Purpose: Laparoscopic hepatectomy has been widely performed by hepatobiliary surgeons for malignancy of liver and gained wide acceptance for various liver tumors, thanks to advances in surgical techniques and devices. But, there are some challenges for right side tumor in patients of cirrhotic liver. Especially, tumor located in right upper area is difficult for wedge resection in patients with marginal liver function, because trans-abdominal approach requires normal parenchymal dissection. Radiofrequency wave ablation is also difficult for such a lesion. So, we demonstrate unique technique of video-assisted transthoracic liver resection (VTLR) for overcome right upper side tumor abutting diaphragm.

Methods: Four patients underwent VTLR. Four ports in right chest wall were created by a chest surgeon and diaphragm was open. Then traction of the diaphragm was done by suture. After exposure of liver surface, tumor localization was done by ultrasound. The mass excision was done by ultrasonic shear.

Results: Four patients were discharged without complications within 11.3 days (range, 6–15 days). On average, patients started to consume a normal diet on an average of 2.4 days (range, 1–4 days).

Conclusion: VTLR is could be performed by an experienced surgeon and chest surgeon for right upper liver malignancy abutting diaphragm in patient of marginal liver function.

INTRODUCTION

Laparoscopic liver resection (LLR) has been very common due to the development of techniques and medical devices since 1992. In 2008, experts in liver surgery established the “Louisville Statement,” a set of guidelines about the rapidly growing area of minimally invasive liver resection. The number of LLRs reported has consistently increased, especially since 2009. Although minor LLRs have been performed usually in clinical practice, reports of major and anatomic LLRs have increased sharply [1,2]. Some specialized centers have reported favorable and competitive outcomes of LLR compared to open liver resection (OLR). Liver cancer lesions located in the right upper lobe of the liver or invading the diaphragm are difficult subjects for LLR. Moreover, in the case of a patient with cirrhosis of Child B and mild ascites, hepatic resection of segment 7 or 8 is more difficult. In this case, LLR unnecessarily removes a large amount of liver parenchyma, reducing the remnant liver volume and also OLR may cause damage to the abdominal wall and cavernous reticulum, resulting in more severe cirrhosis and ascites, and eventually liver failure.

In patients with marginal liver function, no further radiofrequency treatment or trans-arterial chemoembolization (TACE) was possible, and LLR or OLR was not possible. Hepatectomy was attempted through video-assisted transthoracic liver resection...
(VTLR). We report a case of liver resection using the modified Kelly fracture method using Harmonic Scalpel (Ethicon Endo-Surgery, Inc., Cincinnati, OH, USA) ultrasonic shears.

METHODS

All of the procedures were in accordance with the ethical standards of the responsible committees on human experimentation (institutional and national) and with the 1964 Declaration of Helsinki and later versions. This study was approved by the Institutional Review Board of Hallym University Sacred Hospital (registration number: HALLYM 2020-11-003). Between March 2017 and February 2020, patients who underwent VTLR were collected retrospectively from a prospectively established database.

In the cases with moderate liver cirrhosis, radiofrequency ablation, and TACE were not possible due to severe cirrhosis, marginal liver function, or diaphragm invasion, liver resection could be achieved through thoracoscopic approach. The patient was placed left lateral decubitus position with the surgeon standing behind of the patient (Fig. 1). One lung ventilation was required under general anesthesia to perform VTLR. After the injection of sodium fluorescein, the diaphragm adjacent to the area of the sodium fluorescein enhanced lesion visible through the diaphragm was incised, and Vicryl 3-0 (Ethicon Endo-Surgery, Inc.) traction tagging was performed in 3 to 4 places. Additionally, the surgeon identified the location of the lesion and the boundary of the segment using intraoperative ultrasound, then marked the lesion using a monopolar coagulator, and cuts the hepatic parenchyma using the Kelly fracture method with Harmonic Scalpel (Ethicon Endo-Surgery, Inc.) ultrasonic shears. The Glissonean pedicle and hepatic vein is seen on intraoperative ultrasound should be ligated using a metal clip if possible (Fig. 2).

Fig. 2. Procedure of video-assisted transthoracic liver resection. (A) Diaphragm 3-point traction was done. (B, C) After tagging suture for counter traction, the counter traction was performed by assistant. (D) Attention for bleeding from the hepatic vein is required during the modified Kelly fracture method by ultrasonic shear.
right, resection is relatively easy. However, laparoscopic resection of tumors located in the posterior segment, especially in the right upper lobe that invades the diaphragm, is difficult. This is a study to evaluate the technique of performing VTLR for liver malignancy located in right upper area with marginal liver function.

Several studies have shown the usefulness of thoracoscopic liver resection. Excessive bleeding is a major problem in cirrhotic liver resection, and many studies have used coagulation techniques such as microwave tissue coagulation, TissueLink monopolar sealer, or radiofrequency waves [3,4]. In this study, ultrasound was performed before incision of the diaphragm to determine the location of the liver lesion, and thoracoscopic liver resection was performed using the Kelly fracture method using an ultrasonic cutting machine rather than the radiofrequency ablation method. An ultrasonic cutting machine made an incision space for the liver parenchyma through ultrasonic cavitation, and the exposed Glissonean pedicle and hepatic vein were ligated with clips.

In determining the location of the sub-diaphragm tumor, in this study, the location was determined using intraoperative ultrasound before incision of the diaphragm. Recently, intervention-guided fluorescence imaging technique or indocyanine green under infrared light methods to confirm the location of liver tumors are also expected to be utilized [5].

Hepatic resection has been proven to be an effective treatment modality for the treatment of hepatocellular carcinoma and metastatic colorectal cancer [6]. In this study, patients with marginal liver function in the upper right liver segment did not have an accessible hepatic artery through frequent TACE, so TACE was no longer possible. It shows that hepatic resection can be performed by maximally preserving the remaining liver parenchyma through VTLR and securing minimal surgical margin.

CONFLICT OF INTEREST

No potential conflict of interest relevant to this article was reported.
