Summary

Women with obesity are at risk of pelvic floor dysfunction with a 3-fold increased incidence of urge urinary incontinence (UUI) and double the risk of stress urinary incontinence (SUI). The National Institute for Health and Care Excellence (NICE) and European Association of Urology (EAU) recommend that women with a body mass index \( \geq 30 \text{ kg/m}^2 \) should consider weight loss prior to consideration for incontinence surgery. This systematic review and meta-analysis will assess this recommendation to aid in the counselling of women with obesity-related urinary incontinence (UI). Medical Literature Analysis and Retrieval System online (MEDLINE), EMBASE, Cochrane, ClinicalTrials.gov, and SCOPUS were systematically and critically appraised for all peer reviewed manuscripts that suitably fulfilled the inclusion criteria established a priori and presented original, empirical data relevant to weight loss intervention in the management of urinary incontinence. Thirty-three studies and their outcomes were meta-analysed. Weight loss interventions were associated in a decreased prevalence in UI (OR 0.222, 95% CI [0.147, 0.336]), SUI (OR 0.354, 95% CI [0.256, 0.489]), UUI (OR 0.437, 95% CI [0.295, 0.649]) and improved quality of life (PFDI-20, SMD -0.774 (95% CI [-1.236, -0.312])). This systematic review and meta-analysis provide evidence that weight loss interventions are effective in reducing the prevalence of obesity-related UI symptoms in women. Bariatric surgery in particular shows greater sustained weight loss and improvements in UI prevalence. Further large scale,
1 | INTRODUCTION

Obesity is a growing pandemic, with the World Health Organization (WHO) reporting that obesity has nearly tripled worldwide since 1975.\(^1\) In 2016, more than 1.9 billion adults were overweight (body mass index \(\text{BMI} \geq 25 \text{ kg/m}^2\)), and of these, over 650 million were obese \(\text{BMI} \geq 30 \text{ kg/m}^2\). Obesity is associated with an increased prevalence in multiple non-communicable diseases.\(^1\)

Urinary incontinence (UI) is defined as the involuntary loss of urine\(^2\) and is a common health condition that can significantly affect an individual's quality of life (QoL).\(^3\) Reportedly, approximately 50% of adult women may experience UI,\(^4\) double the prevalence of UI documented in men.\(^5\) This difference in prevalence is due to the structure of the female urinary tract, as well as risk factors such as pregnancy, childbirth, and hysterectomy that can damage the pelvic floor musculature and connective tissue.\(^6\) Obesity is an independent risk factor for urinary storage (leakage) and UI symptoms;\(^7\) such that a 5 points increase of BMI is associated with a 20%-70% increased risk of UI.\(^8\)

Urge urinary incontinence (UUI) is the involuntary leakage of urine associated with urgency whilst stress urinary incontinence (SUI) presents as involuntary leakage with sneezing or coughing.\(^2\) Women with obesity have a 3-fold increased incidence of urge urinary incontinence (UUI) and double the risk of stress urinary incontinence (SUI).\(^7,8\)

In women with obesity, weight loss interventions have been shown to reduce the frequency of UI.\(^7,9-11\) Currently, clinical guidance bodies such as the National Institute for Health and Care Excellence (NICE) and the European Association of Urology (EAU) recommend life-style intervention as the first-line treatment for women with UI and a BMI \(\geq 30 \text{ kg/m}^2\).\(^12\) This encompasses the advice of weight loss through dietary, pharmacological, behavioural therapy interventions, or a combination of these.\(^12\)

Bariatric surgery, including Roux-en-Y gastric bypass (RYBG), Laparoscopic Adjustable Gastric Band (LAGB) and Laparoscopic Vertical Sleeve Gastrectomy (LVS), is a common intervention to treat morbid obesity \(\text{BMI} \geq 40 \text{ kg/m}^2\).\(^13\) but can be an appropriate measure for individuals with a BMI \(\geq 35 \text{ kg/m}^2\) and related co-morbidities such as diabetes and hypertension. Although behavioural intervention studies have shown to produce statistically significant weight loss in participants,\(^14\) bariatric surgery has proven to lead to significantly greater sustained weight loss in patients with obesity compared to non-surgical alternatives.\(^15\)

randomized control trials assessing the effect of bariatric surgery on women with obesity-related UI are needed to confirm this study’s findings.

**KEYWORDS**

bariatric surgery, behaviour modification, meta-analysis, obesity, systematic review, urinary incontinence, weight loss

---

**What is known on the subject?**

- Obesity is a recognized risk factor for UI
- Weight loss has proven to reduce UI and is currently recommended in the form of behavioural interventions.
- Bariatric surgery is known to lead to greater, sustained weight loss in individuals compared to conservative weight loss methods.

**What does this study add?**

- This study aims to clarify the effects of surgically induced weight loss on urinary incontinence and put forward recommendations for further areas of research.

This systematic review and meta-analysis were carried out in order to compare and understand better the effects of surgical and non-surgical weight loss interventions for female obesity-related UI.

2 | METHODOLOGY

This protocol was developed according to the Preferred Reporting Items for Systematic review and Meta-Analysis Protocols (PRISMA-P), and followed methods outlined in The Cochrane Handbook for Systematic Reviews of Interventions.\(^16\) This systematic review has been registered with PROSPERO (International Prospective Register of Systematic Reviews) with ID number 222714.

2.1 | Search strategy

Two reviewers conducted systematic searches of the following databases: Medical Literature Analysis and Retrieval System Online (MEDLINE), Excerpta Medica (EMBASE), Cochrane Central Register of Controlled Trials (CENTRAL), ClinicalTrials.gov, SCOPUS databases. Our key MeSH (Medical Subject Heading) search terms were: “weight loss surgery” OR “bariatric surgery” OR “metabolic surgery” OR “weight
Studies were evaluated on eight factors, categorized into three groups: selection (including whether the cohort is representative of the population), comparability (assessed on grounds of study design and the analysis performed) and outcome (i.e., the assessment of outcome, follow-up rate and adequacy follow-up period).

Stars were awarded per category, with a maximum of four, two and three stars possible for the "selection", "comparability" and "outcome" categories respectively. By following the guidelines of the Newcastle-Ottawa scale, two reviewers assessed the studies to be of poor (3 stars or less), fair (4-6 stars), or good (7-9 stars) quality.

### 2.5 Data synthesis and statistical analysis

All meta-analytical calculations were performed using MedCalc, the same software was used for generating forest plots. Pooled odds ratios (OR) were calculated with 95% confidence intervals (CI) from the extracted data with count data, while pooled standardized mean differences were calculated from the extracted continuous variables, also with 95% CI. The DerSimonian-Laird random-effects model was used in all calculations. Heterogeneity was assessed using Cochran's Q and I² statistics. Subgroup analyses with respect to the type of weight loss intervention were also performed for BMI and weight change differences as well as the count data variables where at least two subgroup data were available. Publication bias was assessed by using Egger's and Begg's tests along with a visual evaluation of the funnel plots when at least ten studies were available.

### 3 RESULTS

Of the 702 references imported for screening, 157 duplicates were removed, leaving 545 articles to be screened against title and abstract, which resulted in 69 papers progressing to a full-text assessment. Due to one sample of patients from the PRIDE study being reported in 5 different articles only Subak et al. was included in the meta-analysis as this paper reported the outcomes of interest of the present study from the first follow up date. The same decision was made for other articles that reported on one sample of patients, including Treacy et al. and Mazoyer et al. along with Leshem et al. and Shimonov et al. The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA-P) flow diagram is shown in Figure 1, outlining the outcomes of the screening process.

The 33 studies included in the present study, comprise studies from 12 different countries, amassing 5616 participants, with an age range of 18-78 across all intervention types, with sample size ranging from 10 to 1565. Table 1 (25 surgical intervention studies) and Table 2 (8 behavioural intervention studies) provide an overview of the studies included in this systematic review, including the assessment of outcomes used in the study, a summary of findings for change in total UI, and weekly UI episodes as well as Newcastle-Ottawa scale quality assessment scores.
3.1 | Meta-analysis of outcomes

3.1.1 | Changes in BMI and weight

The standardized mean difference (SMD) in BMI pre- and post-intervention, of both intervention types, was calculated from 18 studies as \(-1.948\) (95% CI \([-2.363, -1.532]\), \(p < .001, I^2 = 94.10\%\)), as shown in Figure 2(A). After subgroup analysis, surgical interventions showed a statistically significant SMD with the value of \(-2.120\) (95% CI \([-2.543, -1.696]\), \(p < .001, I^2 = 94.07\%\)), whilst the two non-surgical interventions yielded statistically non-significant difference in pre- and post-BMI (SMD \(-0.402\), 95% CI \([-0.880, 0.076]\), \(p = 0.098, I^2 = 0.00\%\)), as shown in Figures 2(B), (C) respectively. For the six studies that reported weight change, SMD for all intervention types was \(-0.803\) (95% CI \([-1.160, -0.446]\), \(p < 0.001, I^2 = 83.74\%\)), see Figure 3. Out of that pool, weight change was reported in two surgical intervention studies (SMD \(-1.615\), 95% CI \([-2.684, -0.546]\), \(p = 0.003, I^2 = 78.76\%\)) and in four behavioural intervention studies (SMD \(-0.545\), 95% CI \([-0.683, -0.407]\), \(p < .001, I^2 = 0.00\%\)).

3.1.2 | Changes in total UI prevalence

A total of 23 studies reported changes in prevalence of UI before and after weight loss interventions. They yielded a significant pooled odds ratio (OR) of \(0.222\) (95% CI [0.147, 0.336], \(p < .001, I^2 = 89.76\%\)), as shown in Figure 4(A). In the subgroup analysis, 18 surgical studies yielded a statistically significant result (OR 0.209, 95% CI [0.148, 0.296], \(p < .001, I^2 = 64.96\%\)), while the result for five non-surgical interventions did not achieve statistical significance (OR 0.746, 95% CI [0.545, 1.020], \(p = .066, I^2 = 52.17\%\)), shown in Figures 4(B), (C) respectively.

3.1.3 | Change in UI prevalence by subtype

Analysis of the total pool of 20 studies that reported prevalence of SUI pre- and post-weight loss intervention, produced a statistically significant pooled OR of \(0.354\) (95% CI [0.256, 0.489], \(p < .001, I^2 = 82.38\%\)), Figure 5(A). The subgroup analysis of 17 surgical
### TABLE 1  Characteristics of Surgical Intervention Studies

| Study          | Country | Type of Surgery                      | Study design and primary outcome                                                                 | Follow-up (Months) | Sample size (n) | Mean (SD) BMI Pre- and Post-Intervention (kg/m²) | Mean (SD) Weight Pre- and Post-Intervention (kg) | Assessment of outcome                                                                 | Change in Urinary Incontinence Prevalence and/or No. of Episodes | NOS Star Award and Assessment of Quality |

### TABLE 2  
Characteristics of Behavioural Intervention studies

| Study | Country | Description of intervention | Study design and primary outcome | Follow-up (Months) | Sample size (n) | Mean (SD) Weight Pre- and Post-Intervention (kg) | Assessment of outcome | Change in Urinary Incontinence Prevalence and/or No. of Episodes | NOS Star Award and Assessment of Quality |
|-------|---------|-------------------------------|---------------------------------|--------------------|----------------|-----------------------------------------------|-----------------------|---------------------------------------------------------------|----------------------------------------|
| Subak 2005<sup>9</sup> | United States | Behavioural modification; Intensive group-based medical and behavioural weight loss program. Low-calorie liquid diet (800 kcals per day or less), increased exercise (60 mins daily), taught standard cognitive & behavioural skills. Weekly group sessions led by a nutritionist, exercise physiologist or behavioural therapist. | Randomised controlled trial assessing change in weekly UI episodes. | 6 | 19 | 99 to 84 | A 7-day voiding diary, HQ, UDI, SF-36, Urodynamic studies | Median (IQR) Episodes per week: Total UI: At baseline: 21 (11-33); At follow up: 4 (2-28); % improvement: 60% (30-89), p = 0.0005. SUI: At baseline: 8 (2-13); At follow up: 0 (0-4); % improvement: 92% (66-100), p = 0.003. UUI: At baseline: 8 (4-20); At follow up: 2 (0-10); % improvement: 70% (16-100), p = 0.03 | Median (IQR) Change in weekly UI episodes: Total UI: At baseline: 21 (11-33); At follow up: 4 (2-28); % improvement: 60% (30-89), p = 0.0005. SUI: At baseline: 8 (2-13); At follow up: 0 (0-4); % improvement: 92% (66-100), p = 0.003. UUI: At baseline: 8 (4-20); At follow up: 2 (0-10); % improvement: 70% (16-100), p = 0.03 |
| Phelan 2012<sup>10</sup> | United States | The Look AHEAD trial promoted weight loss of at least 7% weight loss by the first year; through a low calorie, low fat, and portion-controlled diet as well as weekly exercise (175 minutes). | Randomised controlled trial on the change of weekly UI episodes. | 12 | 1385 | ILI -7.7 (7.0); Control 0.7(5.0) | Validated self-report questions | Weight loss intervention was associated with a 20% reduction in the odds of having UI (OR 0.80, 95% CI 0.65-0.98, p = 0.03), compared with control group. | At follow-up, SUI prevalence was less in ILI group (10.5%) than in the control group (12.8%), (p = 0.07). Intervention decreased the odds of having SUI by 27% (OR 0.73, 95% CI (0.55 - 0.96), p = 0.03). Total UI prevalence at follow-up; intervention group (25.3%) was lower than the control group (28.6%) (p = 0.05). No significant effect between treatment groups (intervention & control) was seen on the 1 year prevalence of urgency UI (p=0.42). |
| Subak 2009<sup>11</sup> | United States | Behavioural modification; PRIDE: Program modelled on Look AHEAD. Calorie and fat restriction of 1200 to 1800 kcal daily, depending on initial weight, with less than 30% of calories from fat. Encouraged to increase exercise to 200 mins per week. Behavioural skills, including self-monitoring, stimulus control, and problem-solving, were emphasised. | Randomised controlled trial on the percentage change in number of incontinence episodes. | 6 | 226 | 98.17 (17) to 90 (17) | 7-day diary of voiding | At baseline, SUI was prevalent in 44 women and UUI prevalence was 104. At follow-up, 32 women (27% reduction) had SUI, and 94 (19% reduction) had UUI. 41% of women in intervention group had >70% reduction in any UI episodes, compared to 22% of control group (p<0.001). Mean No. of UI episodes per week: Total UI: At baseline: 24 (SD 18); At follow up: 13 (SD 15); % change: -47.4% (95% CI, -54 to -40%), p = 0.01. SUI: At baseline: 9 (SD 11); At follow up: 4 (SD 7); % change: -57.6% (95% CI, -67 to -46), p=0.02. UUI: At baseline:14 (SD 14); UUI: WL: 8 (SD 11); % change: -42% (95% CI, -51 to -32), p=0.14 | No significant effect between treatment groups (intervention & control) was seen on the 1 year prevalence of urgency UI (p=0.42). |
| Brown 2006<sup>12</sup> | United States | Behavioural Modification: Included 3 groups: ILI, Metformin at 850 mg 2x daily, or placebo twice daily. Through a low-fat diet and moderate-intensity physical activity for at least 150 min each week, the ILI aimed to lose a minimum of 7% of initial body weight. | Randomised controlled trial on the change in UI prevalence as a result of lifestyle intervention | 36 | 660 | -3.4 (8.2) | Self-reported questionnaire | Prevalence of weekly incontinence episodes at baseline was 48.1%. At follow-up, reduced to 38.3% (p=0.001). Intensive lifestyle intervention was associated with a 20% reduction in the odds (OR 0.80 [95% CI 0.64-1.01]) of weekly SUI episodes compared with placebo. | 8- Good |
| Study              | Country  | Description of intervention | Study design and primary outcome | Follow-up (Months) | Sample size (n) | Mean (SD) BMI Pre- and Post-Intervention (kg/m²) | Mean (SD) Weight Pre- and Post-Intervention (kg) | Assessment of outcome | Change in Urinary Incontinence and/or No. of Episodes | NOS Star |
|-------------------|----------|-----------------------------|---------------------------------|--------------------|----------------|-------------------------------------------------|-------------------------------------------------|---------------------|-----------------------------------------------------|----------|
| Auwad 2008*11     | UK       | Behavioural modification: All participants were offered a commercially run programme of diet and exercise. Anti-obesity medication, Orlistat, was offered to those who did not lose 5% of starting weight within 9 months. | Prospective Cohort study on the incidence of UI episodes. | 20                 | 42             | 36.2 to 31.9                                     | 36.2 to 31.9                                     | 24-h pad test, KHQ, Perineometry, Modified Oxford score. | At Baseline: 6 had mild incontinence, 26 had moderate incontinence and ten had severe incontinence (before weight loss. At Follow-up: 21 had mild leakage, 15 had moderate leakage, and only four had severe leakage (p < 0.001) Mean 24-hr pad test results (by weight): 38.75g at baseline; 18.5g at follow up (p <0.001). Objective urodynamic baseline UI prevalence: SUI-20, UUI-8, MUI- 8. At follow-up, 8 women (40%) with an initial diagnosis of SUI had become continent. | 8- Good  |
| Fjerbaek 2020*2    | Denmark  | Behavioural modification: Four individual dietary counselling session, (one group received 5 sessions), two training session per week for 12 weeks. | Prospective Cohort study assessing UI impact on quality of life after weight loss. | 9                  | 24             | 32.7 (4.54) to 31.2 (4.23) p=0.0001               | 89.29 (12.58) to 85.5 (12.31)                       | ICIQ-SF, PGI-I, 24-hour pad test, PFMS                 | Mean 24-hr pad test results (by weight): 33.11g at baseline; 14.79g at follow up (p <0.180) | 6- Fair   |

interventions for changes in prevalence of SUI was statistically significant for both surgical interventions (OR 0.312, 95% CI [0.235, 0.414], \( p < .001, I^2 = 61.68\% \)) and non-surgical interventions (OR 0.754, 95% CI [0.614, 0.926], \( p = .007, I^2 = 0.00\% \)), shown in Figures 5(B), (C) respectively.

The calculated OR for UUI with regard to any weight loss intervention was statistically significant (OR 0.437, 95% CI [0.295, 0.649], \( p = .001, I^2 = 61.68\% \)) and non-surgical interventions (OR 0.754, 95% CI [0.614, 0.926], \( p = .007, I^2 = 0.00\% \)), shown in Figures 5(B), (C) respectively.

The calculated OR for UUI with regard to any weight loss intervention was statistically significant (OR 0.437, 95% CI [0.295, 0.649], \( p = .001, I^2 = 61.68\% \)) and non-surgical interventions (OR 0.754, 95% CI [0.614, 0.926], \( p = .007, I^2 = 0.00\% \)), shown in Figures 5(B), (C) respectively.

The calculated OR for UUI with regard to any weight loss intervention was statistically significant (OR 0.437, 95% CI [0.295, 0.649], \( p = .001, I^2 = 61.68\% \)) and non-surgical interventions (OR 0.754, 95% CI [0.614, 0.926], \( p = .007, I^2 = 0.00\% \)), shown in Figures 5(B), (C) respectively.

Meanwhile combined analysis of six studies demonstrated changes in mixed UI prevalence (OR 0.330, 95% CI [0.189, 0.576], \( p < .001, I^2 = 59.10\% \)), all of which were surgical interventions, shown in Figure 7.
3.1.4 | Change in questionnaire scores

Several questionnaires were used to assess improvement of urinary function and QoL in the observed studies. Statistically significant results were obtained while calculating SMDs in all questionnaires of interest. For Pelvic Floor Distress Inventory (PFDI-20), the calculated SMD was $-0.774$ (95% CI $[-1.236, -0.312]$, $p = .001$, $I^2 = 93.42\%$), shown in Figure 8(A). For International Consultation on Incontinence Questionnaire Short Form (ICIQ-UI-SF), SMD was $-1.110$ (95% CI $[-1.497, -0.723]$, $p < .001$, $I^2 = 89.68\%$), as shown in Figure 8(B). Finally, for Urinary Distress Inventory (UDI), SMD was $-0.742$ (95% CI $[-0.911, -0.572]$, $p < .001$, $I^2 = 40.10\%$), shown in Figure 8(C).

4 | DISCUSSION

The results of this meta-analysis demonstrate that the prevalence of UI before and after weight loss was significantly reduced (OR 0.222, 95% CI [0.147, 0.336]). Subgroup analysis of interventions showed surgical weight loss interventions were associated with greater reductions in the odds of patients experiencing UI (OR 0.209, 95% CI [0.148, 0.296]) compared with behavioural intervention studies (OR 0.746, 95% CI [0.545, 1.020]).

SUI and UUI prevalence also significantly improved after weight loss (OR 0.354, 95% CI [0.256, 0.489] and OR 0.437, 95% CI [0.295, 0.649], respectively). In addition, comparison of interventions showed patients who underwent weight loss through surgical means, experienced significantly decreased odds ratios in both SUI and UUI prevalence at follow-up (OR 0.312, 95% CI [0.235, 0.414] and OR 0.378, 95% CI [0.259, 0.552] respectively), whilst behavioural interventions showed a weaker improvement in SUI (OR 0.754, 95% CI [0.614, 0.926]) and a non-significant improvement in UUI (OR 0.943, 95% CI [0.661, 1.344]).

The evidence from this meta-analysis showed the studies where bariatric surgery had been performed led to greater reductions in BMI (SMD $-2.120$, 95% CI $[-2.543, -1.696]$), which may explain the greater improvement in UI, SUI, and UUI prevalence, compared with...
behavioural weight loss interventions that demonstrated less significant reductions in BMI (SMD -0.402, 95% CI [−0.880, 0.0761]).

The Patient Reported Outcome Questionnaires included in this study were PFDI-20, ICIQ-UI-SF, and UDI, commonly used to assess UI, the severity of incontinence symptoms and their effects on quality of life. Pooled analysis of these scores showed statistically significant reductions in standardized mean differences of the scores from baseline to follow-up, suggesting that weight loss was associated with a significant improvement in UI prevalence and patient’s quality of life.

Whilst the underlying pathophysiology of UI is multifactorial and its aetiology not completely known, obesity is a recognized risk factor, and a dose-response relationship between increased weight and UI incidence has been observed. A study by Noblet et al. showed a strong correlation between BMI, intra-abdominal pressure and intravesical (bladder) pressure, with a Pearson correlation coefficient value of 0.76 and 0.71, respectively, both p < .0001. It was hypothesised that this increased intra-abdominal pressure increases stress on pelvic floor organs and supporting structures, and that such stress is responsible for the symptoms presented in SUI. Similarly, an increase in abdominal pressure as a result of increased abdominal adiposity, may also be responsible for detrusor instability (detrusor muscle overactivity) which can cause the symptoms of urgency that present in UUI.

A cohort study examining the effects of surgical weight loss interventions highlighted that reduced abdominal adiposity was associated with significant decreases in urinary bladder pressure. The effects of reduced bladder pressure and SUI were observed by Bump et al., in whose study, patients’ intravesical pressure readings were significantly improved at follow-up and associated with a resolution in SUI in 7 of the 10 patients who complained of SUI at baseline.

Traditional management of UUI can include bladder retraining and lifestyle changes, which typically advise avoidance of bladder irritants and reducing overall fluid intake. Both carbonated drinks and caffeinated beverages are considered to be bladder irritants. Following bariatric surgery, patients are advised to avoid bladder irritants and drinking fluids with meals. In a similar way, the dietary changes promoted in behavioural studies involve reduced calorie intake, which is likely to be associated with reduced fluid intake. The
changes in the amount of fluid intake or type of fluids being consumed may be contributing to the observed improvement in UUI symptoms from the weight loss intervention studies, and not due to weight loss alone. Current understanding of the effects of these dietary factors on urgency symptoms would benefit from further research.

The impact on UI severity following weight loss was only reported in four of the included studies assessing bariatric surgery as an intervention. In each, the number of participants experiencing severe UI decreased significantly. For example, in the study conducted by Kuruba et al, 49% of women complained of severe UI at baseline compared with only 13% at 12 months post-surgery. Furthermore, compared with surgical procedures that treat UI symptoms alone, bariatric surgery can provide further health benefits to obesity-related co-morbidities such as diabetes and hypertension, as well as improved mortality. Despite the paucity in evidence that shows

FIGURE 6  Forest plot of OR values of urge urinary incontinence prevalence from all interventions (A), Surgical intervention studies (B) and behavioural (non-surgical) intervention studies (C)

FIGURE 7  Forest plot of OR values of MUI prevalence from all interventions
bariatric surgery-induced weight loss leads to significant improvements in UI severity, it is tenable that women with UI that are diagnosed with severe obesity (BMI $\geq 35$ kg/m$^2$), could be counselled on the plethora of benefits of bariatric surgery.

Adverse effects were not reported in any behavioural studies and only discussed in one study assessing bariatric surgery. Adverse effects of bariatric surgery are well established and vary depending on the type of procedure carried out. Identifying all associated adverse effects is beyond the scope of this study but should nevertheless be taken into account if bariatric surgery is to be considered as a treatment option. In addition, the short-term cost of bariatric surgery, although beyond the scope of this review, is something to be considered. However, by preventing long-term complications of UI and other obesity-related co-morbidities, it would likely prove cost effective in the long-term.

The limitations of the present study include a disproportionally small number of controlled studies assessing surgical weight loss interventions on UI, compared to a large number of behavioural weight loss intervention studies most of which were randomized control trials. This highlights a paucity of randomized controlled trials evaluating the effects of surgical weight loss interventions on female obesity related IU. The lack of comparison groups suggests the evidence provided by these manuscripts may be of low certainty.

Furthermore, there was a lack of consistency among the use of Patient Reported Outcome Questionnaires to evaluate patients’ UI symptoms and QoL. This meant pooled analysis of scores from infrequently used questionnaires such as the IPSS, BFLUTS, SF-36, USP, and Sandvik severity scale could not be completed. Regarding heterogeneity, meta-analysis of study outcomes showed inconsistency was substantial for many of them ($I^2 > 75$%), despite using a random effects model. This heterogeneity was particularly evident across the outcomes of the surgical intervention studies and may be a result of different bariatric surgery techniques being used. Alternatively, this could be a result of inconsistent follow-up times across studies, some of which were likely too short for maximum weight loss to occur, hence limiting the significance of comparability.

The majority of studies used subjective measures for improvement in symptoms such as the common use of Patient Reported Outcome questionnaires$^{9,22,24,26-32,34-52,54}$ and voiding diaries$^{9,18,33,34,53,54}$ which are arguably the most relevant for clinical care. However, compared with objective urodynamic measurements,$^{9,26,29,33,51}$ the results are
subject to patient response bias and their ability to accurately remember and complete these forms of assessment.65

5 | CONCLUSION

This is the first meta-analysis to study both bariatric surgery and behavioural weight loss interventions and their effects on UI, SUI, and UUI. Across all studies, weight loss was observed to be beneficial in improving UI. Specifically, bariatric surgery was associated with significantly reduced UI prevalence and sustained weight loss compared with behavioural interventions. The implication of these results from this study is that weight loss is an effective treatment for UI management in women with obesity. The authors of this paper recommend that more large-scale trials, with more robust study designs, are carried out to determine the relationship (linear or otherwise) between the degree of weight loss and impact on UI, and assess whether bariatric surgery should be offered to women with obesity-related UI, if other non-surgical UI management options have failed.
