Smoothness of the law of some one-dimensional jumping S.D.E.s with non-constant rate of jump

Nicolas Fournier*

February 1, 2008

Abstract

We consider a one-dimensional jumping Markov process \( \{X^x_t\}_{t \geq 0} \), solving a Poisson-driven stochastic differential equation. We prove that the law of \( X^x_t \) admits a smooth density for \( t > 0 \), under some regularity and non-degeneracy assumptions on the coefficients of the S.D.E. To our knowledge, our result is the first one including the important case of a non-constant rate of jump. The main difficulty is that in such a case, the map \( x \mapsto X^x_t \) is not smooth. This seems to make impossible the use of Malliavin calculus techniques. To overcome this problem, we introduce a new method, in which the propagation of the smoothness of the density is obtained by analytic arguments.

Key words: Stochastic differential equations, Jump processes, Regularity of the density.

MSC 2000: 60H10, 60J75.

1 Introduction

Consider a \( \mathbb{R} \)-valued Markov process with jumps \( \{X^x_t\}_{t \geq 0} \), starting from \( x \in \mathbb{R} \), with generator \( \mathcal{L} \), defined for \( \phi : \mathbb{R} \mapsto \mathbb{R} \) sufficiently smooth and \( y \in \mathbb{R} \), by

\[
\mathcal{L}\phi(y) = b(y)\phi'(y) + \gamma(y) \int_G [\phi(y + h(y,z)) - \phi(y)] q(dz),
\]

for some functions \( \gamma, b : \mathbb{R} \mapsto \mathbb{R} \) with \( \gamma \) nonnegative, for some measurable space \( G \) endowed with a nonnegative measure \( q \), and some function \( h : \mathbb{R} \times G \mapsto \mathbb{R} \).

Roughly, \( b(y) \) is the drift term: between \( t \) and \( t + dt \), \( X^x_t \) moves from \( y \) to \( y + b(y)dt \). Next, \( \gamma(y)q(dz) \) stands for the rate at which \( X^x_t \) jumps from \( y \) to \( y + h(y,z) \).

*Centre de Maths, Faculté des Sciences et Technologies, Université Paris 12, 61 avenue du Général de Gaulle, 94010 Créteil Cedex, France. E-mail: nicolas.fournier@univ-paris12.fr
We aim to investigate the smoothness of the law of $X_t^x$ for $t > 0$. Most of the known results are based on the use of some Malliavin calculus, i.e. on a sort of differential calculus with respect to the stochastic variable $\omega$.

The first results in this direction were obtained by Bismut [4], see also Léandre [10]. Important results are due Bichteler et al. [2]. We refer to Graham-Mélèard [9], Fournier [8] and Fournier-Giet [8] for relevant applications to physic integro-differential equations such as the Boltzmann and the coagulation-fragmentation equations. These results concern the case where $q(dz)$ is sufficiently smooth.

When $q$ is singular, Picard [12] obtained some results using some fine arguments relying on the affluence of small (possibly irregular) jumps. Denis [5] and more recently Bally [1] also obtained some regularity results when $q$ is singular, using the drift and the density of the jump instants, see also Nourdin-Simon [11].

All the previously cited works apply only to the case where the rate of jump $\gamma(y)$ is constant. The case where $\gamma$ is non-constant is much more delicate. The main reason for this is that in such a case, the map $x \mapsto X_t^x$ cannot be regular (and even continuous). Indeed, if $\gamma(x) < \gamma(y)$, and if $q(G) = \infty$, then it is clear that for all small $t > 0$, $X^x$ jumps infinitely more often than $X^y$ before $t$. The only available results with $\gamma$ not constant seem to be those of [7, 8], where only the existence of a density was proved. Bally [1] considers the case where $\gamma(y)q(dz)$ is replaced by something like $\gamma(y,z)q(dz)$, with $\sup_y |\gamma(y,z) - 1| \in L^1(q)$: the rate of jump is not constant, but this concerns only finitely many jumps.

From a physical point of view, the situation where $\gamma$ is constant is quite particular. For example in the (nonlinear) Boltzmann equation, which describes the distribution of velocities in a gas, the rate of collision between two particles heavily depends on their relative velocity (except in the so-called Maxwellian case treated in [9, 6]). In a fragmentation equation, describing the distribution of masses in a system of particles subjected to breakage, the rate at which a particle splits into smaller ones will clearly almost always depend on its mass...

We will show here that when $q$ is smooth enough, it is possible to obtain some regularity results in the spirit of [2]. Compared to [2], our result is

- stronger, since we allow $\gamma$ to be non-constant;
- weaker, since we are not able, at the moment, to study the case of processes with infinite variations, and since we treat only the one-dimensional case (our method could also apply to multidimensional processes, but our non-degeneracy conditions would be very strong).

Our method relies on the following simple ideas:

(a) we consider, for $n \geq 1$, the first jump instant $\tau_n$ of the Poisson measure driving $X^x$, such that the corresponding mark $Z_n$ falls in a subset $G_n \subset G$ with $q(G_n) \simeq n$;
(b) using some smoothness assumptions on $q$ and $h$, we deduce that $X_{\tau_n}^x$ has a smooth density (less and less smooth as $n$ tends to infinity);
(c) we also show that smoothness propagates with time in some sense, so that $X_t^x$ has a smooth density conditionnally to $\{t \geq \tau_n\};$
(d) we conclude by choosing carefully \( n \) very large in such a way that \( \{ t \geq \tau_n \} \) occurs with sufficiently great probability.

As a conclusion, we obtain the smoothness of the density using only the regularizing property of one (well-chosen) jump. On the contrary, Bichteler et al. \[2\] were using the regularization of infinitely many jumps, which was possible using a sort of Malliavin calculus. Surprisingly, our non-degeneracy condition does not seem to be stronger, see Subsection 2.4 for a detailed comparison in a particular (but quite typical) example.

We present our results in Section 2 and we give the proofs in Sections 3 and 4. An Appendix lies at the end of the paper.

## 2 Results

In the whole paper, \( \mathbb{N} = \{1, 2, \ldots \} \). Consider the one-dimensional S.D.E.

\[
X^x_t = x + \int_0^t b(X^x_s)ds + \int_0^t \int_{\mathbb{R}} h(X^x_{s-}, z)1_{\{u \leq \gamma(X^x_{s-})\}}N(ds, du, dz), \tag{2}
\]

where

**Assumption (I):** The Poisson measure \( N(ds, du, dz) \) on \([0, \infty) \times [0, \infty) \times G\) has the intensity measure \( dsduq(dy) \), for some measurable space \((G, \mathcal{G})\) endowed with a nonnegative measure \( q \). For each \( t \geq 0 \) we set \( \mathcal{F}_t := \sigma\{N(A), A \in \mathcal{B}([0, t]) \otimes \mathcal{B}([0, \infty)) \otimes \mathcal{G}\} \).

We will require some smoothness of the coefficients. For \( f(y) : \mathbb{R} \mapsto \mathbb{R} \) (and \( h(y, z) : \mathbb{R} \times G \mapsto \mathbb{R} \)), we will denote by \( f^{(l)} \) (and \( h^{(l)} \)) the \( l \)-th derivative of \( f \) (resp. of \( h \) with respect to \( y \)). Below, \( k \in \mathbb{N} \) and \( p \in [1, \infty) \) are fixed.

**Assumption \((A_{k, p})\):** The functions \( b : \mathbb{R} \mapsto \mathbb{R} \) and \( \gamma : \mathbb{R} \mapsto \mathbb{R} \) are of class \( C^k \), with all their derivatives of order 0 to \( k \) bounded.

The function \( h : \mathbb{R} \times G \mapsto \mathbb{R} \) is measurable, and for each \( z \in G \), \( y \mapsto h(y, z) \) is of class \( C^k \) on \( \mathbb{R} \). There exists \( \eta \in (L^1 \cap L^p)(G, q) \) such that for all \( y \in \mathbb{R} \), all \( z \in G \), all \( l \in \{0, \ldots, k\} \), \( |h^{(l)}(y, z)| \leq \eta(z) \).

Under \((A_{1, 1})\), \( \mathcal{L}\phi \), introduced in \(\Pi\), is well-defined for all \( \phi \in C^1(\mathbb{R}) \) with a bounded derivative. The following result classically holds, see e.g. \(\Pi\) Section 2] for the proof of a similar statement.

**Proposition 2.1** Assume (I) and \((A_{k, p})\) for some \( p \geq 1 \), some \( k \geq 1 \). For any \( x \in \mathbb{R} \), there exists a unique càdlàg \( (\mathcal{F}_t)_{t \geq 0} \)-adapted process \((X^x_t)_{t \geq 0}\) solution to (2) such that for all all \( T \in [0, \infty) \), \( E[\sup_{t \in [0, T]} |X^x_t|^p] < \infty \).

The process \((X^x_t)_{t \geq 0, x \in \mathbb{R}}\) is a strong Markov process with generator \( \mathcal{L} \) defined by \(\Pi\). We will denote by \( p(t, x, dy) := \mathcal{L}(X^x_t) \) its semi-group.
2.1 Propagation of smoothness

We consider the space \( M(\mathbb{R}) \) of finite (signed) measures on \( \mathbb{R} \), and we abusively write \( ||f||_{L^1(\mathbb{R})} := ||f||_{TV} = \int_{\mathbb{R}} |f| \, dy \) for \( f \in M(\mathbb{R}) \). We denote by \( C^k_b(\mathbb{R}) \) (resp. \( C^k_c(\mathbb{R}) \)) the set of \( C^k \)-functions with all their derivatives bounded (resp. compactly supported). We introduce, for \( k \geq 1 \), the space \( \dot{W}^{k,1}(\mathbb{R}) \) of measures \( f \in M(\mathbb{R}) \) such that for all \( l \in \{1, \ldots, k\} \), there exists \( g_l \in M(\mathbb{R}) \) such that for all \( \phi \in C^k_c(\mathbb{R}) \) (and thus for all \( \phi \in C^k_b(\mathbb{R}) \)),

\[
\int_{\mathbb{R}} f(dy) \phi^{(l)}(y) = (-1)^l \int_{\mathbb{R}} g_l(dy) \phi(y).
\]

If so, we set \( f^{(l)} = g_l \). Classically, for \( f \in M(\mathbb{R}) \), \( f \in \dot{W}^{k,1}(\mathbb{R}) \) if and only if

\[
||f||_{\dot{W}^{k,1}(\mathbb{R})} := \sum_{l=0}^{k} \sup \left\{ \int_{\mathbb{R}} f(dy) \phi^{(l)}(y), \ \phi \in C^k_b(\mathbb{R}), \ ||\phi||_{\infty} \leq 1 \right\}
\]

is finite (here \( C^k_b \) could be replaced by \( C^k_c, C^\infty_b, \) or \( C^\infty_c \)), and in such a case,

\[
||f||_{\dot{W}^{k,1}(\mathbb{R})} = \sum_{l=0}^{k} ||f^{(l)}||_{L^1(\mathbb{R})}.
\]

Let us finally recall that

- for \( f \in C^k(\mathbb{R}) \), \( f(y)dy \) belongs to \( \dot{W}^{k,1}(\mathbb{R}) \) if and only if \( \sum_{l=0}^{k} |f^{(l)}| \in L^1(\mathbb{R}) \);
- if \( f \in \dot{W}^{k,1}(\mathbb{R}) \), with \( k \geq 2 \), then \( f(dy) \) has a density of class \( C^{k-2}(\mathbb{R}) \).

We now introduce a first non-degeneracy assumption (here \( h'(y, z) = \partial_y h(y, z) \)).

**Assumption (S):** There exists \( c_0 > 0 \) such that for all \( z \in G \), all \( y \in \mathbb{R} \), if \( 1 + h'(y, z) \geq c_0 \).

**Proposition 2.2** Let \( p \geq k + 1 \geq 2 \) be fixed, assume (I), (A_{k+1,p}), and (S).

For \( t \geq 0 \) and a probability measure \( f \) on \( \mathbb{R} \), we define \( p(t, f, dy) \) on \( \mathbb{R} \) by \( p(t, f, A) = \int_{\mathbb{R}} f(dx) p(t, x, A) \), where \( p(t, x, dy) \) was defined in Proposition 2.1.

There is \( C_k > 0 \) such that for all probability measures \( f \in \dot{W}^{k,1}(\mathbb{R}) \), all \( t \geq 0 \),

\[
||p(t, f, \cdot)||_{\dot{W}^{k,1}(\mathbb{R})} \leq ||f||_{\dot{W}^{k,1}(\mathbb{R})} e^{C_k t}.
\]

Observe that \( p(t, f, dy) \) is the law of \( X_t^{X_0} \) where \( (X_t^{x})_{t \geq 0, x \in \mathbb{R}} \) solves (2) and where \( X_0 \sim f(dy) \) is independent of \( N \).

Assumption (S) is probably far from optimal, but something in this spirit is needed: take \( b \equiv 0, \gamma \equiv 1 \) and \( h(y, z) = -y1_A(z) + y\eta(z) \) for some \( A \subset G \) with \( q(A) < \infty \) and some \( \eta \in L^1(G, q) \). Of course, (S) is not satisfied, and one easily checks that there exists \( \tau_A \) exponentially distributed (with parameter \( q(A) \)) such that a.s., for all \( t \geq \tau_A \), all \( x \in \mathbb{R}, \ X_t^x = 0 \). This forbids the propagation of smoothness, since then \( p(t, f, dy) \geq (1 - e^{-q(A)t})\delta_0(dy) \), even if \( f \) is smooth.
2.2 Regularization

We now give the non-degeneracy condition that will provide a smooth density to our process. A generic example of application (in the spirit of [2]) will be given below. For two nonnegative measures \( \nu, \tilde{\nu} \) on \( G \), we say that \( \nu \leq \tilde{\nu} \) if for all \( A \in \mathcal{G} \), \( \nu(A) \leq \tilde{\nu}(A) \). Here \( k \in \mathbb{N} \), \( p \in [0, \infty) \) and \( \theta > 0 \).

Assumption \((H_{k,p,\theta})\): Consider the jump kernel \( \mu(y, du) \) associated to our process, defined by \( \mu(y, A) = \gamma(y) \int_G I_A(h(y, z))q(dz) \) (which may be infinite) for all \( A \in \mathcal{B}(\mathbb{R}) \).

There exists a (measurable) family \((\mu_n(y, du))_{n \geq 1, y \in \mathbb{R}}\) of measures on \( \mathbb{R} \) meeting the following points:

(i) for \( n \geq 1 \), \( y \in G \), \( 0 \leq \mu_n(y, du) \leq \mu(y, du) \) and \( \mu_n(y, \mathbb{R}) \geq n \);

(ii) for all \( r > 0 \), \( n \geq 1 \), \( \sup_{|y| \leq r} \mu_n(y, \mathbb{R}) < \infty \);

(iii) there exists \( C > 0 \) such that for all \( n \in \mathbb{N} \), \( y \in \mathbb{R} \),

\[
\frac{1}{\mu_n(y, \mathbb{R})} ||\mu_n(y, .)||_{W^{k,1}(\mathbb{R})} \leq C(1 + |y|^p)e^{\theta n}.
\]

The principle of this assumption is quite natural: it says that at any position \( y \), our process will have sufficiently many jumps with a sufficiently smooth density. Our main result is the following.

Theorem 2.3 Let \( p \geq k + 1 \geq 3 \) and \( \theta > 0 \) be fixed. Assume \( (I) \), \( (A_{k+1,p}) \), \( (S) \) and \( (H_{k,p,\theta}) \). Consider the law \( p(t, x, dy) \) at time \( t \geq 0 \) of the solution \( (X^x_t)_{t \geq 0} \).

(a) Let \( t \geq \theta/(k - 1) \). For any \( x \in \mathbb{R} \), \( p(t, x, dy) \) has a density \( y \mapsto p(t, x, y) \) of class \( C^k_b(\mathbb{R}) \) as soon as \( 0 \leq n < kt/(\theta + t) - 1 \).

(b) In particular, if \((H_{k,p,\theta})\) holds for all \( \theta > 0 \), then for all \( t > 0 \), all \( x \in \mathbb{R} \), \( y \mapsto p(t, x, y) \) is of class \( C^{k-2}_b(\mathbb{R}) \).

2.3 Another assumption

It might seem strange to state our regularity assumptions with the help of \( \gamma, h, q \), and to our nondegeneracy conditions with the help of the jump kernel \( \mu \). However, it seems to us to be the best way to give understandable assumptions.

Let us give some conditions on \( \gamma, h, q \), in the spirit of [2], which imply \((H_{k,p,\theta})\).

Assumption \((B_{k,p,\theta})\): \( G = \mathbb{R} \), and for all \( y \in \mathbb{R} \), \( \gamma(y) > 0 \) and there exists \( I(y) = (a(y), \infty) \) (or \( (-\infty, a(y)) \)) with \( a(y) \in \mathbb{R} \), with \( y \mapsto a(y) \) measurable, such that \( q(dz) \geq 1_{I(y)}(z)dz \) and such that the following conditions are fulfilled:

(a) for all \( y \in \mathbb{R} \), \( z \mapsto h(z) \) is of class \( C^{k+1} \) on \( I(y) \). The derivatives \( h^{(l)} \) (w.r.t. \( z \)) for \( l = 1, ... , k + 1 \) are uniformly bounded on \( \{ (y, z); y \in \mathbb{R}, z \in I(y) \} \);

(b) for all \( y \in \mathbb{R} \), all \( z \in I(y), h^{(l)}_z(y, z) \neq 0 \), and with \( I_n(y) = [a(y), a(y) + n/\gamma(y)] \) (or \( [a(y) - n/\gamma(y), a(y)] \)),

\[
\gamma(y) \frac{1}{n} \int_{I_n(y)} |h_z'(y, z)|^{-2k}dz \leq C(1 + |y|^p)e^{\theta n}.
\] (4)
Lemma 2.4 $(B_{k,p,\theta})$ and $(A_{1,1})$ imply $(H_{k,p,\theta})$.

This lemma is proved in the Appendix. Let us give some examples for $(1)$.

Examples: Assume that $|h'_{z}(y,z)| \geq \epsilon (1+|y|)^{-\alpha} \zeta(z)$, for all $y \in \mathbb{R}$, all $z \in I(y)$, for some $\alpha \geq 0$, $\epsilon > 0$.

- If $\zeta(z) = (1+|z|)^{-\delta}$, for some $\delta \geq 0$, and $\gamma(y) \geq c(1+|y|)^{-\beta}$ for some $c > 0$, $\beta \geq 0$, then $(1)$ holds for all $k \geq 1$, all $\theta > 0$ and all $p \geq 2k(\alpha + \beta \delta)$.
- If $\zeta(z) = e^{-d|z|}$, for some $d > 0$, $\delta \in (0,1)$, and if $\gamma(y) \geq c[\log(2+|y|)]^{-\beta}$, with $c > 0$, $\beta \in [0,(1-\delta)/\delta)$, then $(1)$ holds for all $k \geq 1$, all $\theta > 0$, all $p > 2k\alpha$.
- If $\zeta(z) = e^{-d|z|}$, for some $d > 0$, if $\gamma(y) \geq c > 0$, then $(1)$ holds for all $k \geq 1$, all $\theta \geq 2kd/c$ and all $p \geq 2k\alpha$.
- With our assumption that $\gamma$ is bounded, $(1)$ does never hold if $\zeta(z) = e^{-d|z|}$ for some $d > 0$, $\delta > 1$.

Observe on these examples that there is a balance between the rate of jump $\gamma$ and the regularization power of jumps (given, in some sense, by lowerbounds of $|h'_{z}|$). The more the power of regularization is small, the more the rate of jump has to be bounded from below. This is quite natural and satisfying.

2.4 Comments

Let us mention that when $\gamma$ is constant, the result of $(2)$ (in dimension 1), is essentially the following. Roughly, they also assume something like $q(dz) \geq 1_{(a,\infty)}(z)dz$ (they actually consider the case where $q(dz) \geq 1_{O(z)}dz$ for some infinite open subset $O$ of $\mathbb{R}$).

They assume more integrability on the coefficients (something like $(A_{k,p})$ for all $p > 1$). They assume $(S)$, and much more joint regularity (in $y,z$) of $h$ (see Assumption $(A-r)$ page 9 in $(2)$), the uniform boundedness of $\partial_{x_{a}}\partial_{y^{b}}h$ as soon as $a \geq 1$.

Their non-degeneracy condition (see Assumption $(SB-(\zeta,\theta))$ page 14 in $(2)$) is of the form $|h'_{z}(y,z)|^{2} \geq \epsilon (1+|x|)^{-\delta} \zeta(z)$, for some $\delta \geq 0$, some $\epsilon > 0$, and some broad function $\zeta$ (see Definition 2-20 and example 2-35 pages 13 and 17 in $(2)$). This notion is probably not exactly comparable to $(1)$. Roughly,

- when $\zeta(z) = e^{-\alpha|z|}$ with $\delta > 1$, their result does not apply (as ours);
- when $\zeta(z) = e^{-\alpha|z|}$ with $\delta < 1$, or when $\zeta(z) = (1+|z|)^{-\beta}$ with $\beta > 0$, their result applies for all times $t > 0$ (as ours);
- when $\zeta(z) = e^{-\alpha|z|}$, their result applies for sufficiently large times (as ours).

As a conclusion, we have slightly less technical assumptions. About the non-degeneracy assumption, it seems that the condition in $(2)$ and ours are very similar (when $\gamma \equiv 1$). Let us insist on the fact that this is quite surprising: one could think that since we use only the regularization of one jump, our nondegeneracy condition should be much stronger than that of $(2)$. 6
We could probably state an assumption as \((B_{k,p,θ})\) for a general lowerbound of the form \(q( dz) ≥ 1_{O}(z)ϕ(z)dz\), for some open subset \(O\) of \(\mathbb{R}\) and some \(C^∞\) function \(ϕ: O \mapsto \mathbb{R}\), but this would be very technical.

Finally, it seems highly probable that one may assume, instead of \((S)\), that \(0 < 1/(1 + h'(x, z)) ≤ α(z) ∈ L^1 ∩ L^r(G, q)\) (with \(r\) large enough); and that the assumptions \(b, γ\) bounded and \(|h(x, z)| ≤ η(z)\) (in \((A_{k,p})\)) could be replaced by \(|b(x)| ≤ C(1 + |x|)\) and \(γ(x)|h(x, z)| ≤ (1 + |x|)η(z)\), with \(η ∈ L^1 ∩ L^p(G, q)\).

However, the paper is technical enough.

We prove Theorem 2.3 in Section 3 and Proposition 2.2 in Section 4.

3 Smoothness of the density

In this section, we assume that Proposition 2.2 holds, and we give the proof of our main result. We refer to the introduction for the main ideas of the proof.

Proof of Theorem 2.3

We consider here \(x ∈ \mathbb{R}\), the associated process \((X^x_t)_{t≥0}\). We assume \((I)\), \((S)\), \((A_{k+1,p})\), and \((H_{k,p,θ})\) for some \(p ≥ k + 1 ≥ 3\), some \(θ > 0\). Due to Proposition 2.1

\[∀ t > 0, \quad C_t := E \left[ \sup_{[0,t]} |X^x_t|^p \right] < ∞. \tag{5} \]

Recall \((H_{k,p,θ})\), and denote by \(f_n(y, u)\) the density (bounded by 1) of \(μ_n(y, du)\) with respect to \(μ(y, du)\). Then for \(q_n(y, dz) := d_n(y, z)q(dz)\) with \(d_n(y, z) := f_n(y, h(y, z))\) (which is bounded by 1), one easily checks that for all \(A ∈ \mathcal{B}(\mathbb{R})\), \(μ_n(y, A) = γ(y) \int_A 1_A(h(y, z))q_n(y, dz)\). As a consequence, still using \((H_{k,p,θ})\),

(i) \(0 ≤ q_n(y, dz) ≤ q(dz)\), and \(γ(y)q_n(y, G) = μ_n(y, G) ≥ n; \)

(ii) for all \(r > 0, n ∈ \mathbb{N}, \sup_{|y| ≤ r} γ(y)q_n(y, G) < ∞.\)

We now divide the proof into four parts.

Step 1. We first introduce some well-chosen instants of jump that will provide a density to our process. To this end, we write \(N = \sum_{i≥1} δ_{(t_i, u_i, z_i)}\), we consider a family of i.i.d. random variables \((v_i)_{i≥1}\) uniformly distributed on \([0, 1]\), independent of \(N\). We introduce the Poisson measure \(M = \sum_{i≥1} δ_{(t_i, u_i, v_i, z_i)}\) on \([0, ∞) × [0, ∞) × G × [0, 1]\) with intensity measure \(dsduq(dz)dv\). Then we observe that \(N(ds, du, dz) = M(ds, du, dz, [0, 1])\). Let \(\mathcal{H}_t = σ\{M(A), \ A ∈ \mathcal{B}([0, t]) ⊗ \mathcal{B}([0, ∞)) ⊗ G ⊗ \mathcal{B}([0, 1])\}\).

Next, we observe, using point (ii) above and \((5)\), that a.s., for all \(t ≥ 0, \)

\[\sup_{[0,t]} \int_0^∞ \int_G \int_0^1 1_{u ≤ γ(X^x_{t-}) ∧ v ≤ d_n(X^x_{t-})}duq(dz)dv = \sup_{[0,t]} γ(X^x_{t-})q_n(X^x_{t-}, G) < ∞.\]

We thus may consider, for each \(n ≥ 1\), the a.s. positive \((\mathcal{H}_t)_{t≥0}\)-stopping time

\[τ_n = \inf \left\{ t ≥ 0; \int_0^t ∫_0^∞ ∫_G ∫_0^1 1_{u ≤ γ(X^x_{t-}) ∧ v ≤ d_n(X^x_{t-})}M(ds, du, dz, dv) > 0 \right\}, \]

7
and the associated mark \((U_n, Z_n, V_n)\) of \(M\). Then one easily checks that
(a) for \(t \geq 0\), \(P[\tau_n \geq t] \leq e^{-nt}\), since due to point (i), a.s., for all \(s \geq 0\),
\[
\int_0^\infty \int_G \int_0^1 1_{\{u \leq \gamma(X_{s-}^x, v \leq d_n(X_{s-}^x, z)\}} duq(dz)dv = \gamma(X_{s-}^x) \int_G d_n(X_{s-}^x)q(dz) = \gamma(X_{s-}^x)q_n(X_{s-}^x, G) \geq n;
\]
(b) \(U_n \leq \gamma(X_{\tau_n}^x)\) a.s. by construction;
(c) conditionally to \(\mathcal{H}_{\tau_n}^x\), \(Z_n \sim q_n(X_{\tau_n}^x, dz)/q_n(X_{\tau_n}^x, G)\). Indeed, the triple
\((U_n, Z_n, V_n)\) classically follows, conditionally to \(\mathcal{H}_{\tau_n}^x\), the distribution
\[
\frac{1}{\gamma(X_{\tau_n}^x)q_n(X_{\tau_n}^x, G)} 1_{\{u \leq \gamma(X_{\tau_n}^x, v \leq d_n(X_{\tau_n}^x, z)\}} duq(dz)dv,
\]
and it then suffices to integrate over \(u \in [0, \infty)\) and \(v \in [0, 1]\) and to use that
\(d_n(y, z)q(dz) = q_n(y, dz)\).

**Step 2.** By construction and due to Step 1-(b),
\[
X_{\tau_n}^x = X_{\tau_n}^x + h(X_{\tau_n}^x, Z_n) 1_{\{U_n \leq \gamma(X_{\tau_n}^x)\}} = X_{\tau_n}^x + h(X_{\tau_n}^x, Z_n).
\]
Hence conditionally to \(\mathcal{H}_{\tau_n}^x\), the law of \(X_{\tau_n}^x\) is \(g_n(\omega, dy) := \mu_n(X_{\tau_n}^x, dy - X_{\tau_n}^x)/\mu_n(X_{\tau_n}^x, \mathbb{R})\). Indeed, for any bounded measurable function \(\phi : \mathbb{R} \mapsto \mathbb{R}\), using Step 1-(c) and that \(\mu_n(y, A) = \gamma(y) \int_G 1_A(h(y, z))q_n(y, dz)\),
\[
E[\phi(X_{\tau_n}^x)|\mathcal{H}_{\tau_n}^x] = \int_G \phi(X_{\tau_n}^x + h(X_{\tau_n}^x, z)) \frac{q_n(X_{\tau_n}^x, dz)}{q_n(X_{\tau_n}^x, G)} = \int_\mathbb{R} \phi(X_{\tau_n}^x + y) \frac{\mu_n(X_{\tau_n}^x, dy)}{\mu_n(X_{\tau_n}^x, \mathbb{R})} = \int_\mathbb{R} \phi(y)gn(dy).
\]
Due to assumption \((H_{k,p,\theta})\), we know that for some constant \(C\), a.s.,
\[
\|gn\|_{\tilde{W}^{k,1}(\mathbb{R})} = \frac{1}{\mu_n(X_{\tau_n}^x, \mathbb{R})}\|\mu_n(X_{\tau_n}^x, \cdot)\|_{\tilde{W}^{k,1}(\mathbb{R})} \leq C(1 + |X_{\tau_n}^x|^p)e^{\theta n}. \tag{6}
\]

**Step 3.** We now use the strong Markov property. For \(t \geq 0\) and \(n \geq 1\), for
\(\phi : \mathbb{R} \mapsto \mathbb{R}\), with the notation of Proposition 2.2 since \(\{t \geq \tau_n\} \in \mathcal{H}_{\tau_n}^x\),
\[
E[\phi(X_{\tau_n}^x)] = E[\phi(X_{\tau_n}^x)1_{\{t < \tau_n\}}] + E\left[1_{\{t \geq \tau_n\}} \int_\mathbb{R} \phi(y)p(t - \tau_n, gn, dy)\right]. \tag{7}
\]
But from Proposition 2.2 and (6), there exists a constant \(C_{t,k}\) such that a.s.
\[
1_{\{t \geq \tau_n\}}\|p(t - \tau_n, gn, \cdot)\|_{\tilde{W}^{k,1}(\mathbb{R})} \leq C_{t,k} 1_{\{t \geq \tau_n\}} \sup_{[0, t]}(1 + |X_{\tau_n}^x|^p)e^{\theta n}. \tag{8}
\]

**Step 4.** Consider finally the application \(\psi(\xi, y) = e^{i\xi y}\). Then the Fourier transform of the law \(p(t, x, dy)\) of \(X_t^x\) is given by \(\hat{p}_{t,x}\).

We
apply (7) with the choice \( \phi(y) = \psi^{(k)}(\xi, y) = (i\xi)^{k} \psi(\xi, y) \). We get, for \( n \geq 1, \, \xi \in \mathbb{R} \),

\[
|\xi|^{k} |\hat{p}_{t,x}(\xi)| \leq |\xi|^{k} P[\tau_{n} > t] + E \left[ 1_{\{t \geq \tau_{n}\}} \left| \int_{\mathbb{R}} \psi^{(k)}(\xi, y)p(t - \tau_{n}, g_{n}, dy) \right| \right]. \tag{9}
\]

But on \( \{t \geq \tau_{n}\} \), an integration by parts and then (8) leads us to

\[
\left| \int_{\mathbb{R}} \psi^{(k)}(\xi, y)p(t - \tau_{n}, g_{n}, dy) \right| \leq \|\psi(\xi, \cdot)\|_{\infty} \|p(t - \tau_{n}, g_{n}, \cdot)\|_{\dot{W}^{k,1}([0, t])} \leq C_{t,k} e^{\theta n} \sup_{[0, t]} (1 + |X_{t,x}^{p}|).
\]

Hence (9) becomes, using Step 1-(a) and (5),

\[
|\xi|^{k} |\hat{p}_{t,x}(\xi)| \leq |\xi|^{k} e^{-nt} + C_{t,k} (1 + C_{t}) e^{\theta n}.
\]

Choosing for \( n \) the integer part of \( \frac{k}{\theta + t} \log |\xi| \), we obtain, for some constant \( A_{t} \),

\[
|\xi|^{k} |\hat{p}_{t,x}(\xi)| \leq (e^{t} + C_{t,k}(1 + C_{t}))|\xi|^{k \theta/(\theta + t)} =: A_{t}|\xi|^{k \theta/(\theta + t)}. \tag{10}
\]

Since on the other hand \( |\hat{p}_{t,x}(\xi)| \) is clearly bounded by 1, we deduce that

\[
|\hat{p}_{t,x}(\xi)| \leq 1 \wedge A_{t}|\xi|^{-k t/(\theta + t)}.
\]

Let finally \( n \geq 0 \) such that \( n < \frac{k t}{\theta + t} - 1 \), which is possible if \( t > \frac{\theta}{k - 1} \). Then (10) ensures us that \( |\xi|^{n} |\hat{p}_{t,x}(\xi)| \) belongs to \( L^{1}(\mathbb{R}, d\xi) \), which classically implies that \( p(t, x, dy) \) has a density of class \( C_{b}^{k}(\mathbb{R}) \).

\[\square\]

4 Propagation of smoothness

It remains to prove Proposition 2.2. It is very technical, but the principle is quite simple: we study the Fokker-Planck integro-partial-differential equation associated with our process, and show that if the initial condition is smooth, so is the solution for all times, in the sense of \( \dot{W}^{k,1}(\mathbb{R}) \) spaces.

In the whole section, \( K \) is a constant whose value may change from line to line, and which depends only on \( k \) and on the bounds of the coefficients assumed in assumptions (\( A_{k+1,p} \)) and (S).

For functions \( f(y) : \mathbb{R} \rightarrow \mathbb{R} \), \( g(t,y) : [0, \infty) \times \mathbb{R} \rightarrow \mathbb{R} \), \( h(y, z) : \mathbb{R} \times G \rightarrow \mathbb{R} \), we will always denote by \( f^{(l)}, g^{(l)}, \) and \( h^{(l)} \) the \( l \)-th derivative of \( f, g, h \) with respect to the variable \( y \).

A map \( (t, y) \mapsto f(t, y) \) is of class \( C_{b}^{1,k}([0, T] \times \mathbb{R}) \) if the derivatives \( f^{(l)}(t, y) \) and \( \partial_{t} f^{(l)}(t, y) \) exist, are continuous and bounded, for all \( l \in \{0, \ldots, k\} \) .
We consider for $i \geq 1$ the approximation $\mathcal{L}^i$ of $\mathcal{L}$, recall (11), defined for all bounded and measurable $\phi : \mathbb{R} \mapsto \mathbb{R}$ by

$$
\mathcal{L}^i \phi (y) = i \left[ \phi \left( y + \frac{b(y)}{t} \right) - \phi (y) \right] + \gamma (y) \int_{G_i} q(dz) \left[ \phi (y + h[y,z]) - \phi (y) \right].
$$

Here, $(G_i)_{i \geq 1}$ is an increasing sequence of subsets of $G$ such that $\bigcup_{i \geq 1} G_i = G$ and such that for each $i \geq 1$, $q(G_i) < \infty$.

**Lemma 4.1** Assume (I) and (A$_{1,1}$).

(i) For any $i \geq 1$, any probability measure $f_i(dy)$ on $\mathbb{R}$, there exists a unique family of (possibly signed) bounded measures $(f_i(t,dy))_{t \geq 0}$ on $\mathbb{R}$ such that for all $T > 0$, $\sup_{0 \leq t \leq T} \int_{\mathbb{R}} |f_i(t)(dy)| < \infty$, and for all bounded measurable $\phi : \mathbb{R} \mapsto \mathbb{R}$,

$$
\int_{\mathbb{R}} \phi (y) f_i(t,dy) = \int_{\mathbb{R}} \phi (y) f_i(dy) + \int_0^t ds \int_{\mathbb{R}} \mathcal{L}^i \phi (y) f_i(s,dy).
$$

Furthermore, $f_i(t)$ is a probability measure for all $t \geq 0$.

(ii) Assume now that $f_i(dy)$ goes weakly to some probability measure $f(dy)$ as $i$ tends to infinity. Then for all $t \geq 0$, $f_i(t,dy)$ tends weakly to $p(t,dy)$ as $i$ tends to infinity, where we use the notation of Proposition 2.2.

**Proof** Let us first prove the uniqueness part. We observe that for $\phi$ bounded and measurable, $\mathcal{L}^i \phi$ is also measurable and satisfies $||\mathcal{L}^i \phi||_{\infty} \leq C_i ||\phi||_{\infty}$, where $C_i := 2i + 2||\gamma||_{\infty} q(G_i)$. Hence for two solutions $f_i(t,dy)$ and $\tilde{f}_i(t,dy)$ to (11), an immediate computation leads us to

$$
||f_i(t) - \tilde{f}_i(t)||_{TV} \leq C_i \int_0^t ds ||f_i(s) - \tilde{f}_i(s)||_{TV},
$$

since the total variation norm satisfies $||\nu||_{TV} : = \sup_{||\phi||_{\infty} \leq 1} \int_{\mathbb{R}} \phi (y) \nu(dy)$. The uniqueness of the solution to (11) follows from the Gronwall Lemma.

Let us consider $X_0 \sim f$ independent of $N$, and $(X^t_i)_{t \geq 0, x \in \mathbb{R}}$ the solution to (2), associated to the Poisson measure $N$. Recall that $p(t,f,dy) = \mathcal{L}(X^t_0)$. We introduce another Poisson measure $M^i(ds)$ on $[0, \infty)$ with intensity measure $id \nu$, independent of $N$, and $X^i_0 \sim f_i$, independent of $(M^i, N)$. Let $(X^i_t)_{t \geq 0}$ be the (clearly unique) solution to

$$
X^i_t = X^i_0 + \int_0^t b(X^i_{s-}) M^i(ds) + \int_0^t \int_0^\infty h(X^i_{s-},z) 1_{\{u \leq \gamma(X^i_{s-})\}} N(ds,du,dz).
$$

Then one immediately checks that $f_i(t,dy) = \mathcal{L}(X^i_t)$ solves (11). This shows the existence of a solution to (11), and that this solution consists of a family of probability measures. Finally, we use the Skorokhod representation Theorem: we build $X^i_0 \sim f_i$ in such a way that $X^i_0$ tends a.s. to $X_0$. Then one easily proves that $\sup_{0 \leq t} |X^i_t - X^{X^0}_t|$ tends to 0 in probability, for all $t \geq 0$, using repeatedly (A$_{1,1}$). We refer to [8, Step 1 page 653] for a similar proof. This of course implies that for all $t \geq 0$, $f_i(t,dy) = \mathcal{L}(X^i_t)$ tends weakly to $p(t,f,dy) = \mathcal{L}(X^0_t)$. \[Q.E.D.\]

We now introduce some inverse functions in order to write (11) in a strong form.
Lemma 4.2 Assume (S) and \((A_{k+1,p})\) for some \(p \geq k + 1 \geq 2\).

(i) For each fixed \(z \in G\), the map \(y \mapsto y + h(y, z)\) is an increasing \(C^{k+1}\) diffeomorphism from \(\mathbb{R}\) into itself. We thus may introduce its inverse function \(\tau(y, z) : \mathbb{R} \times G \rightarrow \mathbb{R}\) defined by \(\tau(y, z) + h(\tau(y, z), z) = y\). For each \(z \in G\), \(y \mapsto \tau(y, z)\) is of class \(C^{k+1}(\mathbb{R})\). There exist \(\alpha\) and \(K > 0\) such that

\[
|\tau(y, z) - y| + |\tau'(y, z) - 1| + \frac{|\tau'(y, z) - 1|}{\tau'(y, z)} \leq \alpha(z) \in L^1(G, q),
\]

\[
0 < \tau'(y, z) \leq K.
\]

For all \(l \in \{0, ..., k\}\), there exist some functions \(\alpha_{l,r} : \mathbb{R} \times G \rightarrow \mathbb{R}\) with

\[
\left(1 + \frac{1}{\tau'(y, z)}\right) \sum_{r=0}^{l} |\alpha_{l,r}(y, z)| \leq \alpha(z) \in L^1(G, q)
\]

such that for all \(\phi \in C^l(\mathbb{R})\),

\[
(\phi(\tau(y, z)))^{(i)} = \phi^{(i)}(\tau(y, z)) + \sum_{r=0}^{l} \alpha_{l,r}(y, z)\phi^{(r)}(\tau(y, z)).
\]

(ii) For all \(i \geq i_0 := 2|b'|\infty\), the map \(y \mapsto y + b(y)/i\) is an increasing \(C^{k+1}\) diffeomorphism from \(\mathbb{R}\) into itself. Let its inverse \(\tau_i : \mathbb{R} \rightarrow \mathbb{R}\) be defined by \(\tau_i(y) + b(\tau_i(y))/i = y\). Then \(\tau_i \in C^{k+1}(\mathbb{R})\). There exists \(c > 0, K > 0\) such that

\[
|\tau_i(y) - y| \leq K/i, \quad |\tau'_i(y) - 1| \leq K/i, \quad c < \tau'_i(y) \leq K.
\]

For all \(l \in \{0, ..., k\}\), there exist \(\beta_{l,r}^i : \mathbb{R} \rightarrow \mathbb{R}\) with

\[
\sum_{r=0}^{l} i|\beta_{l,r}^i(y)| \leq K
\]

such that for all \(\phi \in C^l(\mathbb{R})\),

\[
(\phi(\tau_i(y)))^{(i)} = \phi^{(i)}(\tau_i(y)) + \sum_{r=0}^{l} \beta_{l,r}^i(y)\phi^{(r)}(\tau_i(y)).
\]

(iii) For all \(i \geq i_0\), all bounded measurable \(\phi : \mathbb{R} \mapsto \mathbb{R}\) and all \(g \in L^1(\mathbb{R})\),

\[
\int_{\mathbb{R}} g(y)L^i\phi(y)dy = \int_{\mathbb{R}} \phi(y)L^ig(y)dy,
\]

where

\[
L^ig(y) = i\left[g(\tau_i(y))\tau'_i(y) - g(y)\right] + \int_{G_1} g(dz)[\gamma(\tau(y, z))g(\tau(y, z))\tau'(y, z) - \gamma(y)g(y)].
\]

Proof We start with

Point (i). The fact that for each \(z \in G\), \(y + h(y, z)\) is an increasing \(C^{k+1}\) diffeomorphism follows immediately from \((A_{k+1,p})\) and (S). Thus its inverse

11
function $y \mapsto \tau(y, z)$ is of class $C^{k+1}$. Next, $\tau'(y, z) = 1/(1 + h'(\tau(y, z), z))$, and thus is positive and bounded by $1/c_0$ due to (S). This shows (13). Of course, $\sup_y |\tau(y, z) - y| = \sup_y [y + h(y, z) - y] \leq \eta(z) \in L^1(G, q)$ due to $(A_{k+1,p})$. Next, $|\tau'(y, z) - 1| = |h'(\tau(y, z), z)|/(1 + h'(\tau(y, z), z)) \leq \eta(z)/c_0 \in L^1(G, q)$, due to (S) and $(A_{k+1,p})$. Finally, $|\tau'(y, z) - 1|/\tau'(y, z) = |h'(\tau(y, z), z)| \leq \eta(z) \in L^1(G, q)$, due to $(A_{k+1,p})$. Thus (12) holds.

We next show that for $l = 1, \ldots, k + 1$,

$$|\tau^{(l)}(y, z)| \leq K(\eta(z) + \eta^{l-1}(z)) \quad (20)$$

When $l = 1$, it suffices to use that $|\tau'(y, z) - 1| \leq K\eta(z)$, which was already proved. For $l \geq 2$, we use (30) (with $f(y) = y + h(y, z)$), the fact that $f'(y) = 1 + h'(y, z) \geq c_0$ due to (S), and that for all $n = 2, \ldots, k + 1$, $f^{(n)}(y) = h^{(n)}(y, z) \leq \eta(z)$ (due to $(A_{k+1,p})$): this yields, setting $I_{l,r} := \{q \in \mathbb{N}, i_1, \ldots, i_q \in \{2, \ldots, l\}; i_1 + \ldots + i_q = r - 1\}$,

$$|\tau^{(l)}(y, z)| \leq K \sum_{r=1}^{2l-1} \sum_{l_i}^{q} \prod_{j=1}^{q} |h^{(l_i)}(\tau(y, z), z)| \leq K \sum_{r=1}^{2l-1} \sum_{l_i}^{q} \eta^{q}(z)$$

$$\leq K \sum_{q=1}^{l-1} \eta^{q}(z) \leq K(\eta(z) + \eta^{l-1}(z)).$$

We now consider $\phi \in C^k(\mathbb{R})$. Due to (20), for $n = 1, \ldots, k$,

$$[\phi(\tau(y, z))]^{(n)} = [\tau'(y, z)]^{(n)} \phi^{(n)}(\tau(y, z)) + \sum_{r=1}^{n-1} \delta_{n,r}(y, z) \phi^{(r)}(\tau(y, z)) \quad (21)$$

with $\delta_{n,r}(y, z) = \sum_j a_{i_1}^{(j)} \cdots a_{i_r}^{(j)} \prod_{j=1}^{r} \tau^{(i_j)}(y, z)$, where $I_{n,r} := \{i_1 \geq 1, \ldots, i_r \geq 1, i_1 + \ldots + i_r = n\}$. Using (20), we get, for $r = 1, \ldots, n - 1$,

$$|\delta_{n,r}(y, z)| \leq K \sum_{j_{n,r}} \prod_{i=1}^{r} (\eta(z) + \eta^{i-1}(z)) \leq K \sum_{m=1}^{n-1} \eta^{m}(z)$$

$$\leq K(\eta(z) + \eta^{n-1}(z)). \quad (22)$$

To obtain the second inequality, we used that since $i_1 + \ldots + i_r = n > r$, there is at least one $j$ with $i_j \geq 2$, and that $\sum_{j=1}^{r} (i_j - 1) \lor 1 = \sum_{j=1}^{r} (i_j - 1) + \sum_{j=1}^{r} 1_{\{i_j=1\}} \leq n - r + r - 1 = n - 1$.

Applying now the Leibniz formula and then (21), we get, for $l = 0, \ldots, k$,

$$[\phi(\tau)]^{(l)} = \tau'[\phi(\tau)]^{(l)} + \sum_{n=0}^{l-1} \binom{l}{n} \tau^{(l+1-n)}[\phi(\tau)]^{(n)}$$

$$= (\tau')^{l+1} \phi^{(l+1)}(\tau) + \sum_{r=0}^{l-1} \phi^{(r)}(\tau) \alpha_{l,r} = \phi^{(l)}(\tau) + \sum_{r=0}^{l} \phi^{(r)}(\tau) \alpha_{l,r},$$

12
where $\alpha_{l,0} = \tau^{(l+1)}$, $\alpha_{l,l} = (\tau')^{l+1} - 1$, and for $r = 1, \ldots, l - 1,$
\[
\alpha_{l,r} = \left( \frac{l}{r} \right) \tau^{(l+1-r)} (\tau')^{r} + \sum_{j=r+1}^{l} \left( \frac{l}{j} \right) \tau^{(l+1-j)} \delta_{j,r}.
\]

It only remains to prove (14). First, since $\tau'$ is bounded, we deduce that $|\alpha_{l,i}(y,z)| \leq K |\tau'(y,z) - 1| \leq K \eta(z)$. Next, using (20), (22) and that $\tau'$ is bounded, we get, for $l = 1, \ldots, k$, (with the convention $\sum_0^0 = 0$),
\[
\sum_{r=0}^{l} |\alpha_{l,r}(y,z)| \leq K \eta(z) + K (\eta(z) + \eta_i(z)) + K \sum_{r=1}^{l-1} (\eta(z) + \eta^{l-r}(z))
\]
\[
+ K \sum_{r=1}^{l-1} \sum_{j=r+1}^{l} (\eta(z) + \eta^{l-j}(z))(\eta(z) + \eta^{l-1-j}(z))
\]
\[
\leq K (\eta(z) + \eta^{l}(z)) \leq K (\eta(z) + \eta^{k}(z)).
\]

Finally, $(1 + 1/\tau'(y,z)) = (1 + 1 + h'((\tau(y,z),z)) \leq 2 + \eta(z)$ by $(A_{k+1,p})$. We conclude that for $l = 1, \ldots, k$,
\[
\left( 1 + \frac{1}{\tau'(y,z)} \right) \sum_{r=0}^{l} |\alpha_{l,r}(y,z)| \leq K (1 + \eta(z))(\eta(z) + \eta^{k}(z)) =: \alpha(z),
\]
and $\alpha \in L^1(G,q)$, since by assumption, $\eta \in L^1 \cap L^p(G,q)$ with $p \geq k + 1 \geq 2$.

**Point (ii).** The proof is the similar (but simpler) to that of Point (i). We observe that for $i \geq i_0$, $(y + b_{i}(y))/i' \geq 1/2$, so that under $(A_{k+1,p})$, $y + b_{i}(y)/i$ is clearly a $C^{k+1}$-diffeomorphism. Next, (10) is easily obtained, and we prove as in Point (i) that
\[
|\tau_{i}^{(l)}(z)| \leq K (1/i + (1/i)^{l-1}) \leq K/i, \quad l = 2, \ldots, k + 1,
\]
using that for all $n = 2, \ldots, k + 1$, $(y + b_{i}(y)/i)^{(n)} \leq K/i$ thanks to $(A_{k+1,p})$. Then (17)-(18) are obtained as (13)-(15).

**Point (iii).** Let thus $\phi$ and $g$ as in the statement. Then
\[
\int_{R} g(y) L^i \phi(y) dy = i \int_{R} \phi(y + b(y)/i) g(y) dy - i \int_{R} \phi(y) g(y) dy
\]
\[
+ \int_{G_i} q(dz) \int_{R} \gamma(y) \phi(y + h[y,z]) g(y) dy - \int_{G_i} q(dz) \int_{R} \gamma(y) \phi(y) g(y) dy
\]
\[
= i \int_{R} \phi(y) g(\tau_i(y)) \tau_i^{(y)}(y) dy - i \int_{R} \phi(y) g(y) dy
\]
\[
+ \int_{G_i} q(dz) \int_{R} \gamma(\tau(y,z)) \phi(y) g(\tau(y,z)) \tau'(y,z) dy
\]
\[
- \int_{G_i} q(dz) \int_{R} \gamma(y) \phi(y) g(y) dy = \int_{R} \phi(y) L^{i*} g(y) dy,
\]
where we used the substitution \( y \mapsto \tau_i(y) \) (resp. \( y \mapsto \tau(y, z) \)) in the first (resp. third) integral.

The following technical lemma shows that when starting with a smooth initial condition, the solution of (11) remains smooth for all times (not uniformly in \( i \)). This will enable us to handle rigorous computations.

**Lemma 4.3** Assume (I), \((A_{k+1,p})\) for some \( p \geq k + 1 \geq 2\), and (S). Let \( i \geq i_0 \) be fixed. Consider a probability measure \( f_i(dy) \) admitting a density \( f_i(y) \) of class \( C^1_k(\mathbb{R}) \), and the associated solution \( f_i(t,dy) \) to (11). Then for all \( t \geq 0 \), \( f_i(t,dy) \) has a density \( f_i(t,y) \), and \( (t,y) \mapsto f_i(t,y) \) belongs to \( C^1_k([0,T] \times \mathbb{R}) \) for all \( T \geq 0 \). For all \( t \geq 0 \), all \( y \in \mathbb{R} \), all \( l = 0,...,k \),

\[
\partial_t f_i^{(l)}(t,y) = \left[ \mathcal{L}^{\ast} f_i(t,y) \right]^{(l)}
\]

\[
= i \left[ f_i(t,\tau_i(y))\tau_i'(y) - f_i(t,y) \right]^{(l)}
+ \int_{G_i} q(dz) \left[ \gamma(\tau(y,z))f_i(t,\tau(y,z))\tau'(y,z) - \gamma(y)f_i(t,y) \right]^{(l)}.\tag{23}
\]

**Proof** We will prove, using a Picard iteration, that (23) (with \( l = 0 \)) admits a solution, which also solves (11), which is regular, and of which the derivatives solve (24). We omit the fixed subscript \( i \geq i_0 \) in this part of the proof, and the initial probability measure \( f(dy) = f(y)dy \) with \( f \in C^1_k(\mathbb{R}) \) is fixed.

**Step 1.** Consider the function \( f^0(t,y) \equiv f(y) \), and define, for \( n \geq 0 \),

\[
f^{n+1}(t,y) = f(y) + \int_0^t \mathcal{L}^{\ast} f^n(s,y)ds.\tag{24}
\]

Then one easily checks by induction (on \( n \)), using Lemma 4.2 \((A_{k+1,p})\) and the fact that \( q(G_i) < \infty \), that for all \( n \geq 0 \), \( f^n(t,y) \) is of class \( C^1_k([0,\infty) \times \mathbb{R}) \), and that for all \( t \in \{0,...,k\} \),

\[
(f^{n+1})^{(l)}(t,y) = f^{(l)}(y) + \int_0^t [\mathcal{L}^{\ast} f^n]^{(l)}(s,y)ds.\tag{25}
\]

**Step 2.** We now show that there exists \( C_{k,i} > 0 \) such that for \( n \geq 1 \), \( t \geq 0 \),

\[
\sum_{i=0}^k ||(\delta^{n+1})^{(l)}(t,\cdot'||_\infty \leq C_{k,i} \int_0^t ds \sum_{i=0}^k ||(\delta^n)^{(l)}(s,\cdot'||_\infty,
\]

where \( \delta^{n+1}(t,y) = f^{n+1}(t,y) - f^n(t,y) \). Due to (24), for \( l = 0,...,k \),

\[
(\delta^{n+1})^{(l)}(t,y) = \int_0^t i \left[ \delta^n(s,\tau_i(y))\tau_i'(y) - \delta^n(s,y) \right]^{(l)} ds
+ \int_0^t ds \int_{G_i} q(dz) \left[ \gamma(\tau(y,z))\delta^n(s,\tau(y,z))\tau'(y,z) - \gamma(y)\delta^n(s,y) \right]^{(l)}.
\]
We now use (15) (with \(\phi = \delta^n(s,.)\)) and (13) (with \(\phi = \gamma \delta^n(s,.)\)), and we easily obtain, since \(q(G_i) < \infty\), for some constant \(C_{k,i}\), for all \(y \in \mathbb{R}\),

\[
|\langle \delta^{n+1}(t) \rangle(t,y)| \leq C_{k,i} \int_0^t ds \sum_{r=0}^l \left( ||\langle \delta^n \rangle^{(r)}(s)||_\infty + ||\langle \gamma \delta^n \rangle^{(r)}(s)||_\infty \right)
\]

\[
\leq C_{k,i} \int_0^t ds \sum_{r=0}^l ||\langle \delta^n \rangle^{(r)}(s)||_\infty,
\]

the last inequality holding since \(l \leq k\) and \(\gamma \in C^k(\mathbb{R})\). Taking now the supremum over \(y \in \mathbb{R}\) and summing for \(l = 0, ..., k\), we get the desired inequality.

**Step 3.** We classically deduce from Step 2 that the sequence \(f^n(t,y) \in C_b^{0,k}([0,T] \times \mathbb{R})\) (for all \(T > 0\)), and that for \(l = 0, ..., k\),

\[
f^{(l)}(t,y) = f^{(l)}(y) + \int_0^t [L^{i*}f]^{(l)}(s,y)ds.
\]

But one can check, using arguments as in Step 1, that since \(f(t,y) \in C_b^{0,k}([0,T] \times \mathbb{R})\), so does \([L^{i*}f](t,y)\). Hence (20) can be differentiated with respect to time, we obtain (23), and thus also that \(f(t,y) \in C_b^{1,k}([0,T] \times \mathbb{R})\).

**Step 4.** It only remains to show that \(f(t,y)dy\) is indeed the solution of (11) defined in Lemma 4.4 (i). First, using (24) and rough estimates, we have

\[
||f^{n+1}(t)||_{L^1} \leq ||f||_{L^1} + C_i \int_0^t ds ||f^n(s)||_{L^1},
\]

where \(C_i = 2i + 2 ||\gamma||_\infty q(G_i)\). This classically ensures that \(||f(t)||_{L^1} \leq \limsup_n ||f^n(t)||_{L^1} \leq ||f||_{L^1} e^{C_i t}\). Thus for \(t \in [0,T]\)

\[
\int_0^T |f(t,y)|dy < \infty
\]

for all \(T > 0\).

Next, we multiply (20) (with \(l = 0\)) by \(\phi(y)\), for a bounded measurable \(\phi : \mathbb{R} \mapsto \mathbb{R}\), we integrate over \(y \in \mathbb{R}\), and we use the duality proved in Lemma 4.2 (iii). This yields (11). □

The central part of this section consists of the following result.

**Lemma 4.4** Assume (I), (S) and (Ak+1,p) for some \(p \geq k + 1 \geq 2\). For \(i \geq i_0\), let \(f_i(dy) \in W^{k,1}(\mathbb{R})\) be a probability measure with a density \(f_i(y) \in C^k(\mathbb{R})\), and consider the unique solution \(f_i(t,dy)\) to (17). There exists a constant \(C_k\) (not depending on \(i \geq i_0\)) such that for all \(t \geq 0\),

\[
||f_i(t,.)||_{W^{k,1}(\mathbb{R})} \leq ||f_i||_{W^{k,1}(\mathbb{R})} e^{C_k t}.
\]

**Proof** We know from Lemma 4.3 that \(f_i(t,y)\) is of class \(C^{1,k}_b([0,T] \times \mathbb{R})\), and that (23) holds for \(l = 0, ..., k\).

Since for each \(l = 0, ..., k\), each \(y \in \mathbb{R}\), \(t \mapsto f^{(l)}_i(t,y)\) is of class \(C^1\), we classically deduce that \(f^{(l)}_i(t,y) = f^{(l)}_i(y) + \int_0^t s g(f^{(l)}_i(s,y))dy + f^{(l)}_i(s,y)ds\), where \(s g(u) = 1_{(0,\infty)}(u) - 1_{(-\infty,0)}(u)\). Using thus (23) and integrating over \(y \in \mathbb{R}\), we get

\[
||f^{(l)}_i(t,.)||_{L^1} = ||f^{(l)}_i||_{L^1} + \int_0^t (A^l_1(s) + B^l_1(s))ds,
\]

where

\[
A^l_1(s) = \int_0^s \left| \frac{\partial}{\partial y} f^{(l)}_i(s,y) \right| dy,
\]

\[
B^l_1(s) = \int_0^s \left( \frac{\partial}{\partial y} f^{(l)}_i(s,y) \right) dy.
\]
for $l = 1, \ldots, k$, where, setting $\gamma f_i(t, y) = \gamma(y)f_i(t, y)$ for simplicity,

$$A_i^l(t) = \int_R dy \left[ f_i(t, \tau_i(y))\tau'_i(y) - f_i(t, y) \right]^{(l)}_{(l)}sg(f_i^{(l)}(t, y))$$

$$B_i^l(t) = \int_{G_i} \phi(z) \int_R dy \left[ \gamma f_i(t, \tau(y, z))\tau'_i(y, z) - \gamma f_i(t, y) \right]^{(l)}_{(l)}sg(f_i^{(l)}(t, y)).$$

Using (18) (with $\phi = f_i(t, .)$) and then (17), we obtain

$$A_i^l(t) \leq \int_R dy \left[ f_i^{(l)}(t, \tau_i(y)) - f_i^{(l)}(t, y) \right]_{(l)}\int_R dy \left[ f_i^{(l)}(t, \tau_i(y)) \right]_{(l)} + K \int_R dy \sum_{r=0}^l \left| f_i^{(r)}(t, \tau_i(y)) \right|$$

$$= A_i^{l,1}(t) + A_i^{l,2}(t).$$

First,

$$A_i^{l,1}(t) \leq i \int_R dy \left| f_i^{(l)}(t, \tau_i(y))\tau'_i(y) - i \int_R dy \left| f_i^{(l)}(t, y) \right|$$

$$+ \int_R dy \left| f_i^{(l)}(t, \tau_i(y)) \right| \times |\tau'_i(y) - 1|.$$
Finally, due to (12), there exists

\[ \int_G q(\tau(y,z)) - \phi(y) \leq \int_G q(z) \int_{y-\alpha(z)}^{y+\alpha(z)} du |\phi'(u)| \leq 2 \int_G \alpha(z) q(\tau(y,z)) |\phi'| \leq K |\phi'|. \]

\[ B_{i}^{1}(t) \leq \int_G q(\tau(y,z)) - \phi(y) \leq \int_G q(z) \int_{y-\alpha(z)}^{y+\alpha(z)} du |\phi'(u)| \leq 2 \int_G \alpha(z) q(\tau(y,z)) |\phi'| \leq K |\phi'|. \]
As a consequence, using that $\gamma \in C^{k+1}_{b}$, we get, since $l \leq k$,
\[
B_{l}^{0,2}(t) \leq K \sum_{r=0}^{l-1} \||\gamma^{(l-r)} f_{i}^{(r)}(\cdot, .)||_{L^{1}} \| \leq K \sum_{r=0}^{l} ||f_{i}^{(r)}(t, .)||_{L^{1}}.
\]

We finally have proved that for $l = 1, ..., k$, for all $t \geq 0$,
\[
||f_{i}^{(l)}(t, .)||_{L^{1}} \leq ||f_{i}^{(1)}||_{L^{1}} + K \sum_{r=0}^{l} \int_{0}^{t} ds ||f_{i}^{(r)}(s, .)||_{L^{1}}.
\]

Using that for all $t \geq 0$, $f_{i}(t, .)$ is a probability measure (so that $||f_{i}(t, .)||_{L^{1}} = 1$) and summing over $l = 0, ..., k$, we immediately conclude that
\[
||f_{i}(t, .)||_{\dot{W}^{k,1}(R)} \leq ||f_{i}||_{\dot{W}^{k,1}(R)} + K \int_{0}^{t} ds ||f_{i}(s, .)||_{\dot{W}^{k,1}(R)}.
\]

The Gronwall Lemma allows us to conclude the proof. \(\Box\)

We finally conclude the

**Proof of Proposition 2.2**. We thus assume (I), (A$_{k+1,p}$) for some $p \geq k+1 \geq 2$, and (S). Consider a probability measure $f \in \dot{W}^{k,1}(R)$, and a sequence of probability measures $f_{i} \in \dot{W}^{k,1}(R)$ with densities $f_{i} \in C^{k}_{b}(R)$, such that $f_{i}$ goes weakly to $f$, and such that $\lim_{i} ||f_{i}||_{\dot{W}^{k,1}(R)} = ||f||_{\dot{W}^{k,1}(R)}$. Consider the unique solution $f_{i}(t, y)$ to (11). Then we deduce from Proposition 4.4 that for $t \geq 0$,
\[
||f_{i}(t, .)||_{\dot{W}^{k,1}(R)} \leq ||f_{i}||_{\dot{W}^{k,1}(R)} e^{C_{k}t}.
\]

On the other hand, Lemma 4.1 implies that for all $t \geq 0$, $f_{i}(t, dy)$ goes weakly to $p(t, f, dy)$ as $i$ tends to infinity. Thus for any $\phi \in C^{k}_{b}(R)$, any $l \in \{0, ..., k\}$, any $t \geq 0$,
\[
\int_{R} \phi^{(l)}(y)p(t, f, dy) = \lim_{i \to \infty} \int_{R} \phi^{(l)}(y)f_{i}(t, dy).
\]

We then immediately deduce from (28), recalling (3), that for any $t \geq 0$,
\[
||p(t, f, .)||_{\dot{W}^{k,1}(R)} \leq ||f||_{\dot{W}^{k,1}(R)} e^{C_{k}t}.
\]

The proof is finished. \(\Box\)

### 5 Appendix

We first gather some formulae about derivatives of composed and inverse functions from $\mathbb{R}$ into itself. Here $f^{(l)}$ stands for the $l$-th derivative of $f$.

Let us recall the Faa di Bruno formula. Let $l \geq 1$ be fixed. The exist some coefficients $a^{l,r}_{i_{1}, ..., i_{r}} > 0$ such that for $\phi : \mathbb{R} \mapsto \mathbb{R}$ and $\tau : \mathbb{R} \mapsto \mathbb{R}$ of class $C^{l}(\mathbb{R})$,
\[
[\phi(\tau)]^{(l)} = [\tau']^{l} \phi^{(l)}(\tau) + \sum_{r=1}^{l-1} \sum_{i_{1} + ... + i_{r} = l} a^{l,r}_{i_{1}, ..., i_{r}} \prod_{j=1}^{r} \tau^{(i_{j})}(\tau) \phi^{(r)}(\tau),
\]

(29)
where the sum is taken over \( i_1 \geq 1, \ldots, i_r \geq 1 \) with \( i_1 + \ldots + i_r = l \).

We carry on with another formula. For \( l \geq 2 \) fixed, there exist some coefficients \( c^{i_1,\ldots,i_q}_{i_1,\ldots,i_q} \in \mathbb{R} \) such that for \( f : \mathbb{R} \to \mathbb{R} \) a \( C^1 \)-diffeomorphism, and for \( \tau \) its inverse function,

\[
\tau^{(l)} = \sum_{r=l+1}^{2l-1} \frac{1}{(f'(\tau))^{i}} \sum_{i_1+\ldots+i_q=r-1} c^{i_1,\ldots,i_q}_{i_1,\ldots,i_q} \prod_{j=1}^{q} f^{(i_j)}(\tau),
\]

where the sum is taken over \( q \in \mathbb{N} \), over \( i_1,\ldots,i_q \in \{2,\ldots,l\} \) with \( i_1 + \ldots + i_q = r - 1 \). This (not optimal) formula can be checked by induction on \( k \geq 2 \).

We finally give the

**Proof of Lemma 2.4.** In the whole proof, \( y \in \mathbb{R} \) is fixed. We assume for example that \( I(y) = (a(y), \infty) \), and we may suppose without loss of generality that \( a(y) = 0 \) (replacing if necessary \( h[y, z] \) by \( h[y, z] := h[y, z + a(y)] \)).

We introduce a family of \( C^\infty \) functions \( \phi_n : \mathbb{R} \to [0, 1] \), such that \( \phi_n(z) = 0 \) for \( z \leq 1 \) and \( z \geq n+3 \), \( \phi_n(z) = 1 \) for \( z \in [2, n+2] \), and \( \text{sup}_n \|\phi_n'\|_\infty \leq C_1 \) for all \( n \in \mathbb{N} \). Then we set \( q_n(y, dz) = \phi_n(\gamma(y).z)dz \), and we define \( \mu_n \) by \( \mu_n(y, A) = \int_A h(y, z)q_n(y, dz) \).

Clearly \( 0 \leq q_n(y, dz) \leq q(dz) \) so that \( \mu_n(y, du) \leq \mu(y, du) \), and an immediate computation leads us to \( \mu_n(y, \mathbb{R}) = \gamma(y)q_n(y, G) \in [n, n+2] \). Thus points (i) and (ii) of assumption (A_{k,p,\theta}) are fulfilled.

Since \( h'_z(y, z) \) does never vanish, \( z \mapsto h(y, z) \) is either increasing or decreasing. We assume for example that we are in the latter case. We also necessarily have \( \lim_{z \to \infty} h(y, z) = 0 \), since \( h(y, z) \in L^1((0, \infty), dz) \) (due to (A_{1,1})). As a conclusion, \( z \mapsto h(y, z) \) is a decreasing \( C^{k+1} \)-diffeomorphism from \( (0, \infty) \) into \( (0, h(y, 0)) \).

Let \( \xi(y, .) : (0, h(y, 0)) \to (0, \infty) \) be its inverse, that is \( h(y, \xi(y, u)) = u \). Then by definition of \( \mu_n \) and by using the substitution \( u = h(y, z) \), we get \( \mu_n(y, du) = \mu_n(y, u)du \) with

\[
\mu_n(y, u) = \gamma(y)\phi_n(\gamma(y)\xi(y, u))\xi'_u(y, u)1_{\{u \in (0, h(y, 0))\}}.
\]

Since the properties of \( \phi_n \) ensure us that \( \mu_n(y, u) = 0 \) for

\[
u \notin (h[y, (n+2)/\gamma(y)], h[y, 1/\gamma(y)])
\]

it suffices to study the regularity of \( \mu_n(y, .) \) on \((0, h(y, 0))\). Since \( \xi(y, .) \) is of class \( C^{k+1} \) and since \( \phi_n \) is \( C^\infty \), we deduce that \( \mu_n(y, .) \) is \( C^k \) on \((0, h(y, 0))\) (and thus on \( \mathbb{R} \)).

Using (30) and that \( h_z^{(l)} \) is uniformly bounded (for all \( l = 1, \ldots, k+1 \)), we easily get, for \( l = 2, \ldots, k+1 \),

\[
|h_z^{(l)}(y, u)| \leq K \sum_{r=l+1}^{2l-1} |h_z^{(l)}(y, \xi(y, u))|^{-r}
\]
Applying finally the Leibniz formula, using (31), (32) and (33), we get, for $l = 1, \ldots, k$ (when $l = 1$, it is obvious).

Applying now (29), using (32) and that $\gamma$ is bounded, we get, for $l = 1, \ldots, k$,

$$||\phi_n(\gamma(y)\xi(y, u))||^{(l)} \leq K \sum_{r=1}^{l} |h'_r(y, \xi(y, u))|^{-2l+r} \phi_n^{(r)}(\gamma(y)\xi(y, u)).$$

We used here that for $i_1 \geq 1, \ldots, i_r \geq 1$ with $i_1 + \ldots + i_r = l$, one has the inequality $\prod_{r=1}^{l} |\xi^{(i_r)}(y, u)| \leq K |h'_r(y, \xi(y, u))|^{\sum_{i}(2i_r+1)} \leq K |h'_r(y, \xi(y, u))|^{-2l+r}$. Hence

$$||\phi_n(\gamma(y)\xi(y, u))||^{(l)} \leq K |h'_r(y, \xi(y, u))|^{-2l+1} 1_{\gamma(y)\xi(y, u) \leq n+3},$$

since $h'_r$ is uniformly bounded and $\phi_n(z) = 0$ for $z \geq n + 3$.

Applying finally the Leibniz formula, using (31), (32) and (33), we get, for $l = 1, \ldots, k$, for $u \in (0, h(y, u))$,

$$|\mu_n^{(l)}(y, u)| \leq K \gamma(y) \sum_{r=0}^{l} |\xi^{(l+1-r)}(y, u)| \times ||\phi_n(\gamma(y)\xi(y, u))||^{(r)} \leq K \gamma(y) |h'_r(y, \xi(y, u))|^{-2l+1} 1_{\gamma(y)\xi(y, u) \leq n+3},$$

and the formula obviously holds for $l = 0$. Finally, since $h'_r$ is uniformly bounded, and performing the substitution $z = \xi(y, u)$, i.e. $u = h(y, z)$, we obtain, recalling that $\mu_n(y, \mathbb{R}) \in [n, n+2]$,

$$\frac{1}{\mu_n(y, \mathbb{R})} ||\mu_n(y, \cdot)||_{\tilde{W}^{k,1}(\mathbb{R})} \leq K \gamma(y) \int_{\mathbb{R}} \sum_{r=0}^{k} |h'_r(y, \xi(y, u))|^{-2l-1} 1_{0 < \xi(y, u) \leq \frac{a+3}{y^{(r)}}} du \leq K \gamma(y) \int_{\mathbb{R}} |h'_r(y, \xi(y, u))|^{-2k-1} 1_{0 < \xi(y, u) \leq \frac{a+3}{y^{(r)}}} du \leq K \gamma(y) \int_{\mathbb{R}} |h'_r(y, z)|^{-2k} 1_{0 < z \leq \frac{(a+3)}{y^{(r)}}} du \leq K Ce^{3\theta} (1 + |y|^p) e^{\theta n},$$

where we finally used (41) (because $I_{\alpha}(y) = [0, n/\gamma(y)]$ here). This proves that $(H_{k, p, \theta})$-(iii) holds. \hfill \Box
