AN IMPROVED PROOF OF
THE ALMOST STABILITY THEOREM

WARREN DICKS*

Abstract. In 1989, Dicks and Dunwoody proved the Almost Stability Theo-
rem, which has among its corollaries the Stallings-Swan theorem that groups
of cohomological dimension one are free. In this article, we use a nestedness re-
result of Bergman, Bowditch, and Dunwoody to simplify somewhat the proof of
the finitely generable case of the Almost Stability Theorem. We also simplify
the proof of the non finitely generable case.

The proof we give here of the Almost Stability Theorem is essen-
tially self
contained, except that in the non finitely generable case we refer the reader
to the original argument for the proofs of two technical lemmas about groups
acting on trees.

Key words. Groups acting on trees. The Almost Stability Theorem.

To Martin Dunwoody, on the occasion of his 80th birthday.

1. Introduction

Throughout, $G$ will denote a discrete, multiplicative group.

Unexplained terminology and notation used in the first two sections will be
defined in Section 3.

1.1. Definitions. For any sets $E$ and $Z$, we write $\text{Maps}(E, Z)$ to denote the set
of all maps of sets from $E$ to $Z$, with each $v \in \text{Maps}(E, Z)$ written as $v : E \to Z,$
$e \mapsto \langle v, e \rangle$. For any $v, w \in \text{Maps}(E, Z)$, we write
$v \downarrow w := \{ e \in E \mid \langle v, e \rangle \neq \langle w, e \rangle \};$
if this set is finite, then we say that $v$ and $w$ are almost equal, and write $v =_a w$.

Almost equality is an equivalence relation on $\text{Maps}(E, Z)$; its equivalence classes
are called almost equality classes.

If $E$ and $Z$ are (left) $G$-sets, then $\text{Maps}(E, Z)$ is a $G$-set, with the conjugation
$G$-action, that is, if $v \in \text{Maps}(E, Z)$, $g \in G$, and $e \in E$, then $\langle gv, e \rangle := g \langle v, g^{-1}e \rangle$,
and, hence, $g(v, e) = (gv, ge)$.

A $G$-set is said to be $G$-free if each element’s $G$-stabilizer is trivial, and is said
to be $G$-quasifree if each element’s $G$-stabilizer is finite. □

The following is one form of [5, III.8.5]; see Remarks (iii) below.

1.2. The Almost Stability Theorem. If $E$ and $Z$ are any $G$-sets such that $E$ is
$G$-quasifree and each element’s $G$-stabilizer stabilizes some element of $Z$, then each
$G$-stable almost equality class in $\text{Maps}(E, Z)$ is the vertex $G$-set of some $G$-tree.
Any such $G$-tree automatically has $G$-quasifree edge $G$-set.

MTM2017-83487-P.
The purpose of this article is to give a revised proof of Theorem 1.2 that incorporates various simplifications which have become available since the original proof was published.

Let \( B(G) \) denote the Boolean algebra of almost right \( G \)-stable subsets of \( G \). For \( G \) finitely generated, Bergman defined a well-ordered measure on \( B(G) \), and Bowditch and Dunwoody used the well-orderedness of Bergman’s measure to show that each Boolean \( G \)-subalgebra of \( B(G) \) is generated by some nested \( G \)-subset. We shall recall their proofs, and then use their results to simplify the proof of the case of Theorem 1.2 where \( G \) is finitely generable. Although it closely follows part of the proof in [5], this argument had not been recorded before now; Bowditch and Dunwoody [2, 14.2] had noted the weaker conclusion that each \( G \)-stable almost equality class embeds in the vertex \( G \)-set of some \( G \)-tree, in the case where \( G \) is finitely generable and \( Z = \mathbb{Z}/2\mathbb{Z} \).

In the complementary case, where \( G \) is not finitely generable, we shall describe some further simplifications in the proof of Theorem 1.2.

The proof we give of the Almost Stability Theorem 1.2 is essentially self-contained, except that in the non finitely generable case we refer the reader to the original argument in [5] for the proofs of two technical lemmas about groups acting on trees.

The article has the following structure.

In Section 2, to provide motivation, we digress to show that Theorem 1.2 yields one form of the result of Stallings [17, 6.8] and Swan [19] that groups of cohomological dimension one are free.

In Section 3, we record rather a large number of definitions, which will provide much of the basic terminology that we shall be using.

In Section 4, we recall from [6] and [5] Dunwoody’s construction of trees from nested sets, here with a simplification by Roller [14].

In Section 5, we recall from [1] Bergman’s well-ordered measure, and we recall from [2] the Bowditch-Dunwoody construction of nested generating sets.

In Section 6, we use the results of Section 4 and the nested sets of Section 5 to construct a tree, and we deduce a result from [5] which strengthened a result of Dunwoody [6].

In Section 7, to provide motivation, we digress to deduce one form of Stallings’ Ends Theorem [18, 4.1].

In Section 8, we recall from [5] the deduction of the finitely generable case of Theorem 1.2 from the results of Section 6.

We then consider the non finitely generable case, closely following [5] but with an improved transfinite induction procedure.

In Section 9, we record, without proofs, two lemmas about trees proved in [5].

In Section 10, we fix notation that applies for the remainder of the proof.

In Section 11, we give results and proofs about finitely generable extensions.

In Section 12, we give results and proofs about countably generable extensions.

In Section 13, we give the proof of the general case.

In Section 14, we give the proof of the analogue for extensions.

In this article, we shall work with trees, and not discuss Bass-Serre theory. We shall mention in each of the two digressions that certain information about trees may be translated by Bass-Serre theory into information about groups.

1.3. Remarks. Let \( E \) and \( Z \) be any \( G \)-sets, and \( V \) be any \( G \)-stable almost equality class in the \( G \)-set Maps(\( E, Z \)).

(i). We denote by Complete(\( V \)) the \( G \)-graph with vertex \( G \)-set \( V \) and edge \( G \)-set \( \{(v, w) \in V \times V \mid v \neq w\} \), where each edge \( (v, w) \) has initial vertex \( v \) and terminal vertex \( w \); here, the \( G \)-stabilizer of \( (v, w) \) is a subgroup of the \( G \)-stabilizer of \( v \vee w \),
and \( v \bigtriangleup w \) is a finite, nonempty subset of \( E \). Thus, if \( E \) is \( G \)-quasifree, then the edge \( G \)-set of \( \text{Complete}(V) \) is also \( G \)-quasifree, and, in particular, any \( G \)-tree with vertex \( G \)-set \( V \) has \( G \)-quasifree edge \( G \)-set.

(ii). Consider the following conditions.

(a) \( G \) stabilizes each element of \( Z \).

(b) \( E \) is such that each element’s \( G \)-stabilizer stabilizes some element of \( Z \); equivalently, there exists some \( G \)-map from \( E \) to \( Z \); equivalently, \( G \) stabilizes some element of \( \text{Maps}(E, Z) \).

(c) Each finite subgroup of \( G \) stabilizes some element of \( V \).

(z) \( E \) is \( G \)-quasifree.

Notice that (b) and (z) are the hypotheses in Theorem 1.2. Since equivalence classes are nonempty by definition, \( V \neq \emptyset \), and \( \text{Maps}(E, Z) \neq \emptyset \); hence, if \( E \neq \emptyset \), then \( Z \neq \emptyset \). It is easy to see that (a) \( \Rightarrow \) (b) and that (c) \( \Rightarrow \) (z) \( \Rightarrow \) (b). It is not difficult to use properties of almost equality to prove that (b) implies (c). Thus, if (z) holds, then (b) \( \Leftrightarrow \) (c).

In 1989, Dicks and Dunwoody [5, III.8.5] proved the case of Theorem 1.2 where (a) holds. In this article, we shall see that (b), as opposed to (a), is the condition that was used in that proof.

Since (c) is a necessary condition for the \( G \)-set \( V \) to be the vertex \( G \)-set of a \( G \)-tree, we now see that Theorem 1.2 says that if (z) holds, then the \( G \)-set \( V \) is the vertex \( G \)-set of some \( G \)-tree if and only if (b) holds.

(iii). In Theorem 1.2, each hypothesis on \( E \) determines a corresponding condition on \( \text{Complete}(V) \), and we have the following formulation: If \( E \) is \( G \)-quasifree, then, first, the edge \( G \)-set of \( \text{Complete}(V) \) is \( G \)-quasifree, and, secondly, the \( G \)-set \( \text{Maps}(E, Z) \) has some \( G \)-stable element if and only if the \( G \)-set consisting of the maximal subtrees of \( \text{Complete}(V) \) has some \( G \)-stable element.

In the simplest case, where \( V \) is the almost equality class of a \( G \)-stable element \( v \) of \( \text{Maps}(E, Z) \), there exists a \( G \)-stable maximal subtree of \( \text{Complete}(V) \) with edge set \( \{ v \} \times (V - \{ v \}) \).

\[ \square \]

2. Digression 1: The Stallings-Swan Theorem

In this section, to motivate interest in the Almost Stability Theorem, we recall how it implies the Stallings-Swan result that groups of cohomological dimension one are free. This and many other applications may be found in [5, Chapter IV].

Let \( ZG \) denote the integral group ring, and \( \omega ZG \) denote its augmentation ideal. In 1953, Fox [9, (2.3)] proved, but did not state, that if the group \( G \) is free, then the left \( ZG \)-module \( \omega ZG \) is free. In 1956, this implication was made explicit by Cartan and Eilenberg [3, X.5], who further observed that if \( G \) is a nontrivial free group, then the projective dimension of the left \( ZG \)-module \( Z \) is equal to 1. In 1957, Eilenberg and Ganea [8] defined ‘the dimension of a group \( G \)’, now called the cohomological dimension of \( G \), to be the projective dimension of the left \( ZG \)-module \( Z \). Thus, by definition, \( G \) has cohomological dimension at most one if and only if the left \( ZG \)-module \( \omega ZG \) is projective. Hence, by Fox’s result, all free groups have cohomological dimension at most one. Eilenberg and Ganea remarked that they did not know whether or not all groups of cohomological dimension one are free. In 1968, Stallings [17, 6.8] proved that all finitely generable groups of cohomological dimension one are free; in 1969, Swan [19] proved that all groups of cohomological dimension one are free. In the academic year within this same period, 1968–9, Serre gave a course on what is now called Bass-Serre theory, and one of the many new results presented was the fact that the group \( G \) is free if and only if \( G \) acts freely on some tree [15, I.3.2.15 and I.3.3.4]. To my knowledge, neither direction
had previously been stated in the literature in exactly this form. It seems plausible
that Dehn knew the ‘only if’ direction in 1910, in the context of his work on Cayley
graphs in [4]. Reidemeister came close to knowing the ‘if’ direction in 1932 in the
context of his tree-based proof in [13, 4.20] of the Nielsen-Schreier theorem that all
subgroups of free groups are free.

In summary then, the left ZG-module ωZG is projective if and only if the group
G is free if and only if G acts freely on some tree.

The currently known proofs of the Almost Stability Theorem [1,2] use many of
the arguments of Stallings and Swan. We shall now recall that one form of their
theorem is in turn a consequence of Theorem [1.2]

2.1. The Stallings-Swan Theorem. If the left ZG-module ωZG is projective,
then G acts freely on some tree.

Proof. By hypothesis, there exists some left ZG-module Q such that the left
ZG-module ωZG ⊕ Q is free. There then exists some free left Z-module A such
that the (free) left ZG-modules ωZG ⊕ Q and AG := ZG ⊗Z A are isomorphic, and
may be identified. In a natural way, Maps(G, A) is a left ZG-module, and we may
identify AG with the (G-stable) almost equality class of 0 in Maps(G, A); here, it
is to be understood that G stabilizes each element of A. Each element r of AG has
a unique expression as p + q with p ∈ ωZG and q ∈ Q, and here we shall write
r = p ⊕ q.

Let g and x represent variable elements of G ranging over all of G.

By (free) left ZG-modules ωZG ⊕ Q is free, then there exists some left ZG-module X
such that (g(x)) := (g−1x) ⊕ 0 ∈ ωZG ⊕ Q = AG ⊆ Maps(G, A).

Notice that g−1 = g − 1, and show that g(ωZG ⊕ Q) ⊆ Maps(G, A) as follows:

\[
gv = g(v, g^{-1}x) \overset{\text{def}}{=} g(1 - g^{-1}x, g^{-1}x)
\]

Hence, the almost equality class v + AG in Maps(G, A) is G-stable. By the Almost
Stability Theorem [1.2] the G-set v + AG is the vertex G-set of some G-tree.

It remains to show that the vertex G-set v + AG is G-free. Suppose then that
we have some g ∈ G and some r ∈ AG such that g(v + r) = v + r in Maps(G, A),
that is, (1 - g)v = (1 - g), write r = p ⊕ q with p ∈ ωZG and q ∈ Q.

Then (1 - g)p ⊕ (1 - g)q = (g - 1) ⊕ 0 in ωZG ⊕ Q. Thus, g(p + q) = p + 1 in
ZG ⊆ Maps(G, Z). Hence, p + 1 is constant on each (g)-orbit (g)x in G. Since
p ∈ ωZG, 0 = p + q = q in Maps(G, Z). Hence, (g) is finite. Now the augmentation
map carries p + 1 to a Z-multiple of ωZG and also to 1. Thus, |(g)| = 1. Hence,
g = 1, as desired.

2.2. Remark. The foregoing argument applies to give Dunwoody’s characterization
of the groups G such that the left RG-module ωRG is projective, where R is any
nonzero associative ring with 1 and ωRG denotes the augmentation ideal of the
group ring RG; see [6, 1.1, 5, IV.3.13].

3. Terminology

In this section, we collect together definitions of many of the concepts that we
shall be using.

3.1. Notation. We write f|D to indicate the map obtained from a map f by
restricting the domain of f to a subdomain D.
We shall find it useful to have notation for intervals in $\mathbb{Z}$ that is different from the notation for intervals in $\mathbb{R}$. Let $i, j \in \mathbb{Z}$. We define the sequence

$$[i \uparrow j] := \begin{cases} (i, i + 1, \ldots, j - 1, j) \in \mathbb{Z}^{j-i+1} & \text{if } i \leq j, \\ (\) \in \mathbb{Z}^0 & \text{if } i > j. \end{cases}$$

The subset of $\mathbb{Z}$ underlying $[i \uparrow j]$ is denoted $[i \uparrow j] := \{i, i + 1, \ldots, j - 1, j\}$.

We set $[i \uparrow \infty] := (i, i + 1, i + 2, \ldots)$ and $[i \uparrow \infty[ := \{i, i + 1, i + 2, \ldots\}$.

Suppose we have a set $V$ and a map $[i \uparrow j] \to V$, $\ell \mapsto v_\ell$. We define the corresponding sequence in $V$ by

$$v_{[i \uparrow j]} := \begin{cases} (v_i, v_{i+1}, \ldots, v_{j-1}, v_j) \in V^{j-i+1} & \text{if } i \leq j, \\ (\) \in V^0 & \text{if } i > j. \end{cases}$$

By abuse of notation, we shall also express this sequence as $(v_\ell | \ell \in [i \uparrow j])$, although “$\ell \in [i \uparrow j]$” on its own will not be assigned a meaning. The set of terms of $v_{[i \uparrow j]}$ is denoted $v_{[i \uparrow j]}$.

We set $v_{[i \uparrow \infty]} := (v_i, v_{i+1}, v_{i+2}, \ldots)$ and $v_{[i \uparrow \infty[} := \{v_i, v_{i+1}, v_{i+2}, \ldots\}$. □

3.2. Definitions. By a well-ordered set, we mean a set $S$ together with a total order $\subseteq$ such that, for each nonempty subset $T$ of $S$, there exists some $x \in T$ such that, for each $t \in T$, $x \subseteq t$. It is then usual to treat the total order as “less than”, and to use phrases such as “all strictly descending sequences are finite”.

An ordinal is a set $\beta$ such that, first, each element of $\beta$ is equal to some subset of $\beta$, and, secondly, $\beta$ is well-ordered by $\in$; see [12] 2.10.

The three lower-case Greek letters $\alpha$, $\beta$, and $\gamma$ will be used to denote ordinals.

We let $\text{Ord}$ denote the class of all ordinals, and, for $\alpha, \beta \in \text{Ord}$, we define $\alpha < \beta$ to mean $\alpha \in \beta$. Thus, for each $\beta \in \text{Ord}$, $\beta = \{\alpha \in \text{Ord} | \alpha < \beta\}$.

Let $S$ be any set. By the axiom of choice, $S$ can be well-ordered, and, hence, there exists some $\alpha \in \text{Ord}$ such that there exists some bijective map of sets from $\alpha$ to $S$. The minimum of the set consisting of such $\alpha$ is denoted $|S|$. We write $\omega_0 := \{0 \uparrow \infty\}$; thus, $\omega_0$ is the smallest infinite ordinal, the set of finite ordinals.

By abuse of notation, we view the elements of $0 \uparrow \infty$ as finite ordinals. □

3.3. Definitions. Let $V$ be any set.

We denote by $\mathcal{P}(V)$ the set of all subsets of $V$, and view $\mathcal{P}(V)$ as a Boolean algebra in the usual way.

Let $A$ and $B$ be any elements of $\mathcal{P}(V)$.

We write $A^c := \{v \in V | v \not\in A\}$.

We say that $A$ and $B$ are nested if $\emptyset \in \{A \cap B, A \cap B^c, A^c \cap B, A^c \cap B^c\}$.

We write $A \cap B := A \cap B^c$.

We write $A \cap B$ to denote $A \cup B$ in the situation where $A \cap B = \emptyset$.

We write $A \cap B := (A \cap B) \cup (B \cap A)$. If $A \cap B$ is a finite set, we say that $A$ and $B$ are almost equal, and write $A \approx B$.

For any subset $E$ of $\mathcal{P}(V)$, we denote by $\langle E \rangle_B$ the Boolean subalgebra of $\mathcal{P}(V)$ generated by $E$.

For each $v \in V$, we write $v^{**} := \{A \in \mathcal{P}(V) | v \in A\} \in \mathcal{P}(\mathcal{P}(V))$. □

3.4. Definitions. We define the rank of the group $G$ by

$$\text{rank}(G) := \min \{|S| : S \text{ is a subset of } G \text{ which generates } G\}.$$ 

For any subgroup $H$ of $G$, we define the rank of $G$ relative to $H$ by

$$\text{rank}(G \text{ rel } H) := \min \{|S| : S \text{ is a subset of } G \text{ such that } S \cup H \text{ generates } G\}.$$ 

By a $G$-set, we mean a set $V$ together with a map $G \times V \to V$, $(g, v) \mapsto gv$, such that, for each $v \in V$, $1v = v$ and, for each $(g_1, g_2) \in G \times G$, $g_1(g_2v) = (g_1g_2)v$. 

AN IMPROVED PROOF OF THE ALMOST STABILITY THEOREM
By a right $G$-set, we mean a set $V$ together with a map $V \times G \to V$, $(v,g) \mapsto vg$, such that, for each $v \in V$, $v1 = v$ and, for each $(g_1,g_2) \in G \times G$, $(vg_1)g_2 = vg_1g_2$. (Here, $V$ is a $G$-set with $vg := vg^{-1}$.) All concepts defined for $G$-sets are understood to have analogues for right $G$-sets.

Consider any $G$-set $V$. For each subset $W$ of $V$, we write

$$GW := \{gw \mid g \in G, w \in W\}.$$

If $GW = W$, we say that $W$ is a $G$-stable subset of $V$ and a $G$-subset of $V$. For each $v \in V$, we define the $G$-stabilizer of $v$ to be $G_v := \{g \in G \mid gv = v\} \leq G$, and the $G$-orbit of $v$ to be $Gv := \{gv \mid g \in G\}$, a $G$-subset of $V$. We let $G \setminus V := \{Gv \mid v \in V\}$, a partition of $V$. We say that $V$ is $G$-finite if $G \setminus V$ is finite. A $G$-transversal in $V$ is a subset of $V$ which contains exactly one element of each $G$-orbit of $V$. A subgroup $H$ of $G$ is said to stabilize an element $v$ of $V$ if $Hv = \{v\}$ or, equivalently, $H_v = H$ or, equivalently, $H \leq G_v$; if $H$ stabilizes some element of $V$, we say that $H$ is a $G$-substabilizer for $V$. We let $G$-substabilizers($V$) denote the set of $G$-substabilizers for $V$.

Consider any $G$-sets $V$ and $W$. By a $G$-map $\varphi : V \to W$, $v \mapsto \varphi(v)$, we mean a map of sets such that, for each $(g,v) \in G \times V$, $\varphi(gv) = g\varphi(v)$. There exists some $G$-map from $V$ to $W$ if and only if $G$-substabilizers($V$) $\subseteq$ $G$-substabilizers($W$).

A $G$-set $V$ is said to be $G$-incompressible if each self $G$-map of $V$ is bijective, or, equivalently, for each $(v,w) \in V \times V$, if $G_v \leq G_w$, then $G_v = G_w$ and $Gv = Gw$. If $V$ is not $G$-incompressible, we say that $V$ is $G$-compressible.

We now consider the right $G$-set $G$. Any $A \in \mathcal{P}(G)$ is said to be almost right $G$-stable if, for each $g \in G$, $Ag =_a A$. We write $\mathcal{B}(G)$ to denote the Boolean subalgebra of $\mathcal{P}(G)$ consisting of all the almost right $G$-stable elements. For each subgroup $H$ of $G$, any $A \in \mathcal{P}(G)$ is said to be almost a right $H$-set if $A$ is almost equal to some right $H$-subset of $G$. For each subset $E$ of $\mathcal{P}(G)$, we let Almosts($E$) denote the set consisting of all those subgroups $H$ of $G$ which have the property that each element of $E$ is almost a right $H$-set.

3.5. Definitions. By a graph $X$, we mean a quadruple $(V(X), E(X), \iota_X, \tau_X)$ where $V(X)$ and $E(X)$ are two disjoint sets and $\iota_X$ and $\tau_X$ are maps from $E(X)$ to $V(X)$. Where $X$ is clear from the context, we write $\iota$ for $\iota_X$ and $\tau$ for $\tau_X$. We define $|X| := |V(X) \cup E(X)|$. We say that $V(X)$ is the vertex set of $X$ and that $E(X)$ is the edge set of $X$, and that $\iota$ and $\tau$ are the incidence maps of $X$. We say that the elements of $V(X)$ are the vertices of $X$, and the elements of $E(X)$ are the edges of $X$. For each edge $e$ of $X$, we say that $e$ is incident to $\iota e$ and $\tau e$, and that $\iota e$ is the initial vertex of $e$ and that $\tau e$ is the terminal vertex of $e$.

A $G$-graph $X$ is a graph for which $V(X), E(X)$ are $G$-sets, and $\iota, \tau$ are $G$-maps. Passing to $G$-orbits gives a quotient graph $G \setminus X$. Here $X$ is $G$-finite if $G \setminus X$ is finite, that is, $|G \setminus X|$ is finite.

For any subset $S$ of $G$, the Cayley graph $X(G, S)$ is defined as the $G$-graph with vertex $G$-set $G$, edge $G$-set $G \times S$ with $G$-action $g_1(g_2, s) := (g_1g_2, s)$, and incidence maps assigning to each edge $(g, s) \in G \times S$ the initial vertex $g$ and the terminal vertex $gs$.

Let $X$ be any graph.

A subgraph of $X$ is a graph whose vertex set and edge set are subsets of the vertex set and edge set of $X$, respectively, and whose incidence maps agree with those of $X$.

For each vertex $v$ of $X$, the valence of $v$ in $X$ is

$$|\{e \in E(X) : \iota e = v\}| + |\{e \in E(X) : \tau e = v\}|.$$

We say that $X$ is locally finite if each vertex’s valence is finite.
We create a set $E^{-1}(X)$ together with a bijective map $E(X) \to E^{-1}(X)$, $e \mapsto e^{-1}$, called inversion. We define $E^{\pm 1}(X) := E(X) \vee E^{-1}(X)$. We extend $\iota$ to a map $\iota: E^{\pm 1}(X) \to V(X)$ by setting $\iota(e^{-1}) := \iota e^{-1}$ for each $e \in E(X)$. Similarly, we extend $\tau$ to a map $\tau: E^{\pm 1}(X) \to V(X)$ by setting $\tau(e^{-1}) := \tau e$ for each $e \in E(X)$. We extend inversion to a map $E^{\pm 1}(X) \to E^{\pm 1}(X)$, $e \mapsto e^{-1}$, by defining $\iota(e^{-1}) := e$ for each $e \in E(X)$.

By an $X$-path, we shall mean any sequence $p = (v_0, e_1, v_1, e_2, \ldots, e_n, v_n)$ such that $n \in [0, \infty]$, $v_{[0,n]}$ is a sequence in $V(X)$, $e_{[1,n]}$ is a sequence in $E^{\pm 1}(X)$, and, for each $i \in [1,n]$, $\iota(e_i) = v_{i-1}$ and $\tau(e_i) = v_i$. We define the inverse of $p$ to be $p^{-1} := (v_0, e_n^{-1}, \ldots, e_{i+1}^{-1}, v_1, e_1^{-1}, v_0)$. We say that $p$ is reduced if, for each $i \in [2 \ldots n]$, $e_i \neq e_{i-1}^{-1}$. We say that $p$ joins $v_0$ to $v_n$, and that the pair $(v_0, v_n)$ is $X$-joined. We define $\ell(p) := n$. If there exists no $X$-path joining $v_0$ to $v_n$ of smaller length, then we say that the $X$-distance between $v_0$ and $v_n$ is $n$. For each finite subset $S$ of $E(X)$, we define the number of times $p$ crosses $S$ to be $|\{i \in [1,n] : e_i \in S^{\pm 1}\}|$; if this number is positive, we say that $p$ crosses $S$. Where $S$ consists of a single edge, we shall usually speak of paths crossing that edge rather than crossing $S$.

We say that $X$ is connected if each pair of vertices of $X$ is $X$-joined. The maximal nonempty connected subgraphs of $X$ are called the components of $X$.

For any subset $E'$ of $E(X)$, the graph obtained from $X$ by collapsing $E'$, denoted $X/E'$, is the graph with edge set $E'' := E(X) - E'$, vertex set the set of components of $X - E''$, and the induced incidence maps. For example, $X/E(X)$ maps bijectively to the set of components of $X$, and here every edge of $X$ gets collapsed.

For each $A \in \mathcal{P}(V(X))$, we define the coboundary of $A$ (in $X$) as $\delta_X(A) := \{e \in E(X) \mid (ie, \tau e) \in ((A \times A^c) \vee (A^c \times A))\} = \{e \in E(X) \mid A \in (ie)^* \vee (\tau e)^*\}$; where $X$ is clear from the context we write $\delta_A$ in place of $\delta_X(A)$.

The Boolean algebra of $X$, denoted $\mathcal{B}(X)$, is defined as the Boolean subalgebra of $\mathcal{P}(V(X))$ consisting of all the elements with finite coboundary in $X$.

We say that $X$ is a tree if, for each $(v, w) \in V(X) \times V(X)$, there exists a unique reduced $X$-path that joins $v$ to $w$. A $G$-tree is a $G$-graph which is a tree. We say that $X$ is a forest if, for each $(v, w) \in V(X) \times V(X)$, there exists at most one reduced $X$-path that joins $v$ to $w$. A $G$-forest is a $G$-graph which is a forest.

Let $T$ be any $G$-tree. We say that $T$ is $G$-incompressible if the $G$-set $V(T)$ is $G$-incompressible. An edge $e$ of $T$ is said to be $G$-compressible if there exists some $(v, w) \in \{(ie, \tau e), (\tau e, ie)\}$ such that $Gv \neq Gw$ and $Gw \subseteq Gv$; here, $Gw = Gc$. \hfill $\Box$

In the following, the important conclusion $\mathcal{B}(X) = \mathcal{B}(G)$ is due to Specker [16].

3.6. Lemma. Let $S$ be any generating set of $G$, and set $X := X(G, S)$. Then $X$ is a nonempty, connected, $G$-free $G$-graph, and $V(X) = G$. Moreover, if $S$ is finite, then $X$ is locally finite, $X$ is $G$-finite, and $\mathcal{B}(X) = \mathcal{B}(G)$.

Proof. Clearly, $X$ is a nonempty, $G$-free $G$-graph, and $V(X) = G$. Also, $X/E(X)$ is a $G$-set with one $G$-orbit, and the image of $1$ in $X/E(X)$ is stabilized by $S$. Since $S$ generates $G$, we see that the image of $1$ in $X/E(X)$ is stabilized by $G$. Hence, $X$ has exactly one component.

Now suppose that $S$ is finite. Then $X$ is locally finite and $G$-finite. It remains to verify that $\mathcal{B}(X) = \mathcal{B}(G)$.

Consider any $A \in \mathcal{P}(G)$. For each $s \in S$,

$$A \overline{\text{span}}(A^{-1}s^{-1}) = \{g \in G \mid g \in A - As^{-1} \text{ or } g \in As^{-1} - A\} = \{g \in G \mid g \in A, gs \in A^c \text{ or } g \in A^c, gs \in A\},$$

$$\Rightarrow$$

AN IMPROVED PROOF OF THE ALMOST STABILITY THEOREM 7
and, hence,
\[(3.6.1)\quad A\forall(As^{-1}) = \{g \in G \mid (g, s) \in \delta(A)\}.\]

Suppose that \(A \in \mathcal{B}(G)\). For each element \(s\) of the finite set \(S\), \(A\forall(As^{-1})\) is a finite set. It follows from (3.6.1) that \(\delta(A)\) is a finite set, that is, \(A \in \mathcal{B}(X)\).

Suppose that \(A \in \mathcal{B}(X)\). For each \(s \in S\), by (3.6.1), \(A\forall As^{-1}\) is a finite set, that is, \(A =_a As^{-1}\). Since \(S\) generates \(G\), it follows that \(A \in \mathcal{B}(G)\). \(\square\)

4. Building trees from nested sets

This section reviews results of Dunwoody \cite{5} with modifications by Dicks and Dunwoody \cite{6} and Roller \cite{14}.

4.1. Notation. Let \(V\) be any set, and \(\mathcal{E}\) be any subset of the Boolean algebra \(\mathcal{P}(V)\).

We say that \(\mathcal{E}\) is \(e\)-stable if, for each \(A \in \mathcal{E}\), we have \(A^e \in \mathcal{E}\).

We say that \(\mathcal{E}\) is \(e\)-finitely separating if, for all \(v, w \in V\), \(v^* \cap \mathcal{E} =_a w^* \cap \mathcal{E}\); note that \(v^* \cap \mathcal{E} = \{d \in \mathcal{E} \mid v \in d\}\).

We say that \(\mathcal{E}\) is nested if, for each \((e, f) \in \mathcal{E} \times \mathcal{E}\), and \(e \neq f\) nested in \(V\), that is, \(\emptyset \in \{e \cap f, e \cap f^c, e^c \cap f, e^c \cap f^c\}\).

For each \(e \in \mathcal{E}\), we define
\[\iota_e := \{d \in \mathcal{E} \mid d \supset e\text{ or }d \supset e^c\},\]
\[\tau_e := \{d \in \mathcal{E} \mid d \supset e\text{ or }d \supset e^c\}\text{ and }\tau'e := \{d \in \mathcal{E} \mid d \supset e\text{ or }d \supset e^c\}.

If \(\mathcal{E} \neq \emptyset\), we define \(T(\mathcal{E})\) to be the graph for which the edge set is \(\mathcal{E}\), the vertex set is \(\{\iota_e, \tau_e \mid e \in \mathcal{E}\} \subseteq \mathcal{P}(\mathcal{P}(V))\), and each \(e \in \mathcal{E}\) has initial vertex \(\iota_e\) and terminal vertex \(\tau_e\).

If \(\mathcal{E} \neq \emptyset\), we define \(U(\mathcal{E})\) to be the graph for which the edge set is \(\mathcal{E}\), the vertex set is \(\{\iota_e, \tau'e \mid e \in \mathcal{E}\} \subseteq \mathcal{P}(\mathcal{P}(V))\), and each \(e \in \mathcal{E}\) has initial vertex \(\iota_e\) and terminal vertex \(\tau'e\).

If \(\mathcal{E} = \emptyset\), we define both \(T(\mathcal{E})\) and \(U(\mathcal{E})\) to be the graph for which the edge set is the empty set \(\mathcal{E}\) and the vertex set is \(\{\mathcal{E}\} \subseteq \mathcal{P}(\mathcal{P}(V))\). \(\square\)

4.2. Example. Let \(T\) be a tree. It is sometimes natural to think of the vertices of \(T\) as certain sets of vertices of \(T\), and it is sometime natural to think of the edges of \(T\) as certain sets of edges of \(T\); to achieve this formally, we create 'double duals' of the edges of \(T\). For each \(e \in E(T)\), we set
\[e^* := \{v \in V(T) \mid \text{the reduced } T\text{-path from } v \text{ to } e \text{ crosses } e\};\]
then \(e^*\) is the vertex set of that component of \(T - \{e\}\) which contains \(\iota_e\); hence, \(\delta_T(e^*) = \{e\}\); hence, \(e^* \in B(T)\). Set \(\iota_e(T) := \{e^* \mid e \in E(T)\}\). For each \(e \in E(T)\),
\[\iota_{U(\mathcal{E}(T))}(e^*) = \{d^* \in \mathcal{E}(T) \mid d^* \supset e^* \text{ or } d^* \supset (e^*)^c\}
\[= \{d^* \in \mathcal{E}(T) \mid \iota_te \in d^*\} = (\iota_te)^* \cap \mathcal{E}(T)\].

There is a natural identification \(T = U(\mathcal{E}(T))\). \(\square\)

The following is due to Dunwoody \cite{3} 2.1 with modifications from \cite{5} II.1.5[].

The proof given here incorporates the approach of Roller \cite{14}.

4.3. Theorem. With Notation \cite{11} if \(V\) is any set and \(\mathcal{E}\) is any e-stable, finitely separating, nested subset of \(\mathcal{P}(V)\) such that \(\emptyset \not\in \mathcal{E}\), then the following hold.

(i) \(T(\mathcal{E})\) is a tree with edge set \(\mathcal{E}\), and, for any \(e, f \in \mathcal{E}\), the \((T, E)\)-distance between \(\iota_e\) and \(\iota_f\) equals \(\rho(\iota_e, \iota_f)\).

(ii) There exists a natural map \(V \to V(T(\mathcal{E}))\), \(v \mapsto v^* \cap \mathcal{E}\). In detail, if \(\mathcal{E} \neq \emptyset\), then, for each \(v \in V\), there exists some \(\subseteq\)-minimal element \(e\) of \(v^* \cap \mathcal{E}\), and then \(v^* \cap \mathcal{E} = \iota_e\).
Proof. The case where $\mathcal{E} = \emptyset$ is straightforward, and we shall assume that $\mathcal{E} \neq \emptyset$.

Here, $U(\mathcal{E})$ is the graph for which the edge set is $\mathcal{E}$, the vertex set is $\{ i e \mid e \in \mathcal{E} \}$, and each $e \in \mathcal{E}$ has initial vertex $i e$ and terminal vertex $\tau e = i(e^e)$. For each $e \in E(U(\mathcal{E})) = E$, $e^e \neq e$, $e^{ee} = e$, $i(e^e) = \tau(e)$, and $\tau(e^e) = i(e)$. By a restricted $U(\mathcal{E})$-path, we shall mean any sequence $p = e_1, e_2, \ldots, e_n \in \mathcal{E}$ such that $n \in [1]^{\infty}$ and, for each $i \in [2^n]$, $i(e_i) = \tau(e_{i-1})$ and $e_i \neq e_{i-1}$.

For each $e \in \mathcal{E}$, $(i e) \vee (i(e^e)) = (e, e^e)$, and $i e$ is a $c$-transversal in $\mathcal{E}$, or ‘orientation’, in the sense of a subset $O$ of $\mathcal{E}$ such that $\mathcal{E} = O \cup \{ f^e \mid f \in O \}$.

Consider any $e, f \in \mathcal{E}$. Set $[e, f] := \{ d \in \mathcal{E} \mid e \subseteq d \subseteq f \}$, and define $[e, f], [e, f]$ and $[e, f]$ analogously. These sets are finite by the finitely separating condition, since we may choose $v \in e$ and $w \in f^e$, and find that $[e, f] \subseteq v^{**} - w^{**}$. We write $e \prec f$ to mean $[e, f] = \{ e \}$ or, equivalently, $[e, f] = \{ f \}$. Now

$$we = \{ d \in \mathcal{E} \mid e \subseteq d or e^e \subseteq d \}, \quad \mathcal{E} - i f = \{ d \in \mathcal{E} \mid d \subset f or d \subseteq f^e \},$$

and also $e = f or e \subset f or e \subseteq f^e or e^e \subset f or e^e \subseteq f^e$. We then see that

$$we - i f = we \cap (\mathcal{E} - i f) = [e, f] \cup [e, f^e] \cup [e^e, f] \cup [e^e, f^e],$$

and that the latter union is empty if and only if $e = f or e^e \prec f$. Thus, $we \subseteq i f$ if and only if $e = f or e^e \prec f$. Since $([e^e, f])^e = [f^e, e]$, the condition $e^e \prec f$ is invariant under interchanging $e$ and $f$, and we see that $we = i f$ if and only if $e = f or e^e \prec f$. By interchanging $e$ and $e^e$, we see that $\tau^e \prec f$ if and only if $e = f^e or e^e \prec f$. (This paragraph is based on the elegant presentation of Roller [14, §2.6-2.7] and is simpler than the discussion in [5, II.1.5].)

A restricted $U(\mathcal{E})$-path $p = e_1, e_2, \ldots, e_n$, $n \in [1]^{\infty}$, may then be viewed as an unrefinable increasing sequence $e_1 \prec e_2 \prec \cdots \prec e_n \in \mathcal{E}$. Since $e_1 \subseteq e_n$, neither $e_1 = e_n$ nor $e_n \prec e_1$ are possible; thus, $\tau^e_n \neq w_1$. Hence, in $U(\mathcal{E})$, no vertex is joined to itself by a restricted $U(\mathcal{E})$-path.

We shall now see that, in $U(\mathcal{E})$, any vertex is joined to any other vertex by a restricted $U(\mathcal{E})$-path. By the nestedness of $\mathcal{E}$, for any $e, f \in \mathcal{E}$, there exist $e' \in \{ e, e^e \}$ and $f' \in \{ f, f^e \}$ such that $e' \subset f'$. Since the set $[e', f']$ is finite, there exists some unrefinable increasing sequence

$$e' = e_1 \prec e_2 \prec \cdots \prec e_n = f' \in \mathcal{E}, n \in [1]^{\infty};$$

this gives a restricted $U(\mathcal{E})$-path which meets the vertices of $e$ and $f$, as desired.

We may pass from the graph $U(\mathcal{E})$ to the graph $T(\mathcal{E})$ by detaching each edge from its terminal vertex and giving the elements of each unordered pair of edges $\{ e, e^e \}$, $e \in \mathcal{E}$, a new common terminal vertex. Hence, $T(\mathcal{E})$ is a tree.

The $T(\mathcal{E})$-distance formula follows since, for each $e \in \mathcal{E}$, $(i e) \vee (i(e^e)) = (e, e^e)$ and $(i e, \tau e, (e^e)^{-1}, i(e^e))$ is a reduced $T(\mathcal{E})$-path.

[3]. We show first that $v^{**} \cap \mathcal{E}$ has $\subseteq$-minimal elements. Since $\mathcal{E} \neq \emptyset$, there exists some $f \in \mathcal{E}$. We may assume that $v \in f$, for otherwise we may replace $f$ with $f^e$. Since $\emptyset \notin \mathcal{E}$, there exists some $w \in f^e$, and we have

$$f \in \{ e \in \mathcal{E} \mid v \in e \subseteq f \} \subseteq \{ e \in \mathcal{E} \mid v \in e, w \in e^e \} = (v^{**} \cap \mathcal{E}) - (w^{**} \cap \mathcal{E}).$$

The latter set is finite, since $\mathcal{E}$ is finitely separating. Thus $\{ e \in \mathcal{E} \mid v \in e \subseteq f \}$ is finite and nonempty, and hence has a $\subseteq$-minimal element, which is then a $\subseteq$-minimal element of $\{ e \in \mathcal{E} \mid v \in e \}$, as desired.

Let $e$ be a $\subseteq$-minimal element of $v^{**} \cap \mathcal{E}$. We shall show that $v^{**} \cap \mathcal{E} = \{ e \}$. Let $d \in we$. Then either $d \supseteq e$ or $e \supseteq d^e$. If $d \supseteq e$ then $d \supseteq d \supseteq \{ v \}$ and, hence, $d \in v^{**} \cap \mathcal{E}$. If $e \supseteq d^e$, then, by the $\subseteq$-minimality of $e$, $v \in (d^e)^e = d$, and, hence $d \in v^{**} \cap \mathcal{E}$. Thus, $we \subseteq v^{**} \cap \mathcal{E}$.

Conversely, suppose that $d \in \mathcal{E} - we$. Then $d^e \in we \subseteq v^{**} \cap \mathcal{E}$. Hence, $d \in \mathcal{E} - v^{**}$. Thus, $\mathcal{E} - we \subseteq \mathcal{E} - v^{**}$.

Now $v^{**} \cap \mathcal{E} = \{ e \}$, as desired. □
4.4. **Corollary.** Let $V$ be any set, and $\mathcal{E}$ be any finitely separating, nested subset of $\mathcal{P}(V)$ such that $\emptyset \not\in \mathcal{E}$, $V \not\in \mathcal{E}$, and, for each $e \in \mathcal{E}$, $e^c \not\in \mathcal{E}$. With Notation 4.3, the following hold.

(i). $U(\mathcal{E})$ is a tree with edge set $\mathcal{E}$, and, for any $v, w \in \mathcal{E}$, the $U(\mathcal{E})$-distance between $v$ and $w$ equals $|v \setminus w|$.

(ii). There exists a natural map $V \rightarrow V(U(\mathcal{E}))$, $v \mapsto v^* \cap \mathcal{E}$.

**Proof.** Set $\mathcal{E}^c := \{e^c \mid e \in \mathcal{E}\}$. By Theorem 5.3, $T(\mathcal{E} \cup \mathcal{E}^c)$ is a tree with edge set $\mathcal{E} \cup \mathcal{E}^c$. Now $T(\mathcal{E} \cup \mathcal{E}^c)/\mathcal{E}^c = U(\mathcal{E})$, and the result follows. (Alternatively, $U(\mathcal{E}) = U(\mathcal{E} \cup \mathcal{E}^c) - \mathcal{E}^c$, the tree obtained from $U(\mathcal{E} \cup \mathcal{E}^c)$ by choosing the orientation $\mathcal{E}$.)

5. **Building nested sets from graphs**

We now review theory developed by Bergman in [1].

5.1. **Definitions.** We introduce a new symbol $t$, and view the power-series ring $Z[[t]]$ as an ordered abelian group with the total order $\preceq$ such that

$$\sum_{\ell \in [0,|t|]} c_\ell t^\ell \preceq \sum_{\ell \in [0,|t|]} d_\ell t^\ell$$

if and only if there exists some $\ell_0 \in [0,|t|]$ such that $c_{\ell_0} < d_{\ell_0}$ and, for each $\ell \in [0,\ell_0]$, $c_\ell = d_\ell$. We view the polynomial ring $Z[t]$ as a subset of $Z[[t]]$.

Let $X$ be any connected, locally finite graph. For any set $P$ of $X$-paths with the property that, for each $\ell \in [0,|t|]$, the set $P_{\ell} := \{p \in P : \text{length}(p) = \ell\}$ is finite, we write

$$\Sigma(P) := \sum_{p \in P} t^{\text{length}(p)} = \sum_{\ell \in [0,|t|]} |P_{\ell}| t^\ell \in Z[[t]].$$

For any element $A$ of $\mathcal{B}(X)$, we let $P(A)$ denote the set of all $X$-paths which begin in $A$ and end in $A^c$, necessarily crossing $\delta A$. Since $X$ is locally finite and $\delta A$ is finite, we see that $P(A)$ has only finitely many elements of any given length. We write $\Sigma P(A) := \Sigma(P(A))$. Inversion of paths carries $P(A)$ bijectively to $P(A^c)$; hence, $\Sigma P(A) = \Sigma P(A^c)$. We write

$$\Sigma P(\mathcal{B}(X)) := \{\Sigma P(A) \mid A \in \mathcal{B}(X)\} \subseteq Z[[t]].$$

For any Boolean subalgebra $A$ of $\mathcal{B}(X)$, any element $C$ of $A$ is said to be $A$-reducible if

$$C \in \{D \in A : \Sigma P(D) \preceq \Sigma P(C)\}_B;$$

otherwise, $C$ is said to be $A$-irreducible. We let $\text{irr}(A)$ denote the set of all $A$-irreducible elements of $A$. Notice that $\emptyset$ and $V(X)$ are $A$-reducible.

The following is the $G$-finite case of a result of Bergman [1] Lemma 2.

5.2. **Theorem.** If $X$ is any connected, locally finite, $G$-finite $G$-graph, then $\Sigma P(\mathcal{B}(X))$ is a well-ordered subset of $Z[[t]]$.

**Proof.** We shall show that a larger subset of $Z[[t]]$ is well-ordered.

Let $\mathcal{S}$ denote the set of all finite subsets of $E(X)$.

Consider any $S \in \mathcal{S}$. We denote by $P(S)$ the set of all those $X$-paths that cross $S$ an odd number of times. For each $\ell \in [0,|t|]$, we denote by $P_{\ell}(S)$ the set of all elements of $P(S)$ whose length equals $\ell$. Since $S$ is finite and $X$ is locally finite, $P_{\ell}(S)$ is finite; $|P_{\ell}(S)|$ is an even number since $P_{\ell}(S)$ is stable under path inversion. Clearly, $|P_0(S)| = 0$ and $|P_1(S)| = 2|S|$. We write

$$\Sigma P(S) := \Sigma P(S) = \sum_{\ell \in [0,|t|]} |P_{\ell}(S)| t^\ell$$

and $\Sigma P(S) := \{\Sigma P(S) : S \in \mathcal{S}\} \subseteq 2tZ[[t]]$. 

\[ \text{□} \]
For any $A \in \mathcal{B}(X)$, we have $\delta A \in S$, and $P(\delta A)$, the set of $X$-paths that cross $\delta A$ an odd number of times, equals $P(A) \cup P(A^c)$; hence, $\Sigma P(\delta A) = 2 \Sigma P(A)$. Thus, $2 \Sigma P(\mathcal{B}(X)) \subseteq \Sigma P(S)$, and it suffices to show that $\Sigma P(S)$ is well-ordered.

Consider any map $S_- : [0,1[ \to S$, $n \mapsto S_n$, such that the composite map $\Sigma P(S_-) : [0,1[ \to \mathbb{Z}[\mathbb{N}]$, $n \mapsto \Sigma P(S_n)$, is decreasing. It suffices to show that there exists some infinite subset $N$ of $[0,1[\mathbb{N}$ such that $\{\Sigma P(S_n) \mid n \in N\}$ has exactly one element. Without loss of generality, we may assume that, for each $n \in [0,1[\mathbb{N}$, $S_n \neq \emptyset$.

Let $K$ denote the set consisting of those $k \in [1,\omega)$ for which there exist
\[(5.2.1)\] an infinite subset $N$ of $[0,1[\mathbb{N}$, a map $[1,\omega) \to S - \{\emptyset\}$, $i \mapsto R_i$, and a map $N \times [1,\omega) \to G$, $(n,i) \mapsto g_{n,i}$, such that, for each $n \in N$, $S_n = \bigcup_{i=1}^k g_{n,i} R_i$.

In the case where $k = 1$, \[\{\Sigma P(S_n) \mid n \in N\} = \{\Sigma P(g_{n,1} R_1) \mid n \in N\} = \{\Sigma P(R_1)\},\] which gives the desired result. We shall show that $K \neq \emptyset$ and that, for each $k \in K$, either $k = 1$ or $k-1 \in K$. This implies that $1 \in K$, which completes the proof.

We now show that $\{S_0\} \subseteq K$, and, hence, $K \neq \emptyset$. Let us choose a finite $G$-transversal $R$ in the $G$-finite $G$-set $E(X)$. Consider any $n \in [0,1[\mathbb{N}$. Since $n \geq 0$ and $\Sigma P(S_-)$ is decreasing, $\Sigma P(S_n) \subseteq \Sigma P(S_0)$. Hence,
\[2 |S_0| t \leq \Sigma P(S_n) \subseteq \Sigma P(S_0) \subseteq 2 (|S_0| + 1) t.\]
Thus, $|S_n| < |S_0| + 1$. Set $k := |S_0|$. Then $1 \leq |S_n| \leq k$, and we may choose a surjective map $[1,\omega) \to S_n$, $i \mapsto s_{n,i}$. For each $i \in [1,\omega)$, there exists a unique $s_{n,i} \in R$ such that $s_{n,i} R s_{n,i} = s_{n,i}$. We have a map $r_{n,-} : [1,\omega) \to R$, $i \mapsto r_{n,i}$. Since
\[|\{r_{n,-} \mid n \in [0,1[\mathbb{N}\}| \leq |R|^k < \omega_0,\]
there exists some infinite subset $N$ of $[0,1[\mathbb{N}$ and some map $r_- : [1,\omega) \to R$, $i \mapsto r_i$, such that, for each $n \in N$, $r_{n,-} = r_-$, and, hence,
\[S_n = \bigcup_{i=1}^k g_{n,i} \{r_{n,i}\} = \bigcup_{i=1}^k g_{n,i} \{r_i\}.\]
We have (5.2.1), and $k \in K$.

For any $R$ and $S \subseteq S - \{\emptyset\}$, we let $d(R,S)$ denote the length of the minimum-length $X$-paths that cross both $R$ and $S$. Set $d := d(R,S) \in [1,\omega)$. The $X$-distance, in the usual sense, from $R$ to $S$ equals $\max\{d-2,0\}$. It may be seen that $P_d(R) \cap P_d(S)$ is nonempty and consists of the minimum-length $X$-paths with the properties that exactly one edge (the first or last) lies in $R$ and exactly one edge (the last or first) lies in $S$. For each $\ell \in [0,d]$, $P_\ell(R \cup S) = P_\ell(R) \cup P_\ell(S)$ and $|P_\ell(R \cup S)| = |P_\ell(R)| + |P_\ell(S)|$, while $P_d(R \cup S) \subseteq P_d(R) \cup P_d(S)$ and $|P_d(R \cup S)| < |P_d(R)| + |P_d(S)|$.

If $d = 1$, then $R \cap S = \emptyset$ and $P_d(R \cup S) = P_d(R) \cup P_d(S)$, while if $d \geq 2$, then $R \cap S = \emptyset$ and $P_d(R \cup S) \subseteq P_d(R) \cap P_d(S)$.)

Now suppose that we have some $k \in K$ with $k \geq 2$; we shall show that $k-1 \in K$. Here, we have (5.2.1). Consider any $n \in \mathbb{N}$. We set
\[d_n := \min\{d(g_{n,i} R_i, g_{n,j} R_j) \mid i, j \in [1,\omega) \text{ with } i < j\} \in [1,\omega).\]

We first prove that $\{d_n \mid N \in \mathbb{N}\}$ is finite. For each $\ell \in [0,1[\mathbb{N}$, set
\[c_\ell := \sum_{i=1}^k |P_\ell(R_i)| = \sum_{i=1}^k |P_\ell(g_{n,i} R_i)|.\]

Then
\[ |P_{d_n}(S_n)| = |P_{d_n}(\bigcup_{i=1}^{k} g_{n,i}R_i)| \leq |\bigcup_{i=1}^{k} P_{d_n}(g_{n,i}R_i)| < \sum_{i=1}^{k} |P_{d_n}(g_{n,i}R_i)| = c_{d_n}. \]

For each \( \ell \in [0|d_n[ \),
\[ |P_{\ell}(S_n)| = |P_{\ell}(\bigcup_{i=1}^{k} g_{n,i}R_i)| = |\bigvee_{i=1}^{k} P_{\ell}(g_{n,i}R_i)| = \sum_{i=1}^{k} |P_{\ell}(g_{n,i}R_i)| = c_{\ell}. \]

Hence,
\[ \sum_{\ell=0}^{d_n-1} c_{\ell} t^{\ell} \subseteq \Sigma P(S_n) \subseteq \sum_{\ell=0}^{d_n} c_{\ell} t^{\ell}. \]

Now consider any \( m \in \mathbb{N} \) such that \( m \geq n \). Then \( \Sigma P(S_m) \subseteq \Sigma P(S_n) \), since \( \Sigma P(S_m) \) is decreasing. Hence,
\[ \sum_{\ell=0}^{d_m-1} c_{\ell} t^{\ell} \subseteq \Sigma P(S_m) \subseteq \Sigma P(S_n) \subseteq \sum_{\ell=0}^{d_n} c_{\ell} t^{\ell}. \]

Thus, \( d_m - 1 < d_n \). Hence, \( d_m \leq d_n \). It follows that \( \{d_N \mid N \in \mathbb{N}\} \) is finite, and we may assume it has exactly one element, \( d_* \), by replacing \( \mathbb{N} \) with a suitable infinite subset.

Fix \( i_n, j_n \in [1|k[ \) such that \( i_n < j_n \) and
\[ d(g_{n,i_n}R_{i_n}, g_{n,j_n}R_{j_n}) = d_n = d_* \]

Now \( \{i_N, j_N \mid N \in \mathbb{N}\} \) is finite, and we may assume it has exactly one element, \( (i_*, j_*) \), by replacing \( \mathbb{N} \) with a suitable infinite subset. By renumbering the \( R_i \), we may assume that \( (i_*, j_*) = (1, k) \). Now
\[ d_* = d(g_{n,1}R_1, g_{n,k}R_k) = d(R_1, g_{n,1}^{-1}g_{n,k}R_k). \]

Since \( X \) is locally finite and \( R_1 \) and \( R_k \) are finite sets of edges, there exist only finitely many elements in the \( G \)-orbit of \( R_k \) whose \( X \)-distance from \( R_1 \) equals \( \max\{d_n - 2, 0\} \). Thus, \( \{g_{n,1}^{-1}g_{n,k}R_k \mid N \in \mathbb{N}\} \) is finite, and we may assume that it has exactly one element, \( R_* \), by replacing \( \mathbb{N} \) with a suitable infinite subset. Now \( g_{n,1}^{-1}g_{n,k}R_k = R_* \), and then \( g_{n,1}R_1 \cup g_{n,k}R_k = g_{n,1}(R_1 \cup R_k) \). Here, we may replace \( R_1 \) with \( R_1 \cup R_* \) and \( k \) with \( k-1 \), and we see that \( k-1 \in \mathbb{K} \).

This completes the proof of Theorem 5.2.

The following is the locally finite case of a result of Bowditch and Dunwoody [2] §8, which was based on work of Bergman [1] Lemma 1 and Dunwoody and Swenson [7] Lemma 3.3.

5.3. Theorem. Let \( X \) be any connected, locally finite, \( G \)-finite \( G \)-graph, and \( A \) be any Boolean \( G \)-subalgebra of \( \mathcal{B}(X) \). Then \( \text{irr}(A) \) is a c-stable, nested \( G \)-subset of \( A \) such that \( \emptyset \notin \text{irr}(A) \) and \( (\text{irr}(A))_{G} = A \).

Proof. It is clear that \( \text{irr}(A) \) is a c-stable \( G \)-subset of \( A \) such that \( \emptyset \notin \text{irr}(A) \). By Theorem 5.2, \( \Sigma P(A) \) is well-ordered, and then a standard argument shows that \( (\text{irr}(A))_{G} = A \). It remains to show that \( \text{irr}(A) \) is nested.

Consider any \( A', B' \in \text{irr}(A) \). It suffices to show that \( A' \) and \( B' \) are nested. Let us choose \( (A, B) \in \{A', A^c\} \times \{B', B^c\} \) to make \( \Sigma P(A \cap B) \) as \( \emptyset \)-small as possible. In particular, \( \Sigma P(A \cap B) \subseteq \Sigma P(A \cap B^c) \), and we see that
\[ A = (A \cap B) \cup (A \cap B^c) \in \langle \{C \in A \mid \Sigma P(C) \subseteq \Sigma P(A \cap B^c)\} \rangle_{G}. \]

Since \( A \) is \( A \)-irreducible, it is not the case that \( \Sigma P(A \cap B^c) \subseteq \Sigma P(A) \). Thus,
\[ \Sigma P(A) \subseteq \Sigma P(A \cap B^c). \]

For any elements \( C, D \) of \( \mathcal{B}(X) \), let us define \( P(C, D) := P(C) \cap P(D^c) \) and \( \Sigma P(C, D) := \Sigma(P(C, D)) \in \mathbb{Z}[t] \). If \( C \cap D = \emptyset \), then \( P(C, D) \) is the set of all
X-paths which begin in C and end in D, and, here, \( \Sigma P(C, D) = \Sigma P(D, C) \). Set 
\[ a := \Sigma P(A \cap B, A^c \cap B), \quad b := \Sigma P(A \cap B, A^c \cap B^c), \quad c := \Sigma P(A \cap B^c, A^c), \]
\[ d := \Sigma P(A \cap B^c, A \cap B). \]
It is not difficult to see that
\[ (a + b) + c = \Sigma P(A, A^c) = \Sigma P(A), \]
\[ (a + c) = \Sigma P(A \cap B^c, A^c) = \Sigma P(A \cap B^c, A^c \cap B) = c + d. \]
Hence, \( b \subseteq d - a \). By interchanging \( A \) and \( B \), we see that \( b \subseteq a - d \), also. Thus, \( b \subseteq 0 \). Hence, there exists no X-path which begins in \( A \cap B \) and ends in \( A^c \cap B^c \); hence, \( A \cap B \) or \( A^c \cap B^c \) is empty; and, hence, \( A' \) and \( B' \) are nested, as desired. \( \square \)

5.4. Remarks. Throughout this section, we have considered connected, locally finite, G-finite G-graphs; these include the Cayley graphs of finitely generated groups, which are the graphs we shall be using. Bergman obtains similar results about connected, locally finite G-graphs. Bergman obtains results about countable groups. We have not seen any way to use these generalizations for our narrow objective of improving the proof of Theorem 1.2 in [3, II.2.20], nested generating sets were constructed for Boolean algebras of arbitrary connected graphs. \( \square \)

6. Building trees from the Boolean algebra of a group

In this section we shall prove a substantial part of the finitely generable case of Theorem 1.2.
Recall Definitions 3.4 and 3.5. The following result is implicit in the finitely generable case of the Almost Stability Theorem. Dunwoody [6, 4.7] showed that 
\( G \)-substaets \( (V(T)) \subseteq \text{Almosts}(\mathcal{F}) \).

6.1. Theorem. Suppose that \( \text{rank}(G) < \omega_0 \). For each G-finite G-subset \( \mathcal{F} \) of \( \mathcal{B}(G) \), there exists some G-finite G-tree \( T \) such that \( G\text{-substaets}(V(T)) = \text{Almosts}(\mathcal{F}) \) and \( E(T) \) is \( G \)-quasifree.

Proof. Let \( S \) be any finite generating set of \( G \), and set \( X := X(G, S) \). By Lemma 5.5, \( X \) is a connected, locally finite, G-finite, G-free G-graph, \( V(X) = G \), and \( \mathcal{B}(X) = \mathcal{B}(G) \).

Set \( A := \langle \mathcal{F} \rangle_B \) in \( \mathcal{B}(G) = \mathcal{B}(X) \).

By Theorem 5.3, \( \text{irr}(A)B = A \), and \( \text{irr}(A) \) is a c-stable, nested G-subset of \( A \) such that \( \emptyset \notin \text{irr}(A) \).

Since \( \mathcal{F} \) is \( G \)-finite, there exists some c-stable, G-finite G-subset \( \mathcal{E} \) of \( \text{irr}(A) \) such that \( \mathcal{F} \subseteq \langle \mathcal{E} \rangle_B \), and then \( \mathcal{E} \) is nested, \( \emptyset \notin \mathcal{E} \), and \( \langle \mathcal{E} \rangle_B = \mathcal{A} \).

We shall now see that \( \mathcal{E} \) is finitely separating. Consider any edge \( e \) of \( X \). For each \( A \in \mathcal{E} \), since \( G_e = \{1\} \), there exist only finitely many \( g \in G \) such that \( ge \in \delta(A) \), or, equivalently, \( e \in \delta(g^{-1}A) \). Since \( \mathcal{E} \) is \( G \)-finite, we then see that there exist only finitely many \( B \in \mathcal{E} \) such that \( e \in \delta B \), that is, \( (e)^{**} \cap \mathcal{E} = a_\mathcal{E} \). Since \( X \) is connected, it follows that \( \mathcal{E} \) is finitely separating.

Now \( \mathcal{E} \) is a c-stable, finitely separating, nested G-subset of \( \mathfrak{P}(G) \) and \( \emptyset \notin \mathcal{E} \). By Theorem 3.3, \( T(\mathcal{E}) \) is a G-tree with edge G-set \( \mathcal{E} \). The edge G-set of \( T(\mathcal{E}) \) is G-finite, and, hence, \( \mathcal{B}(X) = \{\emptyset, V(X)\} \) is G-quasifree. Hence, \( \mathcal{E} \) is G-quasifree, that is, \( E(T(\mathcal{E})) \) is \( G \)-quasifree. Since \( \mathcal{E} \) is \( G \)-finite, we see that \( T(\mathcal{E}) \) is \( G \)-finite.

It remains to show that \( G\text{-substaets}(V(T(\mathcal{E}))) = \text{Almosts}(\mathcal{F}) \). Since
\[ \langle \mathcal{E} \rangle_B = \mathcal{A} = \langle \mathcal{F} \rangle_B, \]
it is not difficult to show that \( \text{Almosts}(\mathcal{E}) = \text{Almosts}(\mathcal{A}) = \text{Almosts}(\mathcal{F}) \), and it suffices to show that \( G\text{-substaets}(V(T(\mathcal{E}))) = \text{Almosts}(\mathcal{E}) \). Notice that if \( \mathcal{E} = \emptyset \), then \( T(\mathcal{E}) \) is a single vertex stabilized by all subgroups of \( G \), in which case it is clear that \( G\text{-substaets}(V(T(\mathcal{E}))) = \text{Almosts}(\mathcal{E}) \). Thus, we may assume that \( \mathcal{E} \neq \emptyset \).
We shall use the following observations. Consider any \(e, f \in E\). Notice that, for each \(g \in G\),
\[
(gf \in 1^{**}) \iff (1 \in gf) \iff (g^{-1} \in f) \iff (g \in f^{-1} := \{g^{-1} \mid g \in f\} \in \mathcal{P}(G)).
\]
With careful interpretation, we may write \(G\{f\} \cap 1^{**} = f^{-1}\{f\} \in \mathcal{P}(\mathcal{P}(G))\). By Theorem 4.3(i), the \(T(\mathcal{E})\) that stabilizes \(\mathcal{E}\) or \(\tau_e\). Consider any \(f \in \mathcal{E}\). Notice that (6.1.1) implies that
\[
f^{-1}\{f\} =_a G\{f\} \cap \mathcal{E} \in \mathcal{P}(\mathcal{P}(G)),
\]
since these are right \(G_f\)-sets and \(G_f\) is finite. Hence, \(f =_a \{g \in G \mid gf \in \mathcal{E}\}\), which is a right \(G_{\mathcal{E}}\)-set. Similarly, \(f =_a \{g \in G \mid f \in g(e^e)\}\) and, hence,
\[
f =_a \{g \in G \mid f \in g\mathcal{E} \text{ and } f \in \mathcal{E}\},
\]
which is a right \(G_{\mathcal{E}}\)-set. Thus, \(f\) is almost a right \(H\)-set. Thus, \(H \in \text{Almosts}(\mathcal{E})\).

For the converse, we now consider any \(H \in \text{Almosts}(\mathcal{E})\). Consider any \(e \in \mathcal{E}\) and any finite \(G\)-transversal \(F\) in the \(G\)-finite \(\mathcal{E}\). For each \(f \in F\), we have \(f \in \mathcal{E}\), and, hence, there exists some right \(H\)-subset \(A_f\) of \(G\) such that \(f =_a A_f \in \mathcal{P}(G)\).

We may then form the \(H\)-set
\[
w := \bigcup_{f \in F} (A_f^{-1}\{f\}) =_a \bigcup_{f \in F} (f^{-1}\{f\}) \subseteq \bigcup_{f \in F} (G\{f\} \cap \mathcal{E}) = \mathcal{E} \in \mathcal{P}(\mathcal{P}(G)).
\]
Set \(d := |(\mathcal{E})\setminus(w)| \in [0\mid\infty|\). For each \(h \in H\),
\[
d = |(\mathcal{E})\setminus(w)| = |(\mathcal{E})\setminus(w)| \text{ and } |(\mathcal{E})\setminus(w)| \leq |(\mathcal{E})\setminus(w)| + |(w)\setminus(\mathcal{E})| = 2d.
\]
By Theorem 4.3(i), the \(T(\mathcal{E})\)-distance between \(\mathcal{E}\) and \(\mathcal{E}\) is at most \(2d\). Hence, the subtree of \(T(\mathcal{E})\) spanned by \(\mathcal{E}\) has finite diameter. Consider any \(H\)-subtree of \(T(\mathcal{E})\) of minimum possible diameter. Then \(H\) has at most one edge, for, otherwise, deleting from \(T\) all vertices of valence one and the edges incident thereto leaves an \(H\)-subtree of smaller diameter. It follows that \(H\) stabilizes some vertex of \(T(\mathcal{E})\). Thus, \(H \in \mathcal{P}(\mathcal{E})\).

7. Digression 2: Stallings’ Ends theorem

In this section, we shall deduce a form of Stallings’ celebrated Ends Theorem \([18]\) 4.1, a result which inspired much subsequent work in combinatorial group theory, including all the theory discussed in this article.

In the case where \(G\) is finitely generable and \(S\) is any finite generating set of \(G\), let \(S\) denote the set of finite subsets of \(E(X(G, S))\), and, for each \(E \in S\), let \(\varphi(E)\) denote the set of infinite components of \(X(G, S)\). Then \(\varphi(E) \mid E \in S\) forms an inverse directed system, and, by a 1945 argument of Freudenthal \([10]\) 6.16.1, the resulting inverse limit is independent of the choice of finite generating set \(S\). The elements of this inverse limit are called the ends of the group \(G\).

We wish to consider the graph-theoretical conditions
\[
(a) \ G \text{ is finitely generable and has more than one end.}
\]
\[
(b) \ There \ exists \ some \ G\text{-tree \ such \ that \ the \ edge \ G\text{-set \ is \ G-quasifree \ and \ no \ vertex \ is \ G\text{-stable}},
\]
and the group-theoretical conditions
\[
(a’) \ \mathcal{B}(G) \text{ has some element } A \text{ such that both } A \text{ and } G\setminus A \text{ are infinite}.
\]
(b') Either $G$ is countably infinite and locally finite, or there exists some finite subgroup $B$ of $G$ such that $G$ is a free product with amalgamation $C *_B D$ where $B < C$ and $B < D$ or $G$ is an HNN extension $C *_{\varphi} D$ where $B \leq C$ and $\varphi : B \to C$ is a monomorphism.

In 1949, Specker [16] showed that if $G$ is finitely generable, then $(a) \Leftrightarrow (a')$. Subsequently, it became a common practice to use some cohomological form of $(a')$ as a definition for 'G has more than one end' even if $G$ is not finitely generable and, hence, ends of $G$ are not defined.

By Bass-Serre theory, $(b) \Leftrightarrow (b')$; see [15], [5], I.4.12.

It is not difficult to show that $(b)+(b') \Rightarrow (a')$; see [5], IV.6.10.

In 1970, Stallings [18, 4.1] proved that $(a) \Rightarrow (b')$; notice that no finitely generable group is both infinite and locally finite. He remarked that a communication from Dunwoody inspired his short proof of his key lemma [18, 1.5] (which is actually the Cayley-graph case of a result of Bergman [1, Theorem 1]). In 1979, Dunwoody [6, 4.4] proved directly that if $G$ is finitely generable, then $(a') \Rightarrow (b)$; this is the restatement of Stallings’ result in which the graph-theoretic hypothesis $(a)$ is replaced with the group-theoretic condition $(a')$ and the group-theoretic conclusion $(b')$ is replaced with the graph-theoretic condition $(b)$.

7.1. Stallings’ Ends Theorem. If $G$ is finitely generable and there exists some element $A$ in $\mathcal{B}(G)$ such that $A$ and $G-A$ are infinite, then there exists some $G$-tree such that no vertex is $G$-stable, the edge $G$-set is $G$-quasifree, and the number of $G$-orbits of edges equals 1.

Proof. Set $\mathcal{F} := \{gA \mid g \in G\} \subseteq \mathcal{B}(G)$. By Theorem 6.1, there exists some $G$-finite $G$-tree $T$ such that $G$-substabs($V(T)$) = Almosts($\mathcal{F}$) and $E(T)$ is $G$-quasifree. Notice that $G \not\subset$ Almosts($\{A\}$) = Almosts($\mathcal{F}$) = $G$-substabs($V(T)$). Now we collapse $G$-orbits of edges of $T$, one $G$-orbit at a time. At some first stage, a $G$-stable vertex appears, and then the $G$-orbit of edges that has just been collapsed is the edge $G$-set of a $G$-tree which has the desired properties.

7.2. Remarks. In 1968, Stallings [17] had proved a special case of $(a) \Rightarrow (b')$, and had written the following: “Since “ends” are, after all, a topological kind of thing, there is no need to make a profuse apology for a topological kind of proof. However, maybe there is some algebraic translation of this which will go over to infinitely generated groups.” An algebraic translation which went over to all groups was given in 1989 when Dicks and Dunwoody proved in [5], IV.6.10] that $(a') \Rightarrow (b')$.

An important advance in the theory had been made by Holt in 1981, who showed in [11] that if $G$ is locally finite, then $(a') \Rightarrow (b')$; notice that no locally finite group is an HNN extension or a proper free product with amalgamation.

8. The finitely generable case of the Almost Stability Theorem

Recall Definitions [12]. We may now prove the case of the Almost Stability Theorem [12] where $G$ is finitely generable.

8.1. Theorem. Suppose that $\text{rank}(G) < \omega_0$. If $E$ and $Z$ are any $G$-sets such that $E$ is $G$-quasifree and each element’s $G$-stabilizer stabilizes some element of $Z$, then each $G$-stable almost equality class in the $G$-set Maps($E, Z$) is the vertex $G$-set of some $G$-tree.

Proof. Let $V$ be any $G$-stable almost equality class in Maps($E, Z$). We shall prove a sequence of three equalities which will relate $V$ to a $G$-incompressible $G$-tree.

Let $S$ be any finite generating set of $G$, and set $X := X(G, S)$. Then $X$ is a connected, locally finite, $G$-finite, $G$-free $G$-graph, $V(X) = G$, and $\mathcal{B}(X) = \mathcal{B}(G)$.

As $V$ is nonempty, we may choose an element $v$ of $V$. 

Consider any $e \in E$. We then have a map $(-v,e) : G \to Z$, $g \mapsto \langle gv, e \rangle$, and we shall be interested in the set of fibres thereof, $\{(-v,e)^{-1}\{z\} \mid z \in Z\}$. The set of edges of $X$ which are broken by this same map $(-v,e) : V(X) \to Z$ is 

$$\delta((-v,e)) := \{(g,s) \in E(X) \mid \langle \tau_X(g,s)v,e \rangle \neq \langle \tau_X(g,s)v,e \rangle\}.$$ 

Thus, 

$$((g,s) \in \delta((-v,e))) \Leftrightarrow (\langle gv, e \rangle \neq \langle gsv, e \rangle) \Leftrightarrow (e \in (gv)\setminus(gsv) = g(v\setminus(sv))).$$ 

Hence, 

$$\delta((-v,e)) = \{(g,s) \in E(X) \mid g^{-1}e \in v\setminus(sv)\}.$$ 

For each $s \in S$, $v\setminus(sv)$ is finite, since $v =_a sv$ in Maps($E,Z$). Since $G_e$ and $S$ are finite, we see that $\delta((-v,e))$ is finite. Since $X$ is connected, the set of fibres of $(-v,e)$ is finite, and each fibre of $(-v,e)$ is then an element of $\mathcal{B}(X) = \mathcal{B}(G)$.

Set $E_G := \{e \in E : (-v,e) \text{ is not constant}\}$. Then 

$$E_G = \{e \in E : \delta((-v,e)) \neq \emptyset\} = \bigcup_{g \in G} \bigcup_{s \in S} \{(g\setminus sv)\}.$$

Since $\bigcup_{s \in S} \{(v\setminus sv)\}$ is finite, we see that $E_G$ is G-finite.

For $g \in G$, $e \in E$, $z \in Z$, we have $g((-v,e)^{-1}\{z\}) = (-v,ge)^{-1}\{gz\}$. Set $\mathcal{F} := \{(-v,e)^{-1}\{z\} \mid z \in Z, e \in E\}$. Then $\mathcal{F}$ is a G-finite $G$-subset of $\mathcal{B}(G)$.

We shall now prove (8.1.1) $G$-subtabs($V$) $\subseteq$ Almosts($\mathcal{F}$), that is, for each $H \in G$-subtabs($V$), each $(-v,e)^{-1}\{z\} \in \mathcal{F}$ is almost equal to some right $H$-set.

**Proof of (8.1.1).** Here, $e \in E$, $z \in Z$, and $H$ stabilizes some element $w$ of $V$. Since $w =_a v$ and $G_e$ is finite, we see that, for all but finitely many $g \in G$, we have $\langle v, g^{-1}e \rangle = \langle w, g^{-1}e \rangle$, that is, $g^{-1}(gv,e) = (gw,e)$, that is, $\langle gv, e \rangle = \langle gw, e \rangle$.

Thus $\langle -v, e \rangle =_a \langle -w, e \rangle$. In particular, $(-v,e)^{-1}\{z\} =_a (-w,e)^{-1}\{z\}$, and the latter set is easily seen to be a right $H$-set. This completes the proof of (8.1.1). □

We shall now prove (8.1.2) $G$-subtabs($V$) $\supseteq$ Almosts($\mathcal{F}$).

**Proof of (8.1.2).** Consider any $H \in$ Almosts($\mathcal{F}$). It suffices to construct some $w \in$ Maps($E,Z$) such that $w =_a v$ and $H$ stabilizes $w$.

Set $E_H := \{e \in E : (-v,e)^{-1}|_H$ is not constant$\}$, an $H$-subset of $E_G$. Thus, for $h \in H$ and $e \in E - E_H$, we have $\langle hv, e \rangle = \langle v, e \rangle$, and we see that $H$ stabilizes $\langle v, - \rangle|_{E - E_H}$.

Consider any $e \in E_G$. We saw above that $\langle -v, e \rangle$ takes only finitely many values in $Z$, and we are assuming that, for each $z \in Z$, $\langle -v, e \rangle^{-1}\{z\}$ is almost equal to a right $H$-subset of $G$. Hence, $\langle -v, e \rangle|_H$ is almost equal to a constant map, and, also, for all but finitely many $g \in H$ a right $H$-transversal in $G$, $\langle -v, e \rangle|_H$ is constant; here, $\langle g^{-1}v, e \rangle|_H$ is constant, $g^{-1}(gv^{-1}e)$ is constant, $\langle -v, g^{-1}e \rangle|_H$ is constant, $g^{-1}e \in E - E_H$, and $Hg^{-1}e \cap E_H = \emptyset$. It follows that $Ge \cap E_H$ is $H$-finite.

We also saw above that $E_G$ is $G$-finite. It now follows that $E_H$ is $H$-finite.

Let us deal first with the case where $H$ is infinite. For each $e \in E$, as $\langle -v, e \rangle|_H$ is almost equal to a constant map and $H$ is infinite, there exists a unique $z_e \in Z$ such that, for all but finitely many $h \in H$, $\langle hv, e \rangle = z_e$. For each $e \in E$ and $h_0 \in H$, we see that, for all but finitely many $h \in H$, $\langle hv, e \rangle = z_e$, and then $\langle hv, h_0^{-1}e \rangle = h_0^{-1}(h_0hv, e) = h_0^{-1}z_e$.
thus, \( z_{h_0^{-1}e} = h_0^{-1}z_e \). Set \( w : E \to Z, e \mapsto \langle w, e \rangle := z_e \); then \( H \) stabilizes \( w \), since
\[
\langle h w, e \rangle = h_0 \langle w, h_0^{-1}e \rangle = h_0 z_{h_0^{-1}e} = z_e = \langle w, e \rangle.
\]
For each \( e \in E - E_H \), \( \langle v, e \rangle = z_e = \langle w, e \rangle \); thus, \( \langle v, - \rangle |_{E - E_H} = \langle w, - \rangle |_{E - E_H} \). For each \( e \in E_H \), for all but finitely many \( h \in H \), \( \langle h v, e \rangle = z_e = \langle w, e \rangle \), and here
\[
\langle v, h^{-1}e \rangle = h^{-1} \langle hv, e \rangle = h^{-1} \langle w, e \rangle = \langle h^{-1}w, h^{-1}e \rangle = \langle w, h^{-1}e \rangle.
\]
Since \( E_H \) is \( H \)-finite, we see that \( \langle v, - \rangle |_E \equiv_a \langle w, - \rangle |_E \). Hence, \( w \in V \) and \( H \in G \)-substabs(\( V \)).

It remains to deal with the case where \( H \) is finite. Here, the \( H \)-finite set \( E_H \) is finite. Since \( G \)-substabs(\( E \)) \( \subseteq \) \( G \)-substabs(\( Z \)) by hypothesis, there exists some \( G \)-stable \( u \in \text{Maps}(E, Z) \). Define \( w \) to be the element of Maps(\( E, Z \)) such that \( \langle w, - \rangle |_{E - E_H} = \langle v, - \rangle |_{E - E_H} \) and \( \langle w, - \rangle |_{E_H} = \langle u, - \rangle |_{E_H} \). Since \( H \) stabilizes both \( \langle v, - \rangle |_{E - E_H} \) and \( \langle u, - \rangle |_{E_H} \), we see that \( H \) stabilizes \( w \). Since \( E_H \) is finite, \( \langle v, - \rangle |_E \equiv_a \langle u, - \rangle |_E \). Hence \( w \in V \) and \( H \in G \)-substabs(\( V \)).

This completes the proof of (8.1.2). \( \square \)

By combining (8.1.1) and (8.1.2), we find that
\[
(8.1.3) \quad G \text{-substabs}(V) = \text{Almosts}(\mathcal{F}).
\]

By Theorem 6.1 since \( \mathcal{F} \) is a \( G \)-finite \( G \)-subset of \( \mathcal{B}(G) \), there exists some \( G \)-finite \( G \)-tree \( T_1 \) such that \( E(T_1) \) is \( G \)-quasifree and
\[
(8.1.4) \quad \text{Almosts}(\mathcal{F}) = G \text{-substabs}(V(T_1)).
\]

By successively collapsing \( G \)-orbits of any \( G \)-compressible edges of \( T_1 \), we arrive at a \( G \)-incompressible \( G \)-tree \( T_2 \) such that
\[
(8.1.5) \quad G \text{-substabs}(V(T_1)) = G \text{-substabs}(V(T_2)).
\]

In summary,
\[
G \text{-substabs}(V) \overset{\text{6.1.1}}{\subseteq} \text{Almosts}(\mathcal{F}) \overset{\text{6.1.3}}{=} G \text{-substabs}(V(T_1)) \overset{\text{8.1.4}}{=} G \text{-substabs}(V(T_2)).
\]

As \( G \)-substabs(\( V \)) \( = \) \( G \)-substabs(\( V(T_2) \)), there exist \( G \)-maps \( \varphi : V \to V(T_2) \) and \( \psi : V(T_2) \to V \). Since \( V(T_2) \) is \( G \)-incompressible, the \( G \)-map \( \varphi \circ \psi : V(T_2) \to V(T_2) \) must be bijective. Hence \( \psi \) is injective, and we may identify \( V(T_2) \) with a \( G \)-subset of \( V \), and \( T_2 \) with a \( G \)-subtree of the \( G \)-graph \( \text{Complete}(V) \). The \( G \)-subgraph \( T_3 \) of \( \text{Complete}(V) \) with vertex \( G \)-set \( V \) and edge \( G \)-set
\[
E(T_3) := E(T_2) \cup \{ (v, \varphi(v)) \mid v \in V - V(T_2) \}
\]
is a maximal subtree of \( \text{Complete}(V) \), as desired. \( \square \)

9. Preliminary results about trees

In the remainder of this article we shall describe some simplifications which may be made in the proof of the general case of the Almost Stability Theorem. We will not simplify the proofs of the preliminary results about trees. We collect together the statements of these here, for the convenience of the reader. The proofs currently known are rather technical and will not be given here.

9.1. Definitions. Let \( \overline{T} = (\overline{V}, \overline{E}, \tau, \eta) \) be any \( G \)-tree such that \( \overline{E} \) is \( G \)-quasifree. Let \( F \) be any \( G \)-forest with \( G \)-quasifree edge \( G \)-set such that the \( G \)-set of components of \( F \) is \( \overline{V} \). Thus, \( F = \bigvee_{w \in \overline{T}} T_w \), for each \( w \in \overline{V}, T_w \) is a \( G_w \)-tree with \( G_w \)-quasifree edge \( G_w \)-set, and, for each \( g \in G \), \( g(T_w) = T_{gw} \).

We shall now extend \( F \) to a \( G \)-graph \( F \vee \overline{E} \) by adding \( \overline{E} \) to the edge \( G \)-set of \( F \) and extending the incidence maps \( \iota \) and \( \tau \) to \( \overline{E} \) as follows. Let \( S \) be any \( G \)-transversal in \( \overline{E} \). Consider any \( \overline{e} \in S \). Then \( G_{\overline{e}} \) is a finite subgroup of \( G_{\overline{\tau}} \), and,
hence, $G_\tau$ stabilizes some vertex of the $G_{\tau(\tau)}$-tree $T_{\tau(\tau)}$. We take some $G_\tau$-stable vertex of $G_{\tau(\tau)}$ to be $e$. For each $g \in G$, we define $\iota_1(g,E) := g(\iota_1(E))$, which is well-defined. This defines $\iota : E \to V(F)$. We define $\tau : E \to V(F)$ in a similar manner. This completes the definition of $F \vee E$.

Collapsing the edges of the subforest $F$ in $F \vee E$ leaves the tree $T$. It follows that $F \vee E$ is a G-tree with G-quasifree edge $G_\tau$. We say that $F \vee E$ is a G-tree obtained from $T$ by $G$-equivariantly blowing up each $w \in V$ to $T_w$.

9.2. Definitions. Let $T$ be any $G$-finite $G$-tree with $G$-quasifree edge $G$-set. For each $n \in [1, \infty]$, set $E_n(T) := \{e \in E(T) : |G_e| = n\}$, and set
\[
\text{size}(T) := |G \setminus E(T)| - |G \setminus V(T)| + \sum_{n \in [1, \infty]} |G \setminus E_n(T)| t^n \in \mathbb{Z}[t].
\]

9.3. Lemma. Let $T$ be any $G$-tree with $G$-quasifree edge $G$-set, $w$ be any vertex of $T$, and $H$ be any subgroup of $G_w$. If $\text{rank}(G \text{ rel } H) < \omega_0$, then the following hold.

(i) $\text{rank}(G_w \text{ rel } H) < \omega_0$.
(ii) For each $v \in V(T) - G_w$, $\text{rank}(G_v) < \omega_0$. 
(iii) There exists some $G$-finite $G$-incompressible $G$-tree $T$ such that $E(T)$ is $G$-quasifree and $G$-substsabs($V(T)$) $= G$-substsabs($V(T)$).

Proof. (i) and (ii) hold by [5 III.8.1], for example.

(iii). Let $S$ be any finite subset of $G$ such that $1 \in S$ and $H \cup S$ generates $G$. Let $T_0$ be any finite subtree of $T$ containing $S$. Then $G(T_0)$ is a $G$-finite $G$-subforest of $T$. Moreover, $G(T_0)/E(G(T_0))$ consists of a single $G$-orbit in which the image of $w$ is stabilized by $H \cup S$; that is, $G(T_0)$ has only one component. Thus, $G(T_0)$ is a $G$-finite $G$-subtree of $T$.

For each $v \in V(T)$, $G_v$ stabilizes both $v$ and $\{G(T_0)\}$. It follows that $G_v$ stabilizes the (unique) vertex of $G(T_0)$ which is closest to $v$. Hence
\[
G$-substsabs($V(G(T_0))$) = $G$-substsabs($V(T)$).
\]

Now successively collapsing $G$-orbits of $G$-compressible edges in $G(T_0)$ leaves a $G$-finite $G$-incompressible $G$-tree $T$ such that $E(T)$ is $G$-quasifree and
\[
G$-substsabs($V(T)$) = $G$-substsabs($V(G(T_0))$) = $G$-substsabs($V(T)$);
\] see [5 III.7.2].

9.4. Lemma. Let $T_1$ and $T_2$ be any $G$-finite, $G$-incompressible $G$-trees with $G$-quasifree edge $G$-sets. If $G$-substsabs($V(T_2)$) $\subseteq$ $G$-substsabs($V(T_1)$), then the following hold.

(i) $3|G \setminus T_2| \leq |G \setminus T_1|$. 
(ii) $\text{size}(T_2) \subseteq \text{size}(T_1)$ in $\mathbb{Z}[t]$.
(iii) If $\text{size}(T_2) = \text{size}(T_1)$, then $G$-substsabs($V(T_2)$) = $G$-substsabs($V(T_1)$).

Proof. By [5 III.7.5], $|G \setminus E(T_1)| + |G \setminus V(T_1)| \geq |G \setminus V(T_2)|$ and (ii) and (iii) hold. By (ii), $|G \setminus E(T_1)| - |G \setminus V(T_1)| \geq |G \setminus E(T_2)| - |G \setminus V(T_2)|$. By multiplying the former inequality by 2 and adding the result to the latter inequality, we see that (i) holds.

10. Notation used in the proof of the general case

Throughout the remainder of the article, the following will apply.

10.1. Notation. Let $E$ and $Z$ be any $G$-sets, and $V$ be any $G$-stable almost equality class in the $G$-set Maps($E, Z$).

Suppose that there exists some $G$-stable element in Maps($E, Z$) and that $E$ is $G$-quasifree.
By Remarks [13](i), the connected $G$-graph $\text{Complete}(V)$ has $G$-quasifree edge $G$-set.

Here $V$ is nonempty. Let us fix $v_0 \in V$.

For any subset $E'$ of $E$, we have $E = E' \cap \langle E - E' \rangle$, and we identify $\text{Maps}(E, Z) = \text{Maps}(E', Z) \times \text{Maps}(E - E', Z) = \bigvee_{w \in \text{Maps}(E - E', Z)} (\text{Maps}(E', Z) \times \{ w \})$, where, for each $w \in \text{Maps}(E - E', Z)$, we write $\text{Maps}(E', Z) \times \{ w \}$ for the fibre over $w$ of the restriction map

$$\text{Maps}(E, Z) \rightarrow \text{Maps}(E - E', Z), \quad v \mapsto \langle v, - \rangle_{|E - E'}.$$ 

For each $v \in \text{Maps}(E, Z)$, we identify

$$\{ v \} = \{ \langle v, - \rangle_{|E'} \} \times \{ \langle v, - \rangle_{|E - E'} \},$$

and by abuse of notation we shall write

$$v = \langle v, - \rangle_{|E'} \times \langle v, - \rangle_{|E - E'}.$$ 

We denote by $\pi_{E'}$ the self-map of $\text{Maps}(E, Z)$ defined by

$$\pi_{E'}(v) := \langle v, - \rangle_{|E'} \times \langle v_0, - \rangle_{|E - E'};$$

thus, the image of $\pi_{E'}$ equals the fibre over $\langle v_0, - \rangle_{|E - E'}$.

We denote by $\nabla(E')$ the image of $V$ under the restriction/projection map $\text{Maps}(E, Z) \rightarrow \text{Maps}(E', Z)$. Then $\nabla(E')$ is a $G_{E'}$-stable almost equality class in $\text{Maps}(E', Z)$. Similarly, we also have a $G_{E'}$-stable almost equality class $\nabla(E - E')$ in $\text{Maps}(E - E', Z)$, and we have the identifications

$$V = \nabla(E') \times \nabla(E - E') = \bigvee_{w \in \nabla(E - E')} (\nabla(E') \times \{ w \}).$$

We may construct $V$ as $G_{E'}$-set by blowing up each $w \in \nabla(E - E')$ to the $(G_{E'})_{w}$-set $\nabla(E') \times \{ w \} \subseteq V$. The restriction map $\text{Maps}(E, Z) \rightarrow \text{Maps}(E', Z)$ carries $\nabla(E') \times \{ w \}$ bijectively to $\nabla(E')$ respecting the $(G_{E'})_{w}$-action. For some purposes, we shall be able to identify $\nabla(E') \times \{ w \}$ with the $(G_{E'})_{w}$-stable almost equality class $\nabla(E')$ in $\text{Maps}(E', Z)$.

Set $w_0 := \langle v_0, - \rangle_{|E - E'} \in \nabla(E - E')$. We write

$$V(E') := \nabla(E') \times \{ w_0 \} = \{ v \in V : \langle v, - \rangle_{|E - E'} = \langle v_0, - \rangle_{|E - E'} \},$$

the fibre over $w_0$. Then $v_0 \in V(E') \subseteq V$. Also, $\pi_{E'}$ maps $V$ to $V(E')$ fixing each element of $V(E')$ and respecting the $(G_{E'})_{w_0}$-action.

Consider any subgroup $H$ of $G$.

We define $E_H := \{ e \in E : \langle v_0, e \rangle_H \neq 0 \}$ as a constant, an $H$-subset of $E$. Notice that $H$ stabilizes $\langle v_0, - \rangle_{|E - E_H}$, and $E_H$ is the smallest $H$-subset of $E$ with this property. Also,

$$V(E_H) = \{ v \in V : \langle v, - \rangle_{|E - E_H} = \langle v_0, - \rangle_{|E - E_H} \} = \nabla(E_H) \times \{ \langle v_0, - \rangle_{|E - E_H} \},$$

and $V(E_H)$ is an $H$-subset of $V$ that is isomorphic to the $H$-stable almost equality class $\nabla(E_H)$ in $\text{Maps}(E_H, Z)$.

We wish to show that some maximal subtree of $\text{Complete}(V)$ is $G$-stable. It suffices to show there exists some $G$-subtree $T_G$ of $\text{Complete}(V)$ with vertex $G$-set $V(E_G)$, for then $V$ itself is the vertex $G$-set of the $G$-subtree of $\text{Complete}(V)$ with edge $G$-set $E(T_G) \cup \{ \langle v, \pi_{E_G}(v) \rangle | v \in V - V(E_G) \}$.

Let $\text{ast}$ denote the class consisting of all those groups for which the Almost Stability Theorem [12] holds.

To show that $G \in \text{ast}$, we may assume that Notation [10.1] holds, and it suffices to show there exists some $G$-subtree of $\text{Complete}(V)$ with vertex $G$-set $V(E_G)$.
11. Finitely generable extensions

The following result is a modified version of [5, III.7.6] differing mainly in the additional hypothesis that $G \in \ast$. The important points are that this weaker form now suffices for our purposes and the proof is simplified in two places by the additional assumption.

11.1. Theorem. Let Notation [10.1] hold, and suppose that the following hold: $G \in \ast$; $\text{rank}(G \cap H) < \omega_0$; for each $g \in G - H$, $gE_H \cap E_H = \emptyset$; and, there exists some $H$-subtree $T_H$ of $\text{Complete}(V)$ with vertex $H$-set $V(E_H)$.

Then there exists some $G$-subtree $T_G$ of $\text{Complete}(V)$ with vertex $G$-set $V(E_G)$ such that $T_H \subseteq T_G$.

Proof. Let $S$ be a finite subset of $G$ such that $H \cup S$ generates $G$.

Set $V_\infty := \{v \in V(E_G) - G(V(E_H)) : G_v$ is infinite $\}$. For the moment, let $W$ be any finite subset of $V_\infty$. In [11.1.4], we shall see that $V_\infty$ is $G$-finite, and then take $W$ to be a $G$-transversal in $V_\infty$.

It is not difficult to show that, for each $g \in G - H$, $\pi_{E_H}$ sends each element of $g \cdot V(E_H)$ to the single point $(g\cdot v_{0,-})|_{E_H} \times (v_{0,-})|_{E - E_H}$. Recall that $\pi_{E_H}$ fixes each element of $V(E_H)$. We may then use the set map $\pi_{E_H}$ to construct a graph map $G(T_H) \to T_H$ which collapses each edge in $(G - H)(T_H)$ and acts as the identity map on $T_H$. Thus, whenever two vertices of $T_H$ are joined by a $(G - H)(T_H)$-path, the two vertices must be equal. It then follows that $G(T_H)$ is a $G$-subforest of $\text{Complete}(V)$. Set $Y := G(W) \cap G(T_H)$, also a $G$-subforest of $\text{Complete}(V)$.

For any subset $E'$ of $E$, we have the restriction map $V(Y) \to \text{Maps}(E', Z)$, $v \mapsto (v_{-})_{E'}$.

The map $V(Y) \to \mathcal{P}(\mathcal{P}(V(Y)))$, $v \mapsto v^{**} := \{e \in \mathcal{P}(V(Y)) \mid v \in e\}$, will be identified with the map $V(Y) \to \text{Maps}(\mathcal{P}(V(Y)), \mathbb{Z}_{2})$, $v \mapsto (v_{-})_{\mathcal{P}(V(Y))}$, where, for each $(v, e) \in V(Y) \times \mathcal{P}(V(Y))$, we set

$$(v, e) := \begin{cases} 1 \in \mathbb{Z}_{2} & \text{if } v \in e, \\ 0 \in \mathbb{Z}_{2} & \text{if } v \in e^{c} := V(Y) - e. \end{cases}$$

For each subset $\mathcal{E}$ of $\mathcal{P}(V(Y))$, we have the restriction map $V(Y) \to \text{Maps}(\mathcal{E}, \mathbb{Z}_{2})$, $v \mapsto (v_{-})_{\mathcal{E}}$.

For each $e \in E(T_H)$, we set

$$(11.1.1) \quad e^{**} := \{v \in V(Y) \mid \text{the reduced } T_H\text{-path from } \pi_{E_H}(v) \text{ to } \tau_{T_H}(e) \text{ crosses } e\}.$$

Here, $\tau_{T_H}(e) \in e^{**}$. For each $g \in G - H$, $g \cdot V(E_H)$ is mapped to a single point in $V(E_H)$ by $\pi_{E_H}$. It follows that $\delta_Y(e^{**}) = \{e\}$. For each $h \in H$, we have $(he)^{**} = h(e^{**})$. For each $g \in G - H$, we write $(ge)^{**} := g(e^{**})$, and this is well-defined. For each subgraph $Y'$ of $Y$, we define $\mathcal{E}(Y') := \{e^{**} \cap V(Y') \mid e \in \mathcal{E}(Y')\}$. For each $e \in \mathcal{E}(Y)$, $\delta_Y(e^{**}) = \{e\}$. It follows that $\mathcal{E}(Y')$ is isomorphic as $G$-set to $\mathcal{E}(Y')$.

We shall now see the following.

(11.1.2) $\mathcal{E}(Y)$ is finitely separating for $V(Y)$.

Proof of (11.1.2). Consider $v, w \in V(Y)$. We shall show $\langle v_{-} \rangle_{\mathcal{E}(Y)} = a \langle w_{-} \rangle_{\mathcal{E}(Y)}$.

For all but finitely many $g$ in a right $H$-transversal in $G$, $(v_{-})_{gE_H} = (w_{-})_{gE_H}$, and here $(v_{-})_{E_H} = (w_{-})_{E_H}$, hence $g^{-1}(v_{-})_{E_H} = g^{-1}(w_{-})_{E_H}$, hence $(g^{-1}v_{-})_{E_H} = (g^{-1}w_{-})_{E_H}$, hence $(g^{-1}v_{-})_{E_{T_H}} = (g^{-1}w_{-})_{E_{T_H}}$ by (11.1.1), hence $g(g^{-1}v_{-})_{E_{T_H}} = g(g^{-1}w_{-})_{E_{T_H}}$, hence $(v_{-})_{E_{T_H}} = (w_{-})_{E_{T_H}}$, and hence $(v_{-})_{gE_{T_H}} = (w_{-})_{gE_{T_H}}$.

For all $g \in G$, $(g^{-1}v_{-})_{E_{T_H}}$ and $(g^{-1}w_{-})_{E_{T_H}}$ differ only on the elements of $E(T_H)$ corresponding to the elements of $E(T_H)$ crossed by the reduced $T_H$-path from $\pi_{E_H}(g^{-1}v)$ to $\pi_{E_H}(g^{-1}w)$, hence $(g^{-1}v_{-})_{E_{T_H}} = a (g^{-1}w_{-})_{E_{T_H}}$, hence
and each element of $G$ follows that $\delta_Y(e^{**}) = \{e\}$ and $\delta_Y(f^{**}) = \{f\}$, it follows that exactly one of the four sets

$$e^{**} \cap f^{**}, \quad e^{**} \cap f^{*\infty}, \quad e^{*\infty} \cap f^{**}, \quad e^{*\infty} \cap f^{*\infty}$$

has empty coboundary in $Y$; we denote that set by $r_{e,f}$. Thus $r_{e,f}$ is the vertex set of a union of components of $Y$; also, $e^{**}$ and $f^{**}$ are nested in $V(Y)$ if and only if $r_{e,f} = \emptyset$.

Set $R := \{r_{e,f} \mid e, f \in E(Y), e \neq f\} - \{\emptyset\}$.

We shall now prove the following crucial facts.

(11.1.3) $R$ is $G$-quasifree.

(11.1.4) $R$ is finitely separating for $V(Y)$.

Proof of (11.1.3) and (11.1.4). We form a $G$-subgraph $X$ of $\text{Complete}(V)$ by adding to $Y$ a $G$-finite $G$-set of edges that will be specified. We begin as follows.

Recall that $v_0 \in V(E_H)$, that $S$ is a finite subset of $G$ such that $H \cup S$ generates $G$, and that $W$ is a finite subset of $V_\infty$. We take as our first approximation

$$X := Y \cup \{(gv_0, gsw_0) \mid g \in G, s \in S - Gv_0 \} \cup \{(gw_0, gw) \mid g \in G, w \in W\},$$

a $G$-subgraph of $\text{Complete}(V)$ obtained by adding to $Y$ a $G$-finite $G$-set of edges. In $X/ E(X)$, each element of $T_H$ is identified with $v_0$, and the image of $v_0$ is stabilized by $H \cup S$ and, hence, is stabilized by $G$; also, each element of $W$ is identified with $v_0$, and each element of $G(W)$ is then identified with $v_0$. Hence, $X/ E(X)$ consists of a single $G$-orbit with a single point, and, therefore, $X$ is connected.

We shall now show that $\mathcal{E}(Y) \subseteq \mathcal{B}(X)$. By (11.1.2), $\mathcal{E}(Y)$ is finitely separating for $V(Y) (= V(X))$. Hence, for each edge $(v, w)$ in $E(X)$, there exist only finitely many $e \in E(Y)$ such that $(v, w) \in \delta_X(e^{**})$. Thus, for each edge $(v, w)$ in $E(X) - E(Y)$, there exist only finitely many $e \in E(Y)$ such that $(v, w) \in \delta_X(e^{**})$. Hence, for each edge $(v, w)$ in $E(X) - E(Y)$, and each $e \in E(Y)$, there exist only finitely many $g \in G$ such that $(v, w) \in \delta_X(ge^{**})$, or, equivalently, $g^{-1}(v, w) \in \delta_X(e^{**})$. Since $E(X) - E(Y)$ is $G$-finite, and $\delta_Y(e^{**}) = \{e\}$, we see that $\delta_X(e^{**})$ is finite. It follows that $\mathcal{E}(Y) \subseteq \mathcal{B}(X)$.

In particular, for each $e \in E(Y)$, $X - \delta_X(e^{**})$ has only a finite number of components.

Also, $\mathcal{R} \subseteq \langle \mathcal{E}(Y) \rangle_{\mathcal{B}} \subseteq \mathcal{B}(X)$. Since $X$ is connected with $G$-quasifree edge $G$-set, while $\emptyset \not\in \mathcal{R}$ and $V(X) \not\in \mathcal{R}$, we see that each element of $\mathcal{R}$ has nonempty, finite coboundary in $X$, and, hence, (11.1.3) holds.

We have seen that each edge in $E(X) - E(Y)$ lies in $\delta_X(e^{**})$ for only finitely many $e \in E(Y)$. Since $E(X) - E(Y)$ is $G$-finite, we see that the $G$-set

$$E' := \{e \in E(Y) \mid \delta_X(e^{**}) \cap (E(X) - E(Y)) \neq \emptyset\}$$

is $G$-finite. Notice that $E' = \{e \in E(Y) \mid \delta_X(e^{**}) \neq \{e\}\}$.

In particular, the $G$-subset of $E(Y)$ consisting of those $e \in E(Y)$ such that $X - \delta_X(e^{**})$ has more than two components is $G$-finite, and, for any such $e$, we may connect every component of $X - \delta_X(e^{**})$ to every other component using a finite set of edges of $\text{Complete}(V)$. Thus adding to $X$ a suitable $G$-finite $G$-set of edges of $\text{Complete}(V)$ ensures that, for each $e \in E(Y)$, $X - \delta_X(e^{**})$ has exactly two components. This is the final form we want for $X$, and we may assume that this is the $X$ that we had from the start, and the definition for $E'$ now refers to the new $X$. 

We next prove that $\mathcal{R}$ is $G$-finite, and for this it suffices to prove the $G$-finiteness of the $G$-set consisting of all the pairs $(e,f) \in E(Y) \times E(Y)$ such that $e^{**}$ and $f^{**}$ are not nested for $V(X)$.

Consider any such $(e,f)$. In particular, $e \neq f$. Consider first the case where $\delta_X(e^{**}) = \{e\}$. Since $X - \delta_X(f^{**})$ has two components, we see that $X - (\delta_X(f^{**}) \cup \delta_X(e^{**}))$ has at most three components, and, hence, $e^{**}$ and $f^{**}$ are nested for $V(X)$.

Thus, we may assume that $e$ and $f$ lie in the $G$-finite $G$-set $E'$, and then it remains to show that for a given $e$ there are only finitely many possibilities for $f$. Let $A$ be any finite, connected subgraph of $X$ containing $\delta_X(e^{**})$. For any $f \in E'$, for all but finitely many $g \in G$, $\delta_X(f^{**}) \cap gA = \emptyset$, and then $\delta_X((g^{-1}f)^{**}) \cap A = \emptyset$. By the $G$-finiteness of $E'$, for all but finitely many $f \in E'$, $\delta_X(f^{**}) \cap A = \emptyset$. If $\delta_X(f^{**}) \cap A = \emptyset$, then the connected graph $A$ lies entirely in either $f^{**}$ or $f^{**}$. Since $A \supseteq \delta_X(e^{**})$, then $f^{**} \cap \delta_X(e^{**}) = \emptyset$ or $f^{**} \cap \delta_X(e^{**}) = \emptyset$, respectively. If $f^{**} \cap \delta_X(e^{**}) = \emptyset$, then, since $f^{**}$ is the vertex set of a connected subgraph of $X$, $f^{**}$ lies entirely in either $e^{**}$ or $e^{**}$, and, hence, $e^{**}$ and $f^{**}$ are nested. A similar argument applies if $f^{**} \cap \delta_X(e^{**}) = \emptyset$.

Thus, $\mathcal{R}$ is $G$-finite. For any edge $(v,w)$ of $X$ and any $r \in \mathcal{R}$, there exist only finitely many $g \in G$ such that $g(v,w) \in \delta_X(r)$, or, equivalently, $(v,w) \in \delta_X(g^{-1}r)$. By the $G$-finiteness of $\mathcal{R}$, $(v,\ldots)|_\mathcal{R} \sim (w,\ldots)|_\mathcal{R}$. Since $X$ is connected, it follows that $\mathcal{R}$ is finitely separating for $V(X)$, hence, $\mathcal{R}$.

This completes the proof of (11.1.4).

By (11.1.3), $\mathcal{R}$ is $G$-quasifree, and, by (11.1.4), the image of the map

\[ V(Y) \to \text{Maps}(\mathcal{R}, \mathbb{Z}_2), \quad v \mapsto (v,\ldots)|_\mathcal{R}, \]

lies in a $G$-stable almost equality class. Since $G \in \mathfrak{as}t$, the latter $G$-stable almost equality class is then the vertex $G$-set of some $G$-tree with $G$-quasifree edge $G$-set, and we let $T_{\text{bottom}}$ denote such a $G$-tree. Here we have a $G$-map

\[ V(Y) \to V(T_{\text{bottom}}) \subseteq \text{Maps}(\mathcal{R}, \mathbb{Z}_2), \quad v \mapsto (v,\ldots)|_\mathcal{R}. \]

Consider any $u \in V(T_{\text{bottom}})$. Let $U_u \subseteq V(Y)$ denote the fibre over $u$. Since each element of $\mathcal{R}$ is the vertex set of a union of components of $Y$, we see that $U_u$ is the vertex set of some subforest $U_u$ of $Y$ that is a union of components of $Y$. In particular, each component of $Y$ lies entirely in a fibre, and we have a fibration of $Y$ into unions of components.

We shall now see the following.

(11.1.5) There exists some $G_u$-tree $T_u$ and some $G_u$-graph map $Y_u \to T_u$ which is bijective on edges.

Proof of (11.1.5). By (11.1.2), $E(Y_u)$ is finitely separating for $V(Y_u)$.

We claim that $E(Y_u)$ is nested for $V(Y_u)$. Consider any $e, f \in E(Y_u)$ with $e \neq f$. We shall show that $r_{e,f} \cap V(Y_u) = \emptyset$. This is clear if $r_{e,f} = \emptyset$. Thus we may suppose that $r_{e,f} \neq \emptyset$, and, hence $r_{e,f} \in \mathcal{R}$. For each $v \in Y_u$, we see that $(v,\ldots)|_\mathcal{R} = (u,\ldots)|_\mathcal{R} = u$. In particular, $(v, r_{e,f}) = (u, r_{e,f})$. In particular, $(v, r_{e,f}) = (u, r_{e,f})$. Now recall that $E(Y_u) = \emptyset$. Hence $(v, r_{e,f}) = (u, r_{e,f}) = (v, r_{e,f}) = \emptyset$. Thus $r_{e,f} \subseteq V(Y_u) = \emptyset$. This proves the claim.

Hence $E(Y_u)$ is a nested, finitely separating, $G_u$-subset of $\mathcal{P}(V(Y_u))$. It follows from Corollary 4.4 that $T_u := U(E(Y_u))$ is a $G_u$-tree and $G_u$-edge set $E(Y_u) \simeq E(Y_u)$, and there exists a natural $G_u$-map $V(Y_u) \to V(T_u)$. For each edge $e$ of $Y_u$, it follows from (11.1.1) that $(v, e)|_E(Y_u) \cap ((v, e)|_E(Y_u)) = \emptyset$. It can then be seen that we have a $G_u$-graph map $Y_u \to T_u$ that is bijective on edges; it is surjective on vertices if $Y_u$ is nonempty. This completes the proof of (11.1.5).
We now create a $G$-tree denoted $T_{\text{middle}}$ by $G$-equivariantly blowing up each vertex $u$ of $T_{\text{bottom}}$ to the $G_u$-tree $T_u$. Then $T_{\text{middle}}$ is a $G$-tree with $G$-quasifree edge $G$-set, and there is specified a $G$-graph map $Y \rightarrow T_{\text{middle}}$ which is injective on edges.

Since $G \in \text{ast}$, there exists some $G$-tree $T_G$ with vertex $G$-set $V(E_G)$ and $G$-quasifree edge $G$-set.

We now create a $G$-tree denoted $T_{\text{top}}$ by $G$-equivariantly blowing up each vertex $v$ of $T_{\text{middle}}$ to the $G_v$-tree $T_G$ using the incidence maps for $Y$ to make each element of $E(Y) \subseteq E(T_{\text{middle}})$ incident to appropriate copies of elements of $V(Y) \subseteq V(T_G)$. Then $T_{\text{top}}$ is a $G$-tree with $G$-quasifree edge $G$-set, $T_{\text{top}}$ contains the $G$-forest $Y$ as a $G$-subgraph, and there is specified a $G$-map $V(T_{\text{top}}) \rightarrow V(E_G)$ which is the identity map on $V(Y)$.

We now make some adjustments to $T_{\text{top}}$.

Recall that $Y = G(W) \vee G(T_H)$. We may choose a finite subtree $T_0$ of $T_{\text{top}}$ which contains the finite set $\{v_0\} \cup S_{v_0} \cup W$, and set $T^+ := G(T_0) \cup Y$. Then $T^+$ is a connected $G$-subgraph of $T_{\text{top}}$. Now $T^+$ is a $G$-tree with $G$-quasifree edge $G$-set, $T^+$ contains the $G$-forest $Y$ as a $G$-subgraph, $T^+ - Y$ is $G$-finite, and there is specified a $G$-map $V(T^+) \rightarrow V(E_G)$ which is the identity map on $V(Y)$.

Then $T^+/E(Y)$ is a $G$-finite $G$-tree with $G$-quasifree edge $G$-set. While it remains possible, we successively collapse $G$-orbits of edges of $T^+$ which become $G$-compressible edges in $T^+/E(Y)$; we thus eventually obtain a quotient $G$-tree of $T^+$, denoted $T$. Then $T$ is a $G$-tree with $G$-quasifree edge $G$-set, $T$ contains the $G$-forest $Y$ as a $G$-subgraph, $T-Y$ is $G$-finite, and there is specified a $G$-map $V(T) \rightarrow V(E_G)$ which is the identity map on $V(Y)$.

Recall that $V_\infty := \{v \in V(E_G) - G(V(E_H)) : G_v \text{ is infinite}\}$ and that $W$ is an arbitrary finite subset of $V_\infty$. We shall now prove the following.

(11.1.6) $V_\infty$ is $G$-finite.

Proof of (11.1.6). Letting $\tau_0$ denote the component of $Y$ containing $v_0$, we may write $Y/E(Y) = G(\tau_0) \vee G(W)$.

Now $T/E(Y)$ is a $G$-finite, $G$-incompressible $G$-tree with $G$-quasifree edge $G$-set, $G(\tau_0) \vee G(W) \subseteq V(T/E(Y))$, and there is specified a $G$-map

$$V(T/E(Y)) - G\tau_0 \rightarrow V(E_G)$$

which is the identity map on $G(W)$.

Let $W'$ be an arbitrary finite subset of $V_\infty$ which contains a $G$-transversal in the intersection of $V_\infty$ with the $G$-finite image of the $G$-map

$$V(T/E(Y)) - G\tau_0 \rightarrow V(E_G).$$

Then $G(W') \supseteq G(W)$.

The entire foregoing argument applies with $W'$ in place of $W$, and we get a $G$-finite, $G$-incompressible $G$-tree $T'/E(Y)$ with $G$-quasifree edge $G$-set, such that $G(\tau_0) \vee G(W') \subseteq V(T'/E(Y))$ and there is specified a $G$-map

$$V(T'/E(Y)) - G\tau_0 \rightarrow V(E_G)$$

which is the identity map on $G(W')$.

By the choice of $W'$, each infinite subgroup of $G$ that stabilizes an element of $V(T'/E(Y))$ stabilizes an element of $G(\tau_0) \vee G(W') \subseteq V(T'/E(Y))$. Each finite subgroup of $G$ stabilizes an element of $V(T'/E(Y))$. Hence

$$G\text{-substabs}(V(T'/E(Y))) \subseteq G\text{-substabs}(V(T'/E(Y))).$$

By Lemma 3.4.6, $|G\tau_0(T'/E(Y))| \geq |G\tau_0(T'/E(Y))|$. Since $V(T'/E(Y)) \geq G(W')$, we see that $3|G\tau_0(T'/E(Y))| \geq |G\tau_0(G(W'))|$. Thus, we have a finite upper bound on the number of $G$-orbits in $V_\infty$. This completes the proof of (11.1.6).
By (11.1.6), we may assume that $W$ is taken to be a $G$-transversal in $V_\infty$ from the start. Then $V_\infty = G(W) \subseteq V(T)$, and any infinite subgroup of $G$ which stabilizes an element of $V(E_G)$ stabilizes an element of $V(T)$. Each finite subgroup of $G$ stabilizes an element of $V(T)$. Thus,

$$G\text{-substabs}(V(E_G)) \subseteq G\text{-substabs}(V(T)),$$

and, hence, there exists a $G$-map $\varphi: V(E_G) \to V(T)$ which is the identity on $V(E_H)$. We already have a $G$-map $\psi: V(T) \to V(E_G)$ which is the identity on $V(E_H)$. Since $T/ E(Y)$ is $G$-incompressible, the composite $V(T) \xrightarrow{\psi} V(E_G) \xrightarrow{\varphi} V(T)$ is bijective, and we may identify $V(T)$ with a $G$-subset of $V(E_G)$ respecting the embeddings of $V(E_H)$ in $V(T)$ and $V(E_G)$. We may then expand $T$ to a $G$-subtree $T_G$ of Complete($V$) with vertex $G$-set $V(E_G)$ and edge $G$-set

$$E(T) \cup \{(v, \varphi(v)) \mid v \in V(E_G) - V(T)\}.$$ 

This completes the proof of Theorem (11.1). \hfill \Box

12. Countably generable extensions

The following is [5, III.8.3].

12.1. Lemma. Let Notation (11.1) hold. If rank($G$ rel $H$) < $\omega_0$, then $E_G - G(E_H)$ is $G$-finite.

Proof. Let $S$ be a finite subset of $G$ such that $H \cup S$ generates $G$, and set $F := \bigcup_{s \in S} (v_0 \cap (sv_0))$. For each $s$ in the finite set $S$, $sv_0 = a v_0$, and, hence, $F$ is a finite subset of $E_G$. Set $E' := G(E_H \cup F)$. Then $E'$ is a $G$-subset of $E_G$. Also, $\langle v_0, \ldots, v_m \rangle_{E' - E}$ is stabilized by each $g \in S \cup H$, and, hence, is stabilized by $G$. Thus $E_G \subseteq E'$, and then $E_G - G(E_H) \subseteq G(F)$ and $E_G - G(E_H)$ is $G$-finite, as desired. \hfill \Box

The following is part of the proof of [5, III.8.5].

12.2. Proposition. Let Notation (10.1) hold.

Suppose that, for each $g \in G - H$, $gE_H \cap E_H = \emptyset$.

Suppose that $H \subseteq K \subseteq G$ and rank($K$ rel $H$) < $\omega_0$.

Then there exists some $L$ such that $H \subseteq K \subseteq L \subseteq G$, rank($L$ rel $H$) < $\omega_0$, and, for each $g \in G - L$, $gE_L \cap E_L = \emptyset$.

Proof. We recursively construct an ascending sequence $L_{[0,\omega_1]}$ of subgroups of $G$ such that, for each $n \in [0,\omega_1]$, the following hold.

1. $\text{rank}(L_n \text{ rel } H) < \omega_0$.
2. $\{g \in G \mid gE_{L_n} \cap E_{L_n} \neq \emptyset\} \subseteq L_{n+1}$.

We set $L_0 := K$. Here (1) holds with $n = 0$.

Suppose that we are given some $m \in [0,\omega_1]$ and $L_m$ satisfying (1) with $n = m$. Let $S_H$ be an $H$-transversal in $E_H$. Let $S_m$ be an $L_m$-transversal in $E_{L_m} - L_m(E_H)$. Set $F := \{g \in G \mid gS_m \cap (S_H \cup S_m) = \emptyset\}$. Set $L_{m+1} := \langle L_m \cup F \rangle \leq G$.

Since, for all $g \in G - H$, $gE_H \cap E_H = \emptyset$, we see that $S_H$ is a $G$-subset in $G(E_H)$. By Lemma (12.1), $S_m$ is finite. Hence $G(S_m) \cap S_H$ is finite. Recall that $E$ is $G$-quasifree. Hence $F$ is finite. Thus (1) holds with $n = m + 1$.

Consider any $g \in G$ such that $gE_{L_m} \cap E_{L_m} = \emptyset$. We wish to show that $g \in L_{m+1}$. Notice that $S_m \cup S_H$ is an $L_m$-transversal in $E_{L_m}$. Hence, on replacing $g$ with an element of $L_m g L_m$, we may assume that $g(S_m \cup S_H) \cap (S_m \cup S_H) = \emptyset$. If $gS_m \cap (S_m \cup S_H) \neq \emptyset$, then $g \in F \subseteq L_{m+1}$. If $gS_H \cap S_m \neq \emptyset$, then $g \in F^{-1} \subseteq L_{m+1}$. If $gS_H \cap S_H \neq \emptyset$, then $gE_H \cap E_H \neq \emptyset$ and $g \in H \leq L_{m+1}$. Thus (2) holds with $n = m$.

This completes the recursive construction of $L_{[0,\omega_1]}$. 

Set \( L := \bigcup_{n \in [0]^{\uparrow\infty}} L_n \).

Then \( K = L_0 \leq L \).

By (1), \( \text{rank}(L \text{ rel } H) \leq \omega_0 \).

We have \( E_L = \bigcup_{n \in [0]^{\uparrow\infty}} E_{L_n} \). For any \( g \in G \) such that \( gE_L \cap E_L \neq \emptyset \), there exist \( m, n \in [0]^{\uparrow\infty} \) such that \( gE_{L_m} \cap E_{L_n} \neq \emptyset \), and then, by (2), \( g \in L_{\text{max}(m,n)+1} \leq L \).

Thus, \( L \) has all the desired properties.

In the remainder of the section we build a corresponding tree \( T_L \).

The following is a modification of [3, III.8.2].

12.3. Lemma. Let Notation \( \text{(III.4)} \) hold, and suppose that \( H \leq K \leq G \).

Suppose that \( \text{rank}(G \text{ rel } H) < \omega_0 \), and that, for each \( g \in G-H \), \( gE_H \cap E_H = \emptyset \).

Suppose that \( \text{rank}(K \text{ rel } H) < \omega_0 \).

Suppose that, for each \( L \) with \( K \leq L \leq G \) and \( \text{rank}(L \text{ rel } K) < \omega_0 \),

(a) \( L \in \text{ast} \), and,

(b) if \( E_K = E_L \), then, for all \( g \in L - K \), \( gE_K \cap E_K = \emptyset \).

Suppose that \( T_H \) is an \( H \)-subtree of Complete(\( V \)) with vertex \( H \)-set \( V(E_H) \).

Suppose that \( T_K \) is a \( K \)-subtree of Complete(\( V \)) with vertex \( K \)-set \( V(E_K) \) such that \( T_H \subseteq T_K \).

Then there exists some \( G \)-subtree \( T_G \) of Complete(\( V \)) with vertex \( G \)-set \( V(E_G) \) such that \( T_K \subseteq T_G \).

Proof. We recursively define a descending sequence \( G_{[0]^{\uparrow\infty}} \) of subgroups of \( G \) containing \( K \) as follows. We set \( G_0 := G \), and, given \( n \in [0]^{\uparrow\infty} \) and \( G_n \), we define \( G_{n+1} \) to be the \( G_n \)-stabilizer of \( \langle v_0, ... \rangle_{E-G_n(E_K)} \in \text{Maps}(E-G_n(E_K), Z) \).

We set \( E_0 = E_G \) and, for each \( n \in [0]^{\uparrow\infty} \), we set \( E_{n+1} = G_n(E_K) \). Then \( E_{[0]^{\uparrow\infty}} \) is a descending sequence of subsets of \( E_G \) containing \( E_K \).

Consider \( n \in [0]^{\uparrow\infty} \). Then \( E_{n+1} = G_n(E_K) \subseteq E_{G_n} \). It may be shown that

\[ G_n = \{ g \in G : \langle gv_0, ... \rangle_{E-E_n} = \langle v_0, ... \rangle_{E-E_n} \} \]

and then that \( E_{G_n} \subseteq E_n \). For each \( g \in G-G_n \), \( \langle gv_0, ... \rangle_{E-E_n} \neq \langle v_0, ... \rangle_{E-E_n} \), and, hence, \( gV(E_n) \cap V(E_n) = \emptyset \), since \( V(E_n) = \nabla(E_n) \times \{ \langle v_0, ... \rangle_{E-E_n} \} \). In particular, \( G_{V(E_n)} = G_n \).

We shall now show the following.

(12.3.1) For each \( n \in [0]^{\uparrow\infty} \), the chain of subsets

\( V(E_H) \subseteq V(E_n) \subseteq V(E_G) \subseteq V \) extends to a chain of subgraphs

\( T_H \subseteq T_{E_n} \subseteq T^{(n)} \subseteq \text{Complete}(V) \) such that \( T^{(n)} \) is a \( G \)-tree with vertex \( G \)-set \( V(E_G) \), and \( T_{E_n} \) is a \( G_n \)-tree with vertex \( G_n \)-set \( V(E_G) \).

Proof of (12.3.1). Notice that \( V(E_0) = V(E_G) \). By (a), \( G \in \text{ast} \). By Theorem [11.3] there exists some \( G \)-subtree of Complete(\( V \)) with vertex \( G \)-set \( V(E_G) \) containing \( T_H \). Here we have the desired conditions for \( n = 0 \).

Suppose then that we are given \( n \in [0]^{\uparrow\infty} \) and \( T^{(n)} \) and \( T_{E_n} \). Notice that \( G_{T_{E_n}} = G_n \).

We have

\[ V(E_n) = \nabla(E_n) \times \{ \langle v_0, ... \rangle_{E-E_n} \} = \nabla(E_{n+1}) \times \nabla(E_{n-E_{n+1}}) \times \{ \langle v_0, ... \rangle_{E-E_{n+1}} \} \]

\[ = \bigvee_{w \in \nabla(E_{n-E_{n+1}}) \times \{ \langle v_0, ... \rangle_{E-E_{n+1}} \}} \nabla(E_{n+1}) \times \{ w \} \]

Now \( \nabla(E_{n-E_{n+1}}) \) is a \( G_n \)-stable almost equality class in \( \text{Maps}(E_{n-E_{n+1}}, Z) \).

By (a), \( G_n \in \text{ast} \). Hence, there exists some \( G_n \)-tree with vertex \( G_n \)-set \( \nabla(E_{n-E_{n+1}}) \)
and \( G_w \)-quasifree edge \( G_w \)-set. Equivalently, there exists some \( G_w \)-tree \( T \) with vertex \( G_w \)-set \( \nabla (E_n - E_{n+1}) \times \{(v_0, -)|E_{E_n}\} \) and with \( G_w \)-quasifree edge \( G_w \)-set.

Let \( w_0 := (v_0, -)|E_{E_n+1} \in \nabla (E - E_{E_n+1}) \).

We now take \( w \in V(T) = \nabla (E_n - E_{n+1}) \times \{(v_0, -)|E_{E_n}\} \) and consider two cases, where in Case 1 \( w \notin G_w(w_0) \) and in Case 2 \( w = w_0 \), and here \( G_n(w_0) = G_{n+1} \geq K \).

By Lemma 0.3 in Case 1, \( \text{rank}(G_n(w)) < \omega_0 \), while in Case 2, we have \( \text{rank}(G_{n+1} \text{ rel } K) < \omega_0 \).

In Case 1, by Theorem 5.1 \( G_n(w) \in \text{ast} \), and there then exists some \( (G_n)_w \)-tree \( G_n \)-set and vertex \( G_n \)-set \( V(E_{n+1}) \). Equivalently, there exists some \( (G_n)_w \)-tree \( T_w \) with \( (G_n)_w \)-quasifree edge \( (G_n)_w \)-set and vertex \( (G_n)_w \)-set \( \nabla(E_{n+1}) \times \{ w \} \).

In Case 2, by (a), \( G_{n+1} \in \text{ast} \). By Theorem 11.1 there exists some \( G_{n+1} \)-subtree \( T_{w_0} \) of \( \text{Complete}(V) \) with vertex \( G_{n+1} \)-set \( V(E_{G_{n+1}}) \) such that \( T_H \subseteq T_{w_0} \). Then \( T_{w_0} \) can be extended to some \( G_{n+1} \)-subtree, denoted \( T_{w_0} \) and \( T_{E_{n+1}} \), of \( \text{Complete}(V) \) with vertex \( G_{n+1} \)-set \( V(E_{n+1}) = \nabla (E_{n+1}) \times \{ w \} \).

We now \( G_n \)-equivariantly blow up each vertex \( w \) of \( T_H \) to \( T_w \) and get a \( G_n \)-tree \( T \) with \( G_n \)-vertex set \( V(E_n) \) having a \( G_{n+1} \)-subtree \( T_{E_{n+1}} \) with vertex \( G_{n+1} \)-set \( V(E_{n+1}) \) such that \( T_H \subseteq T_{E_{n+1}} \).

The \( G \)-tree \( T^{(n)} \) has a \( G_w \)-subtree \( T_{E_n} \) with vertex \( G_n \)-set \( V(E_n) = V(T) \). We now build \( T^{(n+1)} \) from \( T^{(n)} \) by \( G \)-equivariantly removing the edges in \( T_{E_n} \) and replacing them with the edges of the new \( G_n \)-tree \( T \), which has the same vertex \( G_n \)-set as \( T_{E_n} \). This completes the proof of \( 12.3.1 \).

We next show the following.

(12.3.2) The descending sequence of subgroups \( G_{[0, \omega_1]} \) is eventually constant.

Proof of (12.3.2). Here we may assume that all the terms of \( G_{[0, \omega_1]} \) are infinite subgroups.

The \( G \)-set \( V(T^{(0)}/E(G(T_H))) \) is obtained from \( V(E_G) \) by identifying all the elements of \( g V(E_H) \) with each other, for each \( g \in G \). Since \( \text{rank}(G \text{ rel } H) < \omega_0 \), by Lemma 0.3(iii) there exists some \( G \)-finite \( G \)-incompressible \( G \)-tree \( T^{(\omega_0)} \) such that \( E(T^{(\omega_0)}) \) is \( G \)-quasifree and

\[
G \text{-subtabs}(V(T^{(\omega_0)})) = G \text{-subtabs}(V(T^{(0)}/E(G(T_H))))
\]

Consider any \( n \in [0, \omega_1] \).

The \( G \)-set \( V(T^{(n)}/E(G(T_{E_n}))) \) is obtained from \( V(E_G) \) by identifying all the elements of \( g V(E_n) \) with each other, for each \( g \in G \). Since \( \text{rank}(G \text{ rel } H) < \omega_0 \), byLemma 0.3(iii) there exists some \( G \)-finite \( G \)-incompressible \( G \)-tree \( T^{(n)} \) such that \( E(T^{(n)}) \) is \( G \)-quasifree and

\[
G \text{-subtabs}(V(T^{(n)})) = G \text{-subtabs}(V(T^{(n)}/E(G(T_{E_n}))))
\]

Since \( V(E_H) \subseteq V(E_n) \), we see that there exists a natural \( G \)-map

\[
V(T^{(0)}/E(G(T_H))) \to V(T^{(n)}/E(G(T_{E_n}))).
\]

Hence,

\[
G \text{-subtabs}(V(T^{(0)}/E(G(T_H)))) \subseteq G \text{-subtabs}(V(T^{(n)}/E(G(T_{E_n}))))
\]

and this is equivalent to

\[
G \text{-subtabs}(V(T^{(\omega_0)})) \subseteq G \text{-subtabs}(V(T^{(n)})).
\]

By Lemma 0.4.4, \( |G \setminus T^{(\omega_0)}| \geq |G \setminus T^{(n)}| \), and we have now shown that, as \( n \) varies over \([0, \omega_1],[G \setminus T^{(n)}]| \) has a finite bound. By definition, \( \text{size}(T^{(n)}) \) is an element of
Lemma 9.4(ii), we see that size($Z$) has a finite bound.

Hence,

$$G\text{-substs}(V(T^{(n+1)}/E(G(T_{E_{n+1}})))) \subseteq G\text{-substs}(V(T^{(n)}/E(G(T_{E_n}))))$$

and this is equivalent to $G\text{-substs}(V(T^{(n+1)})) \subseteq G\text{-substs}(V(T^{(n)})).$ Now, by Lemma 9.4(iii), we see that size($T^{(n+1)}$) \( \geq \) size($T^{(n)}$). Thus, size($T^{(n)}$) increases with $n \in [0,\infty]$. It is not difficult to use the foregoing boundedness restraint to show that there exists some $n \in [0,\infty]$ such that size($T^{(n+1)}$) = size($T^{(n)}$).

By Lemma 9.4(iii), $G\text{-substs}(V(T^{(n+1)})) = G\text{-substs}(V(T^{(n)}))$, and this is equivalent to

$$G\text{-substs}(V(T^{(n+1)}/E(G(T_{E_{n+1}})))) = G\text{-substs}(V(T^{(n)}/E(G(T_{E_n}))))$$

Since $g_{n+1}$ is infinite and the edge $G$-set of $T^{(n+1)}/E(G(T_{E_{n+1}}))$ is $G$-quasifree, we see that $T^{(n+1)}/E(G(T_{E_{n+1}}))$ has at most one $G_{n+1}$-stable vertex. Since $G_{n+1}$ stabilizes the image of $V(E_{n+1})$, we see that the image of $V(E_{n+1})$ is the unique $G_{n+1}$-stable vertex of $T^{(n+1)}/E(G(T_{E_{n+1}}))$. Since $T^{(n)}/E(G(T_{E_n}))$ has a $G_n$-stable vertex, namely the image of $V(E_n)$, we see that $G_n$ stabilizes some vertex of $T^{(n+1)}/E(G(T_{E_{n+1}}))$, and, as such a vertex is then $G_{n+1}$-stable, it must be the image of $V(E_{n+1})$. Thus, $G_n \leq G(V(E_{n+1})) = G_{n+1}$. This completes the proof of 12.3.2.

By 12.3.2, there exists some $n \in [1,\infty]$ such that $G_n = G_{n-1}$. Hence

$$G_nE_{K} = E_{n+1} \subseteq E_{G_n} \subseteq E_n = G_{n-1}E_{K} = G_nE_{K}.$$ 

Thus $G_nE_K = E_{G_n} = E_n$. By (b), for all $g \in G_n - K$, $gE_{K} \cap E_{K} = \emptyset$. By (a) and Theorem 11.1, there exists a $G_n$-subtree $T$ of $\text{Complete}(V)$ with vertex $G_n$-set $V(E_n)$ such that $T_K \subseteq T$.

We now build $T_G$ from $T^{(n)}$ by $G$-equivariantly removing the edges in $T_{E_n}$ and replacing them with the edges of the new $G_n$-tree $T$, which has the same vertex $G_n$-set as $T_{E_n}$. This completes the proof.

The following is a modification of [5, III.8.4].

12.4. **Theorem.** Let Notation 11.1 hold.

Suppose that rank($G$ rel $H$) \( \leq \omega_0 \), and that, for each $g \in G - H$, $gE_{G} \cap E_{H} = \emptyset$. Suppose that, for each subgroup $K$ of $G$, if $H \leq K$ and rank($K$ rel $H$) \( < \omega_0 \), then $K \in \text{ast}$.

Suppose that $T_H$ is some $H$-subtree of $\text{Complete}(V)$ with vertex $H$-set $V(E_{H})$.

Then there exists some $G$-subtree $T_G$ of $\text{Complete}(V)$ with vertex $G$-set $V(E_{G})$ such that $T_H \subseteq T_G$.

**Proof.** Let $g_{[1,\infty[}$ be a sequence in $G$ such that $H \cup g_{[1,\infty[}$ generates $G$.

We now recursively construct an ascending sequence of subgroups $G_{[0,\infty]}$ of $G$ such that $G_0 = H$, and, for each $n \in [1,\infty]$, the following hold.

1. $g_n \in G_n$.
2. rank($G_n$ rel $H$) \( < \omega_0 \).
3. Whenever $G_n \leq K \leq G$ and rank($K$ rel $H$) \( < \omega_0 \) and $K(E_{G_n}) = E_K$, then, for each $k \in K - G_n$, $kE_{G_n} \cap E_{G_n} = \emptyset$. 

AN IMPROVED PROOF OF THE ALMOST STABILITY THEOREM 27
Suppose that we are given \( n \in [1, \omega] \) and \( G_{n-1} \). Let \( K \) denote the set of those subgroups \( K \) of \( G \) such that \( K \) contains \( G_{n-1} \cup \{ \bar{g}_n \} \) and \( \text{rank}(K \text{ rel } H) < \omega_0 \). By Lemma 12.1, for each \( K \in \mathbf{K} \), \( E_K - K(\mathcal{E}_G) \) is \( K \)-finite. Hence, \( K(\mathcal{E}_K - K(\mathcal{E}_G)) \) achieves a minimum value as \( K \) ranges over \( \mathbf{K} \). We take \( G_n \) to be an element of \( \mathbf{K} \) where this minimum is achieved. Then \( G_{n-1} \subseteq G_n, g_n \in G_n, \) and \( \text{rank}(G_n \text{ rel } H) < \omega_0 \). Consider any subgroup \( K \) of \( G \) such that \( K \) contains \( G_n \) and \( \text{rank}(K \text{ rel } H) < \omega_0 \) and \( K(\mathcal{E}_{G_n}) = E_K \). Then \( K \in \mathbf{K} \). By minimality for \( G_n \),

\[
|G_n \setminus (E_{G_n} - G_n(\mathcal{E}_H))| \leq |K \setminus (E_{E_K} - (K(\mathcal{E}_G))(\mathcal{E}_H))|
\]

\[
= |K \setminus (K(E_{G_n}) - (K(\mathcal{E}_G))(\mathcal{E}_H))|
\]

\[
\leq |G_n \setminus (E_{G_n} - G_n(\mathcal{E}_H))|.
\]

We have equality throughout, and then

\[
K(E_{G_n}) - (K(\mathcal{E}_G))(\mathcal{E}_H) = K(E_{G_n} - G_n(\mathcal{E}_H)),
\]

and, for each \( k \in K - G_n \), \( k(E_{G_n} - G_n(\mathcal{E}_H)) \cap (E_{G_n} - G_n(\mathcal{E}_H)) = \emptyset \), while, by hypothesis, \( K_n(\mathcal{E}_H) \cap G_n(\mathcal{E}_H) = \emptyset \). Let \( S \) be a right \( G_n \)-transversal in \( K \). Then

\[
K(E_{G_n}) = (K(E_{G_n}) - (K(\mathcal{E}_G))(\mathcal{E}_H)) \lor (K(\mathcal{E}_G))(\mathcal{E}_H)
\]

\[
= \bigvee_{s \in S} s(E_{G_n} - G_n(\mathcal{E}_H)) \lor \bigvee_{s \in S} sG_n(\mathcal{E}_H) = \bigvee_{s \in S} sE_{G_n},
\]

Hence, for each \( k \in K - G_n \), \( kE_{G_n} \cap E_{G_n} = \emptyset \). This completes the recursive construction of \( G_{[0, \omega]} \).

We next recursively construct an ascending sequence \( T_{[0, \omega]} \) of subtrees of \( \text{Complete}(V) \) containing \( T_H \) such that, for each \( n \in [0, \omega] \), \( T_n \) is a \( G_n \)-subtree of \( \text{Complete}(V) \) with vertex \( G_n \)-set \( V(E_{G_n}) \).

We take \( T_0 := T_H \). Suppose that we are given \( n \in [0, \omega] \) and \( T_n \). By Lemma 12.3 there exists some \( G_{n+1} \)-subtree of \( \text{Complete}(V) \) with vertex \( G_{n+1} \)-set \( V(E_{G_{n+1}}) \) such that \( T_n \subseteq T_{n+1} \). This completes the recursive construction of \( T_{[0, \omega]} \).

We now take \( T_G := \bigcup_{n \in [0, \omega]} T_n \).

We shall use two different forms of this result.

12.5. Corollary. Let Notation 10.1 hold.
Suppose that \( |G| \leq \omega_0 \).
Then there exists some \( G \)-subtree \( T_G \) of \( \text{Complete}(V) \) with vertex \( G \)-set \( V(E_G) \).

Proof. We take \( H = \{ 1 \} \) in Theorem 12.4. Here, \( E_H = \emptyset \) and, for each subgroup \( K \) of \( G \), if \( \text{rank}(K) < \omega_0 \), then \( K \in \mathbf{ast} \) by Theorem 5.1.

12.6. Corollary. Let Notation 10.1 hold.
Suppose that \( \text{rank}(G \text{ rel } H) \leq \omega_0 \), and that, for each \( g \in G - H \), \( gE_H \cap E_H = \emptyset \).
Suppose that every subgroup of \( G \) lies in \( \mathbf{ast} \).
Suppose that \( T_H \) is some \( H \)-subtree of \( \text{Complete}(V) \) with vertex \( H \)-set \( V(E_H) \).
Then there exists some \( G \)-subtree \( T_G \) of \( \text{Complete}(V) \) with vertex \( G \)-set \( V(E_G) \) such that \( T_H \subseteq T_G \).

13. THE PROOF

Proof of the Almost Stability Theorem 1.2. We may assume that Notation 10.1 holds and it suffices to show that there exists some \( G \)-subtree of \( \text{Complete}(V) \) with vertex \( G \)-set \( V(E_G) \).

By Corollary 12.5 we may assume that \( \omega_0 < |G| \).
By transfinite induction, we may assume that, for each subgroup \( H \) of \( G \), if \( |H| < |G| \), then \( H \in \text{ast} \).

Set \( \gamma := |G| \) and choose a bijective map \( \gamma \to G \), \( \beta \mapsto g_{\beta} \). We shall recursively construct an ascending chain of subgroups \( (G_\beta \mid \beta \leq \gamma) \) of \( G \) and, at the same time, an ascending chain of subtrees \( (T_\beta \mid \beta \leq \gamma) \) of \( \text{Complete}(V) \). For each \( \beta \leq \gamma \), we shall set \( E_\beta := E_{G_\beta}, V_\beta := V(E_\beta) \), and the following will hold.

1. \( \{g_\alpha \mid \alpha < \beta\} \subseteq G_\beta \).
2. \( |G_\beta| \leq \max\{\omega_0, |\beta|\} \).
3. For each \( g \in G \setminus G_\beta \), \( gE_\beta \cap E_\beta = \emptyset \).
4. \( V(T_\beta) = V_\beta \text{ and } G_\beta E(T_\beta) = E(T_\beta) \).

Suppose that we are given some \( \beta \leq \gamma \) and a chain of subgroups \( (G_\alpha \mid \alpha < \beta) \) and a chain of subtrees \( (T_\alpha \mid \alpha < \beta) \) satisfying (1)--(4) at each step.

**Case 1.** \( \beta = 0 \).

We define \( G_0 := \{1\} \text{ and } T_0 = \{v_0\} \). Here \( E_0 = \emptyset, V_0 = \{v_0\} \) and conditions (1)--(4) hold in Case 1.

**Case 2.** \( \beta \) is a successor ordinal.

By Proposition 12.2 there exists some subgroup \( G_\beta \) of \( G \) with the properties that \( G_{\beta-1} \cup \{g_{\beta-1}\} \subseteq G_\beta \) and \( \text{rank}(G_\beta, \text{rel } G_{\beta-1}) \leq \omega_0 \) and, for each \( g \in G \setminus G_\beta \), \( gE_\beta \cap E_\beta = \emptyset \). Hence, (3) holds.

Then \( \{g_\alpha \mid \alpha < \beta\} = \{g_\alpha \mid \alpha < \beta-1\} \cup \{g_{\beta-1}\} \subseteq G_{\beta-1} \cup \{g_{\beta-1}\} \subseteq G_\beta \), and (1) holds.

Since \( \text{rank}(G_\beta, \text{rel } G_{\beta-1}) \leq \omega_0 \), we have \( |G_\beta| \leq \max\{\omega_0, |G_{\beta-1}|\} \). Now \( |G_\beta| \leq \max\{\omega_0, |G_{\beta-1}|\} \leq \max\{\omega_0, |\beta|\} \leq \max\{\omega_0, |\beta|\} \leq \max\{\omega_0, |\beta|\} \) and (2) holds.

Since \( |\beta-1| \leq |\beta| \leq |\gamma| \), we also have \( |G_\beta| \leq \max\{\omega_0, |\beta|\} < |\gamma| \), and then every subgroup of \( G_\beta \) lies in \( \text{ast} \), by the transfinite induction hypothesis. By Corollary 12.6 there exists some \( G_\beta \)-subtree \( T_\beta \) of \( \text{Complete}(V) \) with vertex \( G_\beta \)-set \( V_\beta \) such that the \( T_{\beta-1} \subseteq T_\beta \). Hence, (4) holds.

Now conditions (1)--(4) hold in Case 2.

**Case 3.** \( \beta \) is a limit ordinal.

Here, we set \( G_\beta := \bigcup_{\alpha < \beta} G_\alpha \text{ and } T_\beta := \bigcup_{\alpha < \beta} T_\alpha \).

Notice that \( E_\beta = \bigcup_{\alpha < \beta} E_\alpha \text{ and } V_\beta = \bigcup_{\alpha < \beta} V_\alpha \). Hence (4) holds.

For each \( \alpha < \beta \), we have \( \alpha+1 < \beta \) and \( g_\alpha \in G_{\alpha+1} \subseteq G_\beta \). Hence (1) holds.

Notice that \( \omega_0 \leq |\beta| \). Thus

\[
|G_\beta| = | \bigcup_{\alpha < \beta} G_\alpha | \leq \sum_{\alpha < \beta} |G_\alpha| \leq \sum_{\alpha < \beta} \max\{\omega_0, |\alpha|\} \leq \sum_{\alpha < \beta} |\beta| \leq |\beta|^2 = |\beta|;
\]

see, for example, [12] Theorem 3.5 and [12] Lemma 5.2. Hence (2) holds.

For each \( g \in G \), if \( gE_\beta \cap E_\beta \neq \emptyset \), then there exist \( \alpha_1 < \beta \) and \( \alpha_2 < \beta \) such that \( gE_{\alpha_1} \cap E_{\alpha_2} \neq \emptyset \), and then \( g \in G_{\max\{\alpha_1, \alpha_2\}} \subseteq G_\beta \). Hence (3) holds.

Thus conditions (1)--(4) hold in Case 3.

This completes the recursive construction.

By (1), \( G_\gamma = G \). By (4), \( T_\gamma \) is a \( G \)-subtree of \( \text{Complete}(V) \) with vertex \( G \)-set \( V(E_G) \). This completes the proof. \( \square \)
14. Arbitrary extensions

With a similar argument, we get the relative version, [5, III.8.5].

14.1. Theorem. Let Notation 10.1 hold.

Suppose that, for each $g \in G - H$, $gE_H \cap E_H = \emptyset$, and that there exists some $H$-subtree $T_H$ of Complete($V$) with vertex $H$-set $V(E_H)$. Then there exists some $G$-subtree $T_G$ of Complete($V$) with vertex $G$-set $V(E_G)$ such that $T_H \subseteq T_G$.

Proof. Set $\gamma := |G|$, and choose a bijective map $\gamma \to G$, $\beta \mapsto g_\beta$. We shall recursively construct an ascending chain of subgroups $(G_\beta \mid \beta \leq \gamma)$ of $G$ and, at the same time, an ascending chain of subtrees $(T_\beta \mid \beta \leq \gamma)$ of Complete($V$). For each $\beta \leq \gamma$, we shall write $E_\beta := E_{G_\beta}$, $V_\beta := V(E_\beta)$, and the following will hold.

1. $\{ g_\alpha \mid \alpha < \beta \} \subseteq G_\beta$.
2. For each $g \in G - G_\beta$, $gE_\beta \cap E_\beta = \emptyset$.
3. $V(T_\beta) = V_\beta$ and $G_\beta E(T_\beta) = E(T_\beta)$.

Suppose that we are given some $\beta \leq \gamma$ and a chain of subgroups $(G_\alpha \mid \alpha < \beta)$ and a chain of subtrees $(T_\alpha \mid \alpha < \beta)$ satisfying (1)–(3) at each step.

Case 1. $\beta = 0$.

We define $G_0 := H$ and $T_0 = T_H$. Now conditions (1)–(3) hold in Case 1.

Case 2. $\beta$ is a successor ordinal.

By Proposition 12.2 there exists some subgroup $G_\beta$ of $G$ with the properties that $G_{\beta - 1} \cup \{g_{\beta - 1}\} \subseteq G_\beta$ and $\text{rank}(G_\beta \cap G_{\beta - 1}) \leq \omega_0$ and, for each $g \in G - G_\beta$, $gE_\beta \cap E_\beta = \emptyset$. Hence, (2) holds.

Then $\{ g_\alpha \mid \alpha < \beta \} \subseteq G_{\beta - 1} \cup \{g_{\beta - 1}\} \subseteq G_\beta$, and (1) holds.

By Theorem 12.2 every subgroup of $G_\beta$ lies in $\ast$. By Corollary 12.6 there exists some $G_\beta$-subtree $T_\beta$ of Complete($V$) with vertex $G_\beta$-set $V_\beta$ such that the $T_{\beta - 1} \subseteq T_\beta$. Hence, (3) holds.

Now conditions (1)–(3) hold in Case 2.

Case 3. $\beta$ is a limit ordinal.

Here, we define $G_\beta := \bigcup_{\alpha < \beta} G_\alpha$ and $T_\beta := \bigcup_{\alpha < \beta} T_\alpha$.

Notice that $E_\beta = \bigcup_{\alpha < \beta} E_\alpha$ and $V_\beta = \bigcup_{\alpha < \beta} V_\alpha$. Hence (3) holds.

For each $\alpha < \beta$, we have $\alpha + 1 < \beta$ and $g_\alpha \in G_{\alpha + 1} \subseteq G_\beta$. Hence (1) holds.

For each $g \in G$, if $gE_\beta \cap E_\beta \neq \emptyset$, then there exist $\alpha_1 < \beta$ and $\alpha_2 < \beta$ such that $gE_{\alpha_1} \cap E_{\alpha_2} \neq \emptyset$, and then $g \in G_{\max(\alpha_1, \alpha_2)} \subseteq G_\beta$. Hence (2) holds.

Thus conditions (1)–(3) hold in Case 3.

This completes the recursive construction.

By (1), $G_\gamma = G$. By (3), $T_\gamma$ is a $G$-subtree of Complete($V$) with vertex $G$-set $V(E_G)$. Since $T_0 = T_H$, this completes the proof. \[\square\]
