Abstract

We investigate the structure of the $D_1^0(2420[2430])(J^P = 1^+)$ mesons via analyzing the semileptonic $B_c \rightarrow D_1^0l\nu$ transition in the frame work of the three–point QCD sum rules and the heavy quark effective theory. We consider the $D_1^0$ meson in three ways; the pure $|c\bar{u}\rangle$ state, a mixture of two $|3P_1\rangle$ and $|1P_1\rangle$ states with a mixing angle $\theta$ and a combination of two mentioned states with mixing angle $\theta = 35.3^\circ$ in the heavy quark limit. Taking into account the gluon condensate contributions, the relevant form factors are obtained for the three above conditions. These form factors are numerically calculated for $|c\bar{u}\rangle$ and the heavy quark limit cases. The obtained results for the form factors are used to evaluate the decay rates and the branching ratios. Also for mixed states, all of the mentioned physical quantities are plotted with respect to the unknown mixing angle $\theta$.

I. INTRODUCTION

There is some difference between the measured and predicted masses of the even–parity charmed mesons ($J^P = 1^+$), observed in the laboratories [1–5] and considered in many phenomenological models [6–11]. So much efforts have been dedicated to realize this unexpected disparity between theory and experiment [12–17]. Therefore the study of the processes involving these mesons is important for understanding of the structure and quark content of them. Some physicists presumed that these discovered states are conventional $c \bar{u}$ and $c \bar{s}$ mesons [18–26]. Among these mesons, we focus on the non–strange $D_0(2420)$ meson. So far the two confirmed $D_0$ states, with mass of $2423.4 \pm 3.2$ MeV and $2427 \pm 26 \pm 25$ MeV, have been observed [5]. The narrow–width state with lower mass is known as $D'_0(2420)$ and the wide–width state with more mass is identified as $D_0(2430)$ [27]. Theoretically, the discovered states do not fit easily into the $c \bar{u}$ spectroscopy [21]. One of the proposals, could be the introduction of the $D_0$ meson as a mixture of two $|1^P_1 \rangle$ and $|3^P_1 \rangle$ states with the $c \bar{u}$ quark content [18–21, 28, 29]. In this work, we plan to analyze $D_0$ meson as conventional meson with pure $|c \bar{u} \rangle$ state and also as a combination of $|1^P_1 \rangle$ and $|3^P_1 \rangle$ states.

Heavy–light mesons are not charge conjugation eigen states and so mixing can occur among states with the same $J^P$ and different mass that are forbidden for neutral states [21]. So the mixing of the physical $D_1$ and $D'_1$ states can be parameterized in terms of a mixing angle $\theta$, as follow:

$$
\begin{bmatrix}
|D_1\rangle \\
|D'_1\rangle
\end{bmatrix} =
\begin{bmatrix}
\cos \theta & \sin \theta \\
-\sin \theta & \cos \theta
\end{bmatrix}
\times
\begin{bmatrix}
|1^P_1\rangle \\
|3^P_1\rangle
\end{bmatrix},
$$

(1)

where we used the spectroscopic notation $^{2S+1}L_J$ for introduction of the mixing states. Considering $|3^P_1 \rangle \equiv |D_11 \rangle$ and $|1^P_1 \rangle \equiv |D_12 \rangle$ with different masses and decay constants [21, 28], we can apply these relations, beyond the heavy quark model, for axial vectors $D_1(2420)$ and $D_1(2430)$ mesons with two different masses. i.e.,

$$
|D_1(2420)\rangle = \sin \theta \ |D_11\rangle + \cos \theta \ |D_12\rangle,
$$

$$
|D_1(2430)\rangle = \cos \theta \ |D_11\rangle - \sin \theta \ |D_12\rangle.
$$

(2)

The masses and decay constant of the $D_{11}$ and $D_{12}$ states are presented in Tables I and II.
| Ref     | [18] | [20] | [30] |
|---------|------|------|------|
| $D_1 1^3P_1$ | 2.49 | 2.42 | 2.47 |
| $D_1 2^1P_1$ | 2.44 | 2.49 | 2.46 |

**TABLE I:** Masses of $D_1 1^3P_1$ and $D_1 2^1P_1$ states in GeV.

| Ref     | [28] |
|---------|------|
| $D_1 1^3P_1$ | 183  |
| $D_1 2^1P_1$ |  89  |

**TABLE II:** Decay constant of $D_1 1^3P_1$ and $D_1 2^1P_1$ states in MeV.

In the heavy quark limit where the quark mass $m_c \to \infty$, both axial vector $D_0^0(2420)$ and $D_0^0(2430)$ mesons can be produced and identified with $|P^{3/2}_1\rangle$ and $|P^{1/2}_1\rangle$, respectively. It is useful to change from the $L - S$ basis $^{2S+1}L_J$ to the $j - j$ coupling basis $L^j_J$, where $j$ is the total angular momentum of the light quark. The relationship between these states are given as [21, 28, 29]:

$$
\begin{bmatrix}
D_0^0(2420) \\
D_0^0(2430)
\end{bmatrix}
\equiv
\begin{bmatrix}
|P^{3/2}_1\rangle \\
|P^{1/2}_1\rangle
\end{bmatrix}
= 
\begin{bmatrix}
\sqrt{\frac{2}{3}} & \sqrt{\frac{1}{3}} \\
-\sqrt{\frac{1}{3}} & \sqrt{\frac{2}{3}}
\end{bmatrix}
\times
\begin{bmatrix}
|D_1 2\rangle \equiv |^1P_1\rangle \\
|D_1 1\rangle \equiv |^3P_1\rangle
\end{bmatrix}.
$$

These relations occur for the mixing angle $\theta = 35.3^\circ$ in Eq. (1). But note that the value of the mixing angle can be positive equal to $\theta = 35.3^\circ$ or negative corresponding $\theta = -54.7^\circ$ if the expectation of the heavy–quark spin–orbit interaction is positive or negative, respectively [21].

The $B_c \to D^{(*)0}l\nu$ [31] and $B_c \to Dll/\nu\bar{\nu}$ [32] have been studied via three–point QCD sum rules (3PSR). In this work, we analyze the semileptonic $B_c \to D_0^0(2420|2430)]l\nu$ decays in 3PSR and heavy quark effective theory (HQET). For this aim, we consider the structure of the $D_0^0$ meson in three conditions:

1- The $D_0^0$ meson as a pure state ($|c\bar{u}\rangle$).

2- The $D_0^0$ meson as a mixture of two states of the $|^1P_1\rangle$ and $|^3P_1\rangle$ with a mixing angle $\theta$ (see Eq. (2)).

3- The $D_0^0$ meson as a combination of two $|^1P_1\rangle$ and $|^3P_1\rangle$ states with the mixing angle
\[ \theta = 35.3^\circ \] in the heavy quark limit (see Eq. (3)).

Taking into account the gluon condensate corrections, as the important term of the non-perturbative part of the correlation function, the form factors of the \( B_c \to D_1^0 \) transition are obtained within 3PSR for the condition 1, 2 and within HQET approach for the condition 3. For the condition 1 and 3, the form factors of the \( B_c \to D_1^0(2420[2430]) \) transitions are a function of the transferred momentum square \( q^2 \). So, we plot these form factors and decay widths of these decays with respect to \( q^2 \). Also the branching ratios for these cases are evaluated. But, it should be remarked, when we consider the \( D_1^0 \) as a mixture of two states with mixing angle \( \theta \) in the region \(-180 \leq \theta \leq 180\), the transition form factors of the \( B_c \to D_1^0(2420[2430]) \) decays are a function of two variables \( \theta \) and \( q^2 \). Since the decay width of the \( B_c \to D_1^0 \) transition is related to the form factors, then it is a function of mixing angle \( \theta \) and \( q^2 \), too. For a better analysis, we plot the form factors and the decay widths of the \( B_c \to D_1^0(2420[2430]) \) in three dimensions. In this case, the branching ratios are shown with respect to the mixing angle \( \theta \). Detection of these channels and their comparison with the phenomenological models like QCD sum rules could give useful information about the structure of the \( D_1^0 \) meson and the unknown mixing angle \( \theta \).

This paper is organized as follow. In Section II, we calculate the form factors for the \( B_c \to D_1^0 \) transition in 3PSR for above condition 1 and 2. In Section III, the transition form factors are evaluated via HQET approach for condition 3. Finally, Section IV is devoted to the numeric results and discussions.

### II. SUM RULES METHOD

In this section, we study the transition form factors of the semileptonic \( B_c \to D_1^0 l \nu \) decay by QCD sum rules mechanism. For this aim, first, we consider the \( D_1^0 \) meson as a pure state. The \( B_c \to D_1^0 l \nu \) process is governed by the tree level \( b \to ul \nu \) transition and \( c \) quark is the spectator, at quark level (see Fig. 1). The three-point correlation function is considered for the evaluation of the transition form factors in the framework of the 3PSR. The three-point correlation function is constructed from the vacuum expectation value of time ordered product of three currents as follow:

\[
\Pi_{\mu\nu}(p^2, p'^2, q^2) = i^2 \int d^4xd^4y\, e^{+ip'x-iqy} \langle 0 \mid T \left\{ J_{\nu}^{D_1^0}(x), J_{\mu}^{W}(0), J_{B_c}^{\dagger}(y) \right\} \mid 0 \rangle , \tag{4}
\]
where \( J_D^{D_0}(x) = \bar{c}\gamma_\nu\gamma_5 u \) and \( J_{Bc}(y) = \bar{c}\gamma_5 b \) are the interpolating currents of the \( D_0^0 \) and \( B_c \) mesons. \( J_W = \bar{\nu}\gamma_\mu(1 - \gamma_5) b \) is the current of the weak transition.

We can obtain the correlation function of Eq. (4) in two sides. The phenomenological or physical part is calculated saturating the correlation by a tower of hadrons with the same quantum numbers as interpolating currents. The QCD or theoretical part, on the other side is obtained in terms of the quarks and gluons interacting in the QCD vacuum. To derive the phenomenological part of the correlation given in Eq. (4), two complete sets of intermediate states with the same quantum numbers as the currents \( J_D^{D_0} \) and \( J_{Bc} \) are inserted. This procedure leads to the following representations of the above-mentioned correlation:

\[
\Pi_{\mu\nu}(p^2, p'^2, q^2) = \frac{\langle 0 | J_{D_1}^{D_0}(p', \epsilon) | D_0^0(p', \epsilon) \rangle \langle D_0^0(p', \epsilon) | J_D^{D_0}(p) \rangle \langle B_c(p) | J_{Bc} | 0 \rangle}{(p'^2 - m_{D_1}^2)(p^2 - m_{Bc}^2)} + \text{higher resonances and continuum states}.
\]

The general expression for the hadronic matrix element of the weak current with definition of the transition form factors is given by the formula:

\[
\langle D_0^0(p', \epsilon) | \bar{\nu}\gamma_\mu(1 - \gamma_5) b | B_c(p) \rangle = f'_V(q^2)\varepsilon_{\mu\alpha\beta}\varepsilon^*\nu p^\alpha p'^\beta - i\left[f'_0(q^2)\varepsilon^*_\mu + f'_1(q^2)(\varepsilon^* p)P_\mu + f'_2(q^2)(\varepsilon^* p)q_\mu\right],
\]

where:

\[
f'_V(q^2) = \frac{2f_V(q^2)}{(m_{Bc} + m_{D_1})}, \quad f'_0(q^2) = f_0(q^2)(m_{Bc} + m_{D_1}),
\]

\[
f'_1(q^2) = -\frac{f_1(q^2)}{(m_{Bc} + m_{D_1})}, \quad f'_2(q^2) = -\frac{f_2(q^2)}{(m_{Bc} + m_{D_1})}.
\]
and the $f_V(q^2)$, $f_0(q^2)$, $f_1(q^2)$ and $f_2(q^2)$ are the transition form factors, $P_\mu = (p + p')_\mu$, $q_\mu = (p - p')_\mu$ and $\epsilon$ is the four–polarization vector of the $D_1^0$ meson. Also the following matrix elements are defined in the standard way in terms of the leptonic decay constants of the $D_1^0$ and $B_c$ mesons as:

$$
\langle 0 | J_\mu^\nu | D_1^0(p', \epsilon) \rangle = f_{D_1^0} m_{D_1^0} \epsilon^\nu, \quad \langle 0 | J_{B_c} | B_c(p) \rangle = i \frac{f_{B_c} m_{B_c}^2}{m_b + m_c},
$$

where $f_{D_1^0}$ and $f_{B_c}$ are the leptonic decay constants of $D_1^0$ and $B_c$ mesons, respectively. Using Eq. (6) and Eq. (8) in Eq. (5) and performing summation over the polarization of the $D_1^0$ meson, we get the following result for the physical part:

$$
\Pi_{\mu\nu}(p^2, p'^2, q^2) = - \frac{f_{B_c} m_{B_c}^2}{(m_b + m_c)} \frac{f_{D_1^0} m_{D_1^0}^2}{(p'^2 - m_{D_1^0}^2)(p^2 - m_{B_c}^2)} \times \left[ i f_{f_V}(q^2) \epsilon_{\mu\alpha\beta} p^\alpha p'^\beta + f_0'(q^2) g_{\mu\nu} 
+ f_1'(q^2) P_{\mu\nu} + f_2'(q^2) q_\mu p_\nu \right] + \text{excited states.}
$$

The coefficients of Lorentz structures $i \epsilon_{\mu\alpha\beta} p^\alpha p'^\beta$, $g_{\mu\nu}$, $P_{\mu\nu}$ and $q_{\mu\nu}$ in the correlation function $\Pi_{\mu\nu}$ will be chosen in determination of the form factors $f_V(q^2)$, $f_0(q^2)$, $f_1(q^2)$ and $f_2(q^2)$, respectively. So the Lorentz structures in the correlation function can be written down as:

$$
\Pi_{\mu\nu}(p^2, p'^2, q^2) = i \Pi_V \epsilon_{\mu\alpha\beta} p^\alpha p'^\beta + \Pi_0 g_{\mu\nu} + \Pi_1 P_{\mu\nu} + \Pi_2 q_{\mu\nu},
$$

where, each $\Pi_i$ function is defined in terms of the perturbative and non-perturbative parts as:

$$
\Pi_i(p^2, p'^2, q^2) = \Pi_i^{\text{per}}(p^2, p'^2, q^2) + \Pi_i^{\text{nonper}}(p^2, p'^2, q^2).
$$

With the help of the operator product expansion (OPE), in the deep Euclidean region where $p^2 \ll (m_b + m_c)^2$ and $p'^2 \ll m_c^2$, the vacuum expectation value of the expansion of the correlation function in terms of the local operators, is written as follow:

$$
\Pi_{\mu\nu}(p^2, p'^2, q^2) = (C_0)_{\mu\nu} + (C_3)_{\mu\nu} \langle \bar{q} q \rangle + (C_4)_{\mu\nu} \langle G^2 \rangle + (C_5)_{\mu\nu} \langle \bar{q} \sigma_{\alpha\beta} G^{\alpha\beta} q \rangle 
+ (C_6)_{\mu\nu} \langle \bar{q} \Gamma \bar{q} \Gamma' q \rangle,
$$

where $(C_i)_{\mu\nu}$ are the Wilson coefficients, $G_{\alpha\beta}$ is the gluon field strength tensor, $\Gamma$ and $\Gamma'$ are the matrices appearing in the calculations. The non-perturbative part contains the quark and gluon condensate diagrams. We consider the condensate terms of dimension 3, 4 and 5.
It’s found that the heavy quark condensate contributions are suppressed by inverse of the heavy quark mass and can be safely omitted. The light $u$ quark condensate contribution is zero after applying the double Borel transformation with respect to the both variables $p^2$ and $p'^2$, because only one variable appears in the denominator. Therefore in this case, we consider the two gluon condensate diagrams with mass dimension 4 as a important term of the non-perturbative corrections, only i.e.,

$$
\Pi_i(p^2, p'^2, q^2) = \Pi_i^{\text{per}}(p^2, p'^2, q^2) + \Pi_i^{(G^2)}(p^2, p'^2, q^2) \langle \frac{\alpha_s}{\pi} G^2 \rangle.
$$

The diagrams for contribution of the gluon condensates are depicted in Fig. 2. To obtain

\begin{align*}
\Pi_i^{\text{per}} = -\frac{1}{(2\pi)^2} \int \int \frac{\rho_i^{\text{per}}(s, s', q^2)}{(s - p^2)(s' - p'^2)} ds ds' + \text{subtraction terms}.
\end{align*}

FIG. 2: Contribution of two gluon condensates for $B_c \to D_1^0$ transition.
By replacing the propagators with the Dirac-delta functions (Cutkosky rules):

$$\frac{1}{k^2 - m^2} \rightarrow -2\pi\delta(k^2 - m^2),$$

the spectral densities $\rho^\text{per}_i(s, s', q^2)$ are found as:

$$\rho^\text{per}_V = \frac{N_c}{\lambda^{1/2}(s, s', q^2)} \left\{ \frac{(2s'\Delta - \Delta'u)(m_b - m_c)}{\lambda(s, s', q^2)} - \frac{(2s'\Delta - \Delta'u)(m_u + m_c)}{\lambda(s, s', q^2)} - m_c \right\},$$

$$\rho^\text{per}_0 = -\frac{N_c}{2\lambda^{1/2}(s, s', q^2)} \left\{ \Delta(m_c + m_u) - \Delta'(m_b - m_c) + 2m_c^2(m_b - m_c - m_u) + \frac{2(4ss'm_c^2 - s\Delta'^2 - s'\Delta'^2 - u^2m_c^2 + u\Delta\Delta')(m_b - m_c)}{\lambda(s, s', q^2)} + m_c(2m_bm_u - u) \right\},$$

$$\rho^\text{per}_1 = \frac{N_c}{2\lambda^{1/2}(s, s', q^2)} \left\{ \frac{(2s'\Delta - \Delta'u)(m_b - 3m_c)}{\lambda(s, s', q^2)} - \frac{(2s'\Delta - \Delta'u)(m_u + m_c)}{\lambda(s, s', q^2)} - m_c \right\},$$

$$\rho^\text{per}_2 = \frac{N_c}{2\lambda^{1/2}(s, s', q^2)} \left\{ \frac{(2\Delta' - \Delta'u)(m_c + m_u)}{\lambda(s, s', q^2)} - \frac{(2s'\Delta - \Delta'u)(m_b + m_c)}{\lambda(s, s', q^2)} - m_c \right\},$$

where $\lambda(a, b, c) = a^2 + b^2 + c^2 - 2ac - 2bc - 2ab$. The $N_c = 3$ is the color factor, $u = s + s' - q^2$, $\Delta = s + m_c^2 - m_b^2$ and $\Delta' = s' + m_c^2 - m_u^2$.

For the heavy quarkonium $bc$, where the relative velocity of quark movement is small, an essential role is taken by the Coulomb-like $\alpha_s/v$-corrections. It leads to the finite renormalization for $\rho_i^\text{per}$, so that:

$$\rho_i = \mathcal{C}\rho_i^\text{per},$$

with

$$\mathcal{C}^2 = \frac{4\pi\alpha_s^C}{3v} \frac{1}{1 - \exp\left(-\frac{4\pi\alpha_s^C}{3v}\right)},$$

where $\alpha_s^C$ is the Coulomb coupling constant.
where $\alpha_s^c$ is the coupling constant of effective coulomb interactions. Also $v$ is the relative velocity of quarks in the $b\bar{c}$-system,

$$v = \sqrt{1 - \frac{4m_b m_c}{p^2 - (m_b - m_c)^2}}. \quad (19)$$

The value of $\alpha_s^c$ for $B_c$ meson is [34]:

$$\alpha_s^c[bc] = 0.45.$$

By performing the double Borel transformations over the variables $p^2$ and $p'^2$ on the physical parts of the correlation functions and bare-loop diagrams and also equating two representations of the correlation functions, the sum rules for the $f_i'(q^2)$ are obtained:

$$f_i'(q^2) = \frac{(m_b + m_c)}{f_D^2 m_{B_c}^2 f_{D_1}^2 m_{D_1}^2} e^{\frac{m_b^2}{M_1^2}} e^{\frac{m_{D_1}^2}{M_2^2}} \times \left\{ -\frac{1}{4\pi^2} \int_{m_b^2}^{s_0} ds' \int_{s_L}^{s_0} \rho_i'(s, s', q^2) e^{\frac{s'}{M_1^2}} e^{\frac{s}{M_2^2}} - iM_1^2 M_2^2 \left( \frac{\alpha_s G^2}{\pi} \frac{C_i^4}{6} \right) \right\}, \quad (21)$$

where $i = V, O, 1$ and 2, $s_0$ and $s'_{o}$ are the continuum thresholds in pseudoscalar $B_c$ and axial vector $D_1^0$ channels, respectively, and lower bound integration limit of $s_L$ is as follow:

$$s_L = \frac{(m_c^2 + q^2 - m_b^2 - s')(m_b^2 s' - m_c^2 q^2)}{(m_b^2 - q^2)(m_c^2 - s')}.$$

The explicit expressions for $C_i^4$ are presented in Appendix–A.

Now, we would like to consider the form factors related to the $B_c \rightarrow D_1^0$ transition when the $D_1^0$ meson is a mixture of two $|1P_1\rangle$ and $|3P_1\rangle$ states. For this aim, first the $f_i^{B_c \rightarrow D_1(1,2)}(q^2)$ are obtained from the above equations replacing the $f_{D_i}^2$ by decay constant $f_{D_i(1,2)}^2$ and $m_{D_i}^2$ with $m_{D_1(1,2)}^2$, i.e.,

$$f_i^{B_c \rightarrow D_1(1,2)}(q^2) = -\frac{(m_b + m_c)}{f_{B_c} m_{B_c}^2 f_{D_1(1,2)} m_{D_1(1,2)}^2} e^{\frac{m_b^2}{M_1^2}} e^{\frac{m_{D_1(1,2)}^2}{M_2^2}} \times \left\{ -\frac{1}{4\pi^2} \int_{m_b^2}^{s_0} ds' \int_{s_L}^{s_0} \rho_i^c(s, s', q^2) e^{\frac{s'}{M_1^2}} e^{\frac{s}{M_2^2}} - iM_1^2 M_2^2 \left( \frac{\alpha_s G^2}{\pi} \frac{C_i^4}{6} \right) \right\}. \quad (22)$$

Then using the straight forward calculations, the $f_i^{(2420)}(q^2)$ form factors of $B_c \rightarrow D_1^0(2420)$ transition are found as follows:

$$f_0^{(2420)}(q^2) = \frac{m_{B_c} + m_{D_1 1}}{m_{B_c} + m_{D_1 1}} f_0^{B_c \rightarrow D_1(1)}(q^2) \sin \theta + \frac{m_{B_c} + m_{D_1 2}}{m_{B_c} + m_{D_1 2}} f_0^{B_c \rightarrow D_1(2)}(q^2) \cos \theta,$$

$$f_i^{(2420)}(q^2) = \frac{m_{B_c} + m_{D_1 1}}{m_{B_c} + m_{D_1 1}} f_i^{B_c \rightarrow D_1(1)}(q^2) \sin \theta + \frac{m_{B_c} + m_{D_1 2}}{m_{B_c} + m_{D_1 2}} f_i^{B_c \rightarrow D_1(2)}(q^2) \cos \theta,$$

(23)
where \( i' = V, 1, 2 \). Note that, the \( f_i^{(2430)}(q^2) \) form factors of the \( B_c \to D_1^0(2430) \) decay are obtained from the above equations by replacing the \( \sin \theta \to \cos \theta \) and \( \cos \theta \to -\sin \theta \).

### III. HEAVY QUARK EFFECTIVE THEORY

In this section, we apply the heavy quark effective theory (HQET) to analyze the form factors of \( B_c \to D_1^0 \ell \nu \) calculated by 3PSR. As it was mentioned in the introduction, in the heavy quark mass limit, when \( m_c \to \infty \), the \( D_1^0 \) meson can be considered as Eq. \( (3) \). Therefore, to estimate the \( f_i^{HQ} \) form factors in this approach, first, we present the dependence of the \( f_i^{HQ}(B_c \to D_1^k) \), \( k = 1, 2 \) on \( y \) where

\[
y = \nu \nu' = \frac{m_{B_c}^2 + m_{D_1^k}^2 - q^2}{2m_{B_c}m_{D_1^k}}.
\]

Here, \( \nu \) and \( \nu' \) are the four velocities of \( B_c \) and \( D_1^k \) mesons, respectively (for some details see Refs. \[35, 36\]). After some complicated calculations, the \( y \)–dependent expressions of the \( f_i^{HQ}(B_c \to D_1^k)(y) \) are obtained as follows:

\[
f_V^{HQ(B_c \to D_1^k)}(y) = \frac{1}{\hat{f}_{B_c} \hat{f}_{D_1^k}} e^{\frac{\Delta \tau}{2}} e^{\frac{\tau}{2}} \left\{ \frac{1}{(1 + \sqrt{Z})Z^{\frac{\tau}{2}} \sqrt{-1 + y'}} \times \left[ -3 + 3(3y + 1)\sqrt{Z} - 6(y^2 + y)Z \right] \right. \\
\times \left. \frac{-1}{(2\pi)^2} \int_0^{\nu_0} d\nu \int_0^{\nu_0'} d\nu' e^{-\frac{\nu^2}{2\tau_1}} e^{-\frac{\nu'^2}{2\tau_2}} \theta(2y\nu\nu' - \nu^2 - \nu'^2) \\
+ \left( i \frac{2Z^{\frac{\tau}{2}}}{3(1 + \sqrt{Z})} T_1 T_2 \left\langle \frac{\alpha_s}{\pi} G^2 \right\rangle \right) \times \lim_{m_b \to \infty} C_{V}^{HQET} \right\}, \tag{25}
\]

\[
f_0^{HQ(B_c \to D_1^k)}(y) = \frac{1}{\hat{f}_{B_c} \hat{f}_{D_1^k}} e^{\frac{\Delta \tau}{2}} e^{\frac{\tau}{2}} \left\{ \frac{1}{2(1 + \sqrt{Z})^2 Z^{\frac{\tau}{2}} \sqrt{-1 + y'^2}} \times \left[ -3 - 3(4y - 1)\sqrt{Z} - 6(3y^2 - 2y - 1)Z + 12(y^3 + y^2 - y)Z^{\frac{\tau}{2}} \right] \right. \\
\times \left. \frac{-1}{(2\pi)^2} \int_0^{\nu_0} d\nu \int_0^{\nu_0'} d\nu' e^{-\frac{\nu^2}{2\tau_1}} e^{-\frac{\nu'^2}{2\tau_2}} \theta(2y\nu\nu' - \nu^2 - \nu'^2) \\
+ \left( i \frac{2Z^{\frac{\tau}{2}}}{3(1 + \sqrt{Z})^3} T_1 T_2 \left\langle \frac{\alpha_s}{\pi} G^2 \right\rangle \right) \times \lim_{m_b \to \infty} C_{0}^{HQET} \right\}, \tag{26}
\]
\[ f^1_{HQ(B_c \to D_{1k})}(y) = \frac{1}{\hat{f}_{B_c} \hat{f}_{D_{1k}}} \frac{e^{\lambda_1} e^{\lambda_2}}{4(1 + \sqrt{Z})(\frac{-1+y^2}{Z})^\frac{3}{2}} \times \left[ -9 + 9(5y + 1)\sqrt{Z} - 3(26y^2 + 15y - 2)Z \right. \\
+ 6(9y^3 + 11y^2 - 3y + 1)Z^\frac{3}{2} - 12(y^4 + 2y^3 - y^2 + y)Z^2 \left. \right] \]
\[ \times \frac{-1}{(2\pi)^2} \int_0^{\nu_0} d\nu \int_0^{\nu_0'} d\nu' e^{-\frac{\nu}{\pi} \alpha_s G} e^{-\frac{\nu'}{\pi} \alpha_s G} \theta(2y\nu' - \nu^2 - \nu'^2) \]
\[ + \left( i \frac{2Z^\frac{3}{2}}{3(1 + \sqrt{Z})} T_1 T_2 \left\langle \frac{\alpha_s}{\pi} G^2 \right\rangle \right) \times \lim_{m_b \to \infty} C_{1\text{HQET}} \right\}, \quad (27) \]

\[ f^2_{HQ(B_c \to D_{1k})}(y) = \frac{1}{\hat{f}_{B_c} \hat{f}_{D_{1k}}} \frac{e^{\lambda_1} e^{\lambda_2}}{4(1 + \sqrt{Z})(\frac{-1+y^2}{Z})^\frac{3}{2}} \times \left[ -9 + 9(3y + 1)\sqrt{Z} - 9(2y^2 + 3y - 2)Z \right. \\
- 4y^3 - 9y^2 + 5y + 1)Z^\frac{3}{2} + 12(y^4 + 2y^3 - y^2 + y)Z^2 \left. \right] \]
\[ \times \frac{-1}{(2\pi)^2} \int_0^{\nu_0} d\nu \int_0^{\nu_0'} d\nu' e^{-\frac{\nu}{\pi} \alpha_s G} e^{-\frac{\nu'}{\pi} \alpha_s G} \theta(2y\nu' - \nu^2 - \nu'^2) \]
\[ + \left( i \frac{2Z^\frac{3}{2}}{3(1 + \sqrt{Z})} T_1 T_2 \left\langle \frac{\alpha_s}{\pi} G^2 \right\rangle \right) \times \lim_{m_b \to \infty} C_{2\text{HQET}} \right\}. \quad (28) \]

In these heavy quark limit expressions \( \Lambda = m_{B_c} - m_b, \bar{\Lambda} = m_{D_{1k}} - m_c, \sqrt{Z} = y + \sqrt{y^2 - 1}, \)
\( \hat{f}_{B_c} = \sqrt{m_b^2 f_{B_c}}, \hat{f}_{D_{1k}} = \sqrt{m_c f_{D_{1k}}}. \) The continuum thresholds \( \nu_0, \nu_0' \) and integration variables \( \nu, \nu' \) are defined as:
\[ \nu_0 = \frac{s_0 - m_b^2}{m_b}, \quad \nu_0' = \frac{s'_0 - m_c^2}{m_c}, \quad (29) \]
\[ \nu = \frac{s - m_b^2}{m_b}, \quad \nu' = \frac{s' - m_c^2}{m_c}. \quad (30) \]

Also we apply \( T_1 = M^2_{C} / 2m_b, T_2 = M^2_{C} / 2m_c \) and \( m_c = m_b / \sqrt{Z}. \)

The explicit expressions of the coefficients \( C_{i\text{HQET}} \) are given in Appendix–B. In the expressions of the \( C_{i\text{HQET}}, I_0(a, b, c), I_1(a, b, c), I_j(a, b, c); j = 3, 4, 5 \) and \( I_6(a, b, c) \) are defined as:
\[ I_0(a, b, c) = \frac{(-1)^{a+b+c}}{16\pi^2 G(a) G(b) G(c)} \left( \frac{1}{\sqrt{Z}} \right)^{2-a-c} \left( 2m_b \right)^{4-2a-b-c} T_1^{2-a-b} T_2^{2-a-c} \]
\[ U_0^{\text{HQET}}(a + b + c - 4, 1 - c - b), \]
\[ I_{1(2)}(a, b, c) = i \frac{(-1)^{a+b+c+1}}{16\pi^2 \Gamma(a) \Gamma(b) \Gamma(c)} \left( \frac{1}{\sqrt{Z}} \right)^{4-a-c-1(2)} (2m_b)^{5-2a-b-c} T_1^{1-a-b+1(2)} T_2^{4-a-c-1(2)} \]
\[ U_0^{HQET} (a + b + c - 5, 1 - c - b), \]

\[ I_j(a, b, c) = i \frac{(-1)^{a+b+c}}{16\pi^2 \Gamma(a) \Gamma(b) \Gamma(c)} \left( \frac{1}{\sqrt{Z}} \right)^{7-a-c-j} (2m_b)^{6-2a-b-c} T_1^{a-b+1+j} T_2^{7-a-c-j} \]
\[ U_0^{HQET} (a + b + c - 6, 1 - c - b), \]

\[ I_6(a, b, c) = i \frac{(-1)^{a+b+c+1}}{32\pi^2 \Gamma(a) \Gamma(b) \Gamma(c)} \left( \frac{1}{\sqrt{Z}} \right)^{3-a-c} (2m_b)^{6-2a-b-c} T_1^{3-a-b} T_2^{3-a-c} \]
\[ U_0^{HQET} (a + b + c - 6, 2 - c - b) . \] (31)

The function \( U_0^{HQET}(m, n) \) takes the following form
\[ U_0^{HQET}(m, n) = \int_0^\infty (2m_b)^m \left( \frac{x}{2m_b} + \frac{T_2}{\sqrt{Z}} \right)^m x^n \left[ -\frac{\overline{B}^{-1}}{x} - \overline{B}_0 - \overline{B}_1 x \right] dx, \] (32)

with
\[ \overline{B}^{-1} = \frac{\sqrt{Z}}{T_1 T_2} \left[ \frac{m_b^2}{T_2} T_2 + \frac{1}{\sqrt{Z}} T_1 T_2 (m_b^2 - q^2) \right], \]
\[ \overline{B}_0 = \frac{\sqrt{Z}}{2m_b T_1 T_2} \left[ m_c T_1 + \frac{T_2}{\sqrt{Z}} (m_b^2 + m_c^2) \right], \]
\[ \overline{B}_1 = \frac{1}{4\sqrt{Z} T_1 T_2}. \] (33)

Then by considering \( D_1^0 \) meson as a combination of two states \(|D_1 k\), \( (k = 1, 2)\) the \( f_i^{HQ(2420)}(y) \) and \( f_i^{HQ(2430)}(y) \) form factors for the \( B_c \rightarrow D_1^0(2420)\nu \) and \( B_c \rightarrow D_1^0(2430)\nu \) decays are obtained as:
\[ f_i^{HQ(2420)}(y) = \sqrt{\frac{1}{3}} f_0^{HQ(B_c \rightarrow D_1)}(y) + \sqrt{\frac{2}{3}} f_0^{HQ(B_c \rightarrow D_1)}(y), \]
\[ f_i^{HQ(2430)}(y) = \sqrt{\frac{2}{3}} f_i^{HQ(B_c \rightarrow D_1)}(y) - \sqrt{\frac{1}{3}} f_i^{HQ(B_c \rightarrow D_1)}(y), \] (34)

where \( i = V, 0, 1, 2. \)

**IV. NUMERICAL ANALYSIS**

Now, we present our numerical analysis of the form factors \( f_i(q^2) , (i = V, 0, 1, 2) \) via 3PSR and HQET. From the sum rules expressions of the form factors, it is clear that the
main input parameters entering the expressions are gluon condensates, element of the CKM matrix $V_{ub}$, leptonic decay constants $f_{B_c}$, $f_{D_0}$, $f_{D_{1,1}}$ and $f_{D_{1,2}}$, Borel parameters $M_1^2$ and $M_2^2$ as well as the continuum thresholds $s_0$ and $s'_0$. The sum rules for the form factors contain also four auxiliary parameters: Borel mass squares $M_1^2$ and $M_2^2$ and continuum thresholds $s_0$ and $s'_0$. These are not physical quantities, so the the form factors as physical quantities should be independent of them. The parameters $s_0$ and $s'_0$, which are the continuum thresholds of $B_c$ and $D_1^0$ mesons, respectively, are determined from the condition that guarantees the sum rules to practically be stable in the allowed regions for $M_1^2$ and $M_2^2$. The values of the continuum thresholds calculated from the two–point QCD sum rules are taken to be $s_0 = (45 - 50) \text{ GeV}^2$ and $s'_0 = (6 - 8) \text{ GeV}^2$. The working regions for $M_1^2$ and $M_2^2$ are determined requiring that not only the contributions of the higher states and continuum are small, but the contributions of the operators with higher dimensions are also small. Both conditions are satisfied in the regions $10 \text{ GeV}^2 \leq M_1^2 \leq 25 \text{ GeV}^2$ and $4 \text{ GeV}^2 \leq M_2^2 \leq 10 \text{ GeV}^2$.

For analysis the form factors of the semileptonic $B_c \rightarrow D_1^0(2420[2430])l\nu$ decays, first, we consider the $D_1^0$ meson as a pure state, i.e., $|c\bar{u}\rangle$ and analyze the form factors and the value of the branching ratios of the $B_c \rightarrow D_1^0(2420[2430])$ transitions in 3PSR. Then the form factors, decay widths and branching ratios of these decays are plotted when $D_1^0$ meson is a combination of two states with mixing angle $\theta$. Finally, considering the $D_1^0$ meson as Eq. (3), we investigate and estimate this mentioned physical quantities via HQET approach in $m_b(m_c) \rightarrow \infty$ limit. Therefore, there are three conditions for the study of the form factors of the $B_c \rightarrow D_1^0(2420[2430])l\nu$ decays, related to the structure of the $D_1^0$ meson as following:

| TABLE III: Input values in numerical calculations. |
|-----------------|----------------|
| $\langle \frac{2}{3}G^2 \rangle$ | 0.012 GeV$^4$ |
| $|V_{ub}|$ | 0.0037 |
| $f_{D_1}$ | $(225 \pm 25)$ MeV |
| $f_{B_c}$ | $(350 \pm 25)$ MeV |
• Pure state or \(|c\bar{u}\rangle\) state

If the \(D_1^0\) meson is the pure \(|c\bar{u}\rangle\) state, using Eqs. (7) and (21), the values of the form factors at \(q^2 = 0\) are presented in Table IV. In this case, the values of the transition form factors at \(q^2 = 0\) for \(B_c \to D_1^0(2420) l\nu\) decay are the same as those for \(B_c \to D_1^0(2430) l\nu\). Our calculations show, the other physical quantities of these decays are the same, nearly.

The sum rules for the form factors are truncated at about 9 GeV\(^2\), so to extend our results to the full physical region, we look for a parametrization of the form factors in such a way that in the region \(0 \leq q^2 \leq (m_{B_c} - m_{D_1^0})^2 \) GeV\(^2\), this parametrization coincides with the sum rules predictions. Our numerical calculations show that the sufficient parametrization of the form factors with respect to \(q^2\) is as follows:

\[
f_i(q^2) = \frac{a}{1 - \frac{q^2}{m_{fit}^2}} + \frac{b}{(1 - \frac{q^2}{m_{fit}^2})^2}. \tag{35}
\]

The values of the parameters \(a\), \(b\) and \(m_{fit}\) are given in Table \(\ref{tab:fit-parameters}\). Fig. 3 depicts the fit function of the form factors \(f_i(2420, 2430)(q^2)\), \((i=V, 0, 1, 2)\) of the \(B_c \to D_1^0(2420, 2430) l\nu\) decays with respect to the transferred momentum square \(q^2\). This figure also contains the form factors obtained via 3PSR (see Eq. (21)). The form factors and their fit functions coincide well in the interval \(0 \leq q^2 \leq 9\) GeV\(^2\).

By using the expressions for the form factors, the differential decay width \(d\Gamma/dq^2\) for the process \(B_c \to D_1^0 l\nu\) in terms of \(H_i\) is presented as follow:

\[
\frac{d\Gamma(\pm)(B_c \to D_1^0 l\nu)}{dq^2} = \frac{G^2 |V_{ub}|^2}{192\pi^3 m_{B_c}^3} q^2 \frac{\lambda^{1/2}(m_{B_c}^2, m_{D_1^0}^2, q^2)}{2} |H_{\pm}|^2,
\]
TABLE V: Parameters appearing in the fit function for the form factors of the $B_{c} \rightarrow D_{1}^{0}(2420, 2430)$ at $M_{1}^2 = 15 \text{ GeV}^2$ and $M_{2}^2 = 8 \text{ GeV}^2$.

| Form Factor               | $a$  | $b$  | $m_{fit}$ |
|---------------------------|------|------|-----------|
| $f_{V}^{B_{c} \rightarrow D_{1}^{0}(2420, 2430)}(q^2)$ | -0.35 | -0.18 | 4.94      |
| $f_{0}^{B_{c} \rightarrow D_{1}^{0}(2420, 2430)}(q^2)$ | 0.20  | 0.04  | 6.88      |
| $f_{1}^{B_{c} \rightarrow D_{1}^{0}(2420, 2430)}(q^2)$ | 0.25  | 0.10  | 5.91      |
| $f_{2}^{B_{c} \rightarrow D_{1}^{0}(2420, 2430)}(q^2)$ | -0.37 | -0.21 | 4.82      |

\[
\frac{d\Gamma_{0}(B_{c} \rightarrow D_{1}^{0}l\nu)}{dq^2} = \frac{G^2 |V_{ub}|^2}{192\pi^3 m_{B_{c}}^3} q^2 \lambda^{1/2}(m_{B_{c}}, m_{D_{1}^{0}}, q^2) |H_0|^2 ,
\]

\[
\frac{d\Gamma_{\text{tot}}(B_{c} \rightarrow D_{1}^{0}l\nu)}{dq^2} = \frac{d\Gamma_{\pm}(B_{c} \rightarrow D_{1}^{0}l\nu)}{dq^2} + \frac{d\Gamma_{0}(B_{c} \rightarrow D_{1}^{0}l\nu)}{dq^2} ,
\]

(36)

$H_{\pm}$ and $H_{0}$ are defined as:

\[
H_{\pm}(q^2) = (m_{B_{c}} + m_{D_{1}^{0}})f_{0}(q^2) \pm \frac{\lambda^{1/2}(m_{B_{c}}, m_{D_{1}^{0}}, q^2)}{m_{B_{c}} + m_{D_{1}^{0}}} f_{V}(q^2),
\]

\[
H_{0}(q^2) = \frac{1}{2m_{D_{1}^{0}} \sqrt{q^2}} \left[ (m_{B_{c}}^2 - m_{D_{1}^{0}}^2 - q^2)(m_{B_{c}} + m_{D_{1}^{0}})f_{0}(q^2) - \frac{\lambda(m_{B_{c}}, m_{D_{1}^{0}}, q^2)}{m_{B_{c}} + m_{D_{1}^{0}}} f_{1}(q^2) \right],
\]

where $\pm, 0$ refer to the $D_{1}^{0}$ helicities. Note that in the limit of vanishing lepton mass (in our case electron and muon) the $f_{2}(q^2)$ form factor does not contribute to the decay width formula.

To calculate the branching ratios of the $B_{c} \rightarrow D_{1}(2420, 2430)l\nu$ decays, we integrate Eq. (36) over $q^2$ in the whole physical region and use the total mean life time $\tau_{B_{c}} = (0.46 \pm 0.07) \text{ ps}$. Our numerical analysis shows that the contribution of the non-perturbative part (the gluon condensate diagrams) is about 13% of the total and the main contribution comes from the perturbative part of the form factors. The value for the branching ratio of these decays is obtained as presented in Table VI. The function of decay width of $B_{c} \rightarrow D_{1}^{0}(2420, 2430)l\nu$ decays with respect to $q^2$ is shown in Fig. 4.
TABLE VI: The branching ratio value of the semileptonic $B_c \rightarrow D_1^0(2420, 2430)l\nu$ decays.

| MOD      | BR         |
|----------|------------|
| $B_c \rightarrow D_1^0(2420, 2430)l\nu$ | $(0.72 \pm 0.19) \times 10^{-4}$ |

- **Mixture of $|3P_1\rangle$ and $|1P_1\rangle$ states**

Now, we would like to analyze the form factors of the $B_c \rightarrow D_1^0$ transition when we consider the $D_1^0$ meson as a mixture of two $|3P_1\rangle$ and $|1P_1\rangle$ states with mixing angle $\theta$ (see Eq. (23)). The transition form factors of the $B_c \rightarrow D_1^0(2420[2430])l\nu$ at $q^2 = 0$ in the interval $-180^\circ \leq \theta \leq 180^\circ$ are shown in Figs. 5-6. The dependence of the form factors of the $B_c \rightarrow D_1^0(2420)$ and $B_c \rightarrow D_1^0(2430)$ decays on mixing angle $\theta$ and the transferred momentum square $q^2$ are plotted in Figs. 7-8 in the regions $0 \leq q^2 \leq (m_{B_c} - m_{D_1^0})^2 \text{GeV}^2$ and $-180^\circ \leq \theta \leq 180^\circ$ for $q^2$ and $\theta$, respectively. Using Eq. (36), we denote the variation of the decay widthes with respect to $q^2$ and $\theta$ in the same regions for each decay in Fig. 9. Also the branching ratios only in terms of mixing angle $\theta$ are shown in Fig. 10.

- **Compound state in the heavy quark limit**

Eventually, we study the structure of the $D_1^0$ meson as a mixture of two $|3P_1\rangle$ and $|1P_1\rangle$ states with the mixing angle $\theta = 35.3^\circ$ in the heavy quark limit. The HQET form factors of the $B_c \rightarrow D_1^0$ transition were evaluated in Eq. (34). Figs. 11-12 depict the $f_i^{HQ(2420)}$ and $f_i^{HQ(2430)}$ with respect to the $q^2$ for $B_c \rightarrow D_1^0(2420)l\nu$ and $B_c \rightarrow D_1^0(2430)l\nu$, respectively. It is noted, at $y = 1$ in Eq. (24) called the zero recoil limit (corresponding to $q^2 = (m_{B_c} - m_{D_1^0})^2$), the HQET limit of the form factors are not finite. For other values of $y$ and corresponding $q^2$, the behavior of the $f_i^{(2420, 2430)}$ form factors shown in Fig. 3 and their HQET form factors $f_i^{HQ(2420)}$ and $f_i^{HQ(2430)}$ in Figs. 11-12 are the same, i.e., when $q^2$ increases (y decreases) both the form factors and their HQET values increases.

The values of the HQET form factors at $q^2 = 0$ are presented in Table VII.

Also using Eq. (36) and HEQT form factors, we evaluated the branching ratios of the $B_c \rightarrow D_1^0(2420[2430])l\nu$ decays as given in Table VIII. The Fig. 13 depict the dependence of the decay widths of these decays on the $q^2$ in HQET approach.
TABLE VII: The value of the form factors of the $B_c \to D_1^0(2420)$ and $B_c \to D_1^0(2430)$ transitions via HQET at $q^2 = 0$.

| Form Factor | Value     | Form Factor | Value     |
|-------------|-----------|-------------|-----------|
| $f_V^{HQ(2420)}(0)$ | $-0.71 \pm 0.15$ | $f_V^{HQ(2430)}(0)$ | $-0.68 \pm 0.14$ |
| $f_0^{HQ(2420)}(0)$ | $0.17 \pm 0.04$ | $f_0^{HQ(2430)}(0)$ | $0.16 \pm 0.04$ |
| $f_1^{HQ(2420)}(0)$ | $0.39 \pm 0.09$ | $f_1^{HQ(2430)}(0)$ | $0.37 \pm 0.10$ |
| $f_2^{HQ(2420)}(0)$ | $-0.10 \pm 0.02$ | $f_2^{HQ(2430)}(0)$ | $-0.09 \pm 0.02$ |

TABLE VIII: The branching ratio values of the semileptonic $B_c \to D_1^0(2420)l\nu$ and $B_c \to D_1^0(2430)l\nu$ decays via HQET.

| MOD | $B_c \to D_1^0(2420)l\nu$ | $B_c \to D_1^0(2430)l\nu$ |
|-----|-----------------------------|-----------------------------|
| BR  | $(1.57 \pm 0.41) \times 10^{-4}$ | $(1.09 \pm 0.32) \times 10^{-4}$ |

**Conclusion**

In summary, we analyzed the semileptonic $B_c \to D_1^0(2420)l\nu$ decays in the framework of the three-point QCD sum rules and HQET approach. First, we assumed the $D_1^0(2420)$ and $D_1^0(2430)$ axial vector mesons as the pure $|c\bar{u}\rangle$ state. In this case, the related form factors were computed. The branching ratios of these decays were also estimated. Second, $D_1^0(2420|2430)$ mesons were considered as a combination of two states $|^{3}P_1\rangle \equiv |D_11\rangle$ and $|^{1}P_1\rangle \equiv |D_12\rangle$ with different masses and decay constants. We evaluated the transition form factors and the decay widths of these decays with respect to mixing angle $\theta$ and the transferred momentum square $q^2$. The dependence of the branching ratios on $\theta$ was also presented. Finally, we obtained all of the mentioned physical quantity in HQET approach. Any future experimental measurement on these form factors as well as decay rates and branching fractions and their comparison with the obtained results in the present work can give considerable information about the structure of these mesons and unknown mixing angle $\theta$.

Appendix–A

In this appendix, the explicit expressions of the coefficients of the gluon condensate entering the sum rules of the form factors $f_i(q^2), (i = V, 0, 1, 2)$ are given.

\[ C_V^4 = -10 \hat{I}_1(3, 2, 2)m_b^3m_c^2 + 10 \hat{I}_1(3, 2, 2)m_b^2m_c^3 + 10 \hat{I}_2(3, 2, 2)m_b^2m_c^3 + 10 \hat{I}_0(3, 2, 2)m_b^2m_c^3 + 60 \hat{I}_2(1, 4, 1)m_b^2m_c - 20 \hat{I}_2(3, 2, 1)m_b^2m_c + 10 \hat{I}_2^{[0,1]}(3, 2, 2)m_b^2m_c - 20 \hat{I}_0(3, 2, 1)m_b^2m_c + 10 \hat{I}_2(3, 2, 1)m_b^2m_c^2 + 40 \hat{I}_2(2, 3, 1)m_b^2m_c^2 - 10 \hat{I}_0(3, 2, 1)m_b^2m_c^2 + 20 \hat{I}_1(2, 3, 1)m_b^2m_c^2 - 10 \hat{I}_1(3, 2, 2)m_c^5 + 20 \hat{I}_1(3, 2, 1)m_b^2m_c^2 + 10 \hat{I}_1(2, 2, 2)m_b^2m_c^2 - 20 \hat{I}_1(2, 2, 1)m_b^2m_c^2 + 10 \hat{I}_0(3, 2, 1)m_b^2m_c^3 - 30 \hat{I}_0(3, 2, 1)m_b^2m_c^3 - 20 \hat{I}_0(2, 2, 2)m_c^3 - 20 \hat{I}_0(2, 2, 1)m_c^3 + 20 \hat{I}_0^{[0,1]}(2, 2, 1)m_b + 20 \hat{I}_1^{[0,1]}(2, 3, 1)m_b - 20 \hat{I}_1^{[0,1]}(3, 1, 2)m_b - 20 \hat{I}_0(2, 2, 1)m_b + 30 \hat{I}_1(2, 1, 2)m_b + 100 \hat{I}_2(1, 3, 1)m_b + 30 \hat{I}_2(2, 1, 1)m_c + 30 \hat{I}_2^{[0,1]}(3, 1, 2)m_c + 20 \hat{I}_2^{[0,1]}(3, 2, 2)m_c + 20 \hat{I}_2^{[0,1]}(3, 2, 1)m_c + 10 \hat{I}_0^{[0,1]}(3, 2, 1)m_c + 30 \hat{I}_2(2, 2, 1)m_c - 30 \hat{I}_2(2, 1, 2)m_c + 10 \hat{I}_0(3, 1, 1)m_c + 20 \hat{I}_0^{[0,1]}(2, 2, 2)m_c + 20 \hat{I}_2^{[0,1]}(2, 2, 2)m_c - 10 \hat{I}_2(3, 1, 1)m_c - 20 \hat{I}_1(2, 1, 2)m_c - 30 \hat{I}_0(2, 1, 2)m_c.

\]
FIG. 3: The dependence of the form factors as well as the fit parametrization of the form factors on $q^2$. The small boxes correspond to the form factors, the solid lines belong to the fit parametrization of the form factors.
FIG. 4: The dependence of the decay width of the $B_c \rightarrow D^0_{1}(2420, 2430)$ decays on $q^2$. 
FIG. 5: The dependence of the form factors on $\theta$ at $q^2 = 0$ for the $B_c \rightarrow D^{0}_{1}(2420)$ transition.
FIG. 6: The dependence of the form factors on $\theta$ at $q^2 = 0$ for the $B_c \to D_{1}^{0}(2430)$ transition.
FIG. 7: The dependence of the transition form factors on $q^2$ and $\theta$ for the $B_c \to D_1^0(2420)$ transition. In these figures, $x = \theta$ and $y = q^2$. 
FIG. 8: The dependence of the transition form factors on $q^2$ and $\theta$ for the $B_c \to D^0(2430)$ transition. In these figures, $x = \theta$ and $y = q^2$. 
FIG. 9: The decay width for $B_c \rightarrow D_{1}^{0}l\nu$ with respect to $\theta$ and $q^2$. The left figure shows decay width of the $B_c \rightarrow D_1(2420)l\nu$ and right figure belongs to $B_c \rightarrow D_1^{0}(2430)l\nu$. In these figures, $x = \theta$, $s = q^2/m_{B_c}^2$ and $y = \frac{dBr(B_c \rightarrow D_1^{0}l\nu)}{dq^2} \times 10^{17}$. 
FIG. 10: The branching ratio functions of the $B_c \to D_1^0(2420)[2430]$ with respect to $\theta$. 
FIG. 11: The dependence of the HQET form factors on $q^2$ for the $B_c \rightarrow D_{1}^{0}(2420)$ transition.
FIG. 12: The dependence of the HQET form factors on $q^2$ for the $B_c \to D_{1}^{0}(2430)$ transition.
FIG. 13: The decay widths of the $B_c \rightarrow D^0(2420|2430)$ decays in HQET approach with respect to $q^2$.
