144 | 105/125 | 220/43 | 21.1 | 42/45 |
| c+e+f | 28,002/198 | 134/140 | 15.1/37 | 14.1 | 33/35 |
Fig. 2 The largest 150 eigenvalues of the three-level BDDC and FETI-DP preconditioned operators with coarsening ratio $H_\ell/H_{\ell-1} = 3$, where $\ell = 1, 2$, with corner constraints (left), and corners and arithmetic averages over edges (right).

Fig. 3 Finite element discretization and substructuring of the dam consisting of 3,800,080 elements distributed into 400 subdomains in the first level (top) and 8 subdomains in the second level (bottom left). Model by courtesy of Jaroslav Kruis, images reproduced from [39].
As the second problem we used a real-world model of linear elasticity in a dam discretized using $3,800,080$ finite elements with $2,006,748$ degrees of freedom, distributed into $400$ subdomains with $3990$ corners, $3070$ edges and $2274$ faces. The subdomains in the first level were distributed into $8$ subdomains for the three-level method. The distribution of the elements into subdomains in both substructuring levels was obtained using METIS [15,16], see Figure 3. Table 3 shows the iteration counts of GMRES (and PCG) for inexact and three-level FETI-DP and BDDC methods with varying choices of constraints. The table also shows the largest eigenvalues of the two preconditioned operators for the three-level methods. For the inexact methods we applied algebraic multigrid (AMG) as the preconditioner $M_c$ in (25) and (20)–(21). Specifically, we used a MATLAB version of the routine HSL_MI20 [1], which performs grid coarsening using the classical algorithm by Ruge and Stüben [34]. We used the AMG routine with its default settings. It can be seen that adding more constraints as averages over the edges and faces to the coarse problem (and thus increasing its size) leads to an increase in the iteration count for the inexact methods. Nevertheless with the corner constraints, the inexact methods converge in fewer iterations than the three-level methods. On the other hand, it is expected that adding more constraints would improve convergence for the multilevel methods. We see that this happens, in particular after combining the corners with the averages over edges, and the improvement is less dramatic after adding the averages over faces. We also note that there are adaptive techniques for construction of the the coarse spaces, in particular the Adaptive-Multilevel BDDC [28,42], which could be applied to the multilevel methods presented here, but this is beyond the focus of our study. Also, a thorough comparison of the proposed methods with AMG would be of independent interest. For example, in a recent study Klawonn et al. [19] found that, for the BDDC method, inexact preconditioning using AMG and the two-level BDDC applied to the coarse problem show in most situations a very similar behavior.
Figure 4 displays estimates of the 50 largest eigenvalues for the three-level FETI-DP and BDDC preconditioned operators for the setup using corner constraints (left panel), and using corners combined with arithmetic averages over edges (right panel), for the dam problem. We see that adding averages of the edges reduces the largest eigenvalue approximately four times, and even though the eigenvalues in the case of the corner constraints decrease at a somewhat faster rate, their values remain higher than those in the case when both corner and edges are used for constraints. In both panels a (close) correspondence of the eigenvalue estimates can be observed for all eigenvalues.

Finally, we note that the iteration counts of GMRES and PCG in Table 3 are close also for both inexact methods and each set of constraints. This suggests that the eigenvalues of the inexact methods may be also similar. A comparison of the eigenvalue estimates for the inexact methods is provided by Figure 5. The left panel corresponds to the problem with the same setup as in the second row of Table 1, cf. also the left panel in Figure 2. For this problem, the inexact FETI-DP converged in 11 iterations and the inexact BDDC converged in 12 iterations using both GMRES and PCG. It can be seen that in this case, with geometric discretization and uniform partitioning of the domain into subdomains, the eigenvalue estimates are the same (and real). An agreement can be observed also in the right panel, which displays 50 eigenvalues of the largest magnitude corresponding to the dam problem with corner constraints. Nevertheless, even though all eigenvalues in Figure 5 are real, we note that the eigenvalues of the inexact FETI-DP preconditioned operator are in general complex, and a strategy to make them real was provided in [20].

Fig. 5 The largest 150 eigenvalues of the inexact BDDC and FETI-DP preconditioned operators with geometric discretization and partitioning of the domain (left panel), and 50 eigenvalues of the largest magnitude for the dam problem (right).

Acknowledgements The author is grateful to Jaroslav Kruis for providing the discretization of the dam problem, to Marian Brezina for visualizations using his own software package MyVis, and to Jan Mandel for continuing support and interest in the domain decomposition methods. He would also like to thank the anonymous reviewers for comments and suggestions that helped to improve the quality of the manuscript.

where some terms vanished, because using (29), (33) and (32) we get
\[ H \text{ mark. That is, one would write} \]
the proof for completeness. The proof of Theorem 1 is obtained by dropping the tilde accent mark. That is, one would write \( \tilde{H} \) in place of \( H \), \( F \) in place of \( \tilde{F} \), and \( \tilde{M} \) in place of \( \tilde{M} \).

First, let us note a few properties of the operators: both \( ER \) and \( BDBT \) are projections,
\[
\begin{align*}
BR &= 0, \quad \text{(from the definition),} \\
REB_D^T &= \left( I - B_D^T B \right) B_D^T = B_D^T - B_D^T B B_D^T = 0, \\
EB_D^T B &= E (I - RE) = E - ERE = 0.
\end{align*}
\]

Next, we show that
\[
\begin{align*}
T_P \tilde{M} \tilde{S} &= M_D \tilde{F} T_P, \\
T_P &= B_D SR, \\
T_D M_D \tilde{F} &= \tilde{M} ST_D, \\
T_D &= E \tilde{H} B^T.
\end{align*}
\]

The first identity is derived as
\[
T_P \tilde{M} \tilde{S} = (B_D SR) E \tilde{H} E^T \left( R^T SR \right) = B_D S \left( I - B_D^T B \right) \tilde{H} (RE)^T SR =
\]
\[
= B_D S \tilde{H} (RE)^T SR - B_D S BT_D^T B \tilde{H} \left( I - B_D^T B \right)^T SR =
\]
\[
= B_D S \tilde{H} (RE)^T SR - B_D S B_D^T B \tilde{H} SR + B_D S B_D^T B \tilde{H} B^T B_D SR =
\]
\[
= \left( B_D S B_D^T \right) B \tilde{H} B^T (B_D SR) = M_D \tilde{F} T_P,
\]
where some terms vanished, because using (29), (33) and (32) we get
\[
\begin{align*}
B_D S \tilde{H} (RE)^T SR &= \left( R^T SRE \tilde{H} S B_D^T \right) \left( I \right) = \left( R^T SREB_D^T \right) = 0, \\
B_D S B_D^T B \tilde{H} SR &= B_D S B_D^T B \tilde{H} R = B_D S B_D^T BR = 0.
\end{align*}
\]

The second identity is derived as
\[
T_D M_D \tilde{F} = \left( E \tilde{H} B^T \right) B_D S B_D^T \left( B \tilde{H} B^T \right) = E \tilde{H} (I - RE)^T SREB_D^T B \tilde{H} B^T =
\]
\[
= E \tilde{H} S B_D^T B \tilde{H} B^T - E \tilde{H} (RE)^T S (I - RE) \tilde{H} B^T =
\]
\[
= E \tilde{H} S B_D^T B \tilde{H} B^T - E \til{H} (RE)^T S \til{H} B^T + E \til{H} (RE)^T SRE \til{H} B^T =
\]
\[
= \left( E \til{H} E^T \right) R^T SR \left( E \til{H} B^T \right) = \til{M} ST_D.
\]
where some terms vanished, because using (29), (34) and (32) we get
\[
E \tilde{H} S B_D^T \tilde{H} B^T = E \tilde{H} S B_D^T \tilde{H} B^T = E B_D^T \tilde{H} B^T = 0,
\]
\[
E \tilde{H} (RE)^T S \tilde{H} B^T = \left( B \tilde{H} S R (RE)^T \right)^T = \left( B R E \tilde{H} E^T \right)^T = 0.
\]

Finally, let \( u_P \) be an eigenvector of \( \tilde{M}_S \tilde{S} \) corresponding to eigenvalue \( \lambda_P \). Then \( T_P u_P \) is also an eigenvector of \( M_D \tilde{F} \) provided \( T_P u_P \neq 0 \). So, let us assume \( T_P u_P = 0 \). But then,
\[
0 = T_D T_P u_P = E \tilde{H} B^T B_D S R u_P = E \tilde{H} (I - ER) S R u_P =
\]
\[
= E \tilde{H} S R u_P - E \tilde{H} E S R u_P = E R u_P - E \tilde{H} E S R u_P = E R u_P - \tilde{M}_S \tilde{S} u_P,
\]
but since \( ER \) is a projection, \( \lambda_P \) can be only equal to 0 or 1. Next, let \( u_D \) be an eigenvector of \( M_D \tilde{F} \) corresponding to eigenvalue \( \lambda_D \). Then \( T_D u_D \) is also an eigenvector of \( \tilde{M}_S \tilde{S} \) provided \( T_D u_D \neq 0 \). So, let us assume \( T_D u_D = 0 \). But then,
\[
0 = T_D T_D u_D = B_D S R E \tilde{H} B^T u_D = B_D S \left( I - B_D^T B \right) \tilde{H} B^T u_D =
\]
\[
= B_D S \tilde{H} B^T u_D - B_D S B_D^T \tilde{H} B^T u_D = B_D B^T u_D - B_D S B_D^T \tilde{H} B^T u_D =
\]
\[
= B_D B^T u_D - M_D \tilde{F} u_D,
\]
but since \( B_D B^T \) is a projection, \( \lambda_D \) can be only equal to 0 or 1.
