Abstract
Annotation efforts have resulted in the availability of a number of corpora with rhetorical relation information. The corpora, unfortunately, are annotated under different theoretical approaches and have different hierarchies of relations. In addition, new sets of rhetorical relations have been proposed to account for language variation. The types of relations, however, tend to overlap or be related in specific ways. We believe that differences across approaches are minimal, and a unified set of relations that works across languages is possible. This paper details a new taxonomy of relations organized in four top level-classes with a total of 26 relations. We propose a mapping between existing annotations and show that our taxonomy is robust across theories, and can be applied to multiple languages.

1 Motivation
The annotation of discourse relations in language can be broadly characterized as falling under two main approaches: the lexically grounded approach and an approach that aims at complete discourse coverage. Perhaps the best example of the first approach is the Penn Discourse Treebank (Prasad et al., 2008). The annotation starts with specific lexical items, most of them conjunctions, and includes two arguments for each conjunction. This leads to partial discourse coverage, as there is no guarantee that the entire text is annotated, since parts of the text not related through a conjunction are excluded. On the positive side, such annotations tend to be reliable. PDTB-style annotations have been carried out in a variety of languages (Arabic, Chinese, Czech, Danish, Dutch, French, Hindi and Turkish), and in some cases the taxonomy of relations had to be modified, by adding or merging relations (Prasad et al., 2014).

Complete discourse coverage requires annotation of the entire text, with most of the propositions in the text integrated in a structure. It includes work from two theoretical perspectives, either intentionally driven, such as RST (Mann and Thompson, 1988) or semantically driven, such as SDRT (Asher and Lascarides, 2003). RST proposes a tree-based representation, with relations between adjacent segments, and emphasizes a differential status for discourse components (the nucleus vs. satellite distinction). Annotated resources exist in Basque, Dutch, German, English, Portuguese and Spanish. Captured in a graph-based representation, with long-distance attachments, SDRT proposes relations between abstract objects using a relatively small set of relations. Corpora following SDRT exist in Arabic, French and English.

Manually annotated resources have contributed to a number of applications, most notably discourse segmentation into elementary discourse units, identification of explicit and implicit relations for the purpose of discourse parsing, and development of end-to-end discourse parsers (Hernault et al., 2010; Feng and Hirst, 2014; Joty et al., 2015). These parsers have been successfully deployed in NLP applications including machine translation, sentiment analysis and automatic summarization (Thione et al., 2004; Heerschop et al., 2011; Hardmeier, 2013).

Each approach has its own hierarchy of discourse relations, but relations tend to overlap or be re-
lated in a few specific ways. We suggest there are four general ways of mapping relations across approaches: (1) Specialization, where a relation $R$ in one approach can correspond to several relations in another approach, (2) Generalization, in which several relations in one approach correspond to one relation in another approach, (3) Omission involves a relation defined in one approach, but not taken into account in another. Finally, in (4), Definition, relations have similar names, but different definitions.

We propose here a unified hierarchy of discourse relations. Our proposal has several motivations. First of all, with the wide availability of annotated corpora, it would be beneficial to have a system for mapping relations across approaches. In particular for classification tasks such as discourse parsing, access to larger amounts of data is likely to yield better results. Secondly, and from a more theoretical point of view, we would like to propose that differences across approaches are minimal, and a unified set of relations is possible. This would facilitate the work of discourse analysts and would also result in better annotation efforts. Third, a unified set of discourse relations would allow us to compile a list of discourse markers and other signals for those relations, which would also benefit discourse annotation. Finally, this is a first step towards multilingual discourse analysis. Definitions of relations are based on three further criteria. First of all, we do not define relations on the basis of the status of their arguments. The nucleus-satellite distinction in RST is not relevant for our basic definition of relations. Secondly, we focus on the effect that a relation has on meaning, and not on how it is lexically triggered by a discourse marker or lexical device. Finally, we provide intentional effects when needed. Our taxonomy is both intentionally and semantically driven, motivated by our desire to find a balance between RST and SDRT. Our starting points are the set of RST definitions from the RST website\(^1\) and the definitions provided within the RST-DT (Carlson et al., 2003). For SDRT, we considered the relations defined in the SDRT literature (Asher and Lascarides, 2003), plus the adaptations created when annotating data in different projects: Discor (Reese et al., 2007), Annodis (Afantenos et al., 2012), plus the classification proposed for Arabic (Keskes et al., 2014).

3 Towards a unified hierarchy

We built a hierarchy with four top-level classes: TEMPORAL, STRUCTURAL, THEMATIC and CAUSAL-ARGUMENTATIVE, organized in three levels with a total of 26 relations. We have taken into account all SDRT, PDTB, RST-DT and RST relations, with the exception of the following relations from the RST-DT: Topic Change (topic-shift,  

\(^1\)http://www.sfu.ca/rst/
temporal structure, to accommodate presuppositions in discourse, or to set the stage of a story.

(3) ATTRIBUTION. Attribution relates a communicative agent in the first argument and the content of a communicative act introduced in the second. Both the RST-DT and SDRT take Attribution as a discourse relation. PDTB, on the other hand, treats it as orthogonal to discourse annotation. In our case, we follow Asher et al.’s (2006) position on reportative constructions in discourse, who consider that the treatment of these verbs is necessary for a correct analysis of the semantics and discourse structure of stories in news corpora. We agree, however, with the PDTB, that it is not a fully-fledged relation, with the same intentional effects, but we do believe that it should be annotated.

3.3 Structuring class

This class contains relations of textual organization at a high level, which organize the structure of the information in terms of themes or topics (but are rhetorical, not relations of topic management). ALTERNATION holds when there is a disjunction between a and b. PARALLEL occurs when a and b have similar semantic and syntactic structures, and it requires a and b to share a common theme. It has the same semantics as List in RST-DT. CONTINUATION holds between two segments when they both elaborate or provide background to the same segment. It also occurs in cases where there is no clear rhetorical relation between the segments. Equivalent to the RST-DT relation Elaboration-additional and to Continuation in SDRT.

3.4 Causal-argumentative class

This class contains two broad classes, one causal and one argumentative. We see them as related to each other, as conjunctions and other discourse markers can be present to indicate a causal relation or be more abstract in an argumentative use (e.g., I’m only saying this because I care.).

3.4.1 Causal

We distinguish between CAUSE/RESULT and PURPOSE. Within the first sub-class, REASON holds when the main eventuality of the second argument is understood as the cause of the eventuality in the first argument. RESULT relates a cause to its effect: the
Table 1: Inventory of proposed relations in the unified hierarchy

| Temporal | Thematic | Structuring | Causal-argumentative |
|----------|----------|-------------|----------------------|
| SEQUENCE, INVERTED SEQUENCE, SYNCHRONOUS | ELABORATION → Partitive, Generality, Object, Summary, Restatement, Means | ALTERNATION, PARALLEL, CONTINUATION | CAUSAL-ARGUMENTATIVE |
| FRAMING → Frame, Background | | | Cause/Result → Reason, Result, General Condition |
| | | | Purpose |
| | | | SUPPORT → Motivation, Evidence/Justification, Evaluation/Interpretation |
| | | | Opposition → Contrast, Concession, Antithesis |

Table 2: Temporal class mapping

| RST-DT | Annodis | RST-ST |
|--------|---------|--------|
| Seq.   | 224     | 350    | 74     |
| Sync.  | 160     |        |        |
| Inv. Seq. | 59  | 27     |        |
| **Total TEMPORAL:** | **894** |        |        |

Table 3: Structuring class mapping

| RST-DT | Annodis | RST-ST | Total |
|--------|---------|--------|-------|
| Alter. | 21      | 18     | 9     | 48    |
| Paral. | 1,211   | 59     | 1,270 |       |
| Conti. | 4,144   | 682    | 171   | 4,997 |
| **Total STRUCTURING:** | **6,315** |        |       |

3.4.2 Argumentative

This class includes the SUPPORT and OPPOSITION sub-classes, which are used to advance an argument. SUPPORT mainly captures justification, explanation (not causal), evaluation and evidence. OPPOSITION groups relations where the segments have similar semantic structures, but contrasting themes, i.e., sentence topics, or when one constituent negates a default consequence of the other.

4 Mapping RST and SDRT annotations

To test the stability of our proposed hierarchy across both theoretical and language variations, we mapped it to annotations in three corpora: the RST-DT English corpus (Carlson et al., 2003), the SDRT Annodis French corpus (Afantenos et al., 2012), and the RST Spanish Treebank (RST-ST) (da Cunha et al., 2011). The taxonomies in these corpora respectively contain 78, 17 and 28 relations. The total number of annotated information in terms of frequency of relations is 18,255 for RST-DT, 3,345 for Annodis, and 3,115 for RST-ST. Tables 2, 3, 4, and 5 provide frequency of our relations in each main class. The distribution of our four classes across the corpora is respectively 3.61%, 25.55%, 47.80%, and 23.08%. The proportions are quite similar to the original distribution in each corpus, taking into account the slightly different structures of each taxonomy.

Most mappings were relatively straightforward, except for some relations that can be either missing or too specific. The first case concerns the relations FRAME, PARALLEL and ATTRIBUTION that were not annotated in the RST-ST, as well as the relation FRAME for RST-DT. The second case is the most frequent and occurs when at least two relations having specific semantics or intentional effects need to be merged to find their corresponding instances in a given corpus. For example, the Temporal relations SEQUENCE and SYNCHRONOUS in Annodis were annotated using the same Narration relation. The SDRT Elaboration captures most of our ELABORATION relations (except for OBJECT). On the other hand, the RST-ST corpus considers only one Temporal relation, namely Sequence, and RST-ST Elaboration includes OBJECT, PARTITIVE,
and GENERALITY. Another interesting case concerns the Support relations MOTIVATION and EVIDENCE/JUSTIFICATION. SDRT does not distinguish between the causal and the epistemic use of causal relations and considers only two causal relations, Explanation and Result. This is why we counted SDRT causal relations only in the Causal/Result sub-class (this is marked by (*) and (+) in Table 5). Finally, the RST-DT multinuclear relations Cause-result and Consequence are similar and can correspond to either REASON or RESULT. We only counted them in the total column (see † in Table 5).

|       | RST-DT | Annodis | RST-ST | Total |
|-------|--------|---------|--------|-------|
| Obj.  | 2,698  | 525     |        | 6,995 |
| Part. | 176    |         | 614    |       |
| Gen.  | 884    |         |        | 1,444 |
| Sum.  | 83     |         | 8      | 22    |
| Rest. | 140    |         | 175    |       |
| Means | 226    |         |        |       |
| Frame |        | 225     | 225    |       |
| Backg.| 937    | 157     | 344    | 1,438 |

5 Discussion and conclusions

We have presented a unified taxonomy for discourse relations which can be used to map existing annotations, and to annotate new corpora. We believe our taxonomy is robust across theoretical approaches, and can be applied to multiple languages.

A number of issues are outstanding, the first with regard to segmentation. Different corpora have followed different segmentation methodologies, sometimes impacting the types of relations present in the taxonomy, as is the case with the multiple subtypes of Elaboration relations in the RST-DT corpus. Our intention is to provide coarse and fine-grained segmentation options, so that either can be adopted, depending on the goals of the research.

More crucial to the task of unifying annotations is the issue of the structure of the discourse. RST, RST-DT and RST-ST all take trees as the fundamental structure. SDRT, however, postulates graphs as the basic structure. On the other hand, mapping to a lexically-grounded approach, like that in the PDTB, is certainly possible. We believe that mapping and predicting relations can be a theory-independent task, and that the rich annotations in PDTB are useful for tasks such as discourse parsing.

Two further practical aspects remain unresolved. First, relations with no correspondence across taxonomies need to be considered. One solution is to ignore them and then predict a partial structure for some texts. The second issue is the task of manual annotation. As we have pointed out, in cases where one original taxonomy is more detailed, mapping relations from that taxonomy onto an existing corpus may require further annotation. If annotation is undertaken, then that could solve our first practical problem, because then there is an opportunity to annotate some of the relations with no mapping.

Finally, an excellent test of the usefulness of the taxonomy would be to carry out experiments in discourse parsing. We would like to merge annotated corpora, and test whether the larger size of the training data improves the results of a discourse parser.
