Abstract

The respiratory chain cytochrome \( bc_1 \) complex (cyt \( bc_1 \)) is a major target of numerous antibiotics and fungicides. All cyt \( bc_1 \) inhibitors act on either the ubiquinol oxidation (Q\(_{b}\)) or ubiquinone reduction (Q\(_{a}\)) site. The primary cause of resistance to cyt \( bc_1 \) inhibitors is target site mutations, creating a need for novel agents that act on alternative sites within the cyt \( bc_1 \) to overcome resistance. Pyrimorph, a synthetic fungicide, inhibits the growth of a broad range of plant pathogenic fungi, though little is known concerning its mechanism of action. In this study, using isolated mitochondria from pathogenic fungus \( Phytophthora capsici \), we show that pyrimorph blocks mitochondrial electron transport by affecting the function of cyt \( bc_1 \). Indeed, pyrimorph inhibits the activities of both purified 11-subunit mitochondrial and 4-subunit bacterial cyt \( bc_1 \) with \( IC_{50} \) values of 85.0 \( \mu \text{M} \) and 69.2 \( \mu \text{M} \), respectively, indicating that it targets the essential subunits of cyt \( bc_1 \) complexes. Using an array of biochemical and spectral methods, we show that pyrimorph acts on an area near the Q\(_{b}\) site and falls into the category of a mixed-type, noncompetitive inhibitor with respect to the substrate ubiquinol. In \textit{silico} molecular docking of pyrimorph to cyt \( b \) from mammalian and bacterial sources also suggests that pyrimorph binds in the vicinity of the quinol oxidation site.

Introduction

The cytochrome \( bc_1 \) complex (cyt \( bc_1 \), also known as ubiquinone-cyt \( e \) oxidoreductase, Complex III or cyt \( bc_1 \)) is a central component of the cellular respiratory chain of mitochondria. It catalyzes the reaction of electron transfer (ET) from ubiquinol to cyt \( e \) and couples this reaction to proton translocation across the mitochondrial inner membrane, contributing to the cross-membrane proton motive force essential for cellular functions such as ATP synthesis [1,2]. The indispensable function of cyt \( bc_1 \) in cellular energy metabolism makes it a prime target for numerous natural and synthetic antibiotics. More than 20 synthetic fungicides targeting cyt \( bc_1 \) are in widespread use in agriculture with an annual sale exceeding $2.7 billion [3].

All cyt \( bc_1 \) inhibitors target either the ubiquinol oxidation site (Q\(_{b}\) or Q\(_{a}\)) or the ubiquinone reduction site (Q\(_{b}\) or Q\(_{a}\)), which are defined by the Q-cycle mechanism of cyt \( bc_1 \) function [4,5]. Despite variations in subunit compositions of cyt \( bc_1 \) from various organisms, only three subunits are essential for ET-coupled proton translocation function: they are cyt \( b \), cyt \( e_1 \) and the iron-sulfur protein (ISP). The cyt \( b \) subunit contains two \( b\)-type hemes (\( b_1 \) and \( b_4 \)); the cyt \( e_1 \) subunit has an \( e\)-type heme, and the ISP possesses a 2Fe-2S cluster. Both active sites are located within the cyt \( b \) subunit, as demonstrated by crystallographic studies of mitochondrial and bacterial \( bc_1 \) complexes [6–12]. Resistance to known cyt \( bc_1 \) fungicides has been reported at an alarming rate, rendering many of these reagents ineffective. Most common mechanisms of resistance involve target site mutations and corresponding strategies to overcome drug resistance have been proposed [13].

Developing new agents targeting areas outside the Q\(_{b}\) and Q\(_{a}\) sites of cyt \( bc_1 \) is most attractive primarily because the new compounds presumably are able to circumvent existing fungal resistance.

Pyrimorph, (Z)-3-[(2-chloropyridine-4-yl)-3-(4-tert-butylphenyl)-acryloyl] morpholine, is a novel systemic antifungal agent that belongs to the family of carbboxylic acid amide (CAA) fungicides [14], whose members include mandipropamid, dimethomorph, flumorph, and valinine derivatives. Pyrimorph exhibits excellent activity inhibiting mycelial growth of the fungal species \( Phytophthora infestans \), \( Phytophthora capsici \), and \( Rhizoctonia solani \) and is able to suppress zoosporangia germination of \( Pseudoperonospora cubensis \) with \( EC_{50} \) values in the range between 1.3 and 13.5 \( \mu \text{M} \) [15]. The \textit{in vitro} sensitivities of various asexual stages of \( Peronosphylla litchii \)
to pyrimorph were studied with four single-spore isolates, showing high sensitivity at the stage of mycelial growth with an EC₅₀ of 0.3 M [16].

Although pyrimorph is currently in use to control various fungal pathogens [15–17], its functional mechanism has remained unclear. The presence of a common CAA moiety has led to the suggestion that pyrimorph may work in a fashion similar to that of other CAA-type fungicides [18]. One CAA member, mandipropamid, was shown to target the pathway of cell wall synthesis by inhibiting the CesA3 cellulose synthases [19]. However, treatment of fungal pathogens with pyrimorph appeared to affect multiple cellular pathways, including, but not limited to, those of cellular energy metabolism and cell wall biosynthesis, either directly or indirectly [20]. Indeed, a recent report has correlated the pyrimorph resistance phenotype in *P. capsici* with mutations in the CesA3 gene [21].

Other mechanisms of pyrimorph action have yet to be investigated. In particular, its potential interference with cellular respiratory chain components leading to reduced ATP synthesis appears to be a reasonable hypothesis for the observed inhibitory effects on energy demanding processes such as mycelial growth and cytospor germination of fungi. Here, we report the effects of pyrimorph on electron flow through the isolated fungal mitochondrial respiratory chain and the identification of the cyt bc₁ complex as pyrimorph’s primary target. Kinetic experiments suggest that the mode of pyrimorph inhibition is to interfere with substrate access to the ubiquinol oxidation site but in a way that differs from other bc₁ inhibitors, suggesting a novel mode of inhibitory mechanism.

**Materials and Methods**

The pyrimorph used in all experiments was synthesized in our laboratory. Dimethomorph was a gift from Jiangshu Frey Chemical Co. Ltd. (Jiangshu Province, China). Cyt c (from horse heart, type III) was purchased from Sigma-Aldrich (St. Louis, MO). 2,3-dimethoxy-5-methyl-6-(10-bromodecyl)-1,4-benzoquinol (Q₁₀C₁₀BrH₂) was prepared as previously reported [22]. N-dodecyl-β-D-maltoside (β-DDM) and N-octyl-β-D-glucoside (β-OG) were purchased from Affymetrix (Santa Clara, CA). All other chemicals were purchased and are of the highest grade possible.

**Preparation of Light Mitochondria from Phytophthora capsici**

Light mitochondrial fraction were prepared from cultured mycelia from laboratory strain *Phytophthora capsici Leonia (P. capsici)*, which was grown in CA liquid medium (8% carrot juice and 2% glucose) for 5 days in the dark at 25°C [23]. 10 g mycelia (fresh weight) were washed with 0.6 M mannitol solution and ground up for 5 minutes with an ice-cold mortar and pestle in 100 ml buffer A containing 10 mM MOPS-KOH, pH 7.1, 0.3 M mannitol, 1 mM EDTA and 0.1% (w/v) bovine serum albumin (BSA) and 30 g of sea sand. The homogenate was centrifuged at 3,200 × g for 10 min at 4°C and the supernatant was further centrifuged at 12,000 × g for 30 min. The precipitate, light mitochondrial fraction, was resuspended and washed with 20 ml buffer B containing 10 mM MOPS-KOH, pH 7.1, 0.25 M sucrose and 1 mM EDTA and pelleted again by centrifugation at 12,000 × g for 20 min at 4°C. The mitochondrial preparation was resuspended in buffer A and the protein concentration was adjusted to 0.1 mg/ml.

Inhibition of Cyt bc₁ Complex by Pyrimorph

PLOS ONE | www.plosone.org 2 April 2014 | Volume 9 | Issue 4 | e93765
Inhibition of the ET Activity of P. capsici Mitochondria by Pyrimorph

The activities of mitochondrial respiratory chain components were assayed using the Mitochondria Complex Activity Assay Kit (Genmed Sciences, Inc. USA, Wilmington, DE) following manufacturer’s instruction. Briefly, Complex I activity was measured by following the oxidation of NADH by monitoring the decrease in absorbance difference between 340 nm and 380 nm. The reaction mixture (1 ml) consisted of 50 mM potassium phosphate buffer, pH 7.6, 0.25 mM NADH and 50 mM decylubiquinone as the electron acceptor. Crude mitochondria (200 μg protein) were added to start the reaction.

Figure 1. Inhibition of cyt bc₁ by various inhibitors. (A) Inhibition of Btbc₁ by several amide fungicides and azoxystrobin at indicated concentrations. The control is the activity of bc₁ in the absence of inhibitor, which is set to 100%. (B) Concentration-dependent inhibition of Btbc₁ by pyrimorph. (C) Concentration-dependent inhibition of Rsbc₁ by pyrimorph.

doi:10.1371/journal.pone.0093765.g001
Complex II activity was estimated as the rate of reduction of ubiquinone to ubiquinol by succinate, which can be followed by the secondary reduction of 2,6-dichlorophenolindophenol (DCPIP) as the ubiquinol forms. The reaction mixture (1 ml) contained 50 mM potassium phosphate buffer, pH 7.6, 20 mM succinate, 1.0 mM EDTA, 0.05 mM DCPIP and 3 mM NaN₃, and 50 mM decylubiquinone. Crude mitochondria (65 μg) were added to initiate the reaction and the decrease in absorbance at 600 nm was followed as DCPIP becomes reduced. Complex III activity was assayed by following the increase in absorbance at 550 nm as cyt c becomes reduced using decylubiquinol as an electron donor. Here, the reaction mixture (1 ml) consisted of 50 mM potassium phosphate buffer, pH 7.6, 0.1% BSA, 0.1 mM EDTA, 60 mM oxidized cyt c, and 150 μM decylubiquinol. Crude mitochondria (10 μg protein) were then added to initiate the reaction.

Purification of Cyt bc₁ Complexes from Beef Heart and Photosynthetic Bacterium Rhodobacter sphaeroides

Bovine heart mitochondrial bc₁ (Bbc₁c) complex was prepared starting from highly purified succinate-cyt c reductase, as previously reported [24]. The bc₁ particles were solubilized by deoxycholate and contaminants were removed by a 15-step ammonium acetate fractionation. The purified bc₁ complex was recovered in the oxidized state from the precipitates formed between 18.5% and 33.5% ammonium acetate saturation. The final product was dissolved in 50 mM Tris-HCl buffer, pH 7.8, containing 0.66 M sucrose resulting in a stock solution with a protein concentration of 30 mg/ml, which was stored at −80°C. The concentrations of cyt b and c₁ were determined spectrophotometrically using millimolar extinction coefficients of 28.5 and 17.5 mM⁻¹ cm⁻¹ for cyt b and c₁, respectively.

To prepare bc₁ complex from the photosynthetic bacterium R. sphaeroides (Rsbc₁c), R. sphaeroides strain BC17 cells bearing the pRKD418-fbeFBGEM1Q plasmid [25] were grown photosynthetically at 30°C in an enriched Sistrom medium containing 5 mM glutamate and 0.2% casamino acids [26]. The growth was monitored by measuring the OD₆₀₀ value every 3–5 h. Cells were transferred to a larger batch or harvested when OD₆₀₀ reached 1.8–2.0. Chromatophore membranes were prepared from BC17 cells as described previously [27] and stored at a very high concentration in the presence of 20% glycerol at −80°C. Rsbc₁ complex was isolated in detergent solution [22]. Rsbc₁c complexes were then purified by cold ammonium acetate fractionation. The purified bc₁ complex was eluted with a Qₐ₀C₁₀BrH₂ at a final concentration of 5 mM and a Qₐ₀C₁₀BrH₂ concentration was kept constant at 50 μM. The reactions were initiated by adding 3 μl of diluted bc₁ solution initiating the reaction, which is recorded immediately following the cyt c reduction at 550 nm wavelength for 100 seconds in a two-beam Shimadzu UV-2250 PC spectrophotometer at 23°C. The amount of cyt c reduced over a given period of time was calculated using a millimolar extinction coefficient of 18.5 mM⁻¹ cm⁻¹.

To measure the effect of bc₁ inhibitors, bc₁ was pre-incubated at various concentrations of an inhibitor for 15 minutes prior to the measurement of its activity. The IC₅₀ value was calculated by a least-squares procedure fitting the equation (Y = Aₘᵦᵢₙ + (Aₘᵦᵢₙ–Aₜₐₓₙ)/(1+10^(XIC₅₀))) implemented in the commercial package Prism, where Aₘᵦᵢₙ and Aₜₐₓₙ are maximal and minimal activities, respectively. Although the chemical properties of Qₐ₀C₁₀BrH₂ are comparable to those of Qₐ₀C₁₀H₂, the former is a better substrate for the bc₁ complex isolated in detergent solution [22].

Reaction Kinetics of bc₁ in the Presence of Inhibitors

To measure the enzymatic kinetics of cyt bc₁ complex under inhibitory conditions, purified cyt bc₁, either Bbc₁c or Rsbc₁c, was assayed at different concentrations of substrates. When the Qₐ₀C₁₀BrH₂ concentration was varied (1 μM, 2 μM, 5 μM, 10 μM, 20 μM) the cyt c concentration was kept constant at 80 μM, whereas when the concentration of cyt c varied (1 μM, 2 μM, 4 μM, 8 μM, 12 μM, 16 μM) the Qₐ₀C₁₀BrH₂ concentration was kept constant at 50 μM. The reactions were initiated by adding 3 μl of diluted bc₁ solution (0.1 μM for Bbc₁c or 1.0 μM for Rsbc₁c) pre-in incubated with various concentrations of inhibitors for 15 minutes. The time course of the absorbance change due to cyt c reduction was recorded continuously at 550 nm. Initial rates were determined from the slopes in the linear portion of cyt c reduction time course.

Analysis of Cyt bc₁ Spectra in the Presence of Inhibitors

For each run a solution of 1 ml bovine cyt bc₁ at a cyt b concentration of 5 μM was fully reduced with addition of a tiny amount of sodium dithionite and its spectrum was obtained in the range of 520–600 nm. A specific inhibitor was added at various concentrations to the reduced bc₁ complex and was scanned repeatedly until no changes were observed. All scans were stored digitally and difference spectra were produced by subtracting the corresponding spectrum of the inhibitor-free, fully reduced bc₁ complex.

Measurement of Cyt b and c₁ Reduction Time Course in a Single Turnover Reaction

The enzyme was diluted to a final concentration of about 4 μM of cyt c₁ in 1 ml of B200 buffer (50 mM Tris-HCl, pH 8.0, 0.01% β-β-β-β-DDM, 200 mM NaCl) and oxidized fully by adding a tiny amount of potassium ferricyanide. The spectrum of the fully oxidized enzyme in the range of 520–590 nm was stored.
Inhibitors at various concentrations were introduced and incubated for 2 min followed by addition of the ubiquinol analog Q$_{10}$C$_{10}$BrH$_2$ to a final concentration of 10 mM to start the reaction. Spectra were recorded at 20-second intervals starting immediately after mixing. After 800 seconds the enzyme was fully reduced by dithionite. The spectrum of the fully oxidized complex was subtracted from that at each time point and the amounts of reduced cyt $c_1$ and $b$ at a given time were calculated from the difference spectra at 552–540 nm and 560–576 nm, respectively.

**Figure 2. Influences of cyt $b$ and $c_1$ reduction by pyrimorph.** Isolated Btbc$_1$ was incubated with indicated inhibitors followed by single turnover reaction initiated by addition of 10 μM Q$_{10}$C$_{10}$BrH$_2$. The spectra were recorded immediately following the mixing and every 20 seconds thereafter. At the 800 second time point, a tiny amount of sodium dithionite was added to reduce both cyt $b$ and $c_1$. The amounts of reduced cyt $b$ and $c_1$ were calculated and plotted as a function of time. The green trace is the amount of cyt $b$ reduced over time and the red one is the amount of cyt $c_1$ reduced. (A) 100 μM pyrimorph, (B) 1000 μM pyrimorph, (C) 30 μM myxothiazol, and (D) 30 μM antimycin A.

doi:10.1371/journal.pone.0093765.g002

Inhibition of Cyt bc$_1$ Complex by Pyrimorph

Coordinates for the receptor molecule were taken from the protein data bank (pdb) entry 1SQX, for the stigmatellin inhibited complex of Btbc$_1$. The side chains of residues E271 and F274 were modeled as standard rotamers consistent with their positions in apo Btbc$_1$. The ligand molecule, pyrimorph, was drawn and converted to a SMILES string using tools from the CADD Group [28]. The SMILES string was converted by the program Elbow [29] to 3D coordinates and energy minimized in GAMESS [30].

Molecular Docking of Pyrimorph to Cyt $b$
Figure 3. Difference spectra of inhibitors and inhibitors combinations to reduced Btbc1. All spectra were recorded with purified Btbc1 at a concentration of 5 μM of cyt b with the concentrations of inhibitor as indicated. Prior to spectral scan, the bc1 complex was reduced by addition of dithionite. (A) Spectrum of reduced Btbc1 in the presence of 1 mM pyrimorph (pyr) minus that of reduced Btbc1 alone. Inhibition of Cyt bc\textsubscript{1} Complex by Pyrimorph

Both receptor and ligand molecules were converted to standard pdbqt files using mgtools [31]. For all docking runs, the acrylamide moiety (C7 = C8 - C9 = O16) of pyrimorph was fixed in the syn-periplanar conformation because the alternative anti-conformation would bring the larger morpholino and pyridyl groups into close contact.

Two approaches to docking were taken: (1) as the most likely binding sites for inhibitors are the Q\textsubscript{P} and the Q\textsubscript{N} sites, docking attempts were made first at those known sites. (2) In a second set of runs, no prior knowledge of sites was imposed but the program Q-site-finder [32] was used to locate all potential binding sites and docking was carried out at all sensible locations. Docking pyrimorph to known and unknown inhibitor binding sites was performed using the program Autodock Vina [33].

Results

Pyrimorph Blocks the Mitochondrial Respiratory Chain by Targeting cyt bc\textsubscript{1} Complex

To test whether pyrimorph inhibits fungal growth by interfering with the cellular energy metabolism pathway, in particular the mitochondrial respiratory chain, we isolated light mitochondrial fraction from the pathogenic fungus \textit{P. capsici} and examined the ability of pyrimorph to inhibit various segments of the respiratory chain (Table 1). It is quite clear that pyrimorph has no effect on the activity of Complex I, as a concentration of pyrimorph as high as 16 \textmu M was unable to inhibit NADH oxidation catalyzed by Complex I. By contrast, under the same conditions, pyrimorph inhibits 94.6\% of Complex II activity. Most importantly, Complex III, the cyt bc\textsubscript{1} complex, shows the highest sensitivity toward pyrimorph, with 95.3\% inhibition even at 4 \textmu M concentration.

Although the effects of pyrimorph on the mitochondrial respiratory chain of \textit{P. capsici} were clearly demonstrated, such effects could be indirect. To ascertain that the target of pyrimorph is indeed the cyt bc\textsubscript{1} complex, we used highly purified cyt bc\textsubscript{1} from beef heart (\textit{Bos taurus bc\textsubscript{1} for Bb\textsubscript{bc\textsubscript{1}}} and assayed inhibition of its cyt c reductase activity by pyrimorph. The result was compared to the well-known anti-bc\textsubscript{1} fungicide azoxystrobin and two other CAA-type fungicides, dimethomorph and flumorph. As shown in Fig. 1A, Bb\textsubscript{bc\textsubscript{1}} activities are reduced to 67\% and 42\% of the control, respectively, in the presence of 10 \textmu M and 100 \textmu M of pyrimorph. Azoxystrobin is able to inhibit bc\textsubscript{1} activity by more than 95\% at 10 \textmu M concentration. However, the two CAA-type fungicides, dimethomorph and flumorph, displayed no activity at all against Bb\textsubscript{bc\textsubscript{1}}. These results indicated that pyrimorph is different from other members of CAA-type fungicides and more importantly established that pyrimorph is indeed an inhibitor of the cyt bc\textsubscript{1} complex, albeit a weak one.

We subsequently determined 50\% inhibitory concentration (IC\textsubscript{50}) for pyrimorph against isolated cyt bc\textsubscript{1} complexes from both bovine mitochondria and photosynthetic bacterium \textit{R. sphaeroides} (Rsbc\textsubscript{1}). Pyrimorph is slightly more potent against Rsbc\textsubscript{1}, giving an IC\textsubscript{50} value of 69.2 \textmu M; it gives an IC\textsubscript{50} of 85.0 \textmu M for Bb\textsubscript{bc\textsubscript{1}} (Figs. 1B and 1C). As a comparison, the well-known bc\textsubscript{1} inhibitor stigmatellin and azoxystrobin give IC\textsubscript{50} values of 2.8 \textmu M and 47.7 \textmu M, respectively, for isolated Bb\textsubscript{bc\textsubscript{1}} by our measurement (data not shown) under the same assay conditions. Since Rsbc\textsubscript{1} has only four subunits, it is therefore certain that pyrimorph targets the essential subunits of the bc\textsubscript{1} complex.

Effect of Pyrimorph Binding on Reduction of the Cyt b and c\textsubscript{1} by Ubiquinol

Nearly all cyt bc\textsubscript{1} inhibitors bind to the Q\textsubscript{N} site, Q\textsubscript{P} site or both [34]. It is known that binding of inhibitors produces various effects on spectra of cyt b and c\textsubscript{1} heme groups, as well as on redox potential and conformation of the iron-sulfur protein [34–38]. These effects ultimately determine the rate and amount of cyt b or c\textsubscript{1} reduced under equilibrium conditions and can be exploited to compare modes of action of different inhibitors [39], distinguishing for example a Q\textsubscript{N} site inhibitor from a Q\textsubscript{P} site one. Starting with a completely oxidized enzyme, Bb\textsubscript{bc\textsubscript{1}} was mixed with substrate Q\textsubscript{c}C\textsubscript{10}B\textsubscript{H}\textsubscript{2} in the presence of pyrimorph at two different concentrations (0.1 mM and 1.0 mM); no cyt c was used as the terminal electron acceptor. The amount of cyt b including b\textsubscript{1} and b\textsubscript{H} hemes and cyt c\textsubscript{1} reduced as a function of time was recorded (Figs. 2A and 2B). The results were compared with those produced by Q\textsubscript{N} site inhibitor antimycin A (Fig. 2C) and by Q\textsubscript{P} site inhibitor myxothiazol (Fig. 2D).

In the absence of the high-potential electron acceptor cyt c\textsubscript{1}, only a single enzymatic turnover at the Q\textsubscript{N} site is possible when the Q\textsubscript{N} site inhibitor antimycin A is bound. Under such conditions, both cyt b and c\textsubscript{1} were rapidly reduced reaching maximal reduction of nearly half of the b-type hemes and all of the c\textsubscript{1}-type heme perhaps even before the first measurement was recorded (Fig. 2C). Once reaching maximal reduction, cyt b began non-enzymatic oxidation rather rapidly, whereas the redox state of cyt c\textsubscript{1} remained unchanged. When the Q\textsubscript{P} site is occupied by an inhibitor such as myxothiazol, not a single turnover is possible (Fig. 2D). The
Inhibition of Cyt bc₁, Complex by Pyrimorph

initial rapid reduction of cyt b was most likely via the reverse reaction at the Qₚ site and cyt c₁ reduction was entirely non-enzymatic. Thus, the rate of cyt c₁ reduction and that of cyt b re-oxidation can be employed to determine which site an inhibitor targets.

Clearly, the reduction behavior of cytochromes b and c₁ induced by pyrimorph distinguishes it from that induced by antimycin A (Figs. 2A, 2B and 2C), demonstrating that pyrimorph does not target the Qₚ site. By contrast, the time courses of cyt b and c₁ reduction in the presence of pyrimorph or myxothiazol resemble each other (Figs. 2A, 2B, and 2D), except that the latter inhibitor takes a longer time for cyt c₁ to be maximally reduced than pyrimorph does. This result puts pyrimorph into the category of a Qₚ-site inhibitor by either directly or indirectly competing with ubiquinol for the Qₚ site.

Spectral Analyses Suggest the Binding of Pyrimorph near Qₚ Site

Single turnover experiments suggested that pyrimorph acts in a fashion similar to that of Qₚ site inhibitors. It was thus necessary to determine how pyrimorph interferes with bc₁ function at the Qₚ site. Since spectral changes, especially red shifts in the α- and β-band caused by binding of inhibitors to reduced bc₁, were successfully used to deduce information about their binding interactions [37,40], a similar approach was taken for pyrimorph. By comparing the spectra of reduced bc₁ bound with pyrimorph to those obtained with known Qₚ or Qₐ site inhibitors such as myxothiazol or antimycin A, we hoped to gain insight into the binding interactions and location.

Binding of pyrimorph causes the spectrum to red shift, as the difference spectrum [[(bc₁+pyr)-bc₁]] shows a trough centered around 565 nm (Fig. 3A), which is an indication that binding of pyrimorph affects cyt b hemes. This spectrum was compared to spectra with bound Qₚ site inhibitor myxothiazol [[(bc₁+myx)-bc₁]] and Qₐ site inhibitor antimycin A [[(bc₁+ant)-bc₁]], respectively (Figs. 3B and 3E). At first glance, it seems that the spectral change due to pyrimorph binding resembles that caused by myxothiazol binding, despite considerable differences (see below), indicating that pyrimorph binds closer to the Qₚ site. Indeed, binding pyrimorph to bc₁ does not seem to interfere with subsequent binding of antimycin A, as the difference spectrum of [[(bc₁+pyr+ant) - (bc₁+ant)] (Fig. 3F) looks almost identical to [[(bc₁+pyr)-bc₁]] (Fig. 3A). This experiment confirms that pyrimorph does not target the Qₚ site.

However, binding of pyrimorph to bc₁ does affect subsequent binding of myxothiazol and vice versa, because the difference spectrum [[(bc₁+pyr+myx) - (bc₁+myx)] (Fig. 3C) does not look like that of [[(bc₁+pyr)-bc₁]] (Fig. 3A), nor does the difference spectrum [[(bc₁+pyr+myx) - (bc₁+pyr)] (Fig. 3D) resemble that of [[(bc₁+myx)-bc₁]] (Fig. 3B). These spectra indicate the possibility that both inhibitors can co-exist near the Qₚ pocket and influence each other. Since the binding of myxothiazol to the Qₚ pocket is well established, the experiment further suggests that pyrimorph may have a different binding mode from that of myxothiazol.

Inhibitory Kinetics of Cyt bc₁ Suggests the Mode of Pyrimorph Action

The possibility that pyrimorph has a different mode of action is of particular interest in light of our extensive knowledge on the development of resistance to existing inhibitors. To further probe the mechanism of pyrimorph’s action, we investigated the kinetic properties of bc₁ function under pseudo first-order reaction conditions by measuring its activity with respect to changes in concentration of either substrates QₐC₁₀BrH₂ or cyt c in the presence of different amount of pyrimorph, allowing double reciprocal or Lineweaver-Burk plots to reveal the relationship between 1/V and 1/[S]. The measurements were done for both Bbc₁ and Ribbc₁, revealing nearly identical kinetic behavior (Fig. 4).

As shown in Figs. 4A and 4C, in the presence of a constant 80 μM cyt c and with increasing concentrations of QₐC₁₀BrH₂, both Kₘ and V_max are altered as is the Kₘ/V_max ratio. Expectedly, as the concentration of pyrimorph increases, the V_max decreases; at a constant pyrimorph concentration, the reciprocal enzyme activity 1/V has a positive slope with respect to 1/[S]. However, the Kₘ value for the substrate quinol changed, falling between competitive (Fig. 4E) and non-competitive (Fig. 4F) inhibitions. Thus, pyrimorph falls into the category of a mixed-type, noncompetitive inhibitor with respect to the substrate ubiquinol, suggesting that it competes, both directly and indirectly, with ubiquinol to occupy the Qₚ site.

At a constant 50 μM QₐC₁₀BrH₂ concentration and with varying concentrations of cyt c, double-reciprocal plots show that x-intercepts remain the same with or without pyrimorph (Figs. 4B and 4D), suggesting that the apparent Kₘ for substrate cyt c remains unchanged. Thus, pyrimorph is a noncompetitive inhibitor with respect to cyt c. As a control, we performed the same experiments with Bbc₁ using the classic Qₚ-site inhibitor myxothiazol, showing that myxothiazol is a competitive inhibitor for the substrate quinol but a non-competitive inhibitor for cyt c (Figs. 4E and 4F).

Docking of Pyrimorph to cyt b Subunit

Docking of pyrimorph to known inhibitor-binding sites in the cyt b subunit of Bbc₁ were performed with Autodock Vina and resulted in top solutions at the Qₚ site with a binding free energy of −9.7 kcal/mol and −9.2 kcal/mol at the Qₚ site, representing a 2.3-fold difference in binding affinity between the two sites. These energy values can be compared with binding of other known bc₁ inhibitors such as stigmatellin, giving rise to a binding free energy of −10.5 kcal/mol. Potential inhibitor binding sites outside the known active sites were searched by Q-site-finder and the top 20 sites suggested (which included the Qₚ and Qₐ site) were subjected to extensive docking trials using Autodock Vina but no new locations showing improved affinity over the classic sites were identified. The Qₚ site showed the highest binding affinity to pyrimorph. Unlike traditional inhibitors, pyrimorph does not enter the Qₚ site, but rather blocks the entrance or portal to the quinol oxidation site (Fig. 5A). While its morpholino and 4-(2-chloro pyridyl) moieties stay in the central cavity of the bc₁ dimer, its 4-(tert-butyl) phenyl group enters the access portal, where it is stabilized by the aromatic side chain of P274 and partially by F128. The latter primarily interacts with the pyridyl moiety via aromatic-aromatic (Ar-Ar) interactions. The tert-butyl group that penetrates into the Qₚ site is flanked by the residues Y273, Y131 and P270, establishing beneficial van-der-Waals contacts.

Discussion

Resistance to cyt bc₁ inhibitors has been extensively investigated, revealing a wide variety of underlying mechanisms including target site mutations [41,42], activation of alternative oxidase pathways [43,44], altered metabolic degradation [45], reduced uptake and increased efflux [46,47]. By far, target site mutation is the most prevalent form of resistance that develops against bc₁ inhibitors. Thus, extensive research has been focusing on how to overcome resistance caused by target site mutations. Finding
Inhibitors that target alternative sites seems to be an attractive strategy.

**Pyrimorph is a Multi-target Fungicide Displaying Inhibitory Activity against Cyt bc**

Pyrimorph is a fungicide containing a carboxylic acid amide (CAA) moiety and was shown to be cross-resistant with other CAA fungicides such as manidipropamid, dimethomorph and flumorph [21], suggesting the possibility that pyrimorph may function in a manner similar to that of other CAA-type fungicides such as manidipropamid for which the mode of action was established by inhibiting cellulose synthase 3 or CesA3 [19]. In a recent publication [21], pyrimorph-resistant isolates of *P. capsici* were selected in the presence of the inhibitor and the three most resistant strains share a common mutation (Q1077K) in the CesA3 gene, which is different from the one (G1104V) selected for manidipropamid resistance [19]. However, it remains to be seen whether transfer of the resistant allele to the sensitive parental strain would make the latter pyrimorph-resistant. So far there is no direct evidence from *in vitro* biochemical experiments that shows that at the protein level the inhibition of CesA3 by pyrimorph.

In the current study, we followed up on the previous observation that pyrimorph may act on the cellular respiratory chain of pathogenic fungi [20]. We showed that pyrimorph is able to suppress the respiratory chain function at 4 μM concentration by inhibiting the activity of Complex III in isolated mitochondria of *P. capsici* mycelia (Table 1). We further showed conclusively that pyrimorph inhibits purified mitochondrial as well as bacterial bc1 complexes with IC50 values at sub-millimolar range (Fig. 1). By contrast, two other CAA-type inhibitors, dimethomorph and flumorph, displayed no inhibitory activity against bc1 complex (Fig. 1A).

It did not escape our notice that cyt bc1 in light mitochondrial fraction isolated from *P. capsici* mycelia appears to be more sensitive to pyrimorph than purified bovine or bacterial bc1 complexes, suggesting the following possibilities: (1) Direct comparison between results of two very different assays is not a fair comparison, because in isolated light mitochondrial fraction the estimation of cyt bc1 concentration is difficult in the presence of many different proteins. However, the inhibitory concentrations or IC values are directly related to the amount of enzyme in the assay solution. So the lower IC value could be due to a lower concentration of bc1 in the assay conditions. (2) Being a hydrophobic compound, pyrimorph may preferentially partition into the lipid bilayer of mitochondrial membranes, leading to a higher local concentration and in turn to the apparent 95% inhibition at 4 μM concentration (Table 1, Fig. 1). (3) Conversely, the presence of detergent (micelles) in the solution of purified bc1 complex might lower the effective concentration of pyrimorph. This scenario is less likely, as the concentration of β-DDM in our assay buffer is barely above one critical micelle concentration (CMC). (4) The cyt bc1 of *P. capsici* is more sensitive to pyrimorph than either bovine or bacterial bc1. However, we note that the purified bacterial complex is more sensitive to pyrimorph than bovine bc1 but only by a factor of 1.2. The difference might simply be a reflection of changes in the sequences and we do observe that bacterial bc1 exhibits slightly higher similarity to fungal than bovine mitochondrial cyt b.

**Pyrimorph Likely Acts Near but not at the Qb Site**

The fact that pyrimorph inhibits both 11-subunit Bb bc1 and 4-subunit Rb bc1 demonstrates that the inhibitor acts on cyt b, cyt c1 or ISP subunits of the complex; it does not inhibit mitochondrial bc1 function through binding to the so-called supernumerary subunits (Figs. 1B and 1C). The two potential sites for pyrimorph binding are QN and Qb in the cyt b subunit and so far all experimental evidence suggests a binding site near the Qb site: (1) Single turn-over experiments show the reduction rate of cyt c1 and re-oxidation rate of cyt b in the presence of two different concentrations of pyrimorph (Figs. 2A and 2B) are very similar to those in the presence of the Qb site inhibitor myxothiazol (Fig. 2D), but are drastically different from those in the presence of the QN site inhibitor antimycin A (Fig. 2C). (2) Difference spectra of reduced cyt bc1 also provided strong evidence that pyrimorph targets the Qb site (Fig. 3), because the difference spectrum of [(bc1+pyr)-bc1] (Fig. 3A) resembles that of [(bc1+myx)-bc1] (Fig. 3B) but not that of [(bc1+ant)-bc1] (Fig. 3E).

While the analysis of the difference spectra points to the Qb pocket as the target site, it also suggests that pyrimorph has a non-overlapping binding site with the classic Qb site inhibitor myxothiazol (Fig. 3). Indeed, double-reciprocal or Lineweaver-Burk plots of bc1 activity showed that pyrimorph acts as a mixed-type, non-competitive inhibitor with respect to the substrate ubiquinol (Figs. 4A and 4C), suggesting that pyrimorph may act both competitively and non-competitively for the substrate ubiquinol (Fig. 4E). Mechanistically, it means that pyrimorph is capable of modulating the binding of the substrate ubiquinol without directly competing with it at the active site, which categorizes it as a mixed-type, non-competitive inhibitor [48].

Unlike classic Qb site inhibitors that compete directly with substrate ubiquinol for interactions with the same set of residues in the Qb site, pyrimorph rather seems to block the portal to the Qb site, through which the substrate ubiquinol has to pass to contact ISP. Simultaneously, a good portion of pyrimorph is held outside the substrate-binding pocket by hydrophobic forces. Consequently, ubiquinol has to actively displace pyrimorph from the entrance in order to gain access to the Qb site as in the case of a competitive inhibitor. On the other hand, as pyrimorph has the ability to adhere well to the lipophilic sides of the portal that leads to the Qb site of cyt b, it may stay close and possibly interfere with the necessary motion of the cd1/cd2 helix and with the release of ubiquinone, displaying inhibitory activities more characteristic of non-competitive inhibitors. This picture is entirely consistent with biochemical and spectral characterizations of pyrimorph, qualifying it as a mixed-type, non-competitive inhibitor.

Molecular modeling of other CAA-type fungicides such as dimethomorph indicate a very similar binding position and orientation to the Qb site but with a significantly lower free energy for binding, consistent with the observation that both dimethomorph and flumorph are not bc1 inhibitors (Fig. 1A). Since both dimethomorph and flumorph structurally resemble pyrimorph, it is clear that the shape of pyrimorph is not a dominant factor for its ability to bind bc1. At the very least the binding of pyrimorph has sparked ideas for a dual approach to inhibitor design: (1) on the side that binds to the Qb site, modifications could significantly increase the affinity, making it a better competitive inhibitor. (2) Improvements in hydrophobicity or geometric factors on the side that stays outside the Qb pocket, the inhibitor could enhance its non-competitive properties. Should it be possible to design a dual type inhibitor, fungal resistance may be stalled for an extended period. Suggestions for improvements might include modifications of the tert-butyl group to include polar groups (hydroxy methyl, methoxy methyl, etc.) that are within the reach of E271 (both sidechain and backbone amide) as well as sterically demanding aromatic groups that may take advantage of the large, aromatic cavity of the Qb site. On the side that stays outside of the Qb pocket, variations of saturated and aromatic ring systems seem likely to improve binding properties, as it appears
that the morpholino group and the chloro-pyridyl group can change places with minimal change in binding energy.
