OPTIMAL CONTROL AND ZERO-SUM STOCHASTIC DIFFERENTIAL GAME PROBLEMS OF MEAN-FIELD TYPE

BOUALEM DJEHICHE AND SAID HAMADÈNE

ABSTRACT. We establish existence of nearly-optimal controls, conditions for existence of an optimal control and a saddle-point for respectively a control problem and zero-sum differential game associated with payoff functionals of mean-field type, under dynamics driven by weak solutions of stochastic differential equations of mean-field type.

1. INTRODUCTION

In this work we investigate existence of an optimal control and a saddle-point for a zero-sum game associated with a payoff functional of mean-field type, under a dynamics driven by the weak solution of a stochastic differential equation (SDE) also of mean-field type. The obtained results extend in a natural way those obtained in [HL95] for standard payoffs associated with standard diffusion processes.

Given a control process \( u := (u_t)_{t \leq T} \) with values in some compact metric space \( U \), the controlled SDE of mean-field type we consider in this paper is of the following functional form:

\[
    dx_t = f(t, x_t, P^u \circ x_t^{-1}, u_t)dt + \sigma(t, x_t)dW^u_t, \quad x_0 = \xi \in \mathbb{R}^d,  
\]

i.e. the \( f \) and \( \sigma \) depend on the whole path \( x \) and \( P^u \circ x_t^{-1} \) (this feature can be improved substantially, see Remark 3.2), the marginal probability distribution of \( x_t \) under the probability measure \( P^u \), and where \( W^u_t \) is a standard Brownian motion under \( P^u \). The payoff

Key words and phrases. mean-field, nonlinear diffusion process, backward SDEs, optimal control, zero-sum game, saddle-point.
functional $J(u)$, $u \in \mathcal{U}$, associated with the controlled SDE is of the form

$$J(u) := E^u \left[ \int_0^T h(t,x,P^u \circ x^{-1},u_t)dt + g(x_T,P^u \circ x^{-1}_T) \right],$$

where $E^u$ denotes the expectation w.r.t. $P^u$.

As an example, the functions $f$, $g$, and $h$ can have the following forms

$$f(t,x,E^u[\varphi_1(x_t)],u_t),g(x,E^u[\varphi_2(x_T)])$$

and $h(t,x,E^u[\varphi_3(x_t)],u_t)$

where $\varphi_i$, $i = 1,2,3$, are bounded Borel-measurable functions.

Taking $h = 0$ and $g(x,y) = \varphi_2(x)^2 - y^2$, the cost functional reduces to the variance,

$$J(u) = E^u[\varphi_2(x_T)^2] - (E^u[\varphi_2(x_T)])^2 = \text{Var}_{P^u}[\varphi_2(x_T)].$$

While controlling a strong solution of an SDE means controlling the process $x^u$ defined on a given probability space $(\Omega, \mathcal{F}, \mathbb{P})$ on which a Brownian motion $W$ is defined exists and $\mathbb{F}$ is its natural filtration, controlling a weak solution of an SDE boils down to controlling the Girsanov density process $L^u := dP^u/dP$ of $P^u$ w.r.t. a reference probability measure $P$ on $\Omega$ such that $(\Omega, \mathcal{F})$ carries a Brownian motion $W$ and such that the coordinates process $x_t$ is the unique solution of the following stochastic differential equation:

$$dx_t = \sigma(t,x) dW_t, \quad x_0 = \xi.$$

Integrating by parts, the payoff functional can be expressed in terms of $L^u$ as follows

$$J(u) = E \left[ \int_0^T L^u_t h(t,x,P^u \circ x^{-1}_t,u_t)dt + L^u_T g(x_T,P^u \circ x^{-1}_T) \right],$$

where $E$ denotes the expectation w.r.t. $P$. For this reason, we do not include a control parameter in the diffusion term $\sigma$.

In the first part of this paper we establish conditions for existence of an optimal control associated with $J(u)$: Find a stochastic process $u^*$ with values in $\mathcal{U}$ such that

$$J(u^*) = \min_{u \in \mathcal{U}} J(u).$$

The recent paper by Carmona and Lacker [CL15] discusses a similar problem but in the so-called mean-field game setting (where they further consider the marginal laws of the control process, i.e., $P^u \circ x^{-1}_t$) which has the following structure (cf. [CL15]):

1. Fix a probability measure $\mu$ on the path space and a flow $\nu : t \mapsto \nu_t$ of measures on the control space;
2. Standard optimization: With $\mu$ and $\nu$ frozen, solve the standard optimal control problem:

$$\inf_u E^u \left[ \int_0^T h(t,x,\mu_u,v,u_t)dt + g(x_T,\mu) \right],$$

$$dx_t = f(t,x,\mu,u_t)dt + \sigma(t,x) dW_t^\mu, \quad x_0 = \xi \in \mathbb{R}^d,$$

i.e. find an optimal control $u$, inject it into the dynamics of (1.2), and find the law $\Phi_\ast(\mu,\nu)$ of the optimally controlled state process and the flow $\Phi_u(\mu,\nu)$ of marginal laws of the optimal control process;
3. Matching: Find a fixed point $\mu = \Phi_x(\mu,\nu), \nu = \Phi_u(\mu,\nu)$.
where the marginal law changes with the control process and is approach see also [BFY13] and the references therein. Overall, to show existence of a fixed point is not an easy task and cannot work in broader frameworks. For further details about the mean-field games approach see also [BFY13] and the references therein.

In this paper we use another approach which in a way addresses the full control problem where the marginal law changes with the control process and is not frozen as in the mean-field game approach. Our strategy goes as follows: By a fixed point argument we first show that for any admissible control \( u \) there exists a unique probability \( P^u \) under which the SDE
\[
dx_t = f(t, x, P^u \circ x_t^{-1}, u_t) dt + \sigma(t, x) dW^u_t, \quad x_0 = \xi \in \mathbb{R}^d,
\]
has a weak solution, where \( W^u \) is a Brownian motion under \( P^u \). Moreover, the mapping which to \( u \) associates \( P^u \) is continuous. Therefore, the mean-field terms which appear in the drift of the above equation and in the payoff functional \( f(u) \) are treated as continuous functions of \( u \). Using this point of view, which avoids the irregularity issues encountered in [CL15], we suggest conditions for existence of an optimal control using backward stochastic differential equations (BSDEs) in a similar fashion the standard control problems, i.e. without mean-field terms. Indeed, if \((Y^u, Z^u)\) is the solution of the BSDE associated with the driver (Hamiltonian) \( H(t, x, z, u) := h(t, x, P^u \circ x_t^{-1}, u_t) + z \cdot \sigma^{-1}(t, x) f(t, x, P^u \circ x_t^{-1}, u_t) \) and the terminal value \( g(x_T, P^u \circ x_T^{-1}) \), we have \( Y^u_0 = f(u) \). Moreover, the unique solution \((Y^*, Z^*)\) of the BSDE associated with
\[
H^*(t, x, z) := \text{ess inf}_{u \in \mathcal{U}} H(t, x, z, u), \quad g^*(x) := \text{ess inf}_{u \in \mathcal{U}} g(x_T, P^u \circ x_T^{-1})
\]
satisfies, under appropriate assumptions, \( Y^*(t) = \text{ess inf}_{u \in \mathcal{U}} Y^u(t) \). The use of the essential infimum over the whole set of admissible controls \( \mathcal{U} \) instead of the infimum of the Hamiltonian \( H \) over the set \( \mathcal{U} \) of actions (as is the case for the standard control problem, as discussed e.g. in [HL95]) is simply due to the fact that the mean-field coupling \( P^u \circ x_t^{-1} \) involves the whole path of the control \( u \) over \([0, T]\) and not only on \( u_t \). This nonlocal feature of the dependence of \( H \) on the control does not seem covered by the powerful Benes’ type ‘progressively’ measurable selection, frequently used in standard control problems. Thus, if there exists \( u^* \in \mathcal{U} \) such that \( H^*(t, x, z) = H(t, x, z, u^*) \) and \( g^*(x) = g(x_T, P^{u^*} \circ x_T^{-1}) \), then \( u^* \) is an optimal control for \( f(u) \). We don’t know of any suitable measurable selection theorem that would guarantee existence of \( u^* \).

The zero-sum game we consider is between two players with controls \( u \) and \( v \) valued in some compact metric spaces \( U \) and \( V \), respectively. The dynamics and the payoff function associated with the game are both of mean-field type and are given by
\[
dx_t = f(t, x, P^{u,v} \circ x_t^{-1}, u_t, v_t) dt + \sigma(t, x) dW^{u,v}_t, \quad x_0 = \xi \in \mathbb{R}^d,
\]
and
\[
f(u, v) := E^{u,v} \left[ \int_0^T h(t, x, P^{u,v} \circ x_t^{-1}, u_t, v_t) dt + g(x_T, P^{u,v} \circ x_T^{-1}) \right],
\]
where \( P^{u,v} \circ x_t^{-1} \) is the marginal probability distribution of \( x_t \) under the probability measure \( P^{u,v} \), \( W^{u,v} \) is a standard Brownian motion under \( P^{u,v} \) and \( E^{u,v} \) denotes the expectation w.r.t. \( P^{u,v} \).
In the zero-sum game, the first player (with control $u$) wants to minimize the payoff $J(u, v)$ while the second player (with control $v$) wants to maximize it. The zero-sum game boils down to investigating the existence of a saddle point for the game i.e. to show existence of a pair $(u^*, v^*)$ of strategies such that

$$J(u^*, v) \leq J(u^*, v^*) \leq J(u, v^*),$$

for each $(u, v)$ with values in $U \times V$. By using the same approach as in the control framework, we show that the game has a saddle-point. The recent paper by Li and Min [LM16] deals with the same zero-sum game for weak solutions of SDEs of the form $(1.1)$, where they apply a similar ‘matching argument’ approach as [CL15]. However, due to the irregularity of the functional which provides the fixed point, they could only show existence of a so-called generalized saddle-point i.e. of a pair of strategies $(u^*, v^*)$ which satisfies (see, for instance, Theorem 5.6 in [LM16])

$$J(u^*, v) - C\psi(v, v^*) \leq J(u^*, v^*) \leq J(u, v^*) + C\psi(u, u^*),$$

where $\psi(u, \bar{u}) := (E[\int_0^T d^2(u_s, \bar{u}_s)ds])^{1/4}$ and $C$ is a positive constant depending only on $f$ and $h$.

Instead of the Wasserstein metric which is by now standard in the literature dealing with mean-field models, because it is designed to guarantee weak convergence of probability measures and convergence of finite moments, in this paper we have chosen to use the total variation as a metric between two probability measures, although it does not guarantee existence of finite moments, simply due to its relationship to the Hellinger distance thanks to the celebrated Csiszár-Kullback-Pinsker inequality (see the bound (4.22), Theorem V.4.21 in [JS03]) which gives a simple and direct proof of existence of a unique probability $P^u$ (resp. $P^{\bar{u}, v}$) under which the SDE $(1.1)$ (resp. $(1.3)$) has a weak solution.

The paper is organized as follows. In Section 3, we account for existence and uniqueness of the weak solution of the SDE of mean-field type. In Section 4, we provide conditions for existence of an optimal control and prove existence of nearly-optimal controls. Finally, in Section 5, we investigate existence of a saddle point for a two-persons zero-sum game.

2. Preliminaries

Let $\Omega := C([0, T]; \mathbb{R}^d)$ be the space of $\mathbb{R}^d$-valued continuous functions on $[0, T]$ endowed with the metric of uniform convergence on $[0, T]$; $|w|_t := \sup_{0 \leq s \leq t} |w_s|$, for $0 \leq t \leq T$. Denote by $\mathcal{F}$ the Borel $\sigma$-field over $\Omega$. Given $t \in [0, T]$ and $\omega \in \Omega$, let $x(t, \omega)$ be the position in $\mathbb{R}^d$ of $\omega$ at time $t$. Denote by $\mathcal{F}^0_t := \sigma(x_s, 0 \leq s \leq t)$, the filtration generated by $x$. Below, $C$ denotes a generic positive constant which may change from line to line.

Let $\sigma$ be a function from $[0, T] \times \Omega$ into $\mathbb{R}^{d \times d}$ such that

(A1) $\sigma$ is $\mathcal{F}^0_t$-progressively measurable;

(A2) There exists a constant $C > 0$ such that

(a) For every $t \in [0, T]$ and $w, \bar{w} \in \Omega$, $|\sigma(t, w) - \sigma(t, \bar{w})| \leq C|w - \bar{w}|_t$.

(b) $\sigma$ is invertible and its inverse $\sigma^{-1}$ satisfies $|\sigma^{-1}(t, w)| \leq C(1 + |w|_t^a)$, for some constant $a \geq 0$.

(c) For every $t \in [0, T]$ and $w \in \Omega$, $|\sigma(t, w)| \leq C(1 + |w|_t)$.
Let $P$ be a probability measure on $\Omega$ such that $(\Omega, P)$ carries a Brownian motion $(W_t)_{0 \leq t \leq T}$ and such that the coordinates process $(x_t)_{0 \leq t \leq T}$ is the unique solution of the following stochastic differential equation:

$$dx_t = \sigma(t, x_t)dW_t, \quad x_0 = \xi \in \mathbb{R}^d. \quad (2.1)$$

Such a triplet $(P, W, x)$ exists due to Proposition 4.6 in ([KS12], p.315) since $\sigma$ satisfies (A2). Moreover, for every $p \geq 1$,

$$E[|x|^p] \leq C_p, \quad (2.2)$$

where $C_p$ depends only on $p, T$, the initial value $\xi$ and the linear growth constant of $\sigma$ (see [KS12], p. 306). Again, since $\sigma$ satisfies (A2), $F_t^P$ is the same as $\sigma\{W_s, s \leq t\}$ for any $t \leq T$. We denote by $F := (F_t)_{0 \leq t \leq T}$ the completion of $(F_t^P)_{t \leq T}$ with the $P$-null sets of $\Omega$.

Let $\mathcal{P}(\mathbb{R}^d)$ denote the set of probability measures on $\mathbb{R}^d$ and $\mathcal{P}_2(\mathbb{R}^d)$ the subset of measures with finite second moment. For $\mu, \nu \in \mathcal{P}(\mathbb{R}^d)$, the total variation distance is defined by the formula

$$d(\mu, \nu) = 2 \sup_{B \in \mathcal{B}(\mathbb{R}^d)} |\mu(B) - \nu(B)|. \quad (2.3)$$

Furthermore, let $\mathcal{P}(\Omega)$ be the space of probability measures $P$ on $\Omega$ and $\mathcal{P}_p(\Omega)$, $p \geq 1$, be the subspace of probability measures such that

$$\|P\|_p^p := \int_{\Omega} |w|^p P(dw) = E[|x|^p] < +\infty,$$

where $|x| := \sup_{0 \leq s \leq t} |x_s|, 0 \leq t \leq T$.

Define on $\mathcal{F}$ the total variation metric

$$d(P, Q) := 2 \sup_{A \in \mathcal{F}} |P(A) - Q(A)|. \quad (2.4)$$

Similarly, on the filtration $\mathcal{F}$, we define the total variation metric between two probability measures $P$ and $Q$ as

$$D_t(P, Q) := 2 \sup_{A \in \mathcal{F}_t} |P(A) - Q(A)|, \quad 0 \leq t \leq T. \quad (2.5)$$

It satisfies

$$D_s(P, Q) \leq D_t(P, Q), \quad 0 \leq s \leq t. \quad (2.6)$$

For $P, Q \in \mathcal{P}(\Omega)$ with time marginals $P_t := P \circ x_t^{-1}$ and $Q_t := Q \circ x_t^{-1}$, the total variation distance between $P_t$ and $Q_t$ satisfies

$$d(P_t, Q_t) \leq D_t(P, Q), \quad 0 \leq t \leq T. \quad (2.7)$$

Indeed, we have

$$d(P_t, Q_t) := 2 \sup_{B \in \mathcal{B}(\mathbb{R}^d)} |P_t(B) - Q_t(B)| = 2 \sup_{B \in \mathcal{B}(\mathbb{R}^d)} |P(x_t^{-1}(B)) - Q(x_t^{-1}(B))| \leq 2 \sup_{A \in \mathcal{F}_t} |P(A) - Q(A)| = D_t(P, Q).$$

Endowed with the total variation metric $D_T$, $\mathcal{P}(\Omega)$ is a complete metric space. Moreover, $D_T$ carries out the usual topology of weak convergence.
3. Diffusion process of mean-field type

Hereafter, a process \( \theta \) from \([0, T] \times \Omega \) into a measurable space is said to be progressively measurable if it is progressively measurable w.r.t. \( \mathcal{F} \). Let \( \mathcal{S}_T^2 \) be the set of \( \mathcal{F} \)-progressively measurable continuous processes \( (\xi_t)_{t \leq T} \) such that \( E[\sup_{t \leq T} |\xi_t|^2] < \infty \) and finally let \( \mathcal{H}_T^2 \) be the set of \( \mathcal{F} \)-progressively measurable processes \( (\theta_t)_{t \leq T} \) such that \( E[\int_0^T |\theta_t|^2 ds] < \infty \).

Let \( \theta \) be a measurable function from \([0, T] \times \Omega \times \mathcal{P}(\mathbb{R}^d) \) into \( \mathbb{R}^d \) such that:

(A3) For every \( Q \in \mathcal{P}(\Omega) \), the process \( ((b(t, x, Q \circ x_t^{-1}))_{t \leq T}) \) is progressively measurable.

(A4) For every \( t \in [0, T], w \in \Omega \) and \( \mu, \nu \in \mathcal{P}(\mathbb{R}^d) \),

\[ |b(t, w, \mu) - b(t, w, \nu)| \leq C d(\mu, \nu). \]

(A5) For every \( t \in [0, T], w \in \Omega \) and \( \mu \in \mathcal{P}(\mathbb{R}^d) \),

\[ |b(t, w, \mu)| \leq C (1 + |w|). \]

Next, for \( Q \in \mathcal{P}(\Omega) \), let \( P^Q \) be the measure on \((\Omega, \mathcal{F})\) defined by

\[ dP^Q := L_t^Q dP \]

with

\[ L_t^Q := \mathcal{E}_t \left( \int_0^t \sigma^{-1}(s, x) b(s, x, Q \circ x_s^{-1}) dW_s \right), \quad 0 \leq t \leq T, \]

where, for any \((F, \mathcal{P})\)-continuous local martingale \( M = (M_t)_{0 \leq t \leq T}, \mathcal{E}(M) \) denotes the Doleans exponential \( \mathcal{E}(M) := \exp (M_t - \frac{1}{2} \langle M \rangle_t)_{0 \leq t \leq T} \). Thanks to assumptions (A2) and (A5), \( P^Q \) is a probability measure on \((\Omega, \mathcal{F})\). A proof of this fact follows the same lines of the proof of Proposition A.1 in \([\text{EKH03}]\). Hence, in view of Girsanov’s theorem, the process \((W_t^Q, 0 \leq t \leq T)\) defined by

\[ W_t^Q := W_t - \int_0^t \sigma^{-1}(s, x) b(s, x, Q \circ x_s^{-1}) ds, \quad 0 \leq t \leq T, \]

is an \((F, P^Q)\)-Brownian motion. Furthermore, under \( P^Q \),

\[ dx_t = b(t, x_t, Q \circ x_t^{-1}) dt + \sigma(t, x_t) dW_t^Q, \quad x_0 = \xi \in \mathbb{R}^d. \]

Furthermore, in view of (A2) and (A5), the Hölder and Burkholder-Davis-Gundy inequalities hold, for every \( p \geq 1 \),

\[ \|P^Q\|_p^p = E_{P^Q} \left[ |x_T|^p \right] \leq C_p \left( 1 + E_{P^Q} \left[ \int_0^T |x_s|^p ds \right] \right). \]

where the constant \( C_p \) depends only on \( p, T, \xi \) and the linear growth constants of \( b \) and \( \sigma \). By Gronwall’s inequality, we obtain

\[ E_{P^Q} \left[ |x_T|^p \right] \leq C_p < +\infty. \]

Next, we will show that there is \( \bar{Q} \) such that \( P^Q = \bar{Q} \), i.e., \( \bar{Q} \) is a fixed point. Moreover, \( \bar{Q} \) has a finite moment of any order \( p \geq 1 \).
Theorem 3.1. The map
\[
\Phi : \mathcal{P}(\Omega) \rightarrow \mathcal{P}(\Omega)
\]
\[
Q \mapsto \Phi(Q) := P^Q; \quad dP^Q := L^Q_t dP
\]
admits a unique fixed point.

Moreover, for every \( p \geq 1 \), the fixed point, denoted \( \bar{Q} \), belongs to \( \mathcal{P}_p(\Omega) \), i.e.
\[
E_Q[|x|^p_T] \leq C_p < +\infty,
\]
where the constant \( C_p \) depends only on \( p, T, \xi \) and the linear growth constants of \( b \) and \( \sigma \).

Proof. We show the contraction property of the map \( \Phi \) in the complete metric space \( \mathcal{P}(\Omega) \), endowed with the total variation distance \( D_T \). To this end, given \( Q, \bar{Q} \in \mathcal{P}(\Omega) \), we use an estimate of the total variation distance \( D_T(\Phi(Q), \Phi(\bar{Q})) \) in terms of a version of the Hellinger process associated with the coordinate process \( x \) under the probability measures \( \Phi(Q) \) and \( \Phi(\bar{Q}) \), respectively. Indeed, since by (3.3),
\[
\begin{cases}
\text{under } \Phi(Q), & dx_t = b(t, x, Q_t) dt + \sigma(t, x) dW_t^Q, \quad x_0 = \xi \in \mathbb{R}^d, \\
\text{under } \Phi(\bar{Q}), & dx_t = b(t, x, \bar{Q}_t) dt + \sigma(t, x) dW_t^{\bar{Q}}, \quad x_0 = \xi \in \mathbb{R}^d,
\end{cases}
\]
in view of Theorem IV.1.33 in [JS03], a version of the associated Hellinger process is
\[
\Gamma_T := \frac{1}{8} \int_0^T \Delta b_t(Q, \bar{Q})^t a_t^{-1} \Delta b_t(Q, \bar{Q}) dt,
\]
where
\[
\Delta b_t(Q, \bar{Q}) := b(t, x, Q_t) - b(t, x, \bar{Q}_t)
\]
and \( a_t := (\sigma \sigma^t)(t, x) \) and \( M^t \) denotes the transpose of the matrix \( M \). We may use the estimate (4.22) of Theorem V.4.21 in [JS03], to obtain
\[
D_T(\Phi(Q), \Phi(\bar{Q})) \leq 8 \sqrt{E_{\Phi(Q)}[\Gamma_T]}.
\]
By (A2), (A4) and (3.4), we have
\[
E_{\Phi(Q)}[\Delta b_t(Q, \bar{Q})^t a_t^{-1} \Delta b_t(Q, \bar{Q})] \leq C d^2(Q_t, \bar{Q}_t) \leq C D_t^2(Q, \bar{Q}),
\]
which together with (3.7) yield
\[
D_T^2(\Phi(Q), \Phi(\bar{Q})) \leq C \int_0^T D_t^2(Q, \bar{Q}) dt.
\]
Iterating this inequality, we obtain, for every \( N > 0 \),
\[
D_T^2(\Phi^N(Q), \Phi^N(\bar{Q})) \leq C^N \int_0^T \frac{(T-t)^{N-1}}{(N-1)!} D_t^2(Q, \bar{Q}) dt \leq \frac{C^N T^N}{N!} D_T^2(Q, \bar{Q}),
\]
where \( \Phi^N \) denotes the \( N \)-fold composition of the map \( \Phi \). Hence, for \( N \) large enough, \( \Phi^N \) is a contraction which entails that \( \Phi \) admits a unique fixed point.

Let \( \bar{Q} \) be such a fixed point for the map \( \Phi \). Thus, under \( \bar{Q} \),
\[
dx_t = b(t, x, \bar{Q}_t) dt + \sigma(t, x) dW_t^{\bar{Q}}, \quad x_0 = \xi \in \mathbb{R}^d,
\]
where \( \bar{Q}_t := \bar{Q} \circ x_t^{-1} \). In view of assumptions (A2) and (A5), the Hölder and Burkholder-Davis-Gundy inequalities yield
\[
\|\bar{Q}\|_p^p = \mathbb{E}_Q \left( |x_t|^p \right) \leq C_p \left( 1 + \mathbb{E}_Q \left( \int_0^T |x_s|^p ds \right) \right).
\]
By Gronwall’s inequality, we obtain (3.5) i.e.
\[
\mathbb{E}_\bar{Q}(|x|^p) \leq C_p < +\infty.
\]

Remark 3.2. The dependence of the drift \( b \) with respect to the law of \( x_t \) under \( Q \), i.e., \( Q \circ x_t^{-1} \) can be relaxed substantially since we can replace this latter by \( Q \circ \phi(t, x)^{-1} \) where \( \phi(t, x) \) is an adapted process. For example one can choose \( \phi(t, x) = \sup_{0 \leq s \leq t} x_s \). The main point is the inequality (2.7) which still hold with a general adapted process \( \phi(t, x) \).

\( \square \)

4. Optimal Control of the Diffusion Process of Mean-Field Type

Let \( (U, \delta) \) be a compact metric space with its Borel field \( \mathcal{B}(U) \) and \( \mathcal{U} \) the set of \( \mathcal{F} \)-progressively measurable processes \( u = (u_t)_{t \leq T} \) with values in \( U \). We call \( \mathcal{U} \) the set of admissible controls.

Next let \( f \) and \( h \) be two measurable functions from \([0, T] \times \Omega \times \mathcal{P}(\mathbb{R}^d) \times U \) into \( \mathbb{R}^d \) and \( \mathbb{R} \), respectively, and \( g \) be a measurable functions from \( \mathbb{R}^d \times \mathcal{P}(\mathbb{R}^d) \) into \( \mathbb{R} \) such that

(B1) For any \( u \in \mathcal{U} \) and \( Q \in \mathcal{P}(\Omega) \), the processes \( (f(t, x, Q \circ x_t^{-1}, u_t))_t \) and \( (h(t, x, Q \circ x_t^{-1}, u_t))_t \) are progressively measurable. Moreover, \( g(x_t, Q \circ x_t^{-1}) \) is \( \mathcal{F}_T \)-measurable.

(B2) For every \( t \in [0, T] \), \( w \in \Omega \), \( u, v \in \mathcal{U} \) and \( \mu, \nu \in \mathcal{P}(\mathbb{R}^d) \),
\[
|\phi(t, w, \mu, u) - \phi(t, w, \nu, v)| \leq C(d(\mu, \nu) + \delta(u, v)).
\]
for \( \phi \in \{f, h, g\} \).

(B3) For every \( t \in [0, T] \), \( w \in \Omega \), \( \mu \in \mathcal{P}(\mathbb{R}^d) \) and \( u \in U \),
\[
|f(t, w, \mu, u)| \leq C(1 + |w|).
\]

(B4) \( h \) and \( g \) are uniformly bounded

For \( u \in \mathcal{U} \), let \( \mathcal{P}^u \) be the probability measure on \( (\Omega, \mathcal{F}) \) which is a fixed point of \( \Phi^u \) defined in the same way as in Theorem 3.1 except that the drift term \( b(\cdot) \) depends moreover on \( u \) but this does not rise a major issue. Thus we have
\[
d\mathcal{P}^u := L^u_t d\mathcal{P},
\]
where
\[
L^u_t := \mathcal{E}_t \left( \int_0^t \sigma^{-1}(s, x) f(s, x, \mathcal{P}^u \circ x_s^{-1}, u_s) dW_s \right), \quad 0 \leq t \leq T.
\]
By Girsanov’s theorem, the process \( (W^u_t, 0 \leq t \leq T) \) defined by
\[
W^u_t := W_t - \int_0^t \sigma^{-1}(s, x) f(s, x, \mathcal{P}^u \circ x_s^{-1}, u_s) ds, \quad 0 \leq t \leq T,
\]
Lemma 4.1. For every \( u \mapsto \) \( L \) \( u \in U \), in particular, the function \( u \mapsto \) \( E^u \) \( |x|^2 \) \( C \) \( < \) \( +\infty \), \( \) \( C \) \( H \) \( \epsilon \) \( \mathbb{R}^d \). Let \( E^u \) denote the expectation w.r.t. \( P^u \). In view of (4.5), we have, for every \( u \in U \),

\[
\| P^u \|_2^2 = E^u \| x \|_2^2 \leq C < +\infty,
\]

where the constant \( C \) depends only on \( T, \xi \) and the linear growth constants of \( f \) and \( \sigma \).

We also have the following estimate of the total variation between \( P^u \) and \( P^v \).

Lemma 4.1. For every \( u, v \in U \), it holds that

\[
D_T(\mathcal{P}^u, \mathcal{P}^v) \leq CE^u \int_0^T \delta^2(u_t, v_t) dt.
\]

In particular, the function \( u \mapsto P^u \) from \( U \) into \( \mathcal{P}_2(\Omega) \) is Lipschitz continuous: for every \( u, v \in U \),

\[
D_T(\mathcal{P}^u, \mathcal{P}^v) \leq C\delta(u, v).
\]

Moreover,

\[
K_T := \sup_{u \in U} \| P^u \|_2 \leq C < \infty,
\]

for some constant \( C > 0 \) that depends only on \( T, \xi \) and the linear growth constants of \( f \) and \( \sigma \).

Proof. Using a similar estimate as (3.7), we have

\[
D_T(\mathcal{P}^u, \mathcal{P}^v) \leq 8\sqrt{E^u \left[ \hat{\Gamma}^u \right]},
\]

where \( \hat{\Gamma} \) is the following version of the Hellinger process associated with \( P^u \) and \( P^v \):

\[
\hat{\Gamma}_T := \frac{1}{8} \int_0^T \Delta f_t(u, v)^t a_t^{-1} \Delta f_t(u, v) dt,
\]

where

\[
\Delta f_t(u, v) := f(t, x, P^u \circ x_t^{-1}, u_t) - f(t, x, P^v \circ x_t^{-1}, v_t).
\]

Using (A2) and (B2), we obtain

\[
\Delta f_t(u, v)^t a_t^{-1} \Delta f_t(u, v) \leq C(\delta^2(P^u \circ x_t^{-1}, P^v \circ x_t^{-1}) + \delta^2(u_t, v_t)) \leq C(D_T^2(\mathcal{P}^u, \mathcal{P}^v) + \delta^2(u_t, v_t)).
\]

Hence, in view of (4.8), Gronwall’s inequality yields

\[
D^2_T(\mathcal{P}^u, \mathcal{P}^v) \leq CE^u \int_0^T \delta^2(u_t, v_t) dt.
\]

Inequality (4.6) follows from (4.5) by letting \( u_t \equiv u \in U \) and \( v_t \equiv v \in U \).

It remains to show (4.7). But, this follows from (4.4) and the continuity of the function \( u \mapsto P^u \) from the compact set \( U \) into \( \mathcal{P}_2(\Omega) \).

The cost functional \( J(u) \), \( u \in U \), associated with the controlled SDE (4.3) is

\[
J(u) := E^u \left[ \int_0^T h(t, x, P^u \circ x_t^{-1}, u_t) dt + g(x_T, P^u \circ x_T^{-1}) \right],
\]

where \( h \) and \( g \) satisfy (B1)-(B4) above.
Any \( u^* \in \mathcal{U} \) satisfying

\[
J(u^*) = \min_{u \in \mathcal{U}} J(u)
\]

is called optimal control. The corresponding optimal dynamics is given by the probability measure \( \tilde{P} \) on \((\Omega, \mathcal{F})\) defined by

\[
dP^* = \mathcal{E} \left( \int_0^T \sigma^{-1}(s, x) f(s, x, P^* \circ x^{-1}_s, u^*_s) dW_s \right) dP,
\]

under which

\[
dx_t = f(t, x, P^* \circ x^{-1}_t, u^*_t) dt + \sigma(t, x) dW^*_t, \quad x_0 = \xi \in \mathbb{R}^d.
\]

We want to find such an optimal control and characterize the optimal cost functional \( J(u^*) \).

For \((t, w, \mu, z, u) \in [0, T] \times \Omega \times \mathcal{P}_2(\mathbb{R}^d) \times \mathbb{R}^d \times \mathcal{U}\) we introduce the Hamiltonian associated with the optimal control problem \((4.3)\) and \((4.9)\)

\[
H(t, w, \mu, z, u) := h(t, w, \mu, u) + z \cdot \sigma^{-1}(t, w) f(t, w, \mu, u).
\]

The function \( H \) satisfies the following properties.

**Lemma 4.2.** Assume that \((A1),(A2), (B1)\) and \((B2)\) hold. Then, the function \( H \) satisfies

\[
|H(t, w, \mu, u) - H(t, w, \nu, v)| \leq C(1 + |w|^\alpha)(1 + |\mu|)(d(\mu, \nu) + \delta(u, v)).
\]

Assume further that \((B3)\) holds. Then \( H \) satisfies the (stochastic) Lipschitz condition

\[
|H(t, w, \mu, z, u) - H(t, w, \mu, z', u)| \leq C(1 + |w|^{1+\alpha})|z - z'|.
\]

**Proof.** Inequality \((4.14)\) is a consequence of \((A2)\) and \((B2)\). Assume further that \((B3)\) is satisfied. Then \((4.15)\) is also satisfied since \( f \) and \( \sigma^{-1} \) are of polynomial growth in \( w \).

Next, we show that the payoff functional \( J(u), u \in \mathcal{U} \), can be expressed by means of solutions of a linear BSDE.

**Proposition 4.3.** Assume that \((A1),(A2), (B1), (B2), (B3)\) and \((B4)\) are satisfied. Then, for every \( u \in \mathcal{U} \), there exists a unique \( \mathcal{F}\)-progressively measurable process \((Y^u, Z^u) \in \mathcal{S}_T^2 \times \mathcal{H}_T^2\) such that

\[
\begin{cases}
-dY_t^u = H(t, x, P^u \circ x^{-1}_t, Z^u_t, u_t) dt - Z^u_t dW_t, & 0 \leq t < T, \\
Y_T^u = g(x_T, P^u \circ x^{-1}_T).
\end{cases}
\]

Moreover, \( Y^u_0 = J(u) \).

**Proof.** The mapping \( p \mapsto H(t, x, P^u \circ x^{-1}_t, p, u_t) \) satisfies \((4.15)\) and \( H(t, x, P^u \circ x^{-1}_t, 0, u_t) = h(t, x, u_t) \) and \( g(x_T, P^u \circ x^{-1}_T) \) are bounded, then by Theorem I-3 in \([HL95]\), the BSDE \((4.16)\) has a unique solution.

It remains to show that \( Y^u_0 = J(u) \). Indeed, in terms of the \((\mathcal{F}, P^u)\)-Brownian motion

\[
W^u_t := W_t - \int_0^t \sigma^{-1}(s, x) f(s, x, P^u \circ x^{-1}_s, u_s) ds, \quad 0 \leq t \leq T,
\]

the process \((Y^u, Z^u)\) satisfies

\[
Y^u_t = g(x_T, P^u \circ x^{-1}_T) + \int_t^T h(s, x, P^u \circ x^{-1}_s, u_s) ds - \int_t^T Z^u_s dW^u_s, \quad 0 \leq t \leq T.
\]
Therefore,
\[ Y_t^u = E^u \left[ \int_t^T h(s, x_s, P^u \circ x^{-1}_s, u_s) ds + g(x_T, P^u \circ x^{-1}_T) | \mathcal{F}_t \right] \quad \text{P}^u\text{-a.s.} \]

In particular, since \( \mathcal{F}_0 \) contains only the \( P \)-null sets of \( \Omega \) and, \( P^u \) and \( P \) are equivalent, then
\[ Y_0^u = E^u \left[ \int_0^T h(s, x_s, P^u \circ x^{-1}_s, u_s) dt + g(x_T, P^u \circ x^{-1}_T) \right] = J(u). \]

\[ \square \]

4.1. **Existence of optimal controls.** In the remaining part of this section we want to find \( u^* \in \mathcal{U} \) such that \( u^* = \arg\min_{u \in \mathcal{U}} J(u) \). A way to find such an optimal control is to proceed as in Proposition 4.3 and introduce a BSDE whose solution \( Y^* \) satisfies \( Y_0^* = \inf_{u \in \mathcal{U}} J(u) = Y_0^u \). By the comparison theorem for BSDEs, the problem can be reduced to minimizing the corresponding Hamiltonian and the terminal value \( g \) w.r.t. the control \( u \). Since in the Hamiltonian \( H(t, x, P^u \circ x^{-1}_t, u_t) \) the marginal law \( P^u \circ x^{-1}_t \) of \( x_t \) under \( P^u \) depends on the whole path of \( u \) over \( [0, t] \) and not only on \( u_t \), we should minimize \( H \) w.r.t. the whole set \( \mathcal{U} \) of admissible stochastic controls. Therefore, we should take the essential infimum of the Hamiltonian over \( \mathcal{U} \), instead of the minimum over \( \mathcal{U} \). Thus, for the associated BSDE to make sense, we should show that it exists and is progressively measurable. This is shown in the next proposition.

Let \( \mathcal{I} \) denote the \( \sigma \)-algebra of progressively measurable sets on \( [0, T] \times \Omega \). For \( (t, x, z, u) \in [0, T] \times C \times \mathbb{R}^d \times \mathcal{U} \), set
\[ H(t, x, z, u) := H(t, x, P^u \circ x^{-1}_t, z, u_t). \] (4.17)

Note that since \( H \) is linear in \( z \) and a progressively measurable process, it is an \( \mathcal{I} \times B(\mathbb{R}^d) \) random variable.

Next we have:

**Proposition 4.4.** For any \( z \in \mathbb{R}^d \), there exists an \( \mathcal{I} \)-measurable process \( H^* (\cdot, \cdot, z) \) such that,
\[ H^*(t, x, z) = \text{ess inf}_{u \in \mathcal{U}} H(t, x, z, u), \quad dP \times dt \text{-a.s.} \] (4.18)

Moreover, \( H^* \) is stochastic Lipschitz continuous in \( z \), i.e., for every \( z, z' \in \mathbb{R}^d \),
\[ |H^*(t, x, z) - H^*(t, x, z')| \leq C(1 + |x|^{1+a})|z - z'|. \] (4.19)

**Proof.** For \( n \geq 0 \) let \( z_n \in Q^d \), the \( d \)-cube of rational numbers. Then, since \( (t, \omega) \mapsto H(t, \omega, z_n, u) \) is \( \mathcal{I} \)-measurable, its essential infimum w.r.t. \( u \in \mathcal{U} \) is well defined i.e. there exists a \( \mathcal{I} \)-measurable r.v. \( H^n \) such that
\[ H^n(t, x, z_n) = \text{ess inf}_{u \in \mathcal{U}} H(t, x, z_n, u). \] (4.20)

Moreover, there exists a countable set \( \mathcal{J}_n \) of \( \mathcal{U} \) such that
\[ H^n(t, x, z_n) = \inf_{u \in \mathcal{J}_n} H(t, x, z_n, u), \quad dP \times dt \text{-a.e.} \]

Finally note that the process \( (t, \omega) \mapsto \inf_{u \in \mathcal{J}_n} H(t, \omega, z_n, u) \) is \( \mathcal{I} \)-measurable.
Next, set \( N = \bigcup_{n \geq 0} N_n \), where
\[
N_n := \{ (t, \omega) : H^n(t, \omega, z_n) \neq \inf_{u \in J_n} H(t, \omega, z_n, u) \}.
\]
Then obviously \( dP \otimes dt(N) = 0 \).

We now define \( H^* \) as follows: For \( (t, \omega) \in N \), \( H^* \equiv 0 \) and for \( (t, \omega) \in N^C \) (the complement of \( N \)) we set:
\[
H^*(t, x, z) = \begin{cases} 
\inf_{u \in J_n} H(t, x, z_n, u) & \text{if } z = z_n \in Q^d, \\
\lim_{n \to z} \inf_{u \in J_n} H(t, x, z_n, u) & \text{otherwise.}
\end{cases}
\]

(4.21)
The last limit exists due to the fact that, for \( n \neq m \), we have
\[
| \inf_{u \in J_n} H(t, x, z_n, u) - \inf_{u \in J_m} H(t, x, z_m, u) |
\]
\[
= | H^n(t, x, z_n) - H^m(t, x, z_m) | = | \text{ess inf}_{u \in U} H(t, x, z_n, u) - \text{ess inf}_{u \in U} H(t, x, z_m, u) |
\]
\[
\leq \text{ess inf}_{u \in U} | \sigma^{-1}(t, x) b(t, x, P^u \circ x_t^{-1}, u) | | z_n - z_m |
\]
\[
\leq C(1 + |x|^1_{n+1}) | z_n - z_m |.
\]
Furthermore, the last inequality implies that the limit does not depend on the sequence \( (z_n)_{n \geq 0} \) of \( Q^d \) which converges to \( z \). Finally note that \( H^*(t, x, z) \) is \( L \otimes B(\mathbb{R}^d) \)-measurable and is Lipschitz-continuous in \( z \) with the stochastic Lipschitz constant \( C(1 + |x|^1_{n+1}) \).

It remains to show that, for every \( z \in \mathbb{R}^d \),
\[
H^*(t, x, z) = \text{ess inf}_{u \in U} H(t, x, z, u), \quad dP \otimes dt\text{-a.e.}
\]
(4.22)
If \( z \in Q^d \), the equality follows from the definitions (4.20) and (4.21). Assume \( z \notin Q^d \) and let \( z_n \in Q^d \) such that \( z_n \to z \). Then
\[
H^*(t, x, z_n) = \text{ess inf}_{u \in U} H(t, x, z_n, u), \quad dP \otimes dt\text{-a.e.}
\]
(4.23)
But, \( H^*(t, x, z_n) \to \inf_{u \in U} H(t, x, z, u) \to_n H^*(t, x, z) \) and
\[
\text{ess inf}_{u \in U} H(t, x, z_n, u) \to_n \text{ess inf}_{u \in U} H(t, x, z, u)
\]
which finishes the proof. \( \square \)

Consider further the \( \mathcal{F}_T \)-measurable random variable
\[
g^*(x) := \text{ess inf}_{u \in U^e} g(x_T, P^u \circ x_T^{-1})
\]
(4.24)
and let \( (Y^*, Z^*) \in \mathcal{S}^2_T \times \mathcal{H}^2_T \) be the solution of the following BSDE
\[
Y^*_t = g^*(x_t) + \int_t^T H^*(s, x_s, Z^*_s) ds - \int_t^T Z^*_s dW_s, \ t \leq T.
\]
(4.25)
The existence of the pair \( (Y^*, Z^*) \) follows from the boundedness of \( g^* \) and \( h^* \), the measurability of \( H^* \) and (4.19) (see [HL95] for more details).

The next proposition displays a comparison result between the solutions \( Y^* \) and \( Y^u, u \in U \) of the BSDEs (4.25) and (4.16), respectively.

**Proposition 4.5 (Comparison).** For every \( t \in [0, T] \), we have
\[
Y^*_t \leq Y^u_t, \quad P\text{-a.s.,} \quad u \in U.
\]
(4.26)
**Proof.** For any $t \leq T$, we have:
\[
Y_t^* - Y_t^u = g^*(x_t) - g(x_T, P^u \circ x_T^{-1}) - \int_t^T (Z_s^* - Z_s^u) dW_s \\
+ \int_t^T \{H^u(s, x_s, Z_s^*) - H(s, x_s, Z_s^u)\} ds \\
+ \int_t^T \{H(s, x_s, Z_s^*, u)\} ds.
\]

Since, $g^*(x_t) - g(x_T, P^u \circ x_T^{-1}) \leq 0$ and $H^u(s, x_s, Z_s^*) - H(t, x_s, Z_s^u) \leq 0$, then, performing a change of probability measure and taking conditional expectation w.r.t. $\mathcal{F}_t$, we obtain $Y_t^* \leq Y_t^u$, P-a.s., $\forall u \in \mathcal{U}$.

**Proposition 4.6 (ε-optimality).** Assume that for any $\epsilon > 0$ there exists $u^\epsilon \in \mathcal{U}$ such that P-a.s.,
\[
\begin{align*}
H^u(t, x_t, Z_t^*) &\geq H(t, x_t, Z_t^u) - \epsilon, \quad 0 \leq t < T, \\
g^*(x_t) &\geq g(x_T, P^u \circ x_T^{-1}) - \epsilon.
\end{align*}
\]
Then,
\[
Y_t^* = \essinf_{u \in \mathcal{U}} Y_t^u, \quad 0 \leq t \leq T.
\]

**Proof.** Let $(Y^\epsilon, Z^\epsilon) \in S_T^2 \times \mathcal{H}_T^2$ be the solution of the following BSDE:
\[
Y_t^\epsilon = g(x_T, P^u \circ x_T^{-1}) + \int_t^T H(s, x_s, Z_s^\epsilon, u^\epsilon) ds - \int_t^T Z_s^\epsilon dW_s.
\]
Once more the existence of $(Y^\epsilon, Z^\epsilon)$ follows from [HL95, Theorem 1.3]. We then have
\[
Y_t^* - Y_t^u = g^*(x_t) - g(x_T, P^u \circ x_T^{-1}) - \int_t^T (Z_s^* - Z_s^u) dW_s \\
+ \int_t^T \{H^u(s, x_s, Z_s^*) - H(s, x_s, Z_s^u)\} ds \\
+ \int_t^T \{H(s, x_s, Z_s^*, u^\epsilon)\} ds.
\]
Since $g^*(x_t) - g(x_T, P^u \circ x_T^{-1}) \geq -\epsilon$ and $H^u(s, x_s, Z_s^*) - H(t, x_s, Z_s^u, u^\epsilon) \geq -\epsilon$, then, once more, performing a change of probability measure and taking conditional expectation w.r.t. $\mathcal{F}_t$, we obtain $Y_t^* \geq Y_t^u - \epsilon(t + 1)$. This entails that, in view of (4.26), for every $0 \leq t \leq T$, $Y_t^* = \essinf_{u \in \mathcal{U}} Y_t^u$.

In next theorem, we characterize the set of optimal controls associated with (4.10) under the dynamics (4.3).

**Theorem 4.7 (Existence of optimal control).** If there exists $u^* \in \mathcal{U}$ such that
\[
\begin{align*}
H^u(t, x_t, Z_t^u) &= H(t, x_t, P^u \circ x_t^{-1}, Z_t^u, u^*), \quad dP \times dt\text{-a.e.}, \quad 0 \leq t < T, \\
g^*(x_t) &= g(x_T, P^u \circ x_T^{-1}), \quad dP\text{-a.s.}
\end{align*}
\]
Then,
\[
Y_t^* = Y_t^{u^*} = \essinf_{u \in \mathcal{U}} Y_t^u, \quad 0 \leq t \leq T.
\]
In particular, $Y_T^* = \inf_{u \in \mathcal{U}} J(u) = J(u^*)$.

**Proof.** Under (4.29), for any $t \leq T$ we have
\[
Y_t^* - Y_t^u = \int_t^T (Z_s^* - Z_s^u) dW_s + \int_t^T \{H(s, x_s, P^u \circ x_s^{-1}, Z_s^u, u^*) - H(s, x_s, P^u \circ x_s^{-1}, Z_s^u, u^*)\} ds \\
+ \int_t^T (Z_s^* - Z_s^u) dW_s + \int_t^T \{H(s, x_s, Z_s^*, u^\epsilon)\} ds.
\]
Making now a change of probability and taking expectation leads to $E[Y_t^* - Y_t^u] = 0$, $\forall t \leq T$ where $E$ is the expectation under the new probability $\bar{P}$ which is equivalent to $P$. 

As \( Y^*_t \leq Y^*_{t} \), \( \mathbb{P} \)-a.s. and then \( \mathbb{P} \)-a.s., we obtain, in taking into account of (4.26), \( Y^* = Y^* \) which means, once more by (4.26), that \( u^* \) is an optimal strategy.

**Remark 4.8.** As is the case for any optimality criteria for systems, obviously checking the sufficient condition (4.29) is quite hard simply because there are no general conditions which guarantee existence of essential minima for systems. One should rather solve the problem in particular cases. In the special case where the marginal law \( P^u \circ x^{-1} \) only depends on \((u_t, x)\) at each time \( t \in [0, T] \), we may minimize \( H \) and \( g \) over the action set \( U \), instead of using the essential infimum, and use Beneš selection theorem \([Ben71]\) to find two measurable functions \( u^*_1 \) from \([0, T] \times \Omega \times \mathbb{R}^d \) into \( U \) and \( u^*_2 \) from \( \mathbb{R}^d \) into \( U \) such that

\[
H^*(t, x, z) := \inf_{u \in U} H(t, x, P^u \circ x^{-1}, z, u) = H(t, x, P^{u^*_1} \circ x^{-1}, z, u^*_1(t, x, z))
\]

and

\[
g^*(x) := \inf_{u \in U} g(x_T, P^u \circ x^{-1}) = g(x_T, P^{u^*_2} \circ x^{-1}).
\]

Combining (4.31) and (4.32), it is easily seen that the progressively measurable function \( u^* \) defined by

\[
\tilde{u}(t, x, z) := \begin{cases} u^*_1(t, x, z), & t < T, \\ u^*_2(x_T), & t = T, \end{cases}
\]

satisfies

\[
H^*(t, x, z) = H(t, x, P^{\tilde{u}} \circ x^{-1}, z, \tilde{u}) \quad \text{and} \quad g^*(x) = g(x_T, P^{\tilde{u}} \circ x^{-1}).
\]

4.2. **Existence of nearly-optimal controls.** As noted above, the sufficient condition (4.29) is quite hard to verify in concrete situations, which makes Theorem (4.7) less useful for showing existence of optimal controls. Nevertheless, near-optimal controls enjoy many useful and desirable properties that optimal controls do not have. In fact, thanks to Ekeland’s variational principle \([Eke74]\), that we will use below, under very mild conditions on the control set \( U \) and the payoff functional \( J \), near-optimal controls always exist while optimal controls may not exist or are difficult to establish. Moreover, there are many candidates for near-optimal controls which makes it possible to select among them appropriate ones that are easier to implement and handle both analytically and numerically.

We introduce the Ekeland metric \( d_E \) on the space \( U \) of admissible controls defined as follows. For \( u, v \in U \),

\[
d_E(u, v) := \mathbb{P}\{ (\omega, t) \in \Omega \times [0, T], \, \delta(u_t(\omega), v_t(\omega)) > 0 \},
\]

where \( \mathbb{P} \) is the product measure of \( P \) and the Lebesgue measure on \([0, T]\).

In our proof of existence of near-optimal controls, we need \( L^p \)-boundedness of the Girsanov density \( L^u \) for some \( p > 1 \), which, according to Theorem 2.2 in \([Hau86]\), is achieved under the following assumption on \( \sigma \) which will replace (A2)-(b),(c).

**Assumption (A6):** \( \sigma(t, x, .) \) and \( \sigma^{-1}(t, x, .) \) are bounded.

We have

**Lemma 4.9.**

(i) \( d_E \) is a distance. Moreover, \((U, d_E)\) is a complete metric space.

(ii) Let \((u^n)_n\) and \( u \) be in \( U \). If \( d_E(u^n, u) \to 0 \) then \( \mathbb{E}[\int_0^T \delta^2(u^n_t, u_t)dt] \to 0 \).
Proof. For a proof of (i), see [EK80]. The proof of completeness of \((\mathcal{U}, d_E)\) needs only completeness of the metric space \((\mathcal{U}, \delta)\).

(ii) Let \((u^n)_n\) and \(u\) be in \(\mathcal{U}\). Then, by definition of the distance \(d_E\), since \(d_E(u^n, u) \to 0\) then \(\delta(u^n_t, u_t)\) converges to 0, \(dP \times dt\)-a.e. Now, since the set \(\mathcal{U}\) is compact, the sequence \(\delta(u^n, u)\) is bounded. Thus, by dominated convergence, we have \(\mathbb{E}[\int_0^T \delta^2(u^n_t, u_t)dt] \to 0\).

**Proposition 4.10.** Assume (A1), (A2)-(a),(A6) and (B1)-(B4). Let \((u^n)_n\) and \(u\) be in \(\mathcal{U}\). If \(d_E(u^n, u) \to 0\) then \(D^2_T(P^{u^n}, P^u) \to 0\). Moreover, for every \(t \in [0,T]\), \(L^2_t\) converges to \(L^2_t\) in \(L^1(P)\).

Proof. In view of Lemma (4.9), we have \(\mathbb{E}[\int_0^T \delta^2(u^n_t, u^n_t)dt] \to 0\). Therefore the sequence \((\int_0^T \delta^2(u^n_t, u^n_t)dt)_{n \geq 0}\) converges in probability w.r.t \(P\) to 0 and by compacity of \(\mathcal{U}\) it is bounded.

On the other hand since \(L^2_t\) is integrable then the sequence \((L^2_T \int_0^T \delta^2(u^n_t, u^n_t)dt)_{n \geq 0}\) converges also in probability w.r.t \(P\) to 0. Next by the uniform boundedness of \((\int_0^T \delta^2(u^n_t, u^n_t)dt)_{n \geq 0}\), the sequence \((L^2_T \int_0^T \delta^2(u^n_t, u^n_t)dt)_{n \geq 0}\) is uniformly integrable. Finally as we have

\[
\mathbb{E}^u[\int_0^T \delta^2(u_t, u^n_t)dt] = \mathbb{E}[L^2_T \int_0^T \delta^2(u_t, u^n_t)dt]
\]

then

\[
\mathbb{E}^u[\int_0^T \delta^2(u_t, u^n_t)dt] \to 0.
\]

Now, to conclude it is enough to use the inequality (4.5).

To prove the last statement, set \(M^n_t := \int_0^t f(s, x_s, P^{u^n} \circ x^{-1}_s, u_s) d\mathcal{W}_s\). In view of (B2), we have

\[
\mathbb{E}[|M^n_t - M^n_t|^2] = \mathbb{E}[\int_0^t |f(s, x_s, P^{u^n} \circ x^{-1}_s, u^n_s) - f(s, x_s, P^u \circ x^{-1}_s, u_s)|^2 ds] \\
\leq C(D_1(P^{u^n}, P^u) + \mathbb{E}[\int_0^T \delta^2(u^n_t, u_t) dt]),
\]

which converge to zero as \(n \to +\infty\).

Furthermore, setting \(f(t, x, u) := f(t, x, P^u \circ x^{-1}_t, u)\), we have

\[
\mathbb{E}[\langle M^n_t \rangle_t - \langle M^n_t \rangle_t] \leq \mathbb{E}[\int_0^t |f(s, x_s, u^n_s) - f(s, x_s, u)| \langle \mathbb{E}[\int_0^T |f(s, x_s, u^n_s) - f(s, x_s, u)|^2] \rangle^{1/2}] ds] \\
\leq C(D_1(P^{u^n}, P^u) + \mathbb{E}[\int_0^T \delta^2(u^n_t, u_t) dt])^{1/2} \mathbb{E}[\int_0^T (1 + |x^2_s|) ds]^{1/2}
\]

which converge to zero as \(n \to +\infty\). Therefore, \(L^2_t\) converges to \(L^2_t\) in probability w.r.t. \(P\).

But, by Theorem 2.2 in [Hau86], under (A6) and (B3), \((L^2_t(u^n))_n\) is uniformly integrable. Thus, \(L^2_t(u^n)\) converges to \(L^2_t(u)\) in \(L^1(P)\) when \(n \to +\infty\).

**Proposition 4.11.** For any \(\varepsilon > 0\), there exists a control \(u^\varepsilon \in \mathcal{U}\) such that

\[
J(u^\varepsilon) \leq \inf_{u \in \mathcal{U}} J(u) + \varepsilon. \tag{4.36}
\]

\(u^\varepsilon\) is called near or \(\varepsilon\)-optimal for the payoff functional \(J\).

Proof. The result follows from Ekeland’s variational principle, provided that we prove that the payoff function \(J\), as a mapping from the complete metric space \((\mathcal{U}, d_E)\) to \(\mathbb{R}\), is lower bounded and lower-semicontinuous. Since \(f\) and \(g\) are assumed uniformly bounded, \(J\) is obviously bounded. We now show continuity of \(J\): \(J(u^n)\) converges to \(J(u)\) when
\[ J(u) = E\left[\int_0^T L_t^u h(t, x, P^u \circ x_t^{-1}, u_t) dt + L_T^u g(x_T, P^u \circ x_T^{-1})\right]. \]

Using the inequality
\[ |L_t^u h(t, x, u^n) - L_t^u h(t, x, u)| \leq |L_t^u h(t, x, u^n) - L_t^u h(t, x, u)| + |L_t^u h(t, x, u)| - |h(t, x, u^n) - h(t, x, u)| \]
and (B3) together with the boundedness of \( L_t^u \), by Proposition (4.10), \( E[\int_0^T L_t^u h(t, x, P^u \circ x_t^{-1}, u_t) dt] \) converges to \( E[\int_0^T L_t^u h(t, x, P^u \circ x_t^{-1}, u_t) dt] \) as \( d_E(u^n, u) \to 0 \). A similar argument yields convergence of \( E[L_T^u g(x_T, P^u \circ x_T^{-1})] \) to \( E[L_T^u g(x_T, P^u \circ x_T^{-1})] \) when \( d_E(u^n, u) \to 0 \). \( \square \)

5. The zero-sum game problem

In this section we consider a two-players zero-sum game. Let \( \mathcal{U} \) (resp. \( \mathcal{V} \)) be the set of admissible \( U \)-valued (resp. \( V \)-valued) control strategies for the first (resp. second) player, where \( (\mathcal{U}, \delta_1) \) and \( (\mathcal{V}, \delta_2) \) are compact metric spaces.

For \( (u, v), (\bar{u}, \bar{v}) \in \mathcal{U} \times \mathcal{V} \), we set
\[ \delta((u, v), (\bar{u}, \bar{v})) := \delta_1(u, \bar{u}) + \delta_2(v, \bar{v}). \tag{5.1} \]
The distance \( \delta \) defines a metric on the compact space \( \mathcal{U} \times \mathcal{V} \).

Let \( f \) and \( h \) be two measurable functions from \([0, T] \times \Omega \times \mathcal{P}_2(\mathbb{R}^d) \times \mathcal{U} \times \mathcal{V}\) into \( \mathbb{R}^d \) and \( \mathbb{R} \), respectively, and \( g \) be a measurable function from \( \mathbb{R}^d \times \mathcal{P}_2(\mathbb{R}^d) \) into \( \mathbb{R} \) such that

(C1) For any \( (u, v) \in \mathcal{U} \times \mathcal{V} \) and \( Q \in \mathcal{P}_2(\Omega) \), the processes \( (f(t, x, Q \circ x_t^{-1}, u_t, v_t))_t \) and \( (h(t, x, Q \circ x_t^{-1}, u_t, v_t))_t \) are progressively measurable. Moreover, \( g(x_t, Q \circ x_t^{-1}) \) is \( \mathcal{F}_T \)-measurable.

(C2) For every \( t \in [0, T] \), \( w \in \Omega \), \((u, v), (\bar{u}, \bar{v}) \in \mathcal{U} \times \mathcal{V} \) and \( \mu, v \in \mathcal{P}(\mathbb{R}^d) \),
\[ |\phi(t, w, \mu, u, v) - \phi(t, w, \mu, \bar{u}, \bar{v})| \leq C(d(\mu, v) + \delta((u, v), (\bar{u}, \bar{v}))), \]
for \( \phi \in \{f, h, g\} \).

(C3) For every \( t \in [0, T] \), \( w \in \Omega \), \( \mu \in \mathcal{P}(\mathbb{R}^d) \) and \((u, v) \in \mathcal{U} \times \mathcal{V} \),
\[ |f(t, w, \mu, u, v)| \leq C(1 + |w|_t). \]

(C4) \( h \) and \( g \) are uniformly bounded.

For \((u, v) \in \mathcal{U} \times \mathcal{V} \), let \( P^{u,v} \) be the probability measure on \( (\Omega, \mathcal{F}) \) defined by
\[ dP^{u,v} := L_t^{u,v}dP, \tag{5.2} \]
where
\[ L_t^{u,v} := \mathcal{E}_t \left( \int_0^t \sigma^{-1}(s, x)f(s, x, P^{u,v} \circ x_s^{-1}, u_s, v_s)dW_s \right), \quad 0 \leq t \leq T. \tag{5.3} \]
The proof of existence of $P^{\mu,\nu}$ follows the same lines as the one of $P^{\mu}$ defined in (4.1)-(4.2). Hence, by Girsanov’s theorem, the process $(W^{\mu,\nu}_t, 0 \leq t \leq T)$ defined by

$$W^{\mu,\nu}_t := W_t - \int_0^t \sigma^{-1}(s, x) f(s, x, P^{\mu,\nu} \circ x^{-1}_s, u_s, v_s) ds, \quad 0 \leq t \leq T,$$

is an $(\mathbb{F}, P^{\mu,\nu})$-Brownian motion. Moreover, under $P^{\mu,\nu}$,

$$dx_t = f(t, x, P^{\mu,\nu} \circ x^{-1}_t, u_t, v_t) dt + \sigma(t, x) dW^{\mu,\nu}_t, \quad x_0 = \xi \in \mathbb{R}^d. \quad (5.4)$$

Let $E^{\mu,\nu}$ denote the expectation w.r.t. $P^{\mu,\nu}$. The payoff functional $J(u, v)$, $(u, v) \in \mathcal{U} \times \mathcal{V}$, associated with the controlled SDE (5.4) is

$$J(u, v) := E^{\mu,\nu} \left[ \int_0^T h(t, x, P^{\mu,\nu} \circ x^{-1}_t, u_t, v_t) dt + g(x_T, P^{\mu,\nu} \circ x^{-1}_T) \right]. \quad (5.5)$$

The zero-sum game we consider is between two players, where the first player (with control $u$) wants to minimize the payoff (5.5), while the second player (with control $v$) wants to maximize it. The zero-sum game boils down to showing existence of a saddle-point for the game i.e. to show existence of a pair $(u^*, v^*)$ of strategies such that

$$J(u^*, v) \leq J(u^*, v^*) \leq J(u, v^*) \quad (5.6)$$

for each $(u, v) \in \mathcal{U} \times \mathcal{V}$. The corresponding dynamics is given by the probability measure $P^*$ on $(\Omega, \mathcal{F})$ defined by

$$dP^* = E_T \left( \int_0^T \sigma^{-1}(s, x) f(s, x, P^* \circ x^{-1}_s, u^*_s, v^*_s) dW_s \right) dP \quad (5.7)$$

under which

$$dx_t = f(t, x, P^* \circ x^{-1}_t, u^*_t, v^*_t) dt + \sigma(t, x) dW^{\mu,\nu}_{t}, \quad x_0 = \xi \in \mathbb{R}^d. \quad (5.8)$$

For $(u, v) \in \mathcal{U} \times \mathcal{V}$ and $z \in \mathbb{R}^d$, we introduce the Hamiltonian associated with the game (5.4)-(5.5):

$$H(t, x, z, u, v) := z \cdot \sigma^{-1}(t, x) f(t, x, P^{\mu,\nu} \circ x^{-1}_t, u_t, v_t) + h(t, x, P^{\mu,\nu} \circ x^{-1}_t, u_t, v_t). \quad (5.9)$$

Next, set

- $\mathcal{H}(t, x, z) := \text{ess sup}_{u \in \mathcal{U}} \text{ess inf}_{v \in \mathcal{V}} H(t, x, z, u, v)$,
- $\overline{H}(t, x, z) := \text{ess inf}_{u \in \mathcal{U}} \text{ess sup}_{v \in \mathcal{V}} H(t, x, z, u, v)$,
- $\underline{g}(x) := \text{ess sup}_{v \in \mathcal{V}} \text{ess inf}_{u \in \mathcal{U}} g(x_T, P^{\mu,\nu} \circ x^{-1}_T)$,
- $\overline{g}(x) := \text{ess inf}_{u \in \mathcal{U}} \text{ess sup}_{v \in \mathcal{V}} g(x_T, P^{\mu,\nu} \circ x^{-1}_T)$.

As in Proposition 4.3, $\mathcal{H}$, $\overline{H}$, $\underline{g}$ and $\overline{g}$ exist. On the other hand following a similar proof as the one leading to (4.19), $\mathcal{H}(t, x, z)$ and $\overline{H}(t, x, z)$ are stochastic Lipschitz continuous in $z$ with the Lipschitz constant $C(1 + |x|^{1+\alpha})$.

Let $(Y, Z)$ be the solution of the BSDE associated with $(\mathcal{H}, \underline{g})$ and $(\overline{Y}, \overline{Z})$ the solution of the BSDE associated with $(\overline{H}, \overline{g})$. 

Definition 5.1 (Isaacs’ condition). We say that the Isaacs’ condition holds for the game if
\[
\begin{align*}
H(t, x, z) &= \overline{H}(t, x, z), \quad z \in \mathbb{R}^d, \quad 0 \leq t \leq T,
\mathcal{G}(x) &= \overline{\mathcal{G}}(x),
\end{align*}
\]
Applying the comparison theorem for BSDEs and then uniqueness of the solution, we obtain the following

Proposition 5.2. For every \( t \in [0, T] \), it holds that \( \underline{Y}_t \leq \overline{Y}_t \), P-a.s. Moreover, if the Issac’s condition holds, then
\[
\underline{Y}_t = \overline{Y}_t := Y_t, \quad P\text{-a.s.}, \quad 0 \leq t \leq T. \tag{5.10}
\]

In the next theorem, we formulate conditions for which the zero-sum game has a value. For \((u, v) \in \mathcal{U} \times \mathcal{V}\), let \((Y_{u,v}^{\mathcal{U}, \mathcal{V}}, Z_{u,v}^{\mathcal{U}, \mathcal{V}}) \in \mathcal{S}_T^2 \times \mathcal{H}_T^2\) be the solution of the BSDE
\[
\begin{align*}
-dY_{t,v}^{u,v} &= H(t, x, Z_{t,v}^{u,v}, u, v)dt - Z_{t,v}^{u,v}dW_t, \quad 0 \leq t < T,
Y_{T,v}^{u,v} &= g(x_T, P^{u,v}_T \circ x_T^{-1}),
\end{align*}
\] (5.11)

Theorem 5.3 (Existence of a value of the zero-sum game). Assume that, for every \( t \in [0, T] \),
\[
H(t, x, Z_t) = \overline{H}(t, x, Z_t). \tag{5.12}
\]
If there exists \((u^*, v^*) \in \mathcal{U} \times \mathcal{V}\) such that, for every \( 0 \leq t < T \),
\[
H(t, x, Z_t) = \text{ess inf}_{u \in \mathcal{U}} H(t, x, Z_t, u, v^*) = \text{ess sup}_{v \in \mathcal{V}} H(t, x, Z_t, u^*, v), \tag{5.13}
\]
and
\[
\mathcal{G}(x.) = \overline{\mathcal{G}}(x.) = \text{ess inf}_{u \in \mathcal{U}} \mathcal{G}(x_T, P^{u,v^*}_T \circ x_T^{-1}) = \text{ess sup}_{v \in \mathcal{V}} \mathcal{G}(x_T, P^{u^*, v}_T \circ x_T^{-1}). \tag{5.14}
\]
Then,
\[
Y_t = \text{ess inf}_{u \in \mathcal{U}} \text{ess sup}_{v \in \mathcal{V}} Y_{t,v}^{u,v} = \text{ess sup}_{v \in \mathcal{V}} \text{ess inf}_{u \in \mathcal{U}} Y_{t,v}^{u,v}, \quad 0 \leq t \leq T. \tag{5.15}
\]
Moreover, the pair \((u^*, v^*)\) is a saddle-point for the game.

Proof. First note that we can replace in (5.12) \( Z \) by \( \overline{Z} \) and the result still holds. So assume that \( H(t, x, Z_t) = \overline{H}(t, x, Z_t) \). Then by the uniqueness of the solution of the BSDEs associated with \((H, \mathcal{G})\) and \((\overline{H}, \overline{\mathcal{G}})\) we have \((\underline{Y}, \overline{Z}) = (\overline{Y}, \overline{Z})\).

On the other hand, by (5.13)-(5.14) one can easily check that the pair \((u^*, v^*)\) satisfies a saddle-point property for \( H \) and \( \mathcal{G} \) as well, i.e.,
\[
H(t, x, Z_t, u^*, v^*) \leq H(t, x, Z_t, u, v^*), \quad u \in \mathcal{U}, \quad 0 \leq t < T
\]
and
\[
\mathcal{G}(x_T, P^{u^*, v}_T \circ x_T^{-1}) \leq \mathcal{G}(x_T, P^{u^*, v}_T \circ x_T^{-1}) \leq \mathcal{G}(x_T, P^{u^*, v}_T \circ x_T^{-1}).
\]
The previous equalities and the uniqueness of the solutions of the BSDEs imply that \( \underline{Y}_t = \overline{Y}_t = Y_{t,v}^{u^*, v^*} \).

Now let \((u, v) \in \mathcal{U} \times \mathcal{V}\) and, \((\hat{Y}_u^{\mathcal{U}}, \hat{Z}_u^{\mathcal{U}}), (\overline{Y}_v^{\mathcal{V}}, \overline{Z}_v^{\mathcal{V}})\) be the solutions of the following BSDEs:
\[
\begin{align*}
-d\hat{Y}_t^{u,v} &= \text{ess sup}_{v \in \mathcal{V}} H(t, x, \hat{Z}_t^{u,v}, u, v)dt - \hat{Z}_t^{u,v}dW_t, \quad 0 \leq t < T,
\hat{Y}_T^{u,v} &= \text{ess sup}_{v \in \mathcal{V}} \mathcal{G}(x_T, P^{u,v}_T \circ x_T^{-1}),
\end{align*}
\] (5.16)
Also, $Y$ satisfies

\begin{align}
-d\hat{Y}_t^u &= \essinf_{v \in \mathcal{V}} H(t, x, \hat{Z}_t^u, u, v) dt - \hat{Z}_t^u dW_t, \quad 0 \leq t < T, \\
\hat{Y}_T^u &= \essinf_{v \in \mathcal{V}} g(x_T, P^{u,v} \circ x^{-1}).
\end{align}

(5.17)

Then by comparison we have

\[ \hat{Y}_t^u \geq Y_t^{u^*, v} \quad \text{and} \quad \hat{Y}_t^{v^*} \leq Y_t^{u, v^*}. \]

(5.18)

But $\hat{Y}_t^u$ satisfies the following BSDE:

\begin{align}
-d\hat{Y}_t^u &= \esssup_{v \in \mathcal{V}} H(t, x, \hat{Z}_t^u, u^*, v) dt - \hat{Z}_t^u dW_t, \quad 0 \leq t < T, \\
\hat{Y}_T^u &= \esssup_{v \in \mathcal{V}} g(x_T, P^{u^*, v} \circ x^{-1}).
\end{align}

(5.19)

Taking into account of (5.13)-(5.14) and since the solution of the previous BSDE is unique, we obtain that

\[ Y_t^u = Y_t^{u^*, v^*} = \hat{Y}_t^u. \]

Moreover, (5.18) implies that $Y_t^{u^*, v^*} \geq Y_t^{u^*, v}$ for any $v \in \mathcal{V}$. But in the same way we have also $Y_t^u = Y_t^{u^*, v^*} = \hat{Y}_t^{v^*} \leq Y_t^{u^*, v^*}$, $\mathcal{P}$-a.s., for any $u \in \mathcal{U}$. Therefore,

\[ Y_t^{u^*, v^*} \leq Y_t^{u, v^*} \leq Y_t^{u^*, v^*}. \]

Thus, $(u^*, v^*)$ is a saddle-point of the game and $Y_t^u = Y_t^{u^*, v^*}$ is the value of the game, i.e., it satisfies

\[ Y_t^{u^*, v^*} = Y_t = \essinf_{u \in \mathcal{U}} \esssup_{v \in \mathcal{V}} Y_t^{u, v} = \esssup_{v \in \mathcal{V}} \essinf_{u \in \mathcal{U}} Y_t^{u, v}, \quad 0 \leq t \leq T. \]

Final remark Assumptions (B4) and (C4) on the boundedness of the functions $g$ and $h$ can be substantially weakened by using subtle arguments on existence and uniqueness of solutions of one dimensional BSDEs which are by now well known in the BSDEs literature.
