**Abstract** | The aim of this study was to investigate the effect of ammonia and fermentation treatment on *Cymbopogon nardus* L. waste as a substitute for *Pennisetum purpureum* grass on the nutritional profile and macronutrient digestibility under *in vitro* conditions. Seven rations (3 replications) were formed CN0 (100% *P. purpureum*), ACN1 (25% ammoniated *C. nardus* + 75% *P. purpureum*), ACN2 (50% ammoniated *C. nardus* + 50% *P. purpureum*), ACN3 (100% ammoniated *C. nardus*), FCN1 (25% fermented *C. nardus* + 75% *P. purpureum*), FCN2 (50% fermented *C. nardus* + 50% *P. purpureum*), and FCN3 (100% fermented *C. nardus*). A completely randomized design was used in this study and data integration was done using analysis of variance with posthoc Tukey’s test. The results obtained show that the nutritional profiles of ACN1 and FCN1 were slightly different from CN0. *In vitro* digestibility (%) of dry matter (IVDMD) and organic matter (IVOMD) after 48 h of incubation showed high significant differences (P < 0.001) among the treatments. There was no significant difference (P > 0.05) between CN0, ACN1 and FCN1 on digestibility of CP (IVCPD), NDF (IVNDFD), ADF (IVADFD) and cellulose (IVCLD). In conclusion, ammonia and fermentation treatment on *C. nardus* waste can be utilized as a substitute for *P. purpureum* at a level of 25% in a ruminant ration.

INTRODUCTION

*Cymbopogon nardus* L. or Ceylon citronella plants are one of the primary agribusiness commodities that produce essential oils (Citronella oil) in Indonesia and in the international market. Edible parts (stems and leaves) of *C. nardus* are distilled to produce citronella oil which is widely used in the food and pharmaceutical industries. In 2017, Indonesia had a plantation area that produces citronella oil which was close to 20,000 ha with plant productivity of ± 3000 tons (Sulaswatty et al., 2019). The potential biomass of *C. nardus* waste produced by citronella oil refining industry in Indonesia reaches more than 2,500 tons/year. The proximate analysis shows that *C. nardus* waste contains crude protein and fibre at 5.82 and 35.02%, respectively (Sari et al., 2017). This indicates that *C. nardus* waste has a great opportunity as a source of fibre feed and a substitute for tropical grass to support the production of ruminants. However, the abundant crude fibre fraction in *C. nardus* waste is a limiting factor that must be considered. Therefore, it requires the right feed processing method to optimize the nutritional value and digestibility in fibre materials.

Chemical and biological approaches to agro-industrial waste have been shown to reduce fibre components and neutralize...
anti-nutrients making it safe for consumption by animals. In vitro and in vivo evaluations of tropical agricultural waste in oil palm frond (high in lignocellulose) with ammoniation pretreatment (3-4% urea) and fermentation (Phanerochaete chrysosporium; 3 weeks incubation) showed crude fibre content that was almost similar to native grass; and improved the digestibility of macronutrients (Zain et al., 2008, 2014; Jamarun et al., 2017). Extensive studies on various forms of agricultural biomass by products with alkaline techniques and microorganisms have been shown to remove 16.7% cellulose, 50% lignin, and 32-50.1% methane production. (Kumar and Sharma, 2017; Yanti and Yayota, 2017; Kusi et al., 2018). Recently, studies that are related to Cymbopogon sp. as feed additives and sources of essential oils have provided promising evaluation results which increased rumen fermentation efficiency, reduction of total gas production, and methane inhibitors (Wanapat et al., 2013; Zulfa et al., 2017; Singh et al., 2018).

However, comparative evaluation studies on various pretreatment of C. nardus waste have not been reported. Hence information that are related to the nutritional profile, digestibility, and level of supplementation becomes a necessity. Therefore, the objective of this study was to investigate the effect of ammonia and fermentation pretreatment of C. nardus waste as a substitute for tropical grass P. purpureum on nutrient composition and digestibility under ruminal in vitro conditions.

MATERIALS AND METHODS

DIET PREPARATION AND TREATMENTS

The material used in this study was P. purpureum grass (freshly cut) obtained from the UPT Teaching Farm, Andalas University. C. nardus waste was obtained from refining citronella plants in lemongrass plantations in Solok, West Sumatra. The substrate was chopped at ± 5 cm and was put in a plastic bag. The ammonia process of C. nardus waste was done using prilled urea (CH4 N2O) at a dose of 4% dry matter; and was then stored in an airtight container for 3 weeks. As for the fermentation process, the probiotic starter Starbio® was used with a level of 6% DM of C. nardus waste; FCN1, 50% fermented C. nardus waste; FCN2, 50% fermented C. nardus waste; FCN3, 100% fermented C. nardus waste. The proportions in the diet mixture are presented in Table 1.

CHEMICAL ANALYSIS

Analyses of the content of dry matter (DM), organic matter (OM), crude protein (CP = nitrogen × 6.25), and ether extract (EE) in experimental diet was done following the AOAC procedure (2005). Estimated content of crude fibre (CF) fractions (i.e., NDF, ADF, ADL, cellulose, hemicellulose, lignin, and silica) in feed was based on Goering and Van Soest (1970). Nitrogen-free extract (NFE) content using the formula NFE = 100% - (water + ash + CP + EE + CF). Determination of total digestible nutrient (TDN) using Suitardi (1980) equation on feed nutrient content at level of CF > 18%, CP <20%, TDN = 70.6 + 0.259 CP + 1.01 EE - 0.76 CF + 0.091 NFE. Ash content was determined through a sample burning in an electric furnace at a temperature of 500°C for 6 h. Non-fibre carbohydrates (NFC) that represent cell wall fraction that is rapidly digested in the rumen was calculated using the equation: NFC = 100 - CP - EE - NDF - Ash. The results of chemical analysis are presented in Table 2.

IN VITRO INCUBATION AND DIGESTIBILITY

Rumen in vitro incubation was based on Tilley and Terry Procedure (1963). A total of 2.5 g of experimental diet was put in a 250 ml fermenter tube. Each tube was added with 50 ml rumen fluid from fistulated cow and 200 ml of McDougall’s solution (pH 6.5), which per liter of distilled water was dissolved with 9.8 g NaHCO3, 9.3 g NaHPO4.H2O, 1.2H2O, 0.57 g KCl, 0.47 g NaCl, 0.06 g MgSO4.7H2O, and 0.04 g CaCl2.2H2O. The solution was stirred until the substrate was homogeneously mixed. The blank tube was prepared which contained only rumen liquor and McDougall’s solution without the substrate. Each tube was injected with CO2 gas for 30 seconds and sealed using a rubber cap. The fermenter tube was then placed in a shaker bath with a precondition temperature of 39°C at 100 rpm for 48 h. After the incubation process, the fermenter tube was immersed in iced water to stop the

Different superscripts (a, b, c, d) in a row showed higher significance level (P <0.001).

Microbial fermentation. Then, a rubber cap was opened to measure the pH of the rumen liquor using a digital thermometer. Furthermore, rumen liquid was rotated at 10,000 rpm for 10 min to separate the supernatant from feed suspension. The suspension was added to 20 ml of pepsin with a concentration of 0.2%. Stage two of in vitro digestion ran for 24 h under aerobic conditions. The feed residual was filtered with Whatman paper no. 41.
The comparison of macronutrient compounds in the diet mixtures showed that ammonia and fermentation treatments of *C. nardus* waste have comparable profiles. The study by Manurung et al. (2015) using a substrate of *Cymbopogon winterianus* waste reported contents of CP, CF and NFE to be 9.72, 22.40 and 54.11%, respectively. In addition, Nurhayu and Warda (2018) revealed a proximate analysis of *C. nardus* waste (non-pretreatment) from an essential oil refinery, at DM (93.05%), CP (6.92%), EE (2.83%), and crude fibre (33.71%). Meanwhile, Al-Kindi et al. (2020) reported the contents of CP and CF to be 7.52 and 29.63% respectively, in fermentation approach. But superior results achieved by ammoniation application progressively increased CP concentration. This is affected by the ammonia process using urea as nitrogen source that is able to stretch lignocellulose bonds and silica deposits and increase nitrogen accumulation through NH$_3$ hydrolysis. Decrease of CF content was lesser in *C. nardus* waste, especially in the fermentation treatment due to the shorter incubation time. This reduced the opportunity for microorganisms to produce more extracellular enzymes to break down structural carbohydrates in high fibre feed (Desnamrina et al., 2019).

Fractions of NDF and ADF in the mixture of ammoniated *C. nardus* and *P. purpureum* (Table 2) ranged from 89.97-92.32% (ACN3 and ACN1), while the fermentation treatment had a closely similar value that ranged from 88.55-92.10% (FCN3 and FCN1). The compositions of OM, CP, EE, and ash of citronella waste were almost comparable in both treatments. The highest CF content was FCN3 (34.25%) and the lowest was CN0 (25.14%). For TDN, NDF, and hemicellulose, the addition of ammoniated citronella waste (25, 50, and 100%) had average values that ranged from 7-12%, higher than the CN0 and fermentation treatments. The increased composition of fermented citronella waste at various levels contributed to differences in the content of NFC, ADF, ADL, silica, and lignin among treatments.

**RESULTS AND DISCUSSION**

### CHEMICAL COMPOSITION

The composition of DM in a mixture of ammoniated *C. nardus* and *P. purpureum* (Table 2) ranged from 89.97-92.32% (ACN3 and ACN1), while the fermentation treatment had a closely similar value that ranged from 88.55-92.10% (FCN3 and FCN1). The compositions of OM, CP, EE, and ash of citronella waste were almost comparable in both treatments. The highest CF content was FCN3 (34.25%) and the lowest was CN0 (25.14%). For TDN, NDF, and hemicellulose, the addition of ammoniated citronella waste (25, 50, and 100%) had average values that ranged from 7-12%, higher than the CN0 and fermentation treatments. The increased composition of fermented citronella waste at various levels contributed to differences in the content of NFC, ADF, ADL, silica, and lignin among treatments.

### IN VITRO RUMEN DIGESTIBILITY

Table 3 shows that pretreatment of *C. nardus* waste with different composition had a higher significant difference (P <0.001) on in vitro nutrient digestibility. In general, the pH of the rumen fluid was quite stable in the range of 6.68 - 6.76. The IVDMD parameter, CN0 gave the highest yield (62.53%) followed by ACN1 (58.38%) and the lowest was FCN3 (42.62%). A similar pattern occurred in IVOMD with the highest in CN0 (61.37%) and the lowest in FCN3 (41.35%). The digestibility of CP (IVCPD), NDF (IVNDFD), ADF (IVADFD), and cellulose (IVCLD) were not significantly different (P > 0.05) between CN0, ACN1, and FCN1. Among the ammoniation and fermentation treatments, the best IVCPD was reached by ACN1 (45.78%) and FCN1 (45.74%). Considerable levels of IVNDFD and IVADFD respectively, were CN0, ACN1, and FCN1. The IVCLD regressedly decreased along with the increasing ratio of *C. nardus* waste.
In vitro evaluation of DM and OM digestibility of *C. nardus* waste with preservation treatment showed potential as a source of fibre feed for ruminants. However, an increasing percentage of *C. nardus* waste to more than 50% level can suppress nutrients digestibility. This is due to the fact that higher fibre fraction can act as an inhibitor in ruminal biodegradation (Frei, 2013). Comparative in sacco study conducted by Sari et al. (2017) on *C. nardus* (fresh leaves and stem) and *C. nardus* waste that had been incubated in buffalo rumen for 48 h revealed different levels of degradation of DM (44.1% versus 49.9%) and OM (45.7% versus 52.1%). The widely used agricultural waste as alternative fibre sources in tropical areas, such as fermented cocoa pods (3% molasses + *Phanerochaete chrysosporium*), has IVDMD and IVOMD (<60%) which is almost no different from the value of ACN1 and FCN1 (Laconi and Jayanegara, 2015). However, IVCPD levels in this study were lower than other tropical agricultural waste based diet. In vitro evaluation of ammoniated rice straw based feed (40% DM) showed CP digestibility in a range of 57-71% (Zain et al., 2019). Besides, the digestibility of NDF, ADF and cellulose in total mixed ratio of ammoniated rice straw basis were higher than lemongrass (Ningrat et al., 2019). This can be explained as due to a higher content of plant cell wall in the roughage that implicated limiting access of nitrogen and soluble carbohydrate to rumen microbes for fulfilling growth requirements. Sugiharto et al. (2018) confirmed that some tropical agroindustry waste still contains bioactive agents that influence the activity and the population of microbes. Therefore, utilization of pretreatment *C. nardus* waste is recommended at 25% level as a fibre source replacer.

**CONCLUSION AND RECOMMENDATIONS**

Ammonia and fermentation treatment of *C. nardus* waste did not improve nutrition profile, in vitro dry matter and organic matter digestibility. Nevertheless, partial substitution (25% DM) of *P. purpureum* to *C. nardus* waste presented a comparable degradation level on crude protein and fibre compound.

**ACKNOWLEDGMENTS**

This study was supported by Professor Research Cluster Grant by BOPTN Andalas University Contract No. T/9/UN-16.17/PP. Pangan-IPRJGB/LPPM/2020. This research was carried out together with doctoral students and laboratory staff of Ruminant Nutrition, Faculty of Animal Science, Andalas University.

**AUTHOR’S CONTRIBUTION**
