Abstract

Opinion summarization research has primarily focused on generating summaries reflecting important opinions from customer reviews without paying much attention to the writing style. In this paper, we propose the stylized opinion summarization task, which aims to generate a summary of customer reviews in the desired (e.g., professional) writing style. To tackle the difficulty in collecting customer and professional review pairs, we develop a non-parallel training framework, Noisy Pairing and Partial Supervision (Napa), which trains a stylized opinion summarization system from non-parallel customer and professional review sets. We create a benchmark PROSUM by collecting customer and professional reviews from Yelp and Michelin. Experimental results on PROSUM and FewSum demonstrate that our non-parallel training framework consistently improves both automatic and human evaluations, successfully building a stylized opinion summarization model that can generate professionally-written summaries from customer reviews.1

1 Introduction

Opinion summarization, which focuses on automatically generating textual summaries from multiple customer reviews, has received increasing attention due to the rise of online review platforms. Different from single-document summarization tasks (e.g., news summarization), which can easily collect a large amount of document-summary pairs, manually creating summaries from multiple reviews is expensive; it is not easy to collect large-scale training data for opinion summarization. To address this challenge, existing studies build pseudo-reviews-summary pairs in a self-supervised fashion (Chu and Liu, 2019; Amplayo and Lapata, 2020; Suhara et al., 2020; Amplayo et al., 2021; Iso et al., 2021) or use a small amount of reviews-summary pairs in a few-shot manner (Bražinskas et al., 2020a; Oved and Levy, 2021; Iso et al., 2022) to train opinion summarization models.

However, existing opinion summarization systems have focused on summarizing important opinions in reviews while not paying much attention to the writing style. They leverage customer reviews as pseudo summaries to train models, which generate summaries in the same writing style as the customer reviews as illustrated in Figure 2. On the other hand, professional reviews, such as Michelin Guide—a prestigious and popular restaurant guide, use a quite different writing style to describe the same type of information.

In this paper, we aim to fill this gap between customer and professional reviews by proposing a new branch of opinion summarization—stylized opinion summarization, where the goal is to generate a summary of opinions in the desired writing style. Specifically, besides customer reviews, as the input to the conventional opinion summarization task, we use a few example summaries in the desired writing style.

![Figure 1: Comparison of conventional and stylized opinion summarization. Given multiple reviews as input, stylized opinion summarization aims to generate a summary in the desired writing style.](image-url)
style as auxiliary information to guide the model in learning the writing style. Since a few summaries in the desired writing style may not cover the same entities (e.g., restaurants) as the customer review set, the two review sets for the stylized opinion summarization task are non-parallel, which makes the task more challenging.²

To this end, we develop a non-parallel training framework, Noisy Pairing and Partial Supervision (Napa♥), which builds a stylized opinion summarization model from non-parallel customer and professional review sets. The core idea consists of two functions: Noisy Pairing (§4.1) creates pseudo “noisy” reviews-summary pairs forcibly for each summary in the desired writing style by obtaining input reviews similar to the summary. Then, Partial Supervision (§4.2) trains a model with the collected noisy pairs by focusing on the sub-sequence of the summary that can be reproduced from the input reviews while not learning to hallucinate non-existing content. Figure 2 illustrates the two functions. In this example, for a professionally-written review of a sushi restaurant, Noisy Pairing finds reviews of a steak restaurant as noisy source reviews, which are then partially used by Partial Supervision to train a stylized opinion summarization model.

We also create and release a benchmark for stylized opinion summarization named PROSUM, which consists of 700 paired Yelp reviews and Michelin point-of-views. Experimental results on PROSUM confirm that Napa♥ successfully generates summaries in the desired writing style in a non-parallel training setting, significantly better than models trained by self-supervision and existing non-parallel training methods.

We further performed additional experiments using existing supervised opinion summarization benchmarks, FewSum (Bražinskas et al., 2020a), in a non-parallel setting. We observed that Napa♥ brings significant gains over self-supervised systems and competitive performance with state-of-the-art supervised systems, indicating the generalizability of the proposed method.

2 The PROSUM Corpus

Data Collection We build a stylized opinion summarization dataset, PROSUM, which pairs customer reviews and professional reviews about the same restaurant, as we need customer reviews as the input and a professional review as the summary for evaluation purposes.

We first collected 700 professionally-written restaurant reviews from guide.michelin.com, a famous restaurant review site. Unlike crowd-sourced opinion summaries, these reviews are written by professional writers. Thus, they include more appealing expressions and attractive information than crowd-sourced summaries. Then, we collected customer reviews from a popular customer review platform, yelp.com, by asking crowdsourced workers from Appen³ to find the same restaurant for each of the restaurants we collected in the first step. We collected up to 5,000 customer reviews for each restaurant.

Filtering Since our main focus is to create a stylized opinion summarization benchmark and thousands of input reviews cannot be handled by most pre-trained language models, we filtered source customer reviews to reduce the number of input

³https://appen.com/
reviews to a size that can be handled by commonly used pre-trained language models.

For each reviews-summary pair, we selected source Yelp reviews so that the coverage of the target Michelin review was maximized. Specifically, we use the sum of the ROUGE-1/2 Recall scores between the selected source Yelp reviews and the target Michelin review to measure the coverage. We incrementally added source reviews until the total length exceeded 1,024 words to maximize the coverage in a greedy manner. On average, 6.7 input reviews were selected for each pair. This selection step is to ensure the target Michelin summary can be created by source Yelp reviews.

Finally, we shuffled the selected source reviews to remove the selection order bias. The final benchmark consists of 100/100/500 entities for the training/validation/test set. Note that we keep parallel data (i.e., reviews-summary pairs) in PROSUM for evaluation and for training supervised models. For Napa or other non-parallel training models, we remove source reviews from the training set.

Statistics We summarize the PROSUM dataset and compare it with existing opinion summarization datasets in Table 1. We calculate novel n-grams in gold summaries to evaluate how abstractive/extractive PROSUM is and the performance of the extractive oracle summaries from the source reviews. We confirm that the PROSUM is more abstractive than the existing benchmarks. The extractive oracle performance supports the feasibility of stylized opinion summarization in PROSUM.

|                  | Src len. | Tgt len. | % of novel n-grams in gold summary | Extractive oracle |
|------------------|---------|---------|-----------------------------------|------------------|
|                  |         |         | Unigram | Bigram | Trigram | 4-gram | R1  | R2  | RL   |
| PROSUM (ours)    | 1162.7  | 139.7   | 38.19   | 84.76  | 97.17   | 99.18  | 42.97 | 10.99| 22.59 |
| Yelp (Bražinskas et al., 2020a) | 453.3   | 58.02   | 31.71   | 83.02  | 95.53   | 98.35  | 47.79 | 15.28| 25.84 |
| Amazon (Bražinskas et al., 2020a) | 446.2   | 56.89   | 31.62   | 82.32  | 95.84   | 98.60  | 46.31 | 14.27| 25.44 |

Table 1: Statistics of PROSUM and FewSum Yelp/Amazon benchmarks. PROSUM has a longer source and target length compared to the FewSum benchmarks and offers more abstractive summaries with respect to the novel n-gram ratio. The source and target length is the number of BPE tokens per example using the BART tokenizer.

4 Napa

Although pseudo-reviews-summary pairs creation has been one of the solid approaches for conventional opinion summarization, we cannot directly use it for stylized opinion summarization, as there are two sets of non-parallel reviews in different writing styles.

This section describes a non-parallel training framework for stylized opinion summarization, Noisy Pairing and Partial Supervision (Napa), which trains a summarization model from non-parallel customer and professional review sets.
4.1 Noisy Pairing

Noisy Pairing expands the existing pseudo-reviews-summary construction approach to create “noisy” reviews-summary pairs for each summary in the desired writing style by obtaining input reviews similar to the summary.

To leverage the desired style of summary \(y\) for the entity \(e\), which is not paired with the set of reviews for the same entity \(R_e\), we first build the noisy reviews-summary pairs. Specifically, given the summary \(y\) for entity \(e\), we follow the pseudo data construction approach (§3) to construct the source set of reviews, but we retrieve the reviews from the different entity \(e' \neq e\) with the summary:

\[
\hat{X}' = \arg \max_{X \subset R_{e'}, |X|=N'} \sum_{x \in X} \text{sim}(x, y).
\]

For instance, given a summary of a sushi restaurant, we can use reviews of a steak restaurant to construct a noisy reviews-summary pair as illustrated in Figure 2. Then, using the similar approach used in the pseudo data construction, we obtain the final noisy training set \(\{\hat{X}', y\}\). In particular, the top 10 noisy reviews-summary pairs of the highest similarity score are retained for each summary.

Note that this method could unintentionally select the review of the correct entity as input (i.e., \(e' = e\)), so in our experiments, we explicitly discarded the review of the entity used in summary to maintain the non-parallel setting.

4.2 Partial Supervision

With the noisy pairing method described above, we can build noisy reviews-summary pairs \(\{\hat{X}', y\}\), but obviously, a model trained with these pairs will generate unfaithful summaries. However, even in such noisy reviews-summary pairs, there would be sub-sequences of the summary \(y\) that could be generated from noisy input reviews \(\hat{X}'\).

To implement this intuition into the training, we first compute the token-level alignment between a noisy set of reviews \(\hat{X}'\) and summary \(y\), and then introduce the indicator function \(\delta_t\) inside of the standard log-loss function to ignore the unaligned tokens during the training:

\[
\mathcal{L}' = -\sum_t \delta_t \log p_\theta(y_t|y_{<t}, \hat{X}'),
\]

where the alignment function \(\delta_t\) will be 1 if the token \(y_t\) is aligned with the noisy source reviews \(\hat{X}'\) and otherwise 0 as illustrated in Figure 2b. This allows for using aligned words, such as the style and expressions used in the summary, as a training signal without increasing the likelihood of hallucinated words.

For the alignment function, we use word-level matching between the source and target reviews. Since professional writers have a rich vocabulary, which contains words that rarely appear in customer reviews, we implement word stem matching and synonym matching (e.g., serene ~ calm) to increase the coverage in Partial Supervision. We discuss the design choice of the alignment function in §6.3.

5 Evaluation

We use ProSum and an existing opinion summarization benchmark FewSum (Bražinskas et al., 2020a) to verify the effectiveness and generalizability of Napa. For FewSum, we discarded the source reviews from the training dataset to convert FewSum into a stylized opinion summarization benchmark (i.e., in the non-parallel setting).

5.1 Settings

Training Data For non-parallel training, we first pre-train a self-supervised opinion summarization model using pseudo-reviews-summary pairs (§3). Then, we fine-tune it using noisy reviews-summary pairs using Napa (§4). Therefore, we need two sets of pseudo-reviews-summary pairs for self-supervised pre-training and noisy reviews-summary pairs for Napa.

As ProSum does not contain customer reviews for training, we use the Yelp review dataset\(^4\), which has 7M reviews for 150k entities, to collect reviews-summary pairs for ProSum dataset. We discarded all the entities used in the Michelin reviews in ProSum to avoid unintentionally selecting the same entity for Noisy Pairing. Then, we excluded entities that do not satisfy the following criteria: (1) in either the restaurant or food category; (2) the rating is higher than 4.0/5.0 on average. Then, we filtered reviews with 5-star ratings. Finally, we discarded entities that have less than ten reviews. After this pre-processing, we built 100k pseudo-reviews-summary pairs and 1k noisy reviews-summary pairs for self-supervised pre-training and Napa, respectively. The pre-processing method for the FewSum dataset is described in Appendix.

\(^4\)https://www.yelp.com/dataset
Model We instantiate our summarization models using the Transformer model (Vaswani et al., 2017) initialized with the BART-large checkpoint (Lewis et al., 2020) in the transformers library (Wolf et al., 2020). We used AdamW optimizer (Loshchilov and Hutter, 2019) with a linear scheduler and warmup, whose initial learning rate is set to 1e-5, and label smoothing (Szegedy et al., 2016) with a smoothing factor of 0.1. We tested three configurations: (1) the full version, (2) without Partial Supervision, and (3) without Noisy Pairing and Partial Supervision— the self-supervised base model trained only using pseudo-review-summary pairs.

5.2 Baselines

For the main experiment on ProSUM, we compared the state-of-the-art opinion summarization system (BiMeanVAE) and two text-style transfer models (Pipeline and Multitask). We also evaluated the upper-bound performance of Napa by using the parallel training dataset, where the customer and professionally written reviews for the same entity are correctly paired (Supervised upper-bound). For the FewSum dataset, we compared various opinion summarization models, including self-supervised models and supervised models that use parallel training data, to verify the performance of our non-parallel training framework. The details can be found in Appendix.

BiMeanVAE: BiMeanVAE (Iso et al., 2021) is a self-supervised opinion summarization model based on a variational autoencoder. We further fine-tune this model using Michelin reviews to generate summaries with the desired style.

Pipeline: We combine a self-supervised opinion summarization model and text style transfer model to build a two-stage pipeline. For the self-supervised model, we use the same self-supervised base model as Napa. For the text style transfer model, we use STRAP (Krishna et al., 2020), which uses inverse paraphrasing to perform text style transfer using Yelp and Michelin reviews in the non-parallel setting.

Multitask: We use a multi-task learning framework, TitleStylist (Jin et al., 2020), which combines summarization and denoising autoencoder objectives to train a summarization model that generates summaries in the desired writing style. In the experiment, we use Yelp pseudo-reviews-summary pairs (Michelin reviews) for the summarization (denoising) objective.

5.3 Automatic Evaluation

We use the F1 scores of ROUGE-1/2/L (Lin, 2004) and BERTScore (Zhang et al., 2020) for reference-based automatic evaluation. Additionally, we calculate the CTC score (Deng et al., 2021) to evaluate the consistency and relevance of the generated summaries. The consistency score is measured by the alignment between the source reviews and the generated summary based on the contextual embedding similarity; the relevance score is measured by the alignment between the generated summary and the reference summary multiplied by the consistency score. The contextual embeddings are obtained from the roberta-large model.

ProSUM Table 2 shows the main experimental results on ProSUM. The self-supervised model (i.e., Napa without Noisy Pairing and Partial Supervision) outperforms all the non-parallel baseline systems. The comparison shows that Pipeline, which combines the self-supervised model and STRAP, degrades the summarization quality. The result indicates that it is not easy to achieve stylized opinion summarization by simply combining a summarization model and a text style transfer model. Napa w/o Partial Supervision improves the summarization quality against the self-supervised model while causing degradation in consistency between generated summaries and the source reviews. This degradation is expected, as Noisy Pairing creates pseudo-reviews-summary by sampling reviews from a different entity, only considering the similarity against the pseudo-summary. We will discuss this point in detail in §6.1.

Napa w/o Partial Supervision substantially outperforms the baselines for summarization quality and relevance while maintaining the same level of consistency as the best self-supervised model. This confirms that Partial Supervision successfully alleviates the consistency degradation caused by Noisy Pairing. The experimental results demonstrate that both Noisy Pairing and Partial Supervision are essential to building a robust stylized opinion summarization model, allowing the model to take advantage of useful signals in the noisy reviews-summary pairs.

| PASS (Oved and Levy, 2021) | 36.91 | 8.12 | 23.09 |           |              |           |
| AdaSum (Bražinskas et al., 2022) | 38.82 | 11.75 | 25.14 |           |              |           |
| BART (our implementation) | 39.69 | 11.63 | 25.48 |           |              |           |
| Napa – Non-parallel training |        |           |           |           |              |           |
| Full version | 38.59 | 11.23 | 25.29 |           |              |           |
| w/o Partial Supervision | 37.41 | 10.51 | 24.18 |           |              |           |
| w/o Noisy Pairing and Partial Supervision | 33.39 | 7.64 | 20.67 |           |              |           |

serve the substantial improvements by Napa over the self-supervised systems. Napa shows competitive performance against state-of-the-art supervised systems, which use parallel training data for training. The results further confirm that providing a small number of reference summaries in the desired writing style, even if they are not paired with input reviews, can help Napa train a solid summarization model for stylized opinion summarization.

5.4 Human Evaluation

We conducted human evaluations to compare the performance of our model (Napa) with three baselines: Self-supervision, Pipeline, and Napa without Partial Supervision (PS) on PROSUM with respect to the fluency, relevance, and attractiveness of the generated summary. We asked human annotators recruited from Appen to rate generated summaries on a 4-point Likert scale for each evaluation metric. We describe more details of the human evaluation in Appendix.

Our findings from the results shown in Figure 3 are: (1) using professionally-written summaries for training allows the model to generate more fluent and attractive summaries than other baselines (Napa and Napa w/o PS vs. Self-supervision and Pipeline); (2) Napa without Partial Supervision tends to generate more irrelevant summaries (Napa vs. Napa w/o PS). Overall, our results
The experimental results in Tables 2 and 3 show that Napa without Partial Supervision—just using noisy reviews-summary pairs—demonstrates solid performance for reference-based automatic evaluation metrics. This is a little bit counterintuitive, and this can be attributed to the positive effect of early stopping against noisy training data (Arpit et al., 2017; Li et al., 2020). To analyze this point, we conducted an additional experiment by training Napa with and without Partial Supervision for more training epochs.

Figure 4 shows the ROUGE-1 F1 score on the validation set of PROSUM at different training stages. The orange line denotes the model trained with partial supervision (§4.2), and the green line denotes the model trained without partial supervision.

Figure 5: Comparison of summarization quality with and without pre-training. The blue line denotes the model trained in a supervised setting, orange line denotes the model trained with partial supervision and green line denotes the model trained without partial supervision.

As we observe that the self-supervised baseline (i.e., Napa w/o Noisy Pairing and Partial Supervision) shows solid performance in Table 2 and better performance than the other self-supervised baselines in Table 3, we further investigated the effectiveness of the pre-training using pseudo-reviews-summary pairs (Self-supervision in §3) in the non-parallel training. We conducted ablation studies for the model trained with Partial Supervision (orange line), without Partial Supervision (green line), and supervised setting (blue line).

As shown in Figure 5, pre-training with self-supervision in all the settings helps improve summarization quality. The effect of pre-training is the most remarkable in the non-parallel settings (orange line and green line). This indicates that while non-parallel training helps learn the desired writing style for summary generation, it is difficult to determine what content to include in the
### Reference based metrics

| Napa             | Unigram | Bigram | Trigram | Four-gram |
|------------------|---------|--------|---------|-----------|
| No Partial Supervision ($\delta_t = 1$ for all $t$) | 31.64   | 3.96   | 18.90   | 84.15     |
| + word match     | 32.88   | 4.77   | 19.98   | 84.50     |
| + word or stem match | 32.49   | 4.82   | 20.03   | 84.45     |
| + word or stem or synonym match | 33.54   | 4.95   | 20.67   | 84.77     |

### Novel $n$-gram ratios

| Napa             | Unigram | Bigram | Trigram | Four-gram |
|------------------|---------|--------|---------|-----------|
| Supervised upperbound | 34.50   | 5.70   | 20.65   | 84.96     |

Table 4: Comparison of summaries generated with different alignment criteria; + word match is the strictest alignment criterion; adding + stem and + synonym match allows for more relaxed alignment criteria allowing more words to be used for training. As the alignment criteria are relaxed, more novel $n$-grams can be generated.

summary only from the noisy-reviews-summary pairs. Therefore, we experimentally confirm the effectiveness of self-supervised pre-training for stylized opinion summarization; self-supervision pre-training teaches the model the basics of how to summarize the content, and non-parallel training introduces the model to write in the desired style. The same analysis on the FewSum dataset can be found in Appendix.

### 6.3 Choice of Token Alignment

As discussed in §4.2, the token alignment function should be carefully chosen to appropriately align customer and professional reviews with different vocabularies. For example, the exact word match should naively disregard semantically similar words (e.g., serene and calm). Thus, we further performed a comparative analysis of the token alignment function. We compared Napa with different variants of Partial Supervision that use: (1) exact word matching, (2) stem matching, and (3) synonym matching.

As shown in Table 4, No Partial Supervision (first row) generates too many novel $n$-grams, indicating significant hallucinations; it shows the worst summarization performance. We confirm that the model tends to generate more novel $n$-grams when the alignment criterion is relaxed and also improves summarization performance, suggesting that the stem and synonym matching functions can successfully consider semantically similar tokens to incorporate into training without degrading the summarization performance.

### 7 Related Work

#### Opinion Summarization

Due to the challenges in collecting training data, many studies have developed unsupervised solutions for opinion summarization systems (Chu and Liu, 2019; Amplayo and Lapata, 2020; Suhara et al., 2020; Iso et al., 2021; Basu Roy Chowdhury et al., 2022). Recent studies have explored few-shot learning approaches that utilize a small number of review-summary pairs for training (Bražinskas et al., 2020a; Oved and Levy, 2021; Iso et al., 2022).

Our technique falls in the middle of these two approaches, as we do not use annotated reviews-summary pairs for training while using a large number of customer reviews and a small number of professional reviews as auxiliary supervision signals.

#### Text Style Transfer

Text style transfer is a technique to rewrite the input text into the desired style (McDonald and Pustejovsky, 1985). The primary approach for text style transfer is sentence-level, which is used as our baselines (Pipeline (Krishna et al., 2020) and Multitask (Jin et al., 2020)). Based on the observation that both Pipeline and Multitask do not perform well for the stylized opinion summarization task (in Table 2), we confirm that applying sentence-level style transfer cannot offer high-quality stylized opinion summarization and it requires paragraph-level text style transfer, which needs further exploration (Jin et al., 2022).

#### Noisy Supervision

Learning statistical models under labeling noise is a classic challenge in machine learning (Angluin and Laird, 1988; Natarajan et al., 2013) and is an active research field because of the increasing availability of noisy data (Han et al., 2020; Song et al., 2022). Among the major approaches for noisy supervision, the loss adjustment approach is widely used in the NLP community, as it can be coupled with any type of commonly used Transformer-based language models (Devlin et al., 2019; Brown et al., 2020).

In text generation, previous studies have attempted to improve the model faithfulness by treating hallucinated summaries as noisy supervi-
sion (Kang and Hashimoto, 2020; Fu et al., 2020; Goyal et al., 2022). Our study is different from the line of work in the sense that we combine noisy-reviews-summary pairs and noisy supervision to develop a non-parallel training framework for stylized opinion summarization.

8 Conclusions

This paper proposes stylized opinion summarization, which aims to summarize opinions of input reviews in the desired writing style. As parallel reviews-summary pairs are difficult to obtain, we develop a non-parallel training framework named Noisy Pairing and Partial Supervision (Napa♥); it creates noisy reviews-summary pairs and then trains a summarization model by focusing on the sub-sequence of the summary that can be reproduced from the input reviews. Experimental results on a newly created benchmark ProSum and an existing opinion summarization benchmark FewSum demonstrate that our non-parallel training framework substantially outperforms self-supervised and text-style transfer baselines while competitively performing well against supervised models that use parallel training data.

9 Limitations

We do not see any ethical issues, but we would like to mention some limitations. This study investigates the use of a limited number of unpaired desired summaries during training. We employ partial supervision to reduce the risk of hallucination, but there is still a potential to generate unfaithful summaries. Thus, the model may generate inconsistent opinions with the source reviews. There is also a trade-off between the quality and diversity of our token-level alignment method. We decided to use exact, stem, and synonym-based matching, but these methods may introduce alignment errors, leading to noisier training. For the annotation tasks, we paid $0.96 for each summary for the crowd workers on Appen. The estimated hourly wage on the platform is $13.48 per hour. For the summary evaluation, we only used token-level matching metrics, unlike LLM-as-a-judge (Liu et al., 2023; Wu et al., 2024).
