Abstract: Stein’s method is applied to obtain a general Cramér-type moderate deviation result for dependent random variables whose dependence is defined in terms of a Stein identity. A corollary for zero-bias coupling is deduced. The result is also applied to a combinatorial central limit theorem, the anti-voter model on a complete graph, and the Curie-Weiss model. A general moderate deviation result for independent random variables is also proved.

AMS 2000 subject classifications: Primary 60F10; secondary 60F05.
Keywords and phrases: Stein’s method, Stein identity, Moderate deviations, Berry-Esseen bounds, zero-bias coupling, exchangeable pairs, dependent random variables, combinatorial central limit theorem, general system of binary codes, anti-voter model, Curie-Weiss model.

1. Introduction

Moderate deviations date back to Cramér (1938) who obtained expansions for tail probabilities for sums of independent random variables about the nor-
normal distribution. For independent and identically distributed random variables $X_1, \cdots, X_n$ with $EX_i = 0$ and $\text{Var}(X_i) = 1$ such that $E e^{t_0 |X_1|} \leq c < \infty$ for some $t > 0$, it follows from Petrov (1975), Chapter 8, Theorem 1 that

$$\frac{P(W_n > x)}{1 - \Phi(x)} = 1 + O(1)(1 + x^3)/\sqrt{n}$$

for $0 \leq x \leq n^{1/6}$ where $W_n = (X_1 + \cdots + X_n)/\sqrt{n}$, $\Phi$ is the standard normal distribution function, and $O(1)$ depends on $c$ and $t_0$. The range $0 \leq x \leq n^{1/6}$ and the order of the error term $O(1)(1 + x^3)/\sqrt{n}$ are optimal.

The proof of (1.1) depends on the conjugate method and a Berry-Esseen bound, while the classical proof of Berry-Esseen bound for independent random variables uses the Fourier transform. However, for dependent random variables, Stein’s method performs much better than the method of Fourier transform. Stein’s method was introduced by Charles Stein in 1972 and further developed by him in 1986. Extensive applications of Stein’s method to obtain Berry-Esseen-type bounds for dependent random variables can be found in, for example, Diaconis (1977), Baldi, Rinott and Stein (1989), Barbour (1990), Dembo and Rinott (1996), Goldstein and Reinert (1997), Chen and Shao (2004), Chatterjee (2008), and Nourdin and Peccati (2009). Recent applications to concentration of measures and large deviations can be found in, for example, Chatterjee (2007) and Chatterjee and Dey (2010). Expositions of Stein’s method and its applications in normal and other distributional approximations can be found in Diaconis and Holmes (2004) and Barbour and Chen (2005).

In this paper we apply Stein’s method to obtain a Cramér-type moderate deviation result for dependent random variables whose dependence is defined in terms of an identity, called Stein identity, which plays a central role in Stein’s method. A corollary for zero-bias coupling is deduced. The result is then applied to a combinatorial central limit theorem, the anti-voter model, a general system of binary codes, and the Curie-Weiss model. The bounds obtained in these ex-
amples are as in (1.1) and therefore may be optimal (see Remark 4.1). It is noted that Raic (2007) also used Stein’s method to obtain moderate deviation results for dependent random variables. However, the dependence structure considered by him is related to local dependence and is of a different nature from what we assume through the Stein identity.

This paper is organized as follows. Section 2 is devoted to a description of Stein’s method and to the construction of Stein identities using zero-bias coupling and exchangeable pairs. Section 3 presents a general Cramér-type moderate deviation result and a corollary for zero-bias coupling. The result is applied to the four examples mentioned above in Section 4. Although the general Cramér-type moderate deviation result cannot be applied to unbounded independent random variables, the proof of the general result can be adapted to prove (1.1) under less stringent conditions thereby extending a result of Linnik (1961). These are also presented in Section 4. The rest of the paper is devoted to proofs.

2. Stein’s method and Stein identity

Let $W$ be the random variable of interest and $Z$ be another random variable. In approximating $\mathcal{L}(W)$ by $\mathcal{L}(Z)$ using Stein’s method, the difference between $Eh(W)$ and $Eh(Z)$ for a class of functions $h$ is expressed as:

$$Eh(W) - Eh(Z) = E\{Lf_h(W)\} \quad (2.2)$$

where $L$ is a linear operator and $f_h$ a bounded solution of the equation $Lf = h - Eh(Z)$. It is known that for $N(0,1)$, $Lf(w) = f'(w) - wf(w)$ (see Stein (1972)) and for Poisson($\lambda$), $Lf(w) = \lambda f(w + 1) - wf(w)$ (see Chen (1975)). However $L$ is not unique. For example, for normal approximation $L$ can also be the generator of the Ornstein-Uhlenbeck process and for Poisson approximation $L$ the generator of an immigration-death process. The solution $f_h$ will then be
expressed in terms of a Markov process. This generator approach to Stein’s method is due to Barbour (1988 and 1990).

By (2.2), bounding $Eh(W) - Eh(Z)$ is equivalent to bounding $E\{Lf_h(W)\}$. To bound the latter one finds another operator $\tilde{L}$ such that $E\{\tilde{L}f(W)\} = 0$ for a class of functions $f$ including $f_h$ and write $\tilde{L} = L - R$ for a suitable operator $R$. The error term $E\{Lf_h(W)\}$ is then expressed as $ERf_h(W)$. The equation

$$E\{\tilde{L}f(W)\} = 0 \quad (2.3)$$

for a class of functions $f$ including $f_h$ is called a Stein identity for $L(W)$. For normal approximation there are four methods for constructing a Stein identity: the direct method (Stein (1972)), zero-bias coupling (Goldstein and Reinert (1997) and Goldstein (2005)), exchangeable pairs (Stein (1986)), and Stein coupling (Chen and Röllin (2010)). We discuss below the construction of Stein identities using zero-bias coupling and exchangeable pairs. As proved in Goldstein and Reinert (1997), for $W$ with $EW = 0$ and $\text{Var}(W) = 1$, there always exists $W^*$ such that

$$EWf(W) = Ef'(W^*) \quad (2.4)$$

for all bounded absolutely continuous $f$ with bounded derivative $f'$. The distribution of $W^*$ is called $W$-zero-biased. If $W$ and $W^*$ are defined on the same probability space (zero-bias coupling), we may write $\Delta = W^* - W$. Then by (2.4), we obtain the Stein identity

$$EWf(W) = Ef'(W + \Delta) = E \int_{-\infty}^{\infty} f'(W + t)d\mu(t|W), \quad (2.5)$$

where $\mu(\cdot|W)$ is the conditional distribution of $\Delta$ given $W$. Here $\tilde{L}(w) = \int_{-\infty}^{\infty} f'(w + t)d\mu(t|W = w) - w f(w)$.

The method of exchangeable pairs (Stein (1986)) consists of constructing $W''$ such that $(W, W'')$ is exchangeable. Then for any anti-symmetric function $F(\cdot, \cdot)$,
that is, \( F(w, w') = -F(w', w) \),

\[ EF(W, W') = 0 \]

if the expectation exists. Suppose that there exist a constant \( \lambda (0 < \lambda < 1) \) and a random variable \( R \) such that

\[ E(W - W' | W) = \lambda(W - E(R|W)). \quad (2.6) \]

Then for all \( f \)

\[ E\{(W - W')(f(W) + f(W'))\} = 0 \]

provided the expectation exists. This gives the Stein identity

\[
EW f(W) = -\frac{1}{2\lambda} E\{(W - W')(f(W') - f(W))\} + E(Rf(W)) \\
= E \int_{-\infty}^{\infty} f'(W + t)\tilde{K}(t)dt + E(Rf(W)) \quad (2.7)
\]

for all absolutely continuous functions \( f \) for which expectations exist, where \( \tilde{K}(t) = \frac{1}{2\lambda} \Delta(I(0 \leq t \leq \Delta) - I(\Delta \leq t < 0)) \) and \( \Delta = W' - W \). In this case, \( \tilde{L}(w) = \int_{-\infty}^{\infty} f'(w + t)E(\tilde{K}(t)|W = w)dt + E(R|W = w)f(w) - wf(w) \).

Both Stein identities \((2.5)\) and \((2.7)\) are special cases of

\[
EW f(W) = E \int_{-\infty}^{\infty} f'(W + t)d\tilde{\mu}(t) + E(Rf(W)) \quad (2.8)
\]

where \( \tilde{\mu} \) is a random measure. We will prove a moderate deviation result by assuming that \( W \) satisfies the Stein identity \((2.8)\).

3. A Cramér-type moderate deviation theorem

Let \( W \) be a random variable of interest. Assume that there exist a deterministic positive constant \( \delta \), a random positive measure \( \tilde{\mu} \) with support \([-\delta, \delta]\) and a random variable \( R \) such that

\[
EW f(W) = E \int_{|t| \leq \delta} f'(W + t)d\tilde{\mu}(t) + E(Rf(W)) \quad (3.1)
\]
for all absolutely continuous function $f$ for which the expectation of either side exists. Let

$$D = \int_{|t| \leq \delta} d\hat{\mu}(t). \quad (3.2)$$

**Theorem 3.1.** Suppose that there exist constants $\delta_1, \delta_2$ and $\theta \geq 1$ such that

$$|E(D|W) - 1| \leq \delta_1(1 + |W|), \quad (3.3)$$

$$|E(R|W)| \leq \delta_2(1 + |W|) \quad {\text{or}} \quad |E(R|W)| \leq \delta_2(1 + W^2) & \delta_2|W| \leq \alpha < 1 \quad (3.4)$$

and

$$E(D|W) \leq \theta \quad (3.5)$$

Then

$$\frac{P(W > x)}{1 - \Phi(x)} = 1 + O(1)(1 + x^3)(\delta + \delta_1 + \delta_2) \quad (3.6)$$

for $0 \leq x \leq \theta^{-1} \min(\delta^{-1/3}, \delta_1^{-1/3}, \delta_2^{-1/3})$, where $O(1)$ denotes a quantity whose absolute value is bounded by a universal constant which depends on $\alpha$ only under the second alternative of (3.4).

**Remark 3.1.** Theorem 3.1 is intended for bounded random variables but with very general dependence assumptions. For this reason, the support of the random measure $\hat{\mu}$ is assumed to be within $[-\delta, \delta]$ where $\delta$ is typically of the order of $1/\sqrt{n}$ due to standardization. In order for the normal approximation to work, $E(D|W)$ should be close to 1 and $E(R|W)$ small. This is reflected in $\delta_1$ and $\delta_2$ which are assumed to be small.

For zero-bias coupling, $D = 1$ and $R = 0$, so conditions (3.3), (3.4) and (3.5) are satisfied with $\delta_1 = \delta_2 = 0$ and $\theta = 1$. Therefore, we have

**Corollary 3.1.** Let $W$ and $W^*$ be defined on the same probability space satisfying (2.4). Assume that $EW = 0$, $EW^2 = 1$ and $|W - W^*| \leq \delta$ for some constant $\delta$. Then

$$\frac{P(W \geq x)}{1 - \Phi(x)} = 1 + O(1)(1 + x^3)\delta$$
for $0 \leq x \leq \delta^{-1/3}$.

**Remark 3.2.** For an exchangeable pair $(W, W')$ satisfying (2.6) and $|\Delta| \leq \delta$, (3.1) is satisfied with $D = \Delta^2/(2\lambda)$.

**Remark 3.3.** Although one cannot apply Theorem 3.1 directly to unbounded random variables, one can adapt the proof of Theorem 3.1 to give a proof of (3.1) for independent random variables assuming the existence of the moment generating functions of $|X_i|^{1/2}$ thereby extending a result of Linnik (1961). This result is given in Proposition 4.6. The proof also suggests the possibility of extending Theorem 3.1 to the case where the support of $\hat{\mu}$ may not be bounded.

### 4. Applications

In this section we apply Theorem 3.1 to four cases of dependent random variables, namely, a combinatorial central limit theorem, the anti-voter model on a complete graph, a general system of binary codes, and the Curie-Weiss model. The proofs of the results for the third and the fourth example will be given in the last section. At the end of this section, we will present a moderate deviation result for sums of independent random variables and the proof will also be given in the last section.

#### 4.1. Combinatorial central limit theorem

Let $(a_{ij})_{i,j=1}^n$ be an array of real numbers satisfying $\sum_{j=1}^n a_{ij} = 0$ for all $i$ and $\sum_{i=1}^n a_{ij} = 0$ for all $j$. Set $c_0 = \max_{i,j} |a_{ij}|$ and $W = \sum_{i=1}^n a_{i \pi(i)}/\sigma$, where $\pi$ is a uniform random permutation of $\{1, 2, \cdots, n\}$ and $\sigma^2 = E(\sum_{i=1}^n a_{i \pi(i)})^2$.

In Goldstein (2005) $W$ is coupled with the zero-biased $W^*$ in such a way that $|\Delta| = |W^* - W| \leq 8c_0/\sigma$. Therefore, by Corollary 3.1 with $\delta = 8c_0/\sigma$, we have

$$
\frac{P(W \geq x)}{1 - \Phi(x)} = 1 + O(1)(1 + x^3)c_0/\sigma
$$

(4.1)
for $0 \leq x \leq (\sigma/c_0)^{1/3}$.

### 4.2. Anti-voter model on a complete graph

Consider the anti-voter model on a complete graph with $n$ vertices, $1, \cdots, n$, and $(n-1)n/2$ edges. Let $X_i$ be a random variable taking value 1 or $-1$ at the vertex $i$, $i = 1, \cdots, n$.

Let $X = (X_1, \cdots, X_n)$, where $X_i$ takes values 1 or $-1$. The anti-voter model in discrete time is described as the following Markov chain: in each step, uniformly pick a vertex $I$ and an edge connecting it to $J$, and then change $X_I$ to $-X_J$. Let $U = \sum_{i=1}^{n} X_i$ and $W = U/\sigma$, where $\sigma^2 = \text{Var}(U)$. Let $W' = (U - X_I - X_J)/\sigma$, where $I$ is uniformly distributed on $\{1, 2, \ldots, n\}$ independent of other random variables. Consider the case where the distribution of $X$ is the stationary distribution. Then as shown in Rinott and Rotar (1997), $(W, W')$ is an exchangeable pair and

$$E(W - W'|W) = \frac{2}{n}W.$$  \hspace{1cm} (4.2)

According to (2.7), (3.1) is satisfied with $\delta = 2/\sigma$ and $R = 0$. To check conditions (3.3) and (3.5), let $T$ denote the number of 1’s among $X_1, \cdots, X_n$, $a$ be the number of edges connecting two 1’s, $b$ be the number of edges connecting two $-1$’s, and $c$ be the number of edges connecting 1 and $-1$. Since it is a complete graph, $a = \frac{T(T-1)}{2}$, $b = \frac{(n-T)(n-T-1)}{2}$. Therefore (see, for example, Rinott and Rotar (1997))

$$E[(W - W')^2|X] = \frac{1}{\sigma^2}E[(U' - U)^2|X] = \frac{4}{\sigma^2} \frac{2a + 2b}{n(n-1)}$$

$$= \frac{1}{\sigma^2} \frac{2U^2 + 2n^2 - 4n}{n(n-1)} = \frac{2\sigma^2 W^2 + 2n^2 - 4n}{\sigma^2 n(n-1)}, \hspace{1cm} (4.3)$$

$$E(D|W) - 1 = \frac{n}{4}E((W' - W)^2|W) - 1$$

$$= \frac{W^2}{2(n-1)} - \frac{2\sigma^2(n-1) - (n^2 - 2n)}{2\sigma^2(n-1)}.$$  \hspace{1cm} (4.4)
Noting that $E(E(D|W) - 1) = 0$ and $EW^2 = 1$, we have $\sigma^2 = \frac{n^2 - 2n}{2(n-1)}$. Hence,

$$E(D|W) - 1 = \frac{W^2}{2(n-1)} - \frac{1}{2(n-1)}$$  \hspace{1cm} (4.5)

which means that (3.3) is satisfied with $\delta_1 = O(n^{-1/2})$. Thus, we have the following moderate deviation result.

**Proposition 4.1.** We have

$$\frac{P(W \geq x)}{1 - \Phi(x)} = 1 + O(1)(1 + x^3)/\sqrt{n}$$

for $0 \leq x \leq n^{1/6}$.

### 4.3. A general system of binary codes

In Chen, Hwang and Zacharovas (2011), a general system of binary codes is defined as follows. Suppose each nonnegative integer $x$ is coded by a binary string consisting of 0’s and 1’s. Let $\tilde{S}(x)$ denote the number of 1’s in the resulting coding string of $x$ and let $\tilde{S} = (\tilde{S}(0), \tilde{S}(1), \ldots)$. (4.6)

For each nonnegative integer $n$, define $\tilde{S}_n = \tilde{S}(X)$, where $X$ is a random integer uniformly distributed over the set $\{0, 1, \ldots, n\}$. The general system of binary codes introduced by Chen, Hwang and Zacharovas (2011) is one in which

$$\tilde{S}_{2m-1} = \tilde{S}_{m-1} + I \quad \text{in distribution for all } m \geq 1,$$

where $I$ is an independent Bernoulli(1/2) random variable. Chen, Hwang and Zacharovas (2011) proved the asymptotic normality of $\tilde{S}_n$. Here, we apply Theorem 3.1 to obtain the following Cramér moderate deviation result. For $n \geq 1$, let integer $k$ be such that $2^{k-1} - 1 < n \leq 2^k - 1$, and let $\tilde{W}_n = (\tilde{S}_n - k/2)/\sqrt{k/4}$. 

**Proposition 4.2.** Under the assumption (4.7), we have

\[
P(\tilde{W}_n \geq x) = 1 + O(1)(1 + x^3) \frac{1}{\sqrt{k}}.
\]

(4.8)

for \(0 \leq x \leq k^{1/6}\).

As an example of this system of binary codes, we consider the binary expansion of a random integer \(X\) uniformly distributed over \(\{0, 1, \ldots, n\}\). For \(2^{k-1} - 1 < n \leq 2^k - 1\), write \(X\) as

\[X = \sum_{i=1}^{k} X_i 2^{k-i}\]

and let \(S_n = X_1 + \cdots + X_k\). Set \(W_n = (S_n - k/2) / \sqrt{k/4}\). It is easy to verify that \(S_n\) satisfies (4.7). A Berry-Esseen bound for \(W_n\) was first obtained by Diaconis (1977). Proposition 4.2 provides a Cramér moderate deviation result for \(W_n\). Other examples of this system of binary codes include the binary reflected Gray code and a coding system using translation and complementation. Detailed descriptions of these codes are given in Chen, Hwang and Zacharovas (2011).

### 4.4. Curie-Weiss model

Consider the Curie-Weiss model for \(n\) spins \(\Sigma = (\sigma_1, \sigma_2, \ldots, \sigma_n) \in \{-1, 1\}^n\). The joint distribution of \(\Sigma\) is given by

\[
Z_{\beta, h}^{-1} \exp(\beta \sum_{1 \leq i < j \leq n} \sigma_i \sigma_j + \beta h \sum_{i=1}^{n} \sigma_i),
\]

where \(Z_{\beta, h}\) is the normalizing constant, and \(\beta > 0, h \in \mathbb{R}\) are called the inverse of temperature and the external field respectively. We are interested in the total magnetization \(S = \sum_{i=1}^{n} \sigma_i\). We divide the region \(\beta > 0, h \in \mathbb{R}\) into three parts, and for each part, we list the concentration property and the limiting distribution of \(S\) under proper standardization. Consider the solution(s) to the equation

\[
m = \tanh(\beta(m + h)).
\]

(4.9)
Case 1. $0 < \beta < 1$, $h \in \mathbb{R}$ or $\beta \geq 1$, $h \neq 0$. There is a unique solution $m_0$ to (4.9) such that $m_0 h \geq 0$. In this case, $S/n$ is concentrated around $m_0$ and has a Gaussian limit under proper standardization.

Case 2. $\beta > 1$, $h = 0$. There are two non-zero solutions to (4.9), $m_1 < 0 < m_2$. Given condition on $S < 0$ ($S > 0$ respectively), $S/n$ is concentrated around $m_1$ ($m_2$ respectively) and has a Gaussian limit under proper standardization.

Case 3. $\beta = 1$, $h = 0$. $S/n$ is concentrated around 0 but the limit distribution is not Gaussian.

We refer to Ellis (1985) for the concentration of measure results, Ellis and Newman (1978a, 1978b) for the results on limiting distributions. See also Chatterjee and Shao (2011) for a Berry-Esseen type bound when the limiting distribution is not Gaussian. Here we focus on the Gaussian case and prove the following two Cramér moderate deviation results for Case 1 and Case 2.

**Proposition 4.3.** In Case 1, define

$$W = \frac{S - nm_0}{\sigma},$$

where

$$\sigma^2 = \frac{n(1 - m_0^2)}{1 - (1 - m_0^2)^{\beta}}.$$  

Then we have

$$P(W \geq x) \frac{1}{1 - \Phi(x)} = 1 + O(1)(1 + x^3)/\sqrt{n},$$

for $0 \leq x \leq n^{1/6}$.

**Proposition 4.4.** In Case 2, define

$$W_1 = \frac{S - nm_1}{\sigma_1}, \quad W_2 = \frac{S - nm_2}{\sigma_2},$$

where

$$\sigma_1^2 = \frac{n(1 - m_1^2)}{1 - (1 - m_1^2)^{\beta}}, \quad \sigma_2^2 = \frac{n(1 - m_2^2)}{1 - (1 - m_2^2)^{\beta}}.$$
Then we have
\[ P(W_1 \geq x | S < 0) = 1 + O(1)(1 + x^3)/\sqrt{n}. \] (4.15)
and
\[ P(W_2 \geq x | S > 0) = 1 + O(1)(1 + x^3)/\sqrt{n}. \] (4.16)
for \( 0 \leq x \leq n^{1/6}. \)

4.5. Independent random variables

Moderate deviation for independent random variables has been extensively studied in literature (see, for example, Petrov (1975), Chapter 8) based on the conjugated method. Here, we will adapt the proof of Theorem 3.1 to prove the following moderate deviation result, which is a variant of those in the literature (see again Petrov (1975), Chapter 8).

**Proposition 4.5.** Let \( \xi_i, 1 \leq i \leq n \) be independent random variables with \( E\xi_i = 0 \) and \( Ee^{x|\xi_i|} < \infty \) for some \( t_n \) and for each \( 1 \leq i \leq n \). Assume that
\[ \sum_{i=1}^{n} E\xi_i^2 = 1. \] (4.17)
Then
\[ P(W \geq x) = 1 + O(1)(1 + x^3)\gamma e^{4x^3\gamma} \] (4.18)
for \( 0 \leq x \leq t_n \), where \( \gamma = \sum_{i=1}^{n} E|\xi_i|^3 e^{x|\xi_i|}. \)

We deduce (1.1) under less stringent conditions from Proposition 4.5 and extend a result of Linnik (1961) to independent but not necessarily identically distributed random variables.
Proposition 4.6. Let $X_i, 1 \leq i \leq n$ be a sequence of independent random variables with $EX_i = 0$. Put $S_n = \sum_{i=1}^{n} X_i$ and $B_n^2 = \sum_{i=1}^{n} EX_i^2$. Assume that there exists positive constants $c_1, c_2 > 0, t_0$ such that
\[ B_n^2 \geq c_2^1 n, \quad Ee^{t_0 \sqrt{|X_i|}} \leq c_2 \quad \text{for} \quad 1 \leq i \leq n. \quad (4.19) \]

Then
\[ \frac{P(S_n/B_n \geq x)}{1 - \Phi(x)} = 1 + O(1)(1 + x^3)/\sqrt{n} \quad (4.20) \]
for $0 \leq x \leq t_0 c_1^{1/2} n^{1/6}/4$, where $O(1)$ is an absolute constant depending on $c_2$ and $t_0$. In particular, we have
\[ \frac{P(S_n/B_n \geq x)}{1 - \Phi(x)} \to 1 \quad (4.21) \]
uniformly in $0 \leq x \leq o(n^{1/6})$.

Proof of Proposition 4.6 The main idea is first truncating $X_i$ and then applying Proposition 4.5 to the truncated sequence. W.l.o.g., assume $c_1 = 1$.
Let
\[ \check{X}_i = X_i 1(|X_i| \leq n^{2/3}), \quad \check{S}_n = \sum_{i=1}^{n} \check{X}_i. \]
Observe that
\[
\begin{align*}
|P(S_n/B_n \geq x) - P(\check{S}_n/B_n \geq x)| &\leq \sum_{i=1}^{n} P(|X_i| \geq n^{2/3}) \\
&\leq \sum_{i=1}^{n} e^{-t_0 n^{1/3}} E e^{t_0 \sqrt{|X_i|}} \leq c_2 n e^{-t_0 n^{1/3}} = O(1)(1 - \Phi(x))(1 + x^3)/\sqrt{n}
\end{align*}
\]
for $0 \leq x \leq c_1 t_0 n^{1/6}/4$. Now let $\xi_i = (\check{X}_i - E\check{X}_i)/\check{B}_n$, where $\check{B}_n^2 = \sum_{i=1}^{n} \text{Var}(\check{X}_i)$.
It is easy to see that
\[
\begin{align*}
\sum_{i=1}^{n} |E\check{X}_i| &\leq \sum_{i=1}^{n} E|X_i| 1(|X_i| \geq n^{2/3}) \\
&\leq \sum_{i=1}^{n} n e^{-t_0 n^{1/3}} E e^{t_0 \sqrt{|X_i|}} = o(n^{-2}) \quad (4.22)
\end{align*}
\]
and similarly, \( \tilde{B}_n = B_n(1 + o(n^{-2})) \). Thus, for \( 0 \leq x \leq t_{01}n^{1/6}/4 \)

\[
x|\xi_i| \leq \frac{2x}{c_1 n} |X_i| 1(|X_i| \leq n^{2/3}) + o(1) \leq \frac{2x}{c_1 n^{1/6}} \sqrt{|X_i|} + o(1) \leq t_0 \sqrt{|X_i|}/2 + o(1)
\]

and hence \( \gamma = O(n^{-1/2}) \). Applying Proposition 4.6 to \( \{\xi_i, 1 \leq i \leq n\} \) gives (4.20).

**Remark 4.1.** As has been remarked for (1.1) in the Introduction the range \( 0 \leq x \leq t_{01} c_1^{1/2} n^{1/6}/4 \) and the order of the error term \( O(1)(1 + x^3)/\sqrt{n} \) in Proposition 4.6 are optimal. By comparing with (1.1) the results in the four examples discussed above may be optimal.

### 5. Preliminary Lemmas

To prove Theorem 3.1 we first need to develop two preliminary lemmas. Our first lemma gives a bound for the moment generating function of \( W \).

**Lemma 5.1.** Let \( W \) be a random variable with \( E|W| \leq C \). Assume that there exist \( \delta > 0, \delta_1 \geq 0, 0 \leq \delta_2 \leq 1/4 \) and \( \theta \geq 1 \) such that (3.1), (3.3) - (3.5) are satisfied. Then for all \( 0 < t \leq 1/(2\delta) \) satisfying

\[
t\delta_1 + C_\alpha C_\theta (t_0 + \delta_1^2 + (\delta + \delta_1 + \delta_2)^3) \leq 1/2
\]

where

\[
C_\alpha = \begin{cases} 
12 (3+\alpha) & \text{under the first alternative of (3.3)} \\
\frac{2}{1-\alpha} & \text{under the second alternative of (3.3)}
\end{cases}
\]

we have

\[
E e^{tW} \leq \exp(t^2/2 + c_0(t))
\]

where

\[
c_0(t) = c_1(C, C_\alpha) \theta \left\{ \delta_2 t + \delta_1 t^2 + (\delta + \delta_1 + \delta_2)^3 \right\}
\]

where \( c_1(C, C_\alpha) \) is a constant depending only on \( C \) and \( C_\alpha \).
Proof. Fix $a > 0$, $t \in (0, 1/(2\delta)]$ and $s \in (0, t]$ and let $f(w) = e^{s(w \wedge a)}$. Letting $h(s) = Ee^{s(W \wedge a)}$, firstly we prove that $h'(s)$ can be bounded by $sh(s)$ and $EW^2 f(W)$. By (3.1),

$$h'(s) = E(W \wedge a)e^{s(W \wedge a)} \leq E(Wf(W))$$

$$= E \int f'(W + t)d\mu(t) + E(Rf(W))$$

$$= sE \int e^{s((W+t) \wedge a)}d\mu(t) + E(e^{s(W \wedge a)}E(R|W))$$

$$\leq sE \int e^{s((W+t) \wedge a)}d\mu(t) + E(e^{s(W \wedge a)}E(R|W))$$

$$\leq sE \int e^{s(W \wedge a + \delta)}d\mu(t) + sE \int e^{s(W \wedge a)}(e^{s \delta} - 1)d\mu(t) + E(e^{s(W \wedge a)}E(R|W))$$

$$\leq sEe^{s(W \wedge a)}D + sEe^{s(W \wedge a)}|e^{s \delta} - 1|D + 2\delta_2 E((1 + W^2)e^{s(W \wedge a)})$$

where we have applied (3.2) and (3.4) to obtain the last inequality. Now, applying the simple inequality

$$|e^x - 1| \leq 2|x| \quad \text{for } |x| \leq 1$$

and then (3.5), we find that

$$E(Wf(W)) \leq sEe^{s(W \wedge a)}D + sEe^{s(W \wedge a)}2s\delta D + 2\delta_2 E((1 + W^2)e^{s(W \wedge a)})$$

$$\leq sEe^{s(W \wedge a)}E(D|W) + 2s^2 \theta \delta Ee^{s(W \wedge a)} + 2\delta_2 E((1 + W^2)e^{s(W \wedge a)})$$

$$= sEe^{s(W \wedge a)} + sEe^{s(W \wedge a)}[E(D|W) - 1]$$

$$+ 2s^2 \theta \delta Ee^{s(W \wedge a)} + 2\delta_2 E((1 + W^2)e^{s(W \wedge a)})$$

$$\leq sEe^{s(W \wedge a)} + s\delta_1 Ee^{s(W \wedge a)}(1 + |W|) + 2s^2 \theta \delta Ee^{s(W \wedge a)}$$

$$+ 2\delta_2 E((1 + W^2)e^{s(W \wedge a)})$$

Note that

$$E|W|e^{s(W \wedge a)} = EW e^{s(W \wedge a)} + 2EW^2 e^{s(W \wedge a)}$$

$$\leq E(Wf(W)) + 2E|W| \leq 2C + E(Wf(W)). \quad (5.6)$$
Collecting terms we obtain
\begin{equation}
    h'(s) \leq E(W f(W)) \leq \left\{ (s(1 + \delta_1 + 2t\theta \delta) + 2\delta_2 h(s) + 2\delta_2 EW^2 f(W) + 2C s \delta_1 \right\} / (1 - s \delta_1).
\end{equation}

Secondly, we show that $EW^2 f(W)$ can be bounded by a function of $h(s)$ and $h'(s)$. Letting $g(w) = we^{s(w \wedge a)}$, and then arguing as for (5.7),
\begin{equation}
    EW^2 f(W) = EW g(W)
\end{equation}
\begin{align*}
    &= E \int (e^{s[(W+t) \wedge a]} + s(W+t)e^{s[(W+t) \wedge a]} I(W+t \leq a)) d\mu(t) + E(R W f(W)) \\
    &\leq E \int (e^{s(W \wedge a)} e^{s\delta} + s[(W+t) \wedge a] e^{s(W \wedge a)} e^{s\delta}) d\mu(t) + E(R W f(W)) \\
    &= e^{s\delta} E(f(W) + sf(W)(W \wedge a) + \delta) D + E(R W f(W)) \\
    &\leq \theta e^{0.5}(1 + 0.5 E f(W) + s\theta e^{s\delta} E(W \wedge a) f(W) + E(R W f(W)) \\
    &\leq 1.5e^{0.5}\theta h(s) + 2s\theta h'(s) + E(R W f(W)).
\end{align*}

Note that under the first alternative of (3.4),
\begin{equation}
    |E(R W f(W))| \leq \delta_2 E f(W) + 2\delta_2 EW^2 f(W),
\end{equation}

and under the second alternative of (3.4),
\begin{equation}
    |E(R W f(W))| \leq \alpha E f(W) + \alpha EW^2 f(W).
\end{equation}

Thus, recalling $\delta_2 \leq 1/4$ and $\alpha < 1$, we have
\begin{equation}
    EW^2 f(W) \leq \frac{C_\alpha}{2} (\theta h(s) + s\theta h'(s))
\end{equation}
where $C_\alpha$ is defined in (5.3).
We are now ready to prove (5.4). Substituting (5.11) into (5.7) yields

\[ (1 - s\delta_1)h'(s) \leq (s(1 + \delta_1 + 2t\theta \delta) + 2\delta_2)h(s) + \delta_2 C_\alpha (\theta h(s) + s\theta h'(s)) + 2C s \delta_1 \]

\[ = (s(1 + \delta_1 + 2t\theta \delta) + 2\delta_2 (1 + C_\alpha \theta))h(s) + C_\alpha s \theta \delta_2 h'(s) + 2C s \delta_1 \]

\[ \leq (s(1 + \delta_1 + 2t\theta \delta) + 2\delta_2 (1 + C_\alpha \theta))h(s) + C_\alpha t \theta \delta_2 h'(s) + 2C s \delta_1. \] (5.12)

Solving for \( h'(s) \), we obtain

\[ h'(s) \leq (sc_1(t) + c_2(t))h(s) + \frac{2C s \delta_1}{1 - c_3(t)}, \] (5.13)

where

\[ c_1(t) = \frac{1 + \delta_1 + 2t\theta \delta}{1 - c_3(t)}, \]

\[ c_2(t) = \frac{2\delta_2 (1 + C_\alpha \theta)}{1 - c_3(t)}, \]

\[ c_3(t) = t\delta_1 + C_\alpha t \theta \delta_2. \]

Now taking \( t \) to satisfy (5.2) yields \( c_3(t) \leq 1/2 \), so in particular \( c_2(t) \) is nonnegative for \( i = 1, 2 \), and \( 1/(1 - c_3(t)) \leq 1 + 2c_3(t) \).

Solving (5.13), we have

\[ h(s) \leq \exp \left( \frac{t^2}{2} c_1(t) + tc_2(t) + 2C \delta_1 t^2 \right) \] (5.14)

Note that \( c_3(t) \leq 1/2, \delta_2 \leq 1/4 \) and \( \theta \geq 1 \). Elementary calculations now give

\[ \frac{t^2}{2} (c_1(t) - 1) + tc_2(t) + 2C \delta_1 t^2 \]

\[ = \frac{t^2 \delta_1 + 2t\theta \delta + c_3(t)}{2} + \frac{2t \delta_2 (1 + C_\alpha \theta)}{1 - c_3(t)} + 2C \delta_1 t^2 \]

\[ \leq t^2 (\delta_1 + 2t\theta \delta + t\delta_1 + C_\alpha t \theta \delta_2) + 4t \delta_2 (1 + C_\alpha) + 2C \delta_1 t^2 \]

\[ \leq c_0(t) \]
and hence
\[ t^2c_1(t)/2 + tc_2(t) \leq t^2/2 + c_0(t), \]
thus proving (5.4) by letting \( a \to \infty \).

**Lemma 5.2.** Suppose that for some nonnegative \( \delta, \delta_1 \) and \( \delta_2 \) satisfying \( \max(\delta, \delta_1, \delta_2) \leq 1 \) and \( \theta \geq 1 \) that (5.4) is satisfied, with \( c_0(t) \) as in (5.3), for all
\[ t \in \left[ 0, \theta^{-1} \min(\delta^{-1/3}, \delta_1^{-1/3}, \delta_2^{-1/3}) \right], \tag{5.15} \]
Then for integers \( k \geq 1 \),
\[ \int_0^t u^k e^{u^2/2} P(W \geq u) du \leq c_2(C, C_\alpha) t^k \tag{5.16} \]
where \( c_2(C, C_\alpha) \) is a constant depending only on \( C \) and \( C_\alpha \) defined in Lemma 5.1.

**Proof.** For \( t \) satisfying (5.15) it is easy to see that \( c_0(t) \leq 5c_1(C, C_\alpha) \) where \( c_1(C, C_\alpha) \) is as in Lemma 5.1 and (5.2) is satisfied. Write
\[
\int_0^t u^k e^{u^2/2} P(W \geq u) du = \int_0^t u^k e^{u^2/2} P(W \geq u) du + \int_t^\infty u^k e^{u^2/2} P(W \geq u) du,
\]
where \( [t] \) denotes the integer part of \( t \). For the first integral, noting that \( \sup_{j-1 \leq u \leq j} e^{u^2/2} = \]

\[ e^{(j-1)^2/2-j(j-1)}, \text{ we have} \]

\[
\int_0^{[t]} u^k e^{u^2/2} P(W \geq u) du \\
\leq \sum_{j=1}^{[t]} j^k \int_{j-1}^{j} e^{u^2/2-ju} e^{ju} P(W \geq u) du \\
\leq \sum_{j=1}^{[t]} j^k e^{(j-1)^2/2-j(j-1)} \int_{j-1}^{j} e^{ju} P(W \geq u) du \\
\leq 2 \sum_{j=1}^{[t]} j^k e^{-j^2/2} \int_{-\infty}^{\infty} e^{ju} P(W \geq u) du \\
= 2 \sum_{j=1}^{[t]} j^k e^{-j^2/2} (1/j) E e^{jW} \\
\leq 2 \sum_{j=1}^{[t]} j^{k-1} \exp(-j^2/2 + j^2/2 + c_0(j)) \\
\leq 2 e^{c_0(t)} \sum_{j=1}^{[t]} j^{k-1} \\
\leq c_2(C, C_\alpha) t^k. \tag{5.17}
\]

Similarly, we have

\[
\int_0^{[t]} u^k e^{u^2/2} P(W \geq u) du \\
\leq t^k \int_0^{[t]} e^{u^2/2-ju} e^{tu} P(W \geq u) du \\
\leq t^k e^{[t]^2/2-t[t]} \int_0^{[t]} e^{tu} P(W \geq u) du \\
\leq 2t^k e^{-t^2/2} \int_{-\infty}^{\infty} e^{tu} P(W \geq u) du \\
\leq c_2(C, C_\alpha) t^k.
\]

This completes the proof. \[\blacksquare\]
6. Proofs of results

In this section, let \( O_\alpha(1) \) denote universal constants which depend on \( \alpha \) only under the second alternative of (3.4).

6.1. Proof of Theorem 3.1

If \( \theta^{-1} \min(\delta^{-1/3}, \delta_1^{-1/3}, \delta_2^{-1/3}) \leq O_\alpha(1) \), then \( 1/(1 - \Phi(x)) \leq 1/(1 - \Phi(O_\alpha(1))) \) for \( 0 \leq x \leq O_\alpha(1) \). Moreover, \( \theta^3(\delta + \delta_1 + \delta_2) \geq O_\alpha(1) \). Therefore, (3.6) is trivial.

Hence, we can assume
\[
\theta^{-1} \min(\delta^{-1/3}, \delta_1^{-1/3}, \delta_2^{-1/3}) \geq O_\alpha(1) \tag{6.1}
\]
so that \( \delta \leq 1, \delta_2 \leq 1/4, \delta_1 + 2\delta_2 < 1 \), and moreover, \( \delta_1 + \delta_2 + \alpha < 1 \) under the second alternative of (3.4). Our proof is based on Stein’s method. Let \( f = f_x \) be the solution to the Stein equation
\[
w f(w) - f'(w) = I(w \geq x) - (1 - \Phi(x)) \tag{6.2}
\]
It is known that
\[
f(w) = \begin{cases} 
\sqrt{2\pi} e^{w^2/2} (1 - \Phi(w))\Phi(x), & w \geq x \\
\sqrt{2\pi} e^{w^2/2} (1 - \Phi(x))\Phi(w), & w < x 
\end{cases}
\]
\[
\leq \frac{4}{1 + w} 1(w \geq x) + 3(1 - \Phi(x))e^{w^2/2} 1(0 < w < x) + 4(1 - \Phi(x))\frac{1}{1 + |w|} 1(w \leq 0) \tag{6.3}
\]
by using the following well-known inequality
\[
(1 - \Phi(w))e^{w^2/2} \leq \min\left(\frac{1}{2}, \frac{1}{w\sqrt{2\pi}}\right), \; w > 0.
\]
It is also known that \( w f(w) \) is an increasing function (see Lemma 2.2, Chen and Shao (2005)). By (5.1) we have
\[
EW f(W) - ER f(W) = E \int f'(W + t)d\hat{\mu}(t) \tag{6.4}
\]
and monotonicity of \(w(f)\) and equation (6.2) imply that

\[
f'(W + t) \leq (W + \delta)f(W + \delta) + 1 - \Phi(x) - 1(W \geq x + \delta) \tag{6.5}
\]

Recall that \(\int d\hat{\mu}(t) = D\). Thus using non-negativity of \(\hat{\mu}\) and combining (6.4), (6.5) we have

\[
EWf(W) - ERf(W) \leq E\{1 - \Phi(x) - 1(W > x + \delta)\}D + \theta(EWf(W) + \delta_E(1 + |W|)f(W)) + \delta_1E(1 + |W|)^2f(W) \tag{6.6}
\]

Now, by (3.2), the expression above can be written

\[
E((W + \delta)f(W + \delta) - Wf(W))\]

\[
+EWf(W)D + E\{1 - \Phi(x) - 1(W > x + \delta)\}D
\]

\[
= 1 - \Phi(x) - P(W > x + \delta)
\]

\[
+ E((W + \delta)f(W + \delta) - Wf(W))D + EWf(W)D
\]

\[
+ E\{1 - \Phi(x) - 1(W > x + \delta)\}(D - 1). \tag{6.7}
\]

Therefore, we have

\[
P(W > x + \delta) - (1 - \Phi(x))
\]

\[
\leq E((W + \delta)f(W + \delta) - Wf(W))D + EWf(W)(D - 1)
\]

\[
+ E\{1 - \Phi(x) - 1(W > x + \delta)\}(D - 1) + ERf(W)
\]

\[
\leq \theta E((W + \delta)f(W + \delta) - Wf(W)) + \delta_1E(|W|(1 + |W|)f(W))
\]

\[
+ \delta_1E[1 - \Phi(x) - 1(W > x + \delta)](1 + |W|) + \delta_2E(2 + |W|^2)f(W). \tag{6.8}
\]

where we have again applied the monotonicity of \(w(f)\) as well as (3.5), (3.3) and (3.4). Hence we have that

\[
P(W > x + \delta) - (1 - \Phi(x)) \leq \theta I_1 + \delta_1I_2 + \delta_2I_3 + \delta_2I_4. \tag{6.9}
\]
where
\[ I_1 = E((W + \delta)f(W + \delta) - Wf(W)), \]
\[ I_2 = E(|W|(1 + |W|)f(W)), \]
\[ I_3 = E[1 - \Phi(x) - 1(W > x + \delta)](1 + |W|) \] and
\[ I_4 = E(2 + W^2)f(W). \]

By (6.3) we have
\[
Ef(W) \leq 4P(W > x) + 4(1 - \Phi(x))
+ 3(1 - \Phi(x))Ee^{W^2/2}1(0 < W \leq x).
\]

By (6.3) again
\[
EW^2f(W) \leq 4E|W|1(W > x) + 4(1 - \Phi(x))E|W|
+ 3(1 - \Phi(x))EW^2e^{W^2/2}1(0 < W \leq x)
\]
and by Lemma 5.2
\[
EW^2e^{W^2/2}1(0 < W \leq x) \leq \int_0^x (y^3 + 2y)e^{y^2/2}P(W > y)dy
\]
\[
\leq O_\alpha(1)(1 + x^3).
\]

Note that by (3.1) with \( f(w) = w, \)
\[
EW^2 = E \int d\mu(t) + E(RW)
= ED + E(RW)
\]

Therefore, under the first alternative of (3.4), \( EW^2 \leq (1 + 2\delta_1 + \delta_2) + (\delta_1 + 2\delta_2)EW^2, \) and under the second alternative of (3.4), \( EW^2 \leq (1 + 2\delta_1 + \delta_2) + (\delta_1 + \delta_2 + \alpha)EW^2. \) This shows \( EW^2 \leq O_\alpha(1). \) Hence the hypotheses of Lemma 5.1 is satisfied with \( C = O_\alpha(1), \) and therefore also the conclusion of Lemma 5.2.

In particular,
\[
Ee^{W^2/2}1(0 < W \leq x) \leq P(0 < W \leq x) + \int_0^x ye^{y^2/2}P(W > y)dy
\]
\[
\leq O_\alpha(1)(1 + x).
\]

Similarly, by (6.3) again
\[
EW^2e^{W^2/2}1(0 < W \leq x) \leq \int_0^x (y^3 + 2y)e^{y^2/2}P(W > y)dy
\]
\[
\leq O_\alpha(1)(1 + x^3).
\]
As to

\[ E|W|1(W > x) \leq P(W > x) + EW^2I(W > x), \]

it follows from Lemma 5.1 that

\[ P(W > x) \leq e^{-x^2}Ee^{xW} = O_\alpha(1)e^{-x^2/2} \] (6.13)

and

\[
\int_x^\infty tP(W \geq t)dt \\
\leq Ee^{xW} \int_x^\infty te^{-x^1}dt \\
= Ee^{xW} x^2(1 + x^2)e^{-x^4} \leq O_\alpha(1)e^{-x^2/2}x^2(1 + x^2) \\
\leq O_\alpha(1)e^{-x^2/2} \] (6.14)

for \( x \geq 1. \) Thus, we have for \( x > 1 \)

\[ EW^21(W > x) = x^2P(W > x) + \int_x^\infty 2yP(W > y)dy \]

\[ \leq O_\alpha(1)(1 + x^3)e^{-x^2/2} \leq O_\alpha(1)(1 + x^3)(1 - \Phi(x)) \] (6.15)

Clearly, (6.15) remains valid for \( 0 \leq x \leq 1 \) by the fact that \( EW^21(W > x) \leq EW^2 \leq 2. \) Combining (6.11) to (6.15), we have

\[ I_2 \leq O_\alpha(1)(1 + x^3)(1 - \Phi(x)). \] (6.16)

Similarly,

\[ I_4 \leq O_\alpha(1)(1 + x^3)(1 - \Phi(x)) \] (6.17)

and

\[ I_3 \leq (1 - \Phi(x))E(2 + W^2) + E(2 + W^2)1(W \geq \delta + x) \leq O_\alpha(1)(1 + x^3)(1 - \Phi(x)). \] (6.18)

Let \( g(w) = (wf(w))' \). Then \( I_1 = \int_0^\delta Eg(W + t)dt. \) It is easy to see that (for example, Chen and Shao (2001))

\[
g(w) = \begin{cases} 
\frac{\sqrt{2\pi}(1 + w^2)e^{w^2/2}(1 - \Phi(w)) - w}{1 - \Phi(w)} \Phi(x), & w \geq x \\
\frac{\sqrt{2\pi}(1 + w^2)e^{w^2/2(1 - \Phi(w))} + w}{1 - \Phi(w)}(1 - \Phi(x)), & w < x 
\end{cases} \] (6.19)
and
\[ 0 \leq \sqrt{2\pi}(1 + w^2)e^{w^2/2}(1 - \Phi(w)) - w \leq \frac{2}{1 + w^2}, \tag{6.20} \]
we have for \(0 \leq t \leq \delta\)
\[
Eg(W + t) = E_g(W + t) \mathbb{1}\{W + t \geq x\} + E_g(W + t) \mathbb{1}\{W + t \leq 0\} + E_g(W + t) \mathbb{1}\{0 < W + t < x\}
\leq \frac{2}{1 + x^3} P(W + t \geq x) + 2(1 - \Phi(x))P(W + t \leq 0)
+ \sqrt{2\pi}(1 - \Phi(x))E\left(\left(1 + (W + t)^2 + (W + t)e^{(W + t)^2/2}\right)\mathbb{1}\{0 < W + t < x\}\right)
= O_\alpha(1)(1 + x^3)(1 - \Phi(x))
\]
and hence
\[ I_1 = O_\alpha(1)\delta(1 + x^3)(1 - \Phi(x)). \tag{6.22} \]
Putting (6.9), (6.16), (6.17), (6.18) and (6.22) together gives
\[
P(W \geq x + \delta) - (1 - \Phi(x)) \leq O_\alpha(1)(1 - \Phi(x))\theta(1 + x^3)(\delta + \delta_1 + \delta_2)
\]
and therefore
\[
P(W \geq x) - (1 - \Phi(x)) \leq O_\alpha(1)(1 - \Phi(x))\theta(1 + x^3)(\delta + \delta_1 + \delta_2). \tag{6.23} \]
As to the lower bound, similarly to (6.5) and (6.8), we have
\[
f'(W + t) \geq (W - \delta)f(W - \delta) + 1 - \Phi(x) - \mathbb{1}(W \geq x - \delta)
\]
and
\[
P(W > x - \delta) - (1 - \Phi(x))
\geq \theta E[(W - \delta)f(W - \delta) - Wf(W)] - \delta_1 E(\mathbb{1}[W(1 + |W|)]f(W))
- \delta_1 E[1 - \Phi(x) - \mathbb{1}(W > x - \delta)(1 + |W|) - \delta_2 E(2 + W^2)f(W)
\]
Now following the same proof of (6.23) leads to
\[ P(W \geq x) - (1 - \Phi(x)) \geq -O(1)(1 - \Phi(x))\theta(1 + x^3)(\delta + \delta_1 + \delta_2). \]
This completes the proof of Theorem 3.1.

6.2. Proof of Proposition 4.2

For \( n \geq 2, X \sim U\{0, 1, \ldots, n\} \), let \( \tilde{S}_n = \tilde{S}(X) \) be the number of 1’s in the binary string of \( X \) generated in any system of binary codes satisfying (4.7). Without loss of generality, assume that
\[ \tilde{S}(0) = 0. \] (6.24)

The condition (4.7) allows \( \tilde{S}(X) \) to be represented in terms of the labels of the nodes in a binary tree described as follows. Let \( \tilde{T} \) be an infinite binary tree. For \( k \geq 0 \), the nodes of \( \tilde{T} \) in the \( k \)th generation are denoted by (from left to right) \((V_{k,0}, \ldots, V_{k,2^k-1})\). Each node is labeled by 0 or 1. Assume \( \tilde{T} \) satisfies

C1. The root is labeled by 0
C2. The labels of two siblings are different.
C3. Infinite binary subtrees of \( \tilde{T} \) with roots \( \{V_{k,0} : k \geq 0\} \) are the same as \( \tilde{T} \).

For \( 2^{k-1} - 1 < n \leq 2^k - 1 \), represent \( 0, \ldots, n \) by the nodes \( V_{k,0}, \ldots, V_{k,n} \) respectively. Then \( \tilde{S}(X) \) is the sum of 1’s in the shortest path from \( V_{k,X} \) to the root of the tree. The condition C3 implies that \( \tilde{S}(X) \) does not depend on \( k \) so that the representation is well defined.

We consider two extreme cases. Define a binary tree \( T \) by always assigning 0 to the left sibling and 1 to the right sibling. Then the number of 1’s in the binary string of \( X \) is that in the binary expansion of \( X \). Denote it by \( S_n(= S(X)) \). Next, define a binary tree \( \overline{T} \) by assigning \( V_{k,0} = 0, V_{k,1} = 1 \) for all \( k \) and assigning 1
to the left sibling and 0 to the right sibling for all other nodes. Let the number of 1’s in the binary string of \( X \) on \( \bar{T} \) be \( \bar{S}_n = \bar{S}(X) \). Both \( T \) and \( \bar{T} \) are infinity binary trees satisfying C1, C2 and C3 and both \( S_n \) and \( \bar{S}_n \) satisfy (4.7). It is easy to see that for all integers \( n \geq 0 \),

\[
S_n \leq_{st} \bar{S}_n \leq_{st} \tilde{S}_n
\]

where \( \leq_{st} \) denotes stochastic ordering. Therefore, it suffices to prove Cramér moderate deviation results for \( W_n \) and \( \bar{W}_n \) where \( W_n = (S_n - k^2)/\sqrt{k/4} \) and \( \bar{W}_n = (\bar{S}_n - k^2)/\sqrt{k/4} \). We suppress the subscript \( n \) in the following and follow Diaconis (1977) in constructing the exchangeable pair \((W, W')\). Let \( I \) be a random variable uniformly distributed over the set \( \{1, 2, \ldots, k\} \) and independent of \( X \), and let the random variable \( X' \) be defined by

\[
X' = \sum_{i=1}^{k} X'_i 2^{k-i},
\]

where

\[
X'_i = \begin{cases} X_i & \text{if } i \neq I \\ 1 & \text{if } i = I, X_I = 0 \text{ and } X + 2^{k-I} \leq n \\ 0 & \text{else.} \end{cases}
\]

Let \( S' = S - X_I + X'_I \), \( W' = (S' - k/2)/\sqrt{k/4} \). As proved in Diaconis (1977), \((W, W')\) is an exchangeable pair and

\[
E(W - W'|W) = \lambda(W - ( - \frac{E(Q|W)}{\sqrt{k}})) \tag{6.27}
\]

\[
\frac{1}{2\lambda} E((W - W')^2|W) - 1 = - \frac{E(Q|W)}{k}, \tag{6.28}
\]

where \( \lambda = 2/k \) and \( Q = \sum_{i=1}^{k} I(X_i = 0, X + 2^{k-i} > n) \). From Lemma 6.1 and Theorem 3.1 (with \( \delta = O(k^{-1/2}), \delta_1 = O(k^{-1}), \delta_2 = O(k^{-1/2}) \)),

\[
P(W \geq x) \frac{1}{1 - \Phi(x)} = 1 + O(1)(1 + x^3) \frac{1}{\sqrt{k}}
\]

for \( 0 \leq x \leq k^{1/6} \). Repeat the above argument for \(-W\), we have

\[
P(W \leq -x) \frac{1}{1 - \Phi(x)} = 1 + O(1)(1 + x^3) \frac{1}{\sqrt{k}}
\]
for $0 \leq x \leq k^{1/6}$.

Next, we notice that $S$ and $\bar{S}$ can be written as, with $X \sim U\{0, 1, \ldots, n\}$,

$$S = I(0 \leq X \leq 2^{k-1} - 1)S + I(2^{k-1} \leq X \leq n)S$$

and

$$\bar{S} = I(0 \leq X \leq 2^{k-1} - 1)\bar{S} + I(2^{k-1} \leq X \leq n)\bar{S}.$$ 

Therefore,

$$-W - \frac{1}{\sqrt{k/4}} = -\frac{1}{2} + I(0 \leq X \leq 2^{k-1} - 1)(\frac{k-1}{2} - S) + I(2^{k-1} \leq X \leq n)(\frac{k-1}{2} - S)$$

and

$$\bar{W} = -\frac{1}{2} + I(0 \leq X \leq 2^{k-1} - 1)(\bar{S} - \frac{k-1}{2}) + I(2^{k-1} \leq X \leq n)(\bar{S} - \frac{k-1}{2}).$$

Conditioning on $0 \leq X \leq 2^{k-1} - 1$, both the distributions of $S(X)$ and $\bar{S}(X)$ are Binomial$(k-1, 1/2)$, which yields

$$\mathcal{L}(\frac{k-1}{2} - S|0 \leq X \leq 2^{k-1} - 1) = \mathcal{L}(\bar{S} - \frac{k-1}{2}|0 \leq X \leq 2^{k-1} - 1).$$

On the other hand, when $2^{k-1} \leq X \leq n$, $\bar{S}(X) = k - 1 - S(X)$. Therefore, $\bar{W}$ has the same distribution as $-W - 1/\sqrt{k/4}$, which implies Cramér moderate deviation results also holds for $\bar{W}$. Thus finishes the proof of Proposition 4.2.

**Lemma 6.1.** We have $E(Q|S) = O(1)(1 + |W|)$.

**Proof.** Write

$$n = \sum_{i \geq 1} 2^{k-p_i},$$

with $1 = p_1 < p_2 < \cdots < p_{k_1}$ the positions of the ones in the binary expansion of $n$, where $k_1 \leq k$. Recall that $X$ is uniformly distributed over $\{0, 1, \ldots, n\}$,
and that
\[ X = \sum_{i=1}^{k} X_i 2^{k-i}, \]
with exactly \( S \) of the indicator variables \( X_1, \ldots, X_k \) equal to 1.

We say that \( X \) falls in category \( i, i = 1, \cdots, k_1 \), when
\[ X_{p_1} = 1, X_{p_2} = 1, \cdots, X_{p_{i-1}} = 1 \quad \text{and} \quad X_{p_i} = 0. \quad (6.29) \]

We say that \( X \) falls in category \( k_1 + 1 \) if \( X = n \). This special category is nonempty only when \( S = k_1 \) and in this case, \( Q = k - k_1 \), which gives the last term in (6.30).

Note that if \( X \) is in category \( i \) for \( i \leq k_1 \), then, since \( X \) can be no greater than \( n \), the digits of \( X \) and \( n \) match up to the \( p_i^{th} \), except for the digit in place \( p_i \), where \( n \) has a one, and \( X \) a zero. Further, up to this digit, \( n \) has \( p_i - i \) zeros, and so \( X \) has \( a_i = p_i - i + 1 \) zeros. Changing any of these \( a_i \) zeros except the zero in position \( p_i \) to ones results in a number \( n \) or greater, while changing any other zeros, since digit \( p_i \) of \( n \) is one and of \( X \) zero, does not. Hence \( Q \) is at most \( a_i \) when \( X \) falls in category \( i \). Since \( X \) has \( S \) ones in its expansion, \( i - 1 \) of which are accounted for by (6.29), the remaining \( S - (i - 1) \) are uniformly distributed over the \( k - p_i = k - (i - 1) - a_i \) remaining digits \( \{X_{p_{i+1}}, \cdots, X_k\} \).

Thus, we have the inequality
\[ E(Q|S) \leq \frac{1}{A} \sum_{i \geq 1} \left( \frac{k - (i - 1) - a_i}{S - (i - 1)} \right) a_i + \frac{I(S = k_1)}{A} (k - k_1) \quad (6.30) \]
where
\[ A = \sum_{i \geq 1} \left( \frac{k - (i - 1) - a_i}{S - (i - 1)} \right) + I(S = k_1), \]
and \( 1 = a_1 \leq a_2 \leq a_3 \leq \cdots \).

Note that if \( k_1 = k \), the last term of (6.30) equals 0. When \( k_1 < k \), we have
\[ \frac{I(S = k_1)}{A} (k - k_1) \leq \left( \frac{k - 1}{k_1} \right)^{-1} (k - k_1) \leq 1 \quad (6.31) \]
so we omit this term in the following argument.

We consider two cases.

Case 1: $S \geq k/2$. As $a_i \geq 1$ for all $i$, there are at most $k + 1$ nonzero terms in the sum $\sum_{i=1}^{k-1} a_i$. Divide the summands into two groups, those for which $a_i \leq 2 \log_2 k$ and those with $a_i > 2 \log_2 k$. The first group can sum to no more than $2 \log_2 k$ because the sum is like weighted average of $a_i$.

For the second group, note that

$$
\frac{(k - (i - 1) - a_i)}{S - (i - 1)} / \frac{k - 1}{S - (i - 1)} \leq \frac{a_i}{k - 1} \prod_{j=0}^{a_i-1} \frac{S - j}{k - (a_i - 1) - j} \prod_{j=1}^{a_i-1} \frac{k - S - j}{k - j - 1} \leq \frac{1}{2a_i-1} \leq \frac{1}{k^2},
$$

(6.32)

where the second inequality follows from $S \geq k/2$, and the last inequality from $a_i > 2 \log_2 k$. Therefore, the sum of the second group of terms is bounded by 1.

Case 2: $S < k/2$. Divide the sum on the right hand side into two groups according as to whether $i \leq 2 \log_2 k$ or $i > 2 \log_2 k$. Clearly,

$$
\frac{(k - (i - 1) - a_i)}{S - (i - 1)} / \frac{k - 1}{S - (i - 1)} \leq \prod_{j=0}^{i-2} \frac{S - j}{k - 1 - j} \prod_{j=1}^{a_i-1} \frac{k - S - j}{k - (i - 1) - j} \leq 1/2^{i-1}
$$

using the assumption $S < k/2$ and the fact that $S \geq i - 1$. The above inequality is true for all $i$, so the summation for the part where $i > 2 \log_2 k$ is bounded by 1.

Next we consider $i \leq 2 \log_2 k$. When $S \geq k \left( \frac{\log a_i}{a_i-1} \right) + 2 \log_2 k$, we have $a_i \left( \frac{k-S-1}{k-(i-1)-1} \right)^{a_i-1} \leq 1$. Solving $S$ from the inequality $a_i \left( \frac{k-S-1}{k-(i-1)-1} \right)^{a_i-1} \leq 1$, we see that it is equivalent to the inequality $S \geq (1 - e^{-\frac{\log a_i}{a_i-1}})k - 1 + e^{-\frac{\log a_i}{a_i-1}} i$. 

which is a result of the above assumption on $S$ when $i < 2 \log_2 k$. Now we have

\[
\frac{a_i \left( k - (i - 1) - a_i \right)}{S - (i - 1)} / A \\
\leq a_i \left( \frac{k - (i - 1) - a_i}{S - (i - 1)} \right) / \left( \frac{k - 1}{S} \right)
\]

\[
= a_i \prod_{j=0}^{i-2} \left( \frac{S - j}{k - 1 - j} \right) \prod_{j=1}^{a_i - 1} \left( \frac{k - S - j}{k - (i - 1) - j} \right)
\]

\[
\leq a_i \frac{1}{2^{i-1}} \left( \frac{k - S - 1}{k - (i - 1) - 1} \right)^{a_i - 1} \leq \frac{1}{2^{i-1}}
\]

(6.33)

using the fact that $a_i \left( \frac{k - S - 1}{k - (i - 1) - 1} \right)^{a_i - 1} \leq 1$.

On the other hand, if $S < k \left( \frac{\log a_i}{a_i - 1} \right) + 2 \log_2 k$ then $a_i S / (k - 1) = O(1) \log_2 k$, which implies

\[
\frac{a_i \left( k - (i - 1) - a_i \right)}{S - (i - 1)} / A \leq \frac{a_i S}{k - 1} \prod_{j=1}^{i-2} \left( \frac{S - j}{k - 1 - j} \right) \prod_{j=1}^{a_i - 1} \left( \frac{k - S - j}{k - (i - 1) - j} \right)
\]

\[
= O(1) \log_2 k / 2^{i-2}.
\]

This proves that the right hand side of (6.30) is bounded by $O(1) \log_2 k$.

To complete the proof of the lemma, i.e., to prove $E(Q|W) \leq C(1 + |W|)$, we only need to show that $E(Q|S) \leq C$ for some universal constant $C$ when $|W| \leq \log_2 k$, that is, when $k/2 - \sqrt{k/4} \log_2 k \leq S \leq k/2 + \sqrt{k/4} \log_2 k$. Following the argument in case 2 above, we only need to consider the summands where $i \leq 2 \log_2 k$ because the other part where $i > 2 \log_2 k$ is bounded by 1 as proved in case 2.

When $a_i, k$ are bigger than some universal constant, $k/2 - \sqrt{k/4} \log_2 k \geq \frac{\log a_i}{a_i - 1} \times k + 2 \log_2 k$, which implies $(\frac{k - S - 1}{k - (i - 1) - 1})^{a_i - 1} \times a_i \leq 1$ and $(\frac{k - (i - 1) - a_i}{S - (i - 1)}) \times a_i / A \leq 1 / 2^{i-1}$. Since both parts for $i \leq 2 \log_2 k$ and $i > 2 \log_2 k$ are bounded by some constant, $E(Q|S) \leq C$ when $|W| \leq \log_2 k$ and hence the lemma is proved.
6.3. Proof of Propositions 4.3 and 4.4

Let $\tilde{W}$ have the conditional distribution of $W$ ($W_1$, $W_2$ respectively) given $|W| \leq c_1 \sqrt{n}$ ($|W_1|$, $|W_2| \leq c_1 \sqrt{n}$ respectively) where $c_1$ is to be determined. If we can prove that

$$P(\tilde{W} \geq x) = 1 + O(1)(1 + x^3)/\sqrt{n} \quad (6.34)$$

for $0 \leq x \leq n^{1/6}$, then from the fact that (Ellis (1985))

$$P(|W| > K \sqrt{n}) \leq e^{-nC(K)}, \quad (6.35)$$

and

$$P(|W_1| > K \sqrt{n}|S < 0) \leq e^{-nC(K)}, \quad P(|W_2| > K \sqrt{n}|S > 0) \leq e^{-nC(K)}$$

for any positive number $K$ where $C(K)$ is a positive constant depending only on $K$, we have, with $\delta_2 = O(1/\sqrt{n})$,

$$P(W \geq x) \leq P(\tilde{W} \geq x) + P(\delta_2 |W| > 1/2) / \sqrt{n}$$

for $0 \leq x \leq n^{1/6}$. Similarly, (4.15) and (4.16) are also true. Therefore, we prove Cramér moderate deviation for $\tilde{W}$ (still denoted by $W$ in the following) defined below. Assume the state space of the spins is $\Sigma = \{\sigma_1, \sigma_2, \ldots, \sigma_n\} \in \{-1, 1\}^n$ such that $\sum_{i=1}^{n} \sigma_i/n \in [a, b]$ where $[a, b]$ is any interval within which there is only one solution $m$ to (4.10). Let $S = \sum_{i=1}^{n} \sigma_i$, $W = \frac{S-nm}{\sigma}$ and $\sigma^2 = \frac{n(1-m^2)\beta}{1-(1-m^2)\beta}$. Note that in Case 1 and Case 2, $1 - (1 - m^2)\beta > 0$, thus $\sigma^2$ is well defined. Moreover, $[a, b]$ is chosen such that $|W| \leq c_1 \sqrt{n}$. The joint distribution of the spins is

$$Z_{\beta,h}^{-1} \exp\left(\frac{\beta}{n} \sum_{1 \leq i < j \leq n} \sigma_i \sigma_j + \beta h \sum_{i=1}^{n} \sigma_i\right).$$
Let $I$ be a random variable uniformly distributed over \{1, \cdots, n\} independent of \{\sigma_i, 1 \leq i \leq n\}. Let $\sigma'_i$ be a random sample from the conditional distribution of $\sigma_i$ given $\{\sigma_j, j \neq i, 1 \leq j \leq n\}$. Define $W' = W - (\sigma_I - \sigma'_I)/\sigma$. Then $(W, W')$ is an exchangeable pair. Let

$$A(w) = \frac{\exp(-\beta(m + h) - \beta\sigma w/n + \beta/n)}{\exp(-\beta(m + h) - \beta\sigma w/n + \beta/n) + \exp(\beta(m + h) + \beta\sigma w/n - \beta/n)},$$

and

$$B(w) = \frac{\exp(\beta(m + h) + \beta\sigma w/n + \beta/n)}{\exp(\beta(m + h) + \beta\sigma w/n + \beta/n) + \exp(-\beta(m + h) - \beta\sigma w/n - \beta/n)}.$$

It is easy to see that

$$e^{-\beta(m + h) - \beta\sigma w/n} \leq A(w) \leq \frac{\exp(-\beta(m + h) - \beta\sigma w/n)}{\exp(-\beta(m + h) - \beta\sigma w/n) + \exp(\beta(m + h) + \beta\sigma w/n - 2\beta/n)}$$

and

$$\frac{e^{\beta(m + h) + \beta\sigma w/n}}{e^{\beta(m + h) + \beta\sigma w/n} + e^{-\beta(m + h) - \beta\sigma w/n}} \leq B(w) \leq \frac{\exp(\beta(m + h) + \beta\sigma w/n)}{\exp(\beta(m + h) + \beta\sigma w/n) + \exp(-\beta(m + h) - \beta\sigma w/n - 2\beta/n)}$$

Therefore

$$A(W) + B(W) = 1 + O(1/n)$$

and

$$A(W) - B(W) = -\tanh(\beta(m + h) + \beta\sigma W/n) + O(1/n).$$
Note that

\[ E(W - W'|\Sigma) \]

\[ = \frac{1}{\sigma} E(\sigma I - \sigma I'|\Sigma) \]

\[ = \frac{2}{\sigma} E(I(\sigma I = 1, \sigma' I = -1) - I(\sigma I = -1, \sigma I = 1)|\Sigma) \]

\[ = \frac{2}{\sigma} \sigma W + \frac{nm}{2n} A(W) I(S - 2 \geq an) - \frac{2}{\sigma} \frac{n - \sigma W - nm}{2n} B(W) I(S + 2 \leq bn) \]

\[ = (A(W) + B(W))(\frac{W}{n} + \frac{m}{\sigma}) + \frac{1}{\sigma} (A(W) - B(W)) - \frac{\sigma W + nm + n}{\sigma n} A(W) I(S - 2 < an) + \frac{n - \sigma W - nm}{\sigma n} B(W) I(S + 2 > bn) \]

\[ = \frac{W}{n} + \frac{m}{\sigma}(1 + O(\frac{1}{n})) - \frac{1}{\sigma} (\tanh(\beta(m + h) + \frac{\beta W}{n}) + O(\frac{1}{n})) \]

\[ - \frac{S + n}{\sigma n} A(W) I(S - 2 < an) + \frac{n - S}{\sigma n} B(W) I(S + 2 > bn) \]

\[ = \lambda(W - R) \]

where

\[ \lambda = \frac{1 - (1 - m^2)\beta}{n} > 0 \]

and

\[ R = \frac{1}{\lambda} \tanh''(\beta(m + h) + \xi)\beta^2 \sigma' W^2 + \frac{1}{\lambda} \frac{S + n}{\sigma n} A(W) I(S - 2 < an) \]

\[ - \frac{1}{\lambda} \frac{n - S}{\sigma n} B(W) I(S + 2 > bn) + O(1)(\frac{W}{n} + \frac{1}{\sigma}) \]

where \( \xi \) is between 0 and \( \beta \sigma W/n \). Similarly,

\[ E((W - W'|\Sigma)^2) \]

\[ = \frac{4}{\sigma^2} E(I(\sigma I = 1, \sigma I = -1) + I(\sigma I = -1, \sigma I = 1)|\Sigma) \]

\[ = \frac{2(1 - m^2)}{\sigma^2} + O(1) \frac{W}{n\sigma} + O(\frac{1}{n\sigma^2}) + O(\frac{1}{\sigma^2}(S - 2 < an \text{ or } S + 2 > bn)). \]

Therefore, recall that \( \sigma^2 = n \frac{1 - m^2}{1 - (1 - m^2)\beta} \).

\[ |E(D|W) - 1| \leq O(\frac{1}{\sqrt{n}})(1 + |W|). \]
For $R$, with $\delta_2 = O(1/\sqrt{n})$,
\[ |E(R|W)| \leq \delta_2(1 + W^2), \]
and if $c_1$ is chosen such that $\delta_2|W| \leq 1/2$, the second alternative of (3.4) is satisfied with $\alpha = 1/2$. Thus from Theorem 3.1 we have the following moderate deviation result for $W$
\[ P(W \geq x) \frac{1}{1 - \Phi(x)} = 1 + O(1)(1 + x^3) \frac{1}{\sqrt{n}} \]
for $0 \leq x \leq n^{1/6}$. This completes the proof of (4.12) and (4.15).

### 6.4. Proof of Proposition 4.5

Since $(1 - \Phi(x)) \geq \frac{1}{2(1 + x^2)} e^{-x^2/2}$ for $x \geq 0$, (4.18) becomes trivial if $x\gamma \geq 1/8$. Thus, we can assume
\[ x\gamma \leq 1/8. \tag{6.36} \]

Let $f = f_x$ be the Stein solution to equation (6.2). Let $W^{(i)} = W - \xi_i$ and $K_i(t) = E\xi_i(I\{0 \leq t \leq \xi_i\} - I\{\xi_i \leq t \leq 0\})$. It is known that (see, for example, [(2.18) in Chen and Shao (2005)])
\[ EWf(W) = \sum_{i=1}^n E \int_{-\infty}^{\infty} f'(W^{(i)} + t)K_i(t)dt. \]
Since $\int_{-\infty}^{\infty} K_i(t)dt = E\xi_i^2$, we have
\[
\begin{align*}
P(W \geq x) - (1 - \Phi(x)) & \quad = \quad EWf(W) - Ef'(W) \\
& \quad = \quad \sum_{i=1}^n E \int_{-\infty}^{\infty} (f'(W^{(i)} + t) - f'(W))K_i(t)dt \\
& \quad = \quad \sum_{i=1}^n E \int_{-\infty}^{\infty} ((W^{(i)} + t)f(W^{(i)} + t) - Wf(W))K_i(t)dt \\
& \quad \quad + \sum_{i=1}^n E \int_{-\infty}^{\infty} (I\{W^{(i)} + t \geq x\} - I\{W \geq x\})K_i(t)dt \\
& \quad := \quad R_1 + R_2. \tag{6.37}
\end{align*}
\]
It suffices to show that
\[ |R_1| \leq C(1 + x^3)\gamma(1 - \Phi(x))e^{x^3\gamma} \tag{6.38} \]
and
\[ |R_2| \leq C(1 + x^2)\gamma(1 - \Phi(x))e^{x^3\gamma}. \tag{6.39} \]

To estimate $R_1$, let $g(w) = (wf(w))'$. It is easy to see that
\[ R_1 = \sum_{i=1}^{n} E \int \int \xi_i g(W^{(i)} + s)dsK_i(t)dt. \tag{6.40} \]

By (6.19) and (6.20), following the proof of (6.21), we have
\[ E g(W^{(i)} + s) \]
\[ = E g(W^{(i)} + s)I\{W^{(i)} + s \geq x\}dt + E g(W^{(i)} + s)I\{W^{(i)} + s \leq 0\} \]
\[ + E g(W^{(i)} + s)I\{0 < W^{(i)} + s < x\} \]
\[ \leq \frac{2}{1 + x^3} P(W^{(i)} + s \geq x) + 2(1 - \Phi(x))P(W^{(i)} + s \leq 0) \]
\[ + \sqrt{2\pi}(1 - \Phi(x))E \left\{ (1 + (W^{(i)} + s)^2)e^{(W^{(i)} + s)^2/2}I\{0 < W^{(i)} + s < x\} \right\} \]
\[ \leq \frac{2}{1 + x^3} P(W^{(i)} \geq x - s) + 2(1 - \Phi(x))P(W^{(i)} + s \leq 0) \]
\[ - \sqrt{2\pi}(1 - \Phi(x))\int_{0}^{x} (1 + y^2)e^{y^2/2}dP(W^{(i)} + s > y) \]
\[ = \frac{2}{1 + x^3} P(W^{(i)} \geq x - s) + 2(1 - \Phi(x))P(W^{(i)} + s \leq 0) \]
\[ + \sqrt{2\pi}(1 - \Phi(x))P(W^{(i)} + s > 0) + \sqrt{2\pi}(1 - \Phi(x))J(s) \]
\[ \leq \frac{2}{1 + x^3} P(W^{(i)} \geq x - s) + \sqrt{2\pi}(1 - \Phi(x)) + \sqrt{2\pi}(1 - \Phi(x))J(s), \]

where
\[ J(s) = \int_{0}^{x} (3y + y^3)e^{y^2/2}P(W^{(i)} + s > y)dy. \tag{6.41} \]

Clearly, for $0 < t \leq x$
\[ E e^{t\xi_i} = 1 + t^2E\xi_i^2/2 + \sum_{k=3}^{\infty} \frac{(t\xi_i)^k}{k!} \]
\[ \leq 1 + t^2E\xi_i^2/2 + \frac{t^3}{6}E|\xi_i|^3 e^{t|\xi_i|} \]
\[ \leq \exp\left( t^2E\xi_i^2/2 + \frac{t^3}{6}E|\xi_i|^3 e^{t|\xi_i|} \right) \]
and hence
\[ Ee^{t(W(i)+s)} \leq \exp(t^2/2 + x|s| + x^3 \gamma/6) \quad \text{for } 0 \leq t \leq x. \] (6.43)

By (6.33), following the proof of Lemma 5.2 yields
\[ J(s) \leq C(1 + x^3) + e^{x^3 \gamma + x|s|} \] (6.44)

Noting that (6.43) also implies that
\[
\begin{align*}
P(W^{(i)} \geq x - s) &\leq e^{-x^2} Ee^{x (W^{(i)} + s)} \leq \exp(-x^2/2 + x|s| + x^3 \gamma) \\
&\leq (1 + x)(1 - \Phi(x)) \exp(x|s| + x^3 \gamma)
\end{align*}
\]
we have
\[ Eg(W^{(i)} + s) \leq C(1 + x^3)(1 - \Phi(x))e^{x^3 \gamma + x|s|} \]
and therefore by (6.40)
\[
|R_1| \leq \sum_{i=1}^{n} E \int_{-\infty}^{\infty} \left| \int_{\xi_i}^{t} g(W^{(i)} + s)ds \right| K_i(t)dt
\leq C(1 + x^3)(1 - \Phi(x))e^{x^3 \gamma} \sum_{i=1}^{n} E \int_{-\infty}^{\infty} |t|e^{x|t|} + |\xi_i|e^{x|\xi_i|}) K_i(t)dt
\leq C(1 + x^3)(1 - \Phi(x))e^{x^3 \gamma}
\] (6.45)

This proves (6.38).

As to \( R_2 \), we apply an exponential concentration inequality of Shao (2010) (see Theorem 2.7 in [30]): for \( a \geq 0 \) and \( b \geq 0 \)
\[
P(x - a \leq W^{(i)} \leq x + b)
\leq Ce^{x^2}(\gamma + b + a)(1 + x) + e^{x^2/2 + x^3 \gamma} \exp(-\gamma^2/2)
\leq Ce^{x^2}(\gamma + b + a)(1 + x) + e^{x^2/2 + x^3 \gamma} \exp(-\gamma^2/2)
\leq Ce^{x^2}(\gamma + b + a)(1 + x) + e^{x^2/2 + x^3 \gamma} \exp(-\gamma^2/2)
\leq Ce^{x^2}(\gamma + b + a)(1 + x) + e^{x^2/2 + x^3 \gamma} \exp(-\gamma^2/2)
\leq C(1 - \Phi(x))e^{x^3 \gamma + x^2}(\gamma + b + a)(1 + x^2) + e^{x^2/2 - \gamma^2/2}.
\]
Here we use the fact that $EW^{(i)}_{x_{i}}e^{x_{i}W^{(i)}} \leq xe^{x^{2}/2+x^{3}/2}$, by following the proof of (6.43). Therefore

\[ R_{2} \leq \sum_{i=1}^{n} E \int_{-\infty}^{\infty} P(x - \xi_{i} \leq W^{(i)} \leq x - t | \xi_{i})K_{i}(t)dt \]

\[ \leq C(1 - \Phi(x))e^{x^{3}/2} \sum_{i=1}^{n} \int_{-\infty}^{\infty} \left\{ (1 + x^{2})E(\gamma + |t| + |\xi_{i}|)e^{x^{2}|\xi_{i}|} + \exp(x^{2} - \gamma^{-2}/32) \right\} K_{i}(t)dt \]

\[ \leq C(1 - \Phi(x))e^{x^{3}/2} \left( (1 + x^{2})\gamma + \exp(x^{2} - \gamma^{-2}/32) \right) \]

\[ \leq C(1 - \Phi(x))e^{x^{3}/2} \]

by (6.36). Similarly, the above bound holds for $-R_{2}$. This proves (6.39).
