ON THE MULTI-BUBBLE BLOW-UP SOLUTIONS TO ROUGH NONLINEAR SCHRÖDINGER EQUATIONS

YIMING SU AND DENG ZHANG

Abstract. We are concerned with the multi-bubble blow-up solutions to rough nonlinear Schrödinger equations in the focusing mass-critical case. In both dimensions one and two, we construct the finite time multi-bubble solutions, which concentrate at $K$ distinct points, $1 \leq K < \infty$, and behave asymptotically like a sum of pseudo-conformal blow-up solutions in the pseudo-conformal space $\Sigma$ near the blow-up time. The upper bound of the asymptotic behavior is closely related to the flatness of noise at blow-up points. Moreover, we prove the conditional uniqueness of multi-bubble solutions in the case where the asymptotic behavior in the energy space $H^1$ is of the order $(T - t)^{3+\zeta}, \zeta > 0$. These results are also obtained for nonlinear Schrödinger equations with lower order perturbations, particularly, in the absence of the classical pseudo-conformal symmetry and the conservation law of energy. The existence results are applicable to the canonical deterministic nonlinear Schrödinger equation and complement the previous work [43]. The conditional uniqueness results are new in both the stochastic and deterministic case.

1. Introduction

This work is devoted to the existence and uniqueness of blow-up solutions at multiple points to the rough nonlinear Schrödinger equations in the focusing mass-critical case. Precisely, we consider

\begin{equation}
    idX = -\Delta X dt - |X|^4 X dt - i\mu X dt + iXdW(t),
    \tag{1.1}
    X(0) = X_0 \in H^1(\mathbb{R}^d).
\end{equation}

Here, $W$ is the Wiener process of the form

\[ W(t, x) = \sum_{k=1}^{N} i\phi_k(x) B_k(t), \quad x \in \mathbb{R}^d, \quad t \geq 0, \]

where $\phi_k \in C_0^\infty(\mathbb{R}^d, \mathbb{R})$, $B_k$ are the standard $N$-dimensional real valued Brownian motions on a stochastic basis $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, \mathbb{P})$, $1 \leq k \leq N$, and $\mu = \frac{1}{2} \sum_{k=1}^{N} \phi_k^2$. The last term $X dW(t)$ in (1.1) is taken in the sense of controlled rough path (see Definition 2.1 below). In particular, the rough integration coincides with the usual Itô integration if the corresponding processes are $\{\mathcal{F}_t\}$-adapted (see [27, Chapter 5]). For simplicity we assume that $N < \infty$, but the arguments below can be also applied to the case when $N = \infty$ under suitable summability conditions.

The noise here is mainly considered of conservative type, i.e., $\text{Re}W = 0$. In this case, the quantum system evolves on the unit ball if the initial state is normalized $\|X_0\|_{L^2} = 1$ and thus verifies the conservation of probability.

One significant model of nonlinear Schrödinger equations with noise arises from the molecular aggregates with thermal fluctuations, where the multiplicative noise corresponds to scattering of exciton by phonons, due to thermal vibrations of the molecules. The noise effect on the coherence of the ground state solitary solution was studied in [1, 2] for the two dimensional case with the critical cubic nonlinearity. The influence of noise on collapse in the one dimensional case with quintic nonlinearity was studied in [56].

Another important application is related to the open quantum systems [9], in which the stochastic perturbation $iX\phi_k dB_k$ represents a stochastic continuous measurement via the pointwise quantum observable $R_k(X) = X\phi_k$, while $B_k$ represents the output of continuous measurement, $1 \leq k \leq N$. We refer to [9, Chapter 2] for more physical interpretations. See also [59] for other physical applications of Schrödinger equations.

The local well-posedness of equation (1.1) is quite well known when the stochastic integration is taken in the sense of Itô or rough path. See, e.g., [5, 10, 18, 58]. However, the situation becomes much more delicate for the large time behavior of solutions. As a matter of fact, solutions may formalize singularities in finite time in the focusing mass-(super)critical case.

When the input noise is of conservative type, it was first proved by de Bouard and Debussche [17, 19] that the noise has the effect to accelerate blow-up with positive probability in the mass-supercritical case (i.e., the exponent of nonlinearity is in the region $(1 + \frac{4}{d}, 1 + \frac{4}{(d-2)_+})$). When the noise is of non-conservative type, the explosion, however, can be prevented with high probability as long as the strengthen of noise is large enough, which reflects the damped effect of non-conservative noise ([7]). We also refer to [50] for the global well-posedness below the threshold in the mass-(super)critical case.

Moreover, many numerical simulations have been made to investigate the blow-up phenomena in the stochastic case. It was observed in [20, 21, 22] that the colored multiplicative noise has the effect to delay blow-up, while the white noise may even prevent blow-up. Such phenomena have been also confirmed by the recent numerical results in
The noise effects on the energy, global well-posedness and blow-up profiles are also studied in [51, 52], which partially confirm the conjecture that, in the mass-critical case the stable blow-up solutions with slightly supercritical mass shall have the log log blow-up rate, while in the mass-supercritical case the blow-up rate is of a different polynomial type.

Recently, the minimal mass blow-up solutions have been constructed by the authors in [58], and it is shown that the mass of the ground state characterizes the threshold of global well-posedness and blow-up in the stochastic case. The log-log blow-up solutions have been also constructed in [26] in the stochastic case. We also would like to refer to the recent work [25] for the log-log blow-up solutions with $L^2$-regularity randomized initial data.

In this paper, we are mainly interested in the blow-up dynamics in the large mass regime, particulary, the existence and uniqueness of multi-bubble blow-up solutions in initial data.

Before stating the main results, let us first review the existing results for the deterministic nonlinear Schrödinger equation (NLS)

\[
\begin{aligned}
\begin{cases}
    i\partial_t u + \Delta u + |u|^{\frac{4}{d}} u = 0, \\
u(0) = u_0 \in H^1(\mathbb{R}^d),
\end{cases}
\end{aligned}
\]

Equation (1.2) admits a number of symmetries and conservation laws. It is invariant under the translation, scaling, phase rotation and Galilean transform, i.e., if $u$ solves (1.2), then so does

\[
v(t, x) = \lambda_0^{-\frac{d}{2}} u\left(\frac{t-t_0}{\lambda_0}, \frac{x-x_0}{\lambda_0} - \frac{\beta_0(t-t_0)}{\lambda_0}\right)e^{i\frac{\beta_0}{4}(x-x_0)^2(t-t_0) + i\theta_0},
\]

with $v(t_0, x) = \lambda_0^{-\frac{d}{2}} u_0(\frac{x-x_0}{\lambda_0})e^{i\frac{\beta_0}{4}(x-x_0)^2 + i\theta_0}$, where $(\lambda_0, \beta_0, \theta_0) \in \mathbb{R}^+ \times \mathbb{R}^d \times \mathbb{R}$, $x_0 \in \mathbb{R}^d$, $t_0 \in \mathbb{R}$. In particular, the $L^2$-norm of solutions is preserved under the symmetries above, and thus (1.2) is called the mass-critical equation. Another symmetry, particularly important in the blow-up analysis, is related to the pseudo-conformal transformation in the pseudo-conformal space $\Sigma := \{ u \in H^1(\mathbb{R}^d), \|xu\|_{L^2(\mathbb{R}^d)} < \infty\}$,

\[
(-t)^{-\frac{d}{2}} u\left(\frac{1}{t}, \frac{x}{t}\right)e^{-\frac{|x|^2}{4t}}, \quad t \neq 0.
\]

The conservation laws related to (1.2) contain

\[
\begin{aligned}
\text{Mass} : & \quad M(u)(t) := \int_{\mathbb{R}^d} |u(t)|^2 dx = M(u_0). \\
\text{Energy} : & \quad E(u)(t) := \frac{1}{2} \int_{\mathbb{R}^d} |\nabla u(t)|^2 dx - \frac{d}{2d+4} \int_{\mathbb{R}^d} |u(t)|^{2+\frac{4}{d}} dx = E(u_0). \\
\text{Momentum} : & \quad \text{Mom}(u) := \text{Im} \int_{\mathbb{R}^d} \nabla u \bar{u} dx = \text{Mom}(u_0).
\end{aligned}
\]

An important role here is played by the ground state $Q$, which is the unique positive spherically symmetric solution to the elliptic equation

\[
\Delta Q - Q + Q^{1+\frac{4}{d}} = 0.
\]

It is well known that (see, e.g., [52]), the mass of the ground state characterizes the threshold for the global well-posedness and blow-up of solutions to NLS. More precisely,
solutions to (1.2) exist globally if the initial data have the subcritical mass, i.e., \( \|u_0\|_{L^2} < \|Q\|_{L^2} \), while solutions may form singularities in finite time in the critical mass case, i.e., \( \|u_0\|_{L^2} = \|Q\|_{L^2} \). In particular, by virtue of the pseudo-conformal transformation (1.4), one may construct the so-called pseudo-conformal blow-up solutions

\[
S_T(t, x) = (\omega(T - t))^{-\frac{d}{2}} Q\left(\frac{x - \alpha}{\omega(T - t)}\right) e^{\frac{i}{4} \frac{|x - \alpha|^2}{\omega(T - t)} + \frac{i}{2} \frac{1}{\omega(T - t)^2}} + i \theta, \quad T \in \mathbb{R}.
\]

Note that, \( \|S_T\|_{L^2} = \|Q\|_{L^2} \), and \( S_T \) blows up at time \( T \) with the blow-up rate \( \sim (T - t)^{-1} \). Thus, \( S_T \) is the minimal mass blow-up solution.

When the mass of initial data is slightly above \( \|Q\|_{L^2} \), two different blow-up scenarios have been observed: the pseudo-conformal blow-up rate \( \sim (T - t)^{-1} \), and the log-log blow-up rate \( \sim \sqrt{\log \log |T - t|} \). For the blow-up and classification results in this case we refer to [11, 47, 48, 53] and the references therein.

For even larger mass of initial data, the complete characterization of the formation of singularity is still an open problem. It is conjectured by Merle and Raphael [47] that every \( H^1 \) blow-up solution can be decomposed into a singular part and a \( L^2 \) residual, and the singular part expands asymptotically as multiple bubbles concentrating at a finite number of points. This conjecture is known as the blow-up version of the soliton resolution conjecture.

Thus, an important step to understand the singularity formulation in the large mass regime is to construct multi-bubble blow-up solutions.

In the pioneering work [43], Merle initiated the construction of blow-up solutions concentrating at arbitrary \( K(< \infty) \) distinct points, which behave asymptotically like a sum of \( K \) pseudo-conformal blow-up solutions and thus have the pseudo-conformal blow-up rate. The multi-bubble solutions with the log-log blow-up rate have been constructed by Fan [24]. Moreover, Martel and Raphael [32] constructed blow-up solutions with multiple bubbles concentrating at exactly the same point. Bubbling phenomena have been also exhibited in various other settings. See, e.g., [32] for the energy-critical NLS, and [57] for the nonlinear Schrödinger system. We also would like to refer to [15, 41] for the generalized Korteweg-de Vries equations (gKDV), [33, 34, 39] for the wave maps, and [16, 44] for the nonlinear heat equations.

However, one major challenge in the stochastic case is, that the symmetries and several conservation laws are destroyed, because of the presence of noise. Equation (1.1) is no longer invariant under the pseudo-conformal symmetry, which, however, is the key ingredient in the classification of minimal mass blow-up solutions to NLS in [10]. Moreover, the failure of the conservation law of energy creates a major problem to understand the global behavior in the stochastic case, which motivates the recent numerical tracking of the energy in the works [51, 52]. Another important qualitative difference is, that the perturbation order of profiles is of merely polynomial type in the stochastic case, which makes it rather intricate to decouple different bubbles, particularly, the remainders in the corresponding geometrical decomposition. This is different from the previous construction of multi-bubble solutions in [43] for NLS, where the interactions are exponentially small in time.

In the present work, in both dimensions one and two, we are able to construct the multiple bubble blow-up solutions concentrating at \( K \) distinct points to the rough nonlinear Schrödinger equation (1.1), \( 1 < K < \infty \). The constructed multi-bubble solutions behave asymptotically like a sum of pseudo-conformal blow-up solutions in the pseudo-conformal space \( \Sigma \) near the blow-up time and so have the pseudo-conformal blow-up rate \( \sim (T - t)^{-1} \). The upper bound of the approximation is also obtained and, interestingly,
is closely related to that of the flatness of noise at blow-up points. As a matter of fact, if the noise is more flat at the blow-up points, the approximation can be even taken in the more regular space $H^{\frac{3}{2}}$, and the perturbation orders of the corresponding geometrical parameters and the remainder can be also improved.

Another novelty of this work is concerned with the uniqueness of multi-bubble solutions. The uniqueness issue is of significant importance in the classification of blow-up solutions to dispersive equations. In the remarkable paper [46], Merle obtained the uniqueness of minimal mass blow-up solutions to NLS, which states that the pseudo-conformal blow-up solution is indeed the unique minimal mass blow-up solution up to the symmetries of NLS. Such strong rigidity results were also obtained by Raphaël and Szeftel [55] for the inhomogeneous nonlinear Schrödinger equation, and by Martel, Merle, Raphaël [11] for the mass-critical gKdV equation. We also refer to [49] for the conditional uniqueness result for the Bourgain-Wang solutions, and [36] for the Chern-Simons-Schrödinger equation.

However, to the best of our knowledge, there are very few results on the uniqueness of multi-bubble blow-up solutions to dispersive equations.

We prove that, two multi-bubble blow-up solutions to equation (1.1) are indeed the same if they have the same asymptotic blow-up profile within the order $(T - t)^{3+\zeta}$, $\zeta > 0$, in the energy space $H^1$. Hence, in this asymptotic regime, the $H^1$ multi-bubble blow-up solution is exactly the above constructed solution and so lies in the more regular pseudo-conformal space $\Sigma$. This conditional uniqueness result of multi-bubbles solutions can be also viewed as similar to the local uniqueness results in the elliptic setting, see, e.g., [12, 13, 23].

The existence and conditional uniqueness results are also obtained for a class of non-linear Schrödinger equations with lower order perturbations (see equations (2.11) and (2.17) below), particularly, in the absence of the pseudo-conformal symmetry and the conservation of energy.

In particular, the obtained results are applicable to the single bubble case and give the existence and conditional uniqueness of minimal mass blow-up solutions for both the stochastic equation (1.1) and the deterministic equation (2.17).

We would like to mention that, the existence result is also applicable to the canonical deterministic NLS. The positive frequencies $\{\omega_j\}_{j=1}^K$ in the construction here are allowed to be arbitrarily small, and the asymptotic behavior can be taken in the pseudo-conformal space $\Sigma$ instead of the space $L^{2+\frac{4}{d}}$, which complement the previous results in [43]. Furthermore, the conditional uniqueness results are new in both the stochastic and deterministic case.

The strategy of proof is mainly based on the modulation method developed in [55] for the minimal mass blow-up solutions to the inhomogeneous nonlinear Schrödinger equation. See also the recent work [58] in the stochastic setting. One major difference here is, that the study of multi-bubble solutions requires a delicate localization procedure. A great effort is dedicated to the decoupling of different bubbles. Particularly, because of the low polynomial type perturbation orders, the decoupling of the remainders in the geometrical decomposition is quite delicate. Moreover, a new generalized energy is introduced here, it incorporates the localized functions in an appropriate way such that different bubbles can be decoupled and, simultaneously, the key monotonicity property keeps still preserved. Let us also mention that, the proof of the conditional uniqueness result requires an iterated argument, which is also different from the single bubble case.
We expect the arguments developed here would be also of interest in the further understanding of multi-bubble solutions of other dispersive equations.

**Notations.** For any \( x = (x_1, \ldots, x_d) \in \mathbb{R}^d \) and any multi-index \( \nu = (\nu_1, \ldots, \nu_d) \), let 
\[
|\nu| = \sum_{j=1}^d \nu_j, \quad \langle x \rangle = (1 + |x|^2)^{1/2}, \quad \partial_x^\nu = \partial_{x_1}^{\nu_1} \cdots \partial_{x_d}^{\nu_d}, \quad \langle \nabla \rangle = (I - \Delta)^{1/2}.
\]
We use the standard Sobolev spaces \( H^{s,p}(\mathbb{R}^d) \), \( s \in \mathbb{R}, 1 \leq p \leq \infty \). In particular, \( L^p := H^{0,p}(\mathbb{R}^d) \) is the space of \( p \)-integrable (complex-valued) functions, \( L^2 \) denotes the Hilbert space endowed with the scalar product \( \langle v, w \rangle = \int_{\mathbb{R}^d} v(x) \overline{w}(x) dx \), and \( H^s := H^{s,2} \).

Let \( \Sigma \) denote the pseudo-conformal space, i.e., \( \Sigma := \{ u \in H^1, |x|u \in L^2 \} \). As usual, if \( B \) is a Banach space, \( L^0(0,T;B) \) means the space of all integrable \( B \)-valued functions \( f : (0,T) \to B \) with the norm \( \| f \| : = \| f \|_{L^0(0,T;B)} \), and \( C([0,T];B) \) denotes the space of all \( B \)-valued continuous functions on \([0,T]\) with the sup norm over \( t \). The local smoothing spaces is defined by 
\[
L^2(I;H^s_\nu) = \{ u \in \mathcal{S}': \int_I \int \langle x \rangle^{2s} |\langle \nabla \rangle^\alpha u(t,x)|^2 dx dt < \infty \}, \quad \alpha, \beta \in \mathbb{R}.
\]
Throughout this paper, the positive constants \( C \) and \( \delta \) may change from line to line.

### 2. Formulation of main results

#### 2.1. Main results

To begin with, let us first present the precise definition of solutions to (1.1), in which the noise term is taken in the sense of the controlled rough path. For more details on the theory of rough paths, see [27, 28].

**Definition 2.1.** We say that \( X \) is a solution to (1.1) on \([0,\tau^*)\), where \( \tau^* \in (0,\infty) \) is a random variable, if \( \mathbb{P}\text{-a.s. for any } \varphi \in C^\infty_c \), \( t \mapsto \langle X(t), \varphi \rangle \) is continuous on \([0,\tau^*)\) and for any \( 0 < s < t < \tau^* \),
\[
\langle X(t) - X(s), \varphi \rangle = \int_s^t \langle iX, \nabla \varphi \rangle + \langle i|X|^2 \nabla X, \varphi \rangle - \langle \mu X, \varphi \rangle dr + \sum_{k=1}^N \int_s^t \langle i\phi_k X, \varphi \rangle dB_k(r).
\]

Here, the integral \( \int_s^t \langle i\phi_k X, \varphi \rangle dB_k(r) \) is taken in the sense of controlled rough path with respect to the rough paths \((B, \mathbb{B})\), where \( \mathbb{B} = (\mathbb{B}_{jk}), \mathbb{B}_{jk, st} := \int_s^t \delta B_{j,s,r} dB_k(r) \) with the integration taken in the sense of Itô. That is, \( \langle i\phi_k X, \varphi \rangle \in C^\alpha([s,t]) \),
\[
(2.1) \quad \delta(\langle i\phi_k X, \varphi \rangle)_{st} = -\sum_{j=1}^N \langle \phi_j \phi_k X(s), \varphi \rangle \delta B_{j, st} + \delta R_{k, st},
\]
and \( \| \langle i\phi_j \phi_k X, \varphi \rangle \|_{C^\alpha([s,t])} < \infty, \quad \| R_k \|_{C^\alpha([s,t])} < \infty \).

We mention that, because of the backward propagation procedure in the construction below, the solution to (1.1) is no longer adapted to the filtration \( \{ \mathcal{F}_t \} \). Hence, the stochastic integration in (1.1) should be interpreted in the sense of the controlled rough path, instead of the Itô sense.

The theory of (controlled) rough paths, and the recent development of the theory of regularity structures [30] and the para-controlled calculus [29] have led to significant progress in solving singular parabolic stochastic partial differential equations with white noises. We refer the interested readers to the monograph [27] and the references therein for more details on these topics.

Throughout this paper we assume that
\[
(A0) \quad \text{Asymptotical flatness} \quad \text{For any multi-index } \nu \neq 0 \text{ and } 1 \leq k \leq N,
\]
\[
(2.2) \quad \lim_{|x| \to \infty} (|x|^2 |\partial^\nu_x \phi_k(x)|) = 0.
\]
(A1) (Flatness at blow-up points) There exists \( \nu_\ast \in \mathbb{N} \) such that for every \( 1 \leq k \leq N \) and \( 1 \leq j \leq K \),
\[
\partial_x \phi_k(x_j) = 0, \quad \forall \, 0 \leq |\nu| \leq \nu_\ast.
\]

(2.3)

Remark 2.2. The asymptotical flatness condition guarantees the local well-posedness of equation (1.1) (see [4, 5]), while the flatness condition at blow-up points is mainly for the construction of multi-bubble solutions. More interestingly, the order \( \nu_\ast \) is closely related to that of the asymptotic behavior of solutions near the blow-up time. See (2.4) and (2.5) below.

For the frequencies \( \omega_j > 0 \) and the blow-up points \( x_j \in \mathbb{R}^d, \, 1 \leq j \leq K \), we mainly consider two cases below:

Case (I). \( \{x_j\}_{j=1}^K \) are arbitrary distinct points in \( \mathbb{R}^d \), and \( \{\omega_j\}_{j=1}^K (\subseteq \mathbb{R}^+ \) satisfy that for some \( \omega > 0 \), \( |\omega_j - \omega| \leq \varepsilon \) for any \( 1 \leq j \leq K \), where \( \varepsilon > 0 \);

Case (II). \( \{\omega_j\}_{j=1}^K \) are arbitrary points in \( \mathbb{R}^d \), and \( \{x_j\}_{j=1}^K (\subseteq \mathbb{R}^d \) satisfy that \( |x_j - x_i| \geq \varepsilon^{-1} \) for any \( 1 \leq j \neq l \leq K \), where \( \varepsilon > 0 \).

The existence of multiple bubble solutions is formulated in Theorem 2.3 below.

Theorem 2.3. (Existence) Consider \( d = 1, 2 \). Assume (A0) and (A1) with \( \nu_\ast \geq 5 \). For every \( 1 \leq K < \infty \), let \( \{\vartheta_j\} \subseteq \mathbb{R} \), \( \{x_j\}_{j=1}^K \subseteq \mathbb{R}^d \) be distinct points, \( \{\omega_j\}_{j=1}^K \subseteq \mathbb{R}^+ \), satisfying Case (I) or Case (II).

Then, for \( \mathbb{P}-a.e. \omega \) there exists \( \varepsilon^*(\omega) > 0 \) sufficiently small such that for any \( \varepsilon \in (0, \varepsilon^* \), there exists \( \tau^* > 0 \) small enough such that for any \( T \in (0, \tau^*(\omega) \) there exist \( X_0(\omega) \in \Sigma \) and a corresponding blow-up solution \( X(\omega) \) to (1.1), satisfying that for some \( C > 0, \zeta \in (0, 1), \)

(2.4)
\[
\|e^{-\mathcal{W}(t,\omega)}X(t,\omega) - \sum_{j=1}^{K} S_j(t)\|_{\Sigma} \leq C(T - t)^{\frac{1}{2}(\nu_\ast - 5) + \zeta}, \quad t \in [0, T),
\]

where \( S_j, 1 \leq j \leq K \), are the pseudo-conformal blow-up solutions

(2.5)
\[
S_j(t, x) = (\omega_j(T - t))^{\frac{d}{4}} Q\left(\frac{x - x_j}{\omega_j(T - t)}\right) e^{-\frac{|x - x_j|^2}{|\omega_j|^2(T - t)^{\frac{1}{2}}} + \frac{i}{\omega_j(T - t)} + i \vartheta_j}, \quad t \in (0, T).
\]

Remark 2.4. The asymptotic behavior (2.4) yields that the blow-up solution concentrates at the given \( K \) points, i.e.,

(2.6)
\[
|X(t, \omega)|^2 \rightarrow \sum_{j=1}^{K} \|Q\|^2_{L^2} \delta_{x = x_j}, \quad \text{as } t \rightarrow T.
\]

In particular, \( \|X(t, \omega)\|_{L^2} = K \|Q\|_{L^2} \). Hence the multi-bubble solutions are constructed in the large mass regime, which is different from the minimal mass case in [58]. Moreover, the asymptotic can be taken in the pseudo-conformal space \( \Sigma \), which improves the \( H^1 \)-approximation result in [58].

Remark 2.5. The estimate (2.4) also shows that the order of approximation can be improved if the noise is more flat at the blow-up points. In the case \( \nu_\ast \geq 6 \), the approximation (2.4) can be even taken in the more regular space \( H^\frac{3}{4} \) (see Proposition 7.1 below). One can also improve the perturbation orders of the geometrical parameters and the remainder with more flat noise, see estimates (5.1) - (5.4) and Theorem 6.4 below. Let us also mention that, such asymptotic behavior (2.4) is exhibited only after the stochastic solutions are rescaled by the random transformation \( e^{-\mathcal{W}} \).
Remark 2.6. The multi-bubble blow-up solutions were first constructed by Merle in the pioneering work [13] for NLS in any dimensions, the main blow-up profile in [13] is built on any functions that decay exponentially, while the frequencies \( \{\omega_j\}_{j=1}^K \) are required to have a uniform positive lower bound and the asymptotic behavior is taken in the space \( L^{2+\frac{4}{d}} \). In Theorem 2.3, the multi-bubble solutions are constructed in dimensions one and two and the blow-up profile is built on the ground state, because the corresponding linearized operators are used in the construction. The gain here is that, in Case (I) the frequencies are allowed to be arbitrarily small, and in (2.4) the approximation can be taken in the energy space \( H^1 \), which is important in the proof of uniqueness result below.

Our next main result is concerned with the conditional uniqueness of multi-bubble solutions, which is the content of Theorem 2.7 below.

Theorem 2.7. (Conditional uniqueness) Consider \( d = 1, 2 \). Assume (A0) and (A1) with \( \nu_* \geq 5 \). For any \( 1 \leq K < \infty \), let \( \{\vartheta_j\} \subseteq \mathbb{R} \), \( \{x_j\}_{j=1}^K \subseteq \mathbb{R}^d \) be distinct points, \( \{\omega_j\}_{j=1}^K \subseteq \mathbb{R}^+ \), satisfying Case (I) or Case (II).

Then, for \( \mathbb{P}-\text{a.e.} \omega \) there exists \( \epsilon^*(\omega) > 0 \) sufficiently small such that for any \( \epsilon \in (0, \epsilon^*) \), there exists \( \tau^* > 0 \) small enough such that for any \( T \in (0, \tau^*(\omega)] \), there exists a unique blow-up solution \( X(\omega) \) to (1.1) satisfying

\[
\|e^{-W(t,\omega)}X(t,\omega) - \sum_{j=1}^{K} S_j(t)\|_{H^1} \leq C(T-t)^{3+\zeta}, \quad t \in [0,T),
\]

where \( C > 0 \), \( \zeta \in (0,1) \), and \( S_j \) are the pseudo-conformal blow-up solutions as in (2.5), \( 1 \leq j \leq K \).

Remark 2.8. Theorem 2.7 states that two multi-bubble solutions are the same if they both have the asymptotic behavior (2.7) in the energy space \( H^1 \). Moreover, it also yields that any \( H^1 \) solution satisfying (2.7) is exactly the constructed solution in Theorem 2.3, which lies in the more regular \( \Sigma \) space.

Remark 2.9. The conditional uniqueness result also holds for the (deterministic) non-linear Schrödinger equations with lower order perturbations (see Theorem 2.13 and Remark 2.10 below), which include the canonical NLS equation. Let us also mention that, these conditional uniqueness results are new in both the stochastic and deterministic case.

In particular, in the special single bubble case (i.e., \( K = 1 \)), we have the following existence and conditional uniqueness of minimal mass blow-up solutions.

Theorem 2.10. Consider \( d = 1, 2 \). Assume (A0) and (A1) with \( \nu_* \geq 5 \). Let \( x_*,\omega_*,\vartheta_* \) be any given points. Then, for \( \mathbb{P}-\text{a.e.} \omega \) there exists \( \tau^*(\omega) > 0 \) sufficiently small, such that for any \( T \in (0, \tau^*(\omega)] \) there exists a minimal mass blow-up solution \( X(\omega) \) to (1.1) satisfying that

\[
\|e^{-W(t,\omega)}X(t,\omega) - S_*(t)\|_{\Sigma} \leq C(T-t)^{\frac{1}{2}(\nu_*-5)+\zeta}, \quad t \in [0,T),
\]

where \( C > 0 \), \( \zeta \in (0,1) \), and \( S_* \) is as in (1.9) with \( x_*,\omega_*,\vartheta_* \) replacing \( \alpha_j,\omega_j,\vartheta_j \), respectively.

Moreover, in the case where \( \nu_* \geq 11 \), there exists a unique minimal mass blow-up solution \( X(\omega) \) to (1.1) satisfying that

\[
\|e^{-W(t,\omega)}X(t,\omega) - S_*(t)\|_{H^1} \leq C(T-t)^{3+\zeta}, \quad t \in [0,T).
\]

Remark 2.11. The existence of minimal mass blow-up solutions are proved in the recent work [58], but with the asymptotic (2.8) taken in the \( H^1 \) space. The conditional uniqueness
result is new in the stochastic case. It should be mentioned that, the strong uniqueness of minimal mass blow-up solutions to NLS in the deterministic case was first obtained by Merle in the remarkable paper [46]. Such strong rigidity results have been also obtained for the inhomogeneous NLS equations [55] and for the gKdV equations [41]. For the stochastic equation (1.1) the strong uniqueness of minimal mass blow-up solutions is at present still unclear, due to the lack of the conservation law of energy.

Equation (1.1) is indeed closely related to the nonlinear Schrödinger equations with lower order perturbations. More precisely, by virtue of the rescaling transformation
\[ u := e^{-W}X, \]
we may reduce equation (1.1) to the random equation below
\[ \begin{align*}
  i\partial_t u + \Delta u + |u|^4 du + b \cdot \nabla u + cu &= 0, \\
  u(0) &= u_0,
\end{align*} \]
where \( b \) and \( c \) are the coefficients of lower order perturbations
\[ \begin{align*}
  b(t, x) &= 2\nabla W(t, x) = 2i \sum_{k=1}^{N} \nabla \phi_k(x) B_k(t), \\
  c(t, x) &= \sum_{j=1}^{d} (\partial_j W(t, x))^2 + \Delta W(t, x) \\
  &= -\sum_{j=1}^{d} \left( \sum_{k=1}^{N} \partial_j \phi_k(x) B_k(t) \right)^2 + i \sum_{k=1}^{N} \Delta \phi_k(x) B_k(t).
\end{align*} \]
The key equivalent result has been proved in the recent work [58], based on a delicate analysis of the temporal regularities. Let us mention that, such transformation is known as the Doss-Sussman transformation in finite dimensional case, and proves to be also very robust in the infinite dimensional spaces. One main advantage is that, from the viewpoint of analysis, it enables one to treat equation (1.1) as a random dynamic system outside a uniform probability null set, and thus to perform the sharp path-by-path analysis of stochastic solutions, which is in general not easy by standard stochastic analysis. Furthermore, the rescaling approach also reveals the structure of stochastic equations, which becomes more apparent in the reduced nonlinear Schrödinger equations with lower order perturbations. See, for instance, the stochastic logarithmic Schrödinger equations in [6], the damped effect of non-conservative noise in [7], and the scattering behavior in the stochastic setting in [31]. See also the existence and geometrical characterization of optimal controllers in [8, 65], related to the Ekeland’s variational principle and the theory of \( U^p - V^p \) spaces.

The solutions to equation (2.11) are defined below.

**Definition 2.12.** We say that \( u \) is a solution to (2.11) on \( [0, \tau^*) \), where \( \tau^* \in (0, \infty) \) is a random variable, if \( \mathbb{P} - \text{a.s. } u \in C([0, \tau^*]; H^1), \ |u|^4 u \in L^1(0, \tau^*; H^{-1}), \) and \( u \) satisfies
\[ \begin{align*}
  u(t) &= u(0) + \int_0^t ie^{-W(s)} \Delta(e^{W(s)}u(s)) + i|u(s)|^4 u(s) ds, \quad t \in [0, \tau^*),
\end{align*} \]
as an equation in \( H^{-1} \).

The key equivalent relationship between equations (1.1) and (2.11) is stated in Theorem 2.13 below.
Theorem 2.13. ([20, Theorem 2.10]) (i). Let $u$ be the solution to \((2.11)\) on \([0, \tau^*)\) with $u(0) = u_0 \in H^1$ in the sense of Definition 2.12, where $\tau^* \in (0, \infty]$ is a random variable. Then, $P$-a.s., $X := e^{Wu}$ is the solution to equation \((1.1)\) on \([0, \tau^*)\) with $X(0) = u_0$ in the sense of Definition 2.14. Then, for $\tau^*$, \(2.15\) There, for $\epsilon \in W^1$ and a corresponding blow-up solution $u$ in the sense of Definition 2.12. Hence, by virtue of Theorem 2.13, the proof of Theorems 2.3 and 2.7 is now reduced to that of Theorems 2.14 and 2.15 below corresponding to the equation \((2.11)\).

Theorem 2.14. (Existence) Consider $d = 1, 2$. Assume \((A0)\) and \((A1)\) with $\nu \geq 5$. For any $1 \leq K < \infty$, let $\{\partial_j\}_{j=1}^K \subseteq \mathbb{R}$, $\{x_j\}_{j=1}^K \subseteq \mathbb{R}^d$ be distinct points, and $\{\omega_j\}_{j=1}^K \subseteq \mathbb{R}^+$, satisfying either Case (I) or Case (II).

Then, for $P$-a.e. $\omega$ there exists $\nu^* > 0$ such that for any $\epsilon \in (0, \nu^*)$, there exists $\tau^* > 0$ small enough such that for any $T \in (0, \tau^*(\omega)]$, there exist $u_0(\omega) \in \Omega$ and a corresponding blow-up solution $u(\omega)$ to \((2.11)\) such that
\[
\|u(t, \omega) - \sum_{j=1}^K S_j(t)\|_{\Omega} \leq C(T-t)\frac{\nu}{(\nu-5)+\zeta}, \quad t \in [0, T),
\]
where $C > 0$, $\zeta \in (0, 1)$, and $S_j$ are the pseudo-conformal blow-up solutions given by \((2.5)\), $1 \leq j \leq K$.

Theorem 2.15. (Conditional uniqueness) Consider the situations as in Theorem 2.14. Then, for $P$-a.e. $\omega$ there exists $\nu^* > 0$ such that for any $\epsilon \in (0, \nu^*)$, there exists $\tau^* > 0$ small enough such that for any $T \in (0, \tau^*(\omega)]$, there exists a unique blow-up solution $u(\omega)$ to \((2.11)\) satisfying
\[
\|u(t, \omega) - \sum_{j=1}^K S_j(t)\|_{H^1} \leq C(T-t)^{3+\zeta}, \quad t \in [0, T),
\]
where $C > 0$, $\zeta \in (0, 1)$, and $S_j$ are as in \((2.5)\), $1 \leq j \leq K$.

Remark 2.16. The existence and conditional uniqueness results of multi-bubbles also hold for the deterministic nonlinear Schrödinger equation with lower order perturbations if the Brownian motions $\{B_k\}$ in \((2.11)\) are replaced by any deterministic continuous functions, namely,
\[
i\partial_t v + \Delta v + |v|^\frac{4}{d} v + a_1 \cdot \nabla u + a_2 u = 0,
\]
where
\[
a_1(t, x) = 2i \sum_{k=1}^N \nabla \phi_k(x) h_k(t), \quad a_2(t, x) = - \sum_{j=1}^d \left( \sum_{k=1}^N \partial_j \phi_k(x) h_k(t) \right)^2 + i \sum_{k=1}^N \Delta \phi_k(x) h_k(t),
\]
$\phi_k$ satisfy Assumptions \((A0)\) and \((A1)\) and $h_k \in C(\mathbb{R}^+; \mathbb{R})$, $1 \leq k \leq K$. In particular, these results are applicable to the canonical NLS equation, in which $a_1, a_2 \equiv 0$. Note that, the standard pseudo-conformal symmetry and the conservation law of energy are also destroyed in equation \((2.17)\).
2.2. **Strategy of proof.** By virtue of the equivalent result Theorem 2.13, we shall mainly focus on the proof of Theorems 2.14 and 2.15, namely, the existence and uniqueness of multi-bubble blow-up solutions to nonlinear Schrödinger equations with lower order perturbations (2.11).

As mentioned above, the absence of specific symmetries and the conservation law of energy makes the blow-up analysis rather intricate. A robust modulation method was developed by Raphaël and Szeftel [55] for the existence and uniqueness of minimal mass blow-up solutions to inhomogeneous nonlinear Schrödinger equations, which is a canonical model proposed by Merle [45] to break the pseudo-conformal symmetry. This modulation method has been recently applied in [58] to construct minimal mass blow-up solutions for both equations (1.1) and (2.11). The main strategy consists of geometrical decompositions, a bootstrap device and backward propagation from the singularity.

Here, we use and extend the modulation method to address the multi-bubble problem. More specifically, we first decompose the solution to (2.11) into a main blow-up profile

\[ u(t, x) = \sum_{j=1}^{K} \lambda_j^d Q_j(t, x - \alpha_j) e^{i\theta_j} + R(t, x), \quad \text{with} \quad Q_j(t, y) = Q(y) e^{i(\beta_j y - \frac{1}{4} \gamma_j |y|^2)}, \]

where \( Q_j \) and \( R \) satisfy the orthogonality conditions in (4.5) below, which are related to the null space of the linearized operators around the ground state and ensure the uniqueness of this decomposition. Such geometrical decomposition enables us to reduce the blow-up analysis into those of the five finite-dimensional geometrical parameters \((\lambda_j, \alpha_j, \beta_j, \gamma_j, \theta_j)\) and the infinite-dimensional remainder \( R \). As a first consequence, the estimate of the modulation equations is derived, which indeed captures the dynamics of the geometrical parameters. This part is contained in Section 4.

The key uniform estimates of the geometrical parameters and the remainder are obtained by using a bootstrap device and the propagation backward from the singularity. The main efforts here are dedicated to the analysis of the localized mass, the energy and a new generalized functional.

It should be mentioned that, unlike the single bubble case in [55, 58], the growth in the unstable direction \( Q_j \) is analyzed via a localized mass, instead of the usual whole mass. Moreover, we introduce a new generalized energy (5.28) adapted to the multi-bubble setting. It incorporates the localized functions in an appropriate way, such that different bubbles can be decoupled while the key monotonicity property keeps preserved. One delicate problem here lies in the decoupling of the remainders, due to the corresponding low polynomial type perturbation orders, and, actually, extra decays have to be explored from the test functions. Furthermore, a refined estimate of the modulation parameter \( \beta \) is derived from the coercivity of the energy, of which the proof requires a careful treatment to balance the localized functions and the test functions involved in the localized coercivity of the linearized operators. These constitute the main part of Section 5.

Then in Section 6, the construction of the multi-bubble blow-up solutions follows from a compactness argument, based on the uniform estimates and integrating the flow backward from the blow-up time. Let us mention that, the uniform estimates can be also obtained in the pseudo-conformal space \( \Sigma \), which improves the previous \( H^1 \)-estimate in [58] and also simplifies the compactness argument.

Concerning the uniqueness part in Section 7, the key idea again relies on the monotonicity formula of the generalized energy adapted to the difference of two multi-bubble solutions, and is to show that the implied a priori bound of the difference is exactly zero.
More precisely, via the generalized energy (7.41) below, we obtain the estimate (see Theorem 7.6 below)
\[ \sup_{t \leq s < T} D(s) \leq C \left( \sum_{j=1}^{K} \sup_{t \leq s < T} \frac{\text{Scal}_j(s)}{\lambda_j^2(s)} + \int_t^T \sum_{j=1}^{K} \frac{\text{Scal}_j(s)}{\lambda_j^3(s)} + \varepsilon^* \frac{D(s)}{T-s} ds \right). \]
where \( D(t) := \|\nabla w(t)\|_{L^2}^2 + \sum_{j=1}^{K} \lambda_j^{-2} \|w_j(t)\|_{L^2}^2 \) is defined on the difference \( w, w_j = w\Phi_j \) with the localized function \( \Phi_j \), and \( \text{Scal}_j \) denotes the scalar products of \( w_j \) and the unstable directions in the null space. This step requires a careful analysis of the differences between nonlinearities.

The next step is to control the unstable growth generated by the null space, that is, we prove that (see Theorem 7.7 below), for some \( \zeta \in (0, 1) \),
\[ \text{Scal}_j(t) \leq C(T-t)^{2+\zeta} \sup_{t \leq s < T} D(s). \]
For this purpose, a new renormalized variable is introduced. It satisfies a neat formulation of equation and enables us to obtain the estimates of the scalar products in \( \text{Scal}_j \) in a simplified diagonalized form (see Proposition 7.12 below).

At this stage, by virtue of the two estimates above, we obtain the estimate of \( D(t) \) in a closed form. It should be mentioned that, because of the localization functions in the multi-bubble case, an extra error \( \varepsilon^* \frac{D(t)}{T-t} \) is also involved here. This requires an iterated argument to show that \( D(t) \) is exactly zero, which is different from the single bubble case in [55].

The remainder of this paper is structured as follows. In Section 3 we first present some preliminaries including the localization functions, the coercivity of linearized operator, and the Taylor expansion in the complex situation. Then, Sections 4, 5 and 6 are mainly devoted to the proof of the existence of blow-up solutions at multiple points. In Section 7 we prove the uniqueness of blow-up solutions. Finally, some technical proofs are postponed to the Appendix, i.e., Section 8.

3. Preliminaries

3.1. Localization. We shall use the localization functions in order to construct the blow-up profiles concentrating at distinct blow-up points.

For this purpose, we note that, because equation (2.11) is invariant under orthogonal transforms, we may take an orthonormal basis \( \{ v_j \}_{j=1}^{d} \) of \( \mathbb{R}^d \), such that \( (x_j - x_l) \cdot v_1 \neq 0 \) for any \( 1 \leq j \neq l \leq K \). Hence, we may assume that \( x_1 \cdot v_1 < x_2 \cdot v_1 < \ldots < x_K \cdot v_1 \). Then,
\[ \sigma := \frac{1}{12} \min_{1 \leq j \leq K-1} \{(x_{j+1} - x_j) \cdot v_1\} > 0. \]

Let \( \Phi(x) \) be a smooth function on \( \mathbb{R}^d \) such that \( 0 \leq \Phi(x) \leq 1 \), \( |\nabla \Phi(x)| \leq C \sigma^{-1} \), \( \Phi(x) = 1 \) for \( x \cdot v_1 \leq 4 \sigma \) and \( \Phi(x) = 0 \) for \( x \cdot v_1 \geq 8 \sigma \). The localization functions \( \Phi_j \) are defined by namely,
\[ \Phi_j(x) := \Phi(x - x_j), \quad \Phi_K(x) := 1 - \Phi(x - x_{K-1}), \]
\[ \Phi_j(x) := \Phi(x - x_j) - \Phi(x - x_{j-1}), \quad 2 \leq j \leq K - 1. \]

In particular, we have the partition of unity \( 1 = \sum_{j=1}^{K} \Phi_j \).

Lemma 3.1 below enables us to decouple different blow-up profiles and will be used frequently throughout this paper.
Lemma 3.1. (Interaction estimates) Let $0 < t^* < T_* < T < \infty$. For every $1 \leq j \leq K$, set
\begin{equation}
G_j(t, x) := \lambda_j^{-\frac{j}{2}} g_j(t, \frac{x - \alpha_j}{\lambda_j}) e^{i\theta_j}, \quad \text{with} \quad g_j(t, y) := g(y) e^{i(\beta_j(t) y - \frac{1}{2} \gamma_j(t)|y|^2)},
\end{equation}
where $g \in C^2_0(\mathbb{R}^d)$ decays exponentially fast at infinity
\[|\partial^\nu g(y)| \leq Ce^{-\delta|y|}, \quad |\nu| \leq 2,
\]
with $C, \delta > 0$, for $1 \leq j \leq K$, $P_j := (\lambda_j, \alpha_j, \beta_j, \gamma_j, \theta_j) \in C([t^*, T_*]; \mathbb{R}^{d+3})$ satisfies
\begin{equation}
|\alpha_j(t) - x_j| \cdot \mathbf{v}_1 | \leq \sigma, \quad |x_j - \alpha_j(t)| \leq 1, \quad \frac{1}{2} \leq \frac{\lambda_j(t)}{\omega_j(T - t)} \leq 2, \quad t \in [t^*, T_*],
\end{equation}
and $|\beta_j| + |\gamma_j| \leq 1$,
\begin{equation}
C(T + \max_{1 \leq j \leq K} |x_j|) \leq 1,
\end{equation}
where $C$ is sufficiently large but independent of $T$. Then, there exists $\delta > 0$ such that for any $1 \leq j \neq l \leq K$, $m \in \mathbb{N}$, and for any multi-index $\nu$ with $|\nu| \leq 2$,
\begin{equation}
\int_{\mathbb{R}^d} |x - \alpha_l|^m |\partial^\nu G_l(t)||x - \alpha_j|^m |G_j(t)||dx \leq Ce^{-\frac{\delta|x|}{2}}, \quad t \in [t^*, T_*].
\end{equation}
Moreover, for any $h \in L^1$ or $L^2$, $1 \leq j \neq l \leq K$, $m, n \in \mathbb{N}$, and for any multi-index $\nu$ with $|\nu| \leq 2$,
\begin{equation}
\int_{\mathbb{R}^d} |x - \alpha_l|^m |\partial^\nu G_l(t)||x - \alpha_j|^m |h| \Phi_j dx \leq Ce^{-\frac{\delta|x|}{2}} \min\{\|h\|_{L^1}, \|h\|_{L^2}\}, \quad t \in [t^*, T_*].
\end{equation}

The proof is postponed to the Appendix for simplicity. Lemma 3.1 actually shows that the interactions between $\{U_j\}$ and other profiles are very weak, mainly due to the exponential decay of the ground state.

3.2. Coercivity of linearized operators. We denote $Q$ the ground state that solves the soliton equation (1.8). It follows from [14, Theorem 8.1.1] that $Q$ is smooth and decays at infinity exponentially fast, i.e., there exist $C, \delta > 0$ such that for any multi-index $|\nu| \leq 3$,
\begin{equation}
|\partial^\nu Q(x)| \leq Ce^{-\delta|x|}, \quad x \in \mathbb{R}^d.
\end{equation}

Let $L = (L_+, L_-)$ be the linearized operator around the ground state, defined by
\begin{equation}
L_+ := -\Delta + I - (1 + \frac{4}{d})Q^\frac{2}{d}, \quad L_- := -\Delta + I - Q^\frac{2}{d}.
\end{equation}
The generalized null space of operator $L$ is spanned by $\{Q, xQ, |x|^2Q, \nabla Q, \Lambda Q, \rho\}$, where $\Lambda := \frac{4}{d} I + x \cdot \nabla$, and $\rho$ is the unique $H^1$ spherically symmetric solution to the equation
\begin{equation}
L_+ \rho = -|x|^2 Q,
\end{equation}
which satisfies the exponential decay property (see, e.g., [38, 42]), i.e., for some $C, \delta > 0$,
\[|\rho(x)| + |\nabla \rho(x)| \leq Ce^{-\delta|x|}.
\]
Moreover, we have (see, e.g., [63, (B.1), (B.10), (B.15)])
\begin{equation}
L_+ \nabla Q = 0, \quad L_+ \Lambda Q = -2Q, \quad L_+ \rho = -|x|^2Q,
\end{equation}
\begin{align*}
L_- Q = 0, \quad L_- xQ = -2\nabla Q, \quad L_- |x|^2Q = -4\Lambda Q.
\end{align*}
For any complex valued $H^1$ function $f = f_1 + if_2$ in terms of the real and imaginary parts, we set
\begin{equation}
(Lf, f) := \int f_1 L_+ f_1 dx + \int f_2 L_- f_2 dx.
\end{equation}

Let $\mathcal{K}$ denote the set of all complex valued $H^1$ functions $f = f_1 + if_2$ satisfying the orthogonality conditions below
\begin{equation}
\int Qf_1 dx = 0, \quad \int xQf_1 dx = 0, \quad \int |x|^2 Qf_1 dx = 0,
\end{equation}
\begin{equation}
\int \nabla Q f_2 dx = 0, \quad \int \Lambda Q f_2 dx = 0, \quad \int \rho f_2 dx = 0.
\end{equation}

The coercivity property below is crucial in the proof of main results.

**Lemma 3.2.** ([63, Theorem 2.5]) There exists $C > 0$ such that
\begin{equation}
(Lf, f) \geq C \|f\|_{H^1}^2, \quad \forall f \in \mathcal{K}.
\end{equation}

We define the scalar products along all the unstable directions in the null space
\begin{equation}
\text{Scal}(f) = \langle f_1, Q \rangle^2 + \langle f_1, xQ \rangle^2 + \langle f_1, |x|^2 Q \rangle^2 + \langle f_2, \nabla Q \rangle^2 + \langle f_2, \Lambda Q \rangle^2 + \langle f_2, \rho \rangle^2,
\end{equation}
where $f = f_1 + if_2 \in H^1$. As a consequence of Lemma 3.2 we have

**Corollary 3.3.** ([58, Corollary 3.2]) There exist positive constants $C_1, C_2 > 0$, such that
\begin{equation}
(Lf, f) \geq C_1 \|f\|_{H^1}^2 - C_2 \text{Scal}(f), \quad \forall f \in H^1,
\end{equation}
where $f_1$ and $f_2$ are the real and imaginary parts of $f$, respectively.

**Corollary 3.4.** (Localized coercivity) Let $\phi$ be a positive smooth radial function on $\mathbb{R}^d$, such that $\phi(x) = 1$ for $|x| \leq 1$, $\phi(x) = e^{-|x|}$ for $|x| \geq 2$, $0 < \phi \leq 1$, and $\left| \frac{\nabla \phi}{\phi} \right| \leq C$ for some $C > 0$. Set $\phi_A(x) := \phi \left( \frac{x}{A} \right)$, $A > 0$. Then, for $A$ large enough we have
\begin{equation}
\int (|f|^2 + |\nabla f|^2) \phi_A - (1 + \frac{4}{d}) Q \frac{f_1^2}{4} - Q \frac{f_2^2}{4} dx \geq C_1 \int (|\nabla f|^2 + |f|^2) \phi_A dx - C_2 \text{Scal}(f),
\end{equation}
where $C_1, C_2 > 0$, and $f_1, f_2$ are the real and imaginary parts of $f$, respectively.

The proof of Corollary 3.4 is similar to that of [58, Corollary 3.3] and is postponed to the Appendix for simplicity.

### 3.3. Expansion of the nonlinearity.

We shall use the notations that, for any continuous differentiable function $g : \mathbb{C} \to \mathbb{C}$ and for any $v, R \in \mathbb{C}$,
\begin{align*}
g'(v, R) \cdot R &:= R \int_0^1 \partial_v g(v + sR) ds + \overline{R} \int_0^1 \partial_z g(v + sR) ds, \\
g''(v, R) \cdot R^2 &:= R^2 \int_0^1 t \int_0^1 \partial_{z^2} g(v + stR) ds dt + 2|R|^2 \int_0^1 t \int_0^1 \partial_{zg} g(v + stR) ds dt \\
&\quad + \overline{R}^2 \int_0^1 t \int_0^1 \partial_{\overline{z}g} g(v + stR) ds dt,
\end{align*}
where $\partial_v g$ and $\partial_z g$ are the usual complex derivatives $\partial_v g = \frac{1}{2}(\partial_x g - i \partial_y g)$, $\partial_z g = \frac{1}{2}(\partial_x g + i \partial_y g)$, respectively. Then, one has (see, e.g., [35, (3.10)])
\begin{equation}
g(v + R) = g(v) + g'(v, R) \cdot R.
\end{equation}
Moreover, if \( \partial_z g \) and \( \partial_{\bar{z}} g \) are also continuously differentiable, we may expand \( g \) up to the second order

\[
(3.31) \quad g(v + R) = g(v) + \partial_z g(v)R + \partial_{\bar{z}} g(v)\overline{R} + g''(v, R) \cdot R^2.
\]

In particular, for the complex function \( f(z) = |z|^\frac{\delta}{d} \) with \( d = 1, 2 \), we have

\[
(3.32) \quad |f'(v, R) \cdot R| \leq C(|v|^\frac{\delta}{d} + |R|^\frac{(d-1)}{d})|R|,
\]

\[
(3.33) \quad |f''(v, R) \cdot R^2| \leq C(|v|^\frac{\delta}{d} - 1 + |R|^\frac{(d-1)}{d})|R|^2.
\]

It would be also useful to use the expansion, for \( f(z) = |z|^\frac{\delta}{d} \) with \( d = 1, 2 \),

\[
(3.34) \quad f(v + R) = f(v) + f'(v) \cdot R + f''(v) \cdot R^2 + O\left(\sum_{k=3}^{1+\frac{\delta}{d}} |v|^{1+\frac{\delta}{d} - k} |R|^k\right),
\]

where

\[
(3.35) \quad f'(v) \cdot R := \partial_z f(v)R + \partial_{\bar{z}} f(v)\overline{R} = \left(1 + \frac{2}{d}\right)|v|^\frac{2}{d}R + \frac{2}{d}|v|^{\frac{\delta}{d} - 2}v^2\overline{R},
\]

\[
(3.36) \quad f''(v) \cdot R^2 := \frac{1}{2}\partial_{zz} f(v)R^2 + \partial_{\bar{z}\bar{z}} f(v) |R|^2 + \frac{1}{2}\partial_{z\bar{z}} f(v)\overline{R}^2
\]

\[
= \frac{1}{d}(1 + \frac{2}{d})|v|^\frac{2}{d} - 1\overline{R}^2 + \frac{2}{d}\overline{R}^2|v|^{\frac{\delta}{d} - 2}v^2|R|^2 + \frac{1}{d}(1 - 1)|v|^\frac{\delta}{d} - v^3\overline{R}^2.
\]

Similarly, for \( F(z) := \frac{d}{2d+4} |z|^{\frac{\delta}{d} + \frac{\delta}{d}} \) with \( d = 1, 2 \), we have the expansion

\[
(3.37) \quad F(u) = F(v) + \frac{1}{2}|v|^\frac{\delta}{d} - R + \frac{1}{2}|v|^\frac{\delta}{d} \overline{R}
\]

\[
+ \frac{1}{2d}(1 + \frac{2}{d})|v|^\frac{2}{d} - 1\overline{R}^2 + \frac{2}{d}\overline{R}^2|v|^{\frac{\delta}{d} - 2}v^2|R|^2 + O\left(\sum_{k=3}^{2+\frac{\delta}{d}} |v|^{2+\frac{\delta}{d} - k} |R|^k\right).
\]

In most cases in this paper, the high order terms in the expansion of nonlinearity can be controlled by the Gagliardo-Nirenberg inequality contained in Lemma 3.5 below.

**Lemma 3.5.** ([11, Theorem 1.3.7]) Let \( d \geq 1 \) and \( 2 \leq p < \infty \). Then, there exists \( C > 0 \) such that

\[
(3.38) \quad \|f\|_{L^p} \leq C\|f\|_{L^2}^{1-d(\frac{\delta}{d} - \frac{1}{p})}\|\nabla f\|_{L^2}^{d(\frac{\delta}{d} - \frac{1}{p})}, \quad \forall f \in H^1.
\]

In particular, for any \( 1 < p < \infty \),

\[
(3.39) \quad \|f\|_{L^p} \leq C\|f\|_{H^1}, \quad \forall f \in L^p.
\]

We also have the product rule below.

**Lemma 3.6.** (Product rule [11, p.105, Proposition 1.1]) For any \( s > 0 \),

\[
(3.40) \quad \|uv\|_{H^{s,p}} \leq C(\|u\|_{L^{q_1}}\|v\|_{H^{s,q_2}} + \|v\|_{L^{q_1}}\|u\|_{H^{s,q_2}}),
\]

where \( \frac{1}{p} = \frac{1}{q_1} + \frac{1}{q_2} = \frac{1}{r_1} + \frac{1}{r_2} \), \( q_1, r_1 \in (1, \infty) \), \( q_2, r_2 \in (1, \infty) \).

As a consequence we have

**Lemma 3.7.** For any complex functions \( f, g, h \) and for any \( l, m, n \in \mathbb{N} \), we have

\[
(3.41) \quad \|f^l g^m h^n\|_{L^p} \leq C\|f\|_{H^{l,1}}\|g\|_{H^{m,1}}\|h\|_{H^{n,1}}.
\]

Moreover, we also have

\[
(3.42) \quad \|f^l g^m h^n\|_{H^{\frac{\delta}{d},1}} \leq C\|f\|_{H^{l,1}}\|g\|_{H^{m,1}}\|h\|_{H^{n,1}}.
\]
Proof. (3.31) follows from Hölder’s inequality and (3.29). Regarding (3.32), by the product rule,
\[
\|f^{\prime}g^m h^n\|_{H^\frac{1}{2}} \leq C(\|f\|_{H^\frac{1}{2}, p_1} \|f\|_{L^p, t_1} \|g\|_{L^q, t_1} + \|f\|_{H^{\frac{1}{2}, q_1}} \|g\|_{L^r, t_1}),
\]
where \( \frac{1}{p} = \frac{1}{p_1} + \frac{1}{p_2} + \frac{1}{p_3} = \frac{1}{r_2} + \frac{1}{r_3} + \frac{1}{r_4} = \frac{1}{r_2} + \frac{1}{r_3} + \frac{1}{r_4} \). We then take \( p_1, q_1, r_1 \) close to 2 such that \( H^\frac{1}{2} \) is imbedded into the Sobolev spaces \( H^\frac{1}{2}, p_1 \), \( H^\frac{1}{2}, q_1 \) and \( H^\frac{1}{2}, r_1 \). Then, taking into account (3.32) we obtain (3.32) and finish the proof. □

4. Geometrical decomposition and modulation equations

4.1. Geometrical decomposition. For each \( 1 \leq j \leq K \), define the modulation parameters by \( P_j := (\lambda_j, \alpha_j, \beta_j, \gamma_j, \theta_j) \in \mathbb{R}^{2d+3} \), where \( \lambda_j \in \mathbb{R} \), \( \alpha_j \in \mathbb{R}^d \), \( \beta_j \in \mathbb{R}^d \), \( \gamma_j \in \mathbb{R} \) and \( \theta_j \in \mathbb{R} \), and set \( P_j := |\lambda_j| + |\alpha_j - x_j| + |\beta_j| + |\gamma_j| \), where \( x_j \) are the given blow-up points, \( 1 \leq j \leq K \).

We also set \( P := (P_1, \ldots, P_K) \in \mathbb{R}^{(2d+3)K} \), \( P := \sum_{j=1}^{K} P_j \). Similarly, let \( \lambda := (\lambda_1, \ldots, \lambda_K) \in \mathbb{R}^K \) and \( |\lambda| := \sum_{j=1}^{K} |\lambda_j| \). Similar notations are also used for the remaining parameters.

Proposition 4.1. (Geometrical decomposition) Assume that \( u \in C([\tilde{t}, T_*]; H^1) \) for some \( \tilde{t} \in [0, T_*] \) and \( u(T_*) = S_T u(T_*) \). Then, for \( T_* \) sufficiently close to \( T \), there exist \( t^* < T_* \) and unique modulation parameters \( P \in C^1((t^*, T_*); \mathbb{R}^{(2d+3)K}) \), such that \( u \) can be geometrically decomposed into the main blow-up profile and the remainder
\[
(4.1) \quad u(t, x) = U(t, x) + R(t, x), \quad t \in [t^*, T_*], \quad x \in \mathbb{R}^d,
\]
where the main blow-up profile
\[
(4.2) \quad U(t, x) = \sum_{j=1}^{K} U_j(t, x),
\]
with
\[
(4.3) \quad U_j(t, x) = \lambda_j^{\frac{d}{2}} Q_j(t, x - \frac{\alpha_j}{\lambda_j}) e^{i\theta_j}, \quad Q_j(t, y) = Q(y) e^{i(\beta_j y - \frac{1}{4} \gamma_j |y|^2)},
\]
and \( R(T_*) = 0 \), the modulation parameters satisfy
\[
(4.4) \quad P_j(T_*) = (\omega_j(T - T_*), x_j, 0, \omega_j^2(T - T_*), \omega_j^{-2}(T - T_*)^{-1} + \vartheta_j).
\]
Moreover, for each \( 1 \leq j \leq K \), the following orthogonality conditions hold on \([t^*, T_*] \):
\[
(4.5) \quad \text{Re} \int (x - \alpha_j) U_j(t) \overline{U_j(t)} dx = 0, \quad \text{Re} \int |x - \alpha_j|^2 U_j(t) \overline{U_j(t)} dx = 0,
\]
\[
(4.6) \quad \text{Im} \int \nabla U_j(t) \overline{U_j(t)} dx = 0, \quad \text{Im} \int \Lambda U_j(t) \overline{U_j(t)} dx = 0, \quad \text{Im} \int \varrho_j(t) \overline{U_j(t)} dx = 0,
\]
where
\[
(4.7) \quad \varrho_j(t, x) = \lambda_j^{\frac{d}{2}} \varrho_j(t, x - \frac{\alpha_j}{\lambda_j}) e^{i\theta_j}, \quad \text{with} \quad \varrho_j(t, y) := \rho(y)^{(\beta_j y - \frac{1}{4} \gamma_j |y|^2)},
\]
and \( \rho \) is given by (3.10).

Remark 4.2. Proposition 4.1 is actually a local version of the geometrical decomposition as \( t^* \) may depend on \( T_* \). However, as we shall see later, by virtue of the bootstrap estimates in Theorem 5.1 below we indeed have the global geometrical decomposition on the time interval \([0, T_*] \subseteq [0, T] \) if \( T \) is sufficiently small. See Theorem 6.7 below.
The proof of Proposition 4.3 is quite similar to that of [58, Proposition 4.1] and is mainly based on the implicit function theorem. We mention that, the computations of the Jacobian of transformation also include the interactions between different profiles \( \{U_j\}_{j=1}^K \) which, however, by Lemma 3.1 only contribute exponentially small errors due to the exponential decay of the ground state. Thus the Jacobian is still non-zero. The details are omitted here for simplicity.

### 4.2. Modulation equations.

Let \( \dot{g} := \frac{2}{d}g \) for any \( C^1 \) function \( g \). For each \( 1 \leq j \leq K \), define the vector of modulation equations by

\[
\text{Mod}_j := |\lambda_j \lambda_j + \gamma_j| + |\lambda_j^2 \gamma_j + \gamma_j^2| + |\lambda_j \alpha_{n,j} - 2\beta_j| + |\lambda_j^2 \beta_j + \gamma_j \beta_j| + |\lambda_j^2 \theta_j - 1 - |\beta_j|^2|,
\]

and set \( \text{Mod} := \sum_{j=1}^K \text{Mod}_j \).

The main result of this subsection is formulated in Proposition 4.3 below.

**Proposition 4.3.** Assume that \( u \) has the geometrical decomposition on \( [t^*, T_\star] \subseteq [0,T) \) as in (4.1) with the modulation parameters \( \mathcal{P} = (\lambda, \alpha, \beta, \gamma, \theta) \in \mathbb{R}^{(2d+3)K} \), and

\[
C_1(T - t) \leq |\lambda(t)| \leq C_2(T - t), \quad t \in [t^*, T_\star],
\]

where \( C_1, C_2 > 0 \). Then, for \( T \) small enough and for \( t^* \) close to \( T_\star \), we have for any \( t \in [t^*, T_\star] \),

\[
\text{Mod}(t) \leq C \left( \sum_{j=1}^K \text{Re}(R_j, U_j) \right) + P^2(t)\|R(t)\|_{L^2} + \|R(t)\|_{L^2}^2 + \|R(t)\|_{H^1}^3 + P^{\nu_\star+1}(t) + e^{-\frac{4}{T-t}}
\]

where \( C > 0 \) and \( \nu_\star \) is the index of flatness in Assumption (A1).

The proof relies mainly on the analysis of the equation of remainder \( R \), the almost orthogonality of profiles \( U_j \) and \( R_j \), and the decoupling of different blow-up profiles \( U_j \) and \( U_l, j \neq l \).

To be precise, we use the partition of unity \( 1 = \sum_{j=1}^K \Phi_j \) to get

\[
R = \sum_{j=1}^K R_j, \quad \text{with} \quad R_j := R \Phi_j.
\]

Define the renormalized remainder \( \varepsilon_j \) by

\[
R_j(t, x) = \lambda_j^{-\frac{d}{2}} \varepsilon_j(t, \frac{x - \alpha_j}{\lambda_j}) e^{i\theta_j}.
\]

Then, by (2.11) and (4.1), the remainder \( R \) satisfies the equation

\[
\begin{aligned}
&i \partial_t R + \sum_{t=1}^K (\Delta R_t + (1 + \frac{2}{d})|U_l|^2 R_t + \frac{2}{d}|U_l|^2 U_l \overline{R_t}) + i \partial_l U_l + \Delta U_l + |U_l|^2 U_l) \\
&= - H_1 - H_2 - f''(U, R) \cdot R^2 - \sum_{l=1}^K (b \cdot \nabla (U_l + R_l) + c(U_l + R_l))
\end{aligned}
\]
Here, $H_1, H_2$ contain the interactions between different blow-up profiles

\begin{align}
(4.12) \quad H_1 & := (1 + \frac{2}{d})|U|^2 \mathcal{H}R + \frac{2}{d}|U|^2 U^2 \mathcal{H}R - \sum_{l=1}^{K} ((1 + \frac{2}{d})|U_l|^2 \mathcal{H}R_l + \frac{2}{d}|U_l|^2 U_l^2 \mathcal{H}R_l), \\
(4.13) \quad H_2 & := |U|^2 \mathcal{H}U - \sum_{l=1}^{K} |U_l|^2 U_l,
\end{align}

and $f''(U, R) \cdot R^2$ is defined as in (3.19) with $f, U$ replacing $g$ and $v$, respectively.

Using (4.3) we have

\begin{align}
& i \partial_j U_j + \Delta U_j + |U_j|^2 U_j = \frac{e^{i \theta_j}}{\lambda^j_{2+\delta}} \left\{ - (\lambda^2_j \beta_j - 1 - |\beta_j|^2) Q_j - (\lambda^2_j \beta_j + \gamma_j \beta_j) \cdot yQ_j \\
& + \frac{1}{4} (\lambda^2_j \gamma_j + \gamma_j^2) |y|^2 Q_j - i (\lambda_j \alpha_j - 2 \beta_j) \cdot \nabla Q_j - i (\lambda_j \dot{\lambda}_j + \gamma_j) \Lambda Q_j \right\} (t, x - \frac{\alpha_j}{\lambda_j}).
\end{align}

The important fact here is, that the modulation equations show up on the right-hand side of (4.14) as the coefficients of the five directions in the generalized null space of the operator $L$ defined in (3.9). This enables us to extract each modulation equation by applying the almost orthogonality in Lemma 4.4 below, which in turn follows from Lemma 3.1 and the orthogonality conditions in (4.5).

**Lemma 4.4. (Almost orthogonality) Let $t^*$ be as in Proposition 4.3. Then, for $t^*$ close to $T$, there exists $\delta > 0$ such that for any $1 \leq j \leq K$, it holds on $[t^*, T]$ that

\begin{align}
& |\text{Re} \int (x - \alpha_j) U_j \mathcal{H}R_j dx| + |\text{Re} \int |x - \alpha_j|^2 U_j \mathcal{H}R_j dx| \leq C e^{-\frac{\tau^j_{\alpha_j}}{\tau^j_{\beta_j}}} \|R\|_{L^2}, \\
& |\text{Im} \int \nabla U_j \mathcal{H}R_j dx| + |\text{Im} \int \Lambda U_j \mathcal{H}R_j dx| + |\text{Im} \int \dot{U}_j \mathcal{H}R_j dx| \leq C e^{-\frac{\tau^j_{\beta_j}}{\tau^j_{\alpha_j}}} \|R\|_{L^2}.
\end{align}

**Proof.** By the orthogonality condition (4.5),

\begin{align}
(4.16) \quad \text{Re} \int (x - \alpha_j) U_j(t) \mathcal{H}R_j(t) dx = - \sum_{l \neq j} \text{Re} \int (x - \alpha_j) U_j(t) \mathcal{H}R_l(t) dx,
\end{align}

which along with Lemma 3.1 yields immediately that for some $\delta > 0$,

\begin{align}
(4.17) \quad |\text{Re} \int (x - \alpha_j) U_j(t) \mathcal{H}R_j(t) dx| \leq C e^{-\frac{\tau^j_{\alpha_j}}{\tau^j_{\beta_j}}} \|R\|_{L^2}.
\end{align}

The remaining four estimates in (4.15) can be proved similarly. \qed

We are now ready to prove Proposition 4.3.

**Proof of Proposition 4.3** The proof is similar to that of [58, Proposition 4.3].

Below, we take the modulation equation $\lambda^2_j \gamma_j + \gamma_j^2$, corresponding to the direction $\Lambda U_j$, for an example to illustrate the main arguments and to show that the scalar $\text{Re} \langle R_j, U_j \rangle$ in the unstable direction $U_j$ is also required to bound the modulation equation.
Taking the inner product of (4.11) with $\Lambda U_j$ and then taking the real part we get 
\[
- \text{Im}(\partial_t R, \Lambda U_j) + \text{Re}(\Delta R_j + (1 + \frac{2}{d})|U_j|^{\frac{4}{d}} R_j + \frac{2}{d}|U_j|^{\frac{4}{d}-2} U_j^2 \tilde{R}_j, \Lambda U_j) \\
+ \text{Re}(i\partial_t U_j + \Delta U_j + |U_j|^{\frac{4}{d}} U_j, \Lambda U_j)
\]
\[
= - \text{Re}(\sum_{l \neq j} (\Delta R_l + (1 + \frac{2}{d})|U_l|^{\frac{4}{d}} R_l + \frac{2}{d}|U_l|^{\frac{4}{d}-2} U_l^2 \tilde{R}_l) + H_1, \Lambda U_j) \\
- \text{Re}(\sum_{l \neq j} (i\partial_t U_l + \Delta U_l + |U_l|^{\frac{4}{d}} U_l) + H_2, \Lambda U_j) \\
- \text{Re}(f''(U, R) \cdot R^2, \Lambda U_j)
\]
(4.18) 
\[
- \text{Re}(\sum_{l=1}^{K} (b \cdot \nabla (U_l + R_l) + c(U_l + R_l)), \Lambda U_j),
\]
where $H_1$ an $H_2$ are given by (4.12) and (4.13), respectively.

As we shall see below that, the right-hand side of equation (4.18) merely contribute negligibly small errors.

Actually, we may take $t^*$ close to $T_s$ such that (3.4) and thus Lemma 3.1 hold. By Lemma 3.1, the interactions between different profiles are exponentially small, and thus we infer that for some $\delta > 0$,

\[
|\sum_{l \neq j} (\Delta R_l + (1 + \frac{2}{d})|U_l|^{\frac{4}{d}} R_l + \frac{2}{d}|U_l|^{\frac{4}{d}-2} U_l^2 \tilde{R}_l) + H_1, \Lambda U_j) | \leq C|\lambda|^{-2}e^{-\frac{\delta}{\lambda^2}} ||R||_{L^2},
\]
(4.19) 

Similarly, by (4.14),

\[
|\sum_{l \neq j} (i\partial_t U_l + \Delta U_l + |U_l|^{\frac{4}{d}} U_l) + H_2, \Lambda U_j) | \leq C|\lambda|^{-2}e^{-\frac{\delta}{\lambda^2}}(1 + Mod),
\]
(4.20) 

For the remainder $f''(U, R) \cdot R^2$ containing high order terms of $R$, using (3.28) with $U$ replacing $v$, (3.29) and $||R||_{H^1} \leq 1$, we get

\[
|f''(U, R) \cdot R^2, \Lambda U_j) | \leq C|\lambda|^{-2}(||R||_{L^2}^2 + ||R||_{H^1}^3).
\]
(4.21) 

Regarding the last term involving $b$ and $c$ on the right-hand side of (4.18), using Lemma 3.1 and (4.13), (4.10) to rewrite it in the renormalized variables we have

\[
\text{Re}(\sum_{l=1}^{K} (b \cdot \nabla (U_l + R_l) + c(U_l + R_l)), \Lambda U_j)
\]
(4.22) 
\[
= \text{Re}(\lambda_j^{-1}\tilde{b} \cdot \nabla (Q_j + \varepsilon_j) + \tilde{c}(Q_j + \varepsilon_j), \Lambda Q_j) + O(e^{-\frac{\delta}{\lambda^2}}(1 + ||R||_{L^2})),
\]

where $\tilde{b}(y) := b(\lambda_j y + \alpha_j)$ and $\tilde{c}(y) := c(\lambda_j y + \alpha_j)$, $y \in \mathbb{R}^d$. Then, using (2.12), (2.13) and integrating by parts formula we get

\[
\text{Re}(\lambda_j^{-1}\tilde{b} \cdot \nabla (Q_j + \varepsilon_j) + \tilde{c}(Q_j + \varepsilon_j), \Lambda Q_j)
\]
(4.23) 
\[
= 2\text{Im} \sum_{k=1}^{N} B_k \int \Delta \tilde{\phi}_k(Q_j + \varepsilon_j) \Lambda Q_j dy + 2\lambda_j^{-1}\text{Im} \sum_{k=1}^{N} B_k \int (Q_j + \varepsilon_j) \nabla \tilde{\phi}_k \cdot \nabla (\Lambda Q_j) dy \\
- \sum_{l=1}^{d} \text{Re} \int (\sum_{k=1}^{N} \partial_l \tilde{\phi}_k B_k)^2(Q_j + \varepsilon_j) \Lambda Q_j dy - \text{Im} \sum_{k=1}^{N} \Delta \tilde{\phi}_k B_k(Q_j + \varepsilon_j) \Lambda Q_j dy,
\]

where $\tilde{\phi}_k(y) := \phi_k(\lambda_j y + \alpha_j)$.
where $\partial^\nu \widetilde{\phi}_k(y) := (\partial^\nu \phi_k)(\lambda_j y + \alpha_j)$, $|\nu| \leq 2$. Note that, by the flatness condition (2.3) and the fact that $\partial^\nu \phi_k \in L^\infty$ for any multi-index $\nu$,

\begin{equation}
(4.23) \quad |\partial^\nu \widetilde{\phi}_k(y)| \leq C(\lambda_j y + \alpha_j - x_j)^{\nu_\ast + 1 - |\nu|} \leq C P^{\nu_\ast + 1 - |\nu|} (y)^{\nu_\ast + 1}, \quad 0 \leq |\nu| \leq \nu_\ast.
\end{equation}

This yields that

\begin{equation}
(4.24) \quad |\text{Re}(\lambda_j^{-1} \frac{\partial^\nu \phi_k(y)}{\partial y_j} \cdot \nabla (Q_j + \varepsilon_j) + \partial^\nu \phi_k(y, \Lambda Q_j)| \leq C |\lambda|^{-2} P^{\nu_\ast + 1}(1 + \|R\|_{L^2}).
\end{equation}

Thus, we conclude from estimates (4.19)-(4.24) that

\begin{equation}
(4.25) \quad \text{R.H.S. of (4.31)} \leq C |\lambda|^{-2}((e^{-\frac{\delta}{2T}} + P^{\nu_\ast + 1})(1 + \|R\|_{L^2}) + e^{-\frac{\delta}{2T}} Mod + \|R\|_{L^2}^2 + \|R\|_{H^1}^2).
\end{equation}

Regarding the left-hand side, by the orthogonality condition (4.5), (4.14) and Lemma 3.1,

\begin{equation}
\text{Im}(\partial_t R, \Lambda U_j) = \text{Im}(\Lambda R, \partial_t U_j) = \text{Im}(\Lambda R_j, \partial_t U_j) + \sum_{l \neq j} \text{Im}(\Lambda R_l, \partial_t U_j)
\end{equation}

\begin{equation}
(4.26) \quad \quad \quad \quad = \text{Im}(\Lambda R_j, \partial_t U_j) + |\lambda|^{-2} \mathcal{O}(Mod + e^{-\frac{\delta}{2T}})\|R\|_{L^2}.
\end{equation}

Then, using the identity (4.14) and the renormalized variables $Q_j, \varepsilon_j$ in (4.3) and (4.10), respectively, we get

\begin{equation}
\lambda_j^2 \text{Im}(\Lambda R_j, \partial_t U_j) = -\text{Re}(\Lambda \varepsilon_j, \Delta Q_j + |Q_j|^2 Q_j) + \mathcal{O}(Mod\|R\|_{L^2})
\end{equation}

\begin{equation}
(4.27) \quad \quad \quad \quad = \text{Re}(\varepsilon_j, \Lambda Q_j) + \gamma_j \text{Im}(\Lambda \varepsilon_j, \Lambda Q_j) - 2\beta_j \text{Im}(\Lambda \varepsilon_j, \nabla Q_j)
\end{equation}

where in the last step we used the almost orthogonality (4.15) and the identity

\begin{equation}
(4.28) \quad \Delta Q_j - Q_j + |Q_j|^2 Q_j = |\beta_j - \frac{\gamma_j}{2}|^2 Q_j - i\gamma_j \Lambda Q_j + 2i\beta_j \cdot \nabla Q_j.
\end{equation}

Furthermore, using (4.14), the identities

\begin{equation}
\Lambda Q_j = (\Lambda Q + i(\beta_j \cdot y - \frac{1}{2} \gamma_j |y|^2) Q)e^{i(\beta_j \cdot y - \frac{1}{2} \gamma_j |y|^2)},
\end{equation}

\begin{equation}
(4.29) \quad \nabla Q_j = (\nabla Q + i(\beta_j - \frac{1}{2} \gamma_j y) Q)e^{i(\beta_j \cdot y - \frac{1}{2} \gamma_j |y|^2)},
\end{equation}

and $\langle \Lambda Q, |y|^2 Q \rangle = -\|yQ\|_{L^2}^2$ we have

\begin{equation}
\lambda_j^2 \text{Re}(i\partial_t U_j + \Delta U_j + |U_j|^2 U_j, \Lambda U_j) = -\frac{1}{4} \|yQ\|_{L^2}^2 (\lambda_j^2 \gamma_j + \gamma_j^2) + \mathcal{O}(Mod|\beta_j|).
\end{equation}

Thus, plugging (4.26), (4.27) and (4.31) into (4.18) and rearranging the terms according to the orders of the renormalized variable $\varepsilon_j$ we get

\begin{equation}
\lambda_j^2 \times (\text{L.H.S. of (4.18)})
\end{equation}

\begin{equation}
\begin{aligned}
&= -\frac{1}{4} \|yQ\|_{L^2}^2 (\lambda_j^2 \gamma_j + \gamma_j^2) + \text{Re}(\Delta \varepsilon_j - \varepsilon_j + (1 + \frac{2}{d})|Q_j|^2 \varepsilon_j + \frac{2}{d}|Q_j|^2 \varepsilon_j, \Lambda Q_j)
\end{aligned}
\end{equation}

\begin{equation}
\begin{aligned}
&- \gamma_j \text{Im}(\Lambda \varepsilon_j, \Lambda Q_j) + 2\beta_j \text{Im}(\Lambda \varepsilon_j, \nabla Q_j) + \mathcal{O}((Mod + P^2)\|R\|_{L^2} + Mod|\beta_j|).
\end{aligned}
\end{equation}
By (3.9), straightforward computations show that, if \( \varepsilon_j = \varepsilon_{j,1} + i \varepsilon_{j,2} \),
\[
\text{Re}(\Delta \varepsilon_j - \varepsilon_j + (1 + \frac{2}{d})|Q_j|^2 \varepsilon_j + \frac{2}{d}|Q_j|^4 \varepsilon_j^2 Q_j^2 \varepsilon_j, \Lambda Q_j) = -\langle L+\varepsilon_{j,1}, \Lambda Q \rangle - \langle L+\varepsilon_{j,2}, (\beta_j \cdot y - \frac{\gamma_j}{4}|y|^2) \Lambda Q \rangle
\]
(4.33)
\[-\langle L-\varepsilon_{j,2}, (\beta_j \cdot y - \frac{\gamma_j}{4}|y|^2) Q \rangle + O(P^2\|R\|_{L^2}).
\]
Note that
\[
L_+(\beta_j \cdot y - \frac{\gamma_j}{4}|y|^2) \Lambda Q = (\beta_j \cdot y - \frac{\gamma_j}{4}|y|^2)L_+ \Lambda Q + \gamma_j \Lambda^2 Q - 2\beta_j \cdot \nabla \Lambda Q,
\]
\[
L_-(\beta_j \cdot y - \frac{\gamma_j}{4}|y|^2) Q = (\beta_j \cdot y - \frac{\gamma_j}{4}|y|^2)L_- Q + 2\gamma_j \Lambda Q - 2\beta_j \cdot \nabla Q.
\]
Taking into account the self-adjointness of \( L_\pm \) and \( L_\pm \Lambda Q = -2Q \), \( L_-Q = 0 \) we get
\[
\text{Re}(\Delta \varepsilon_j - \varepsilon_j + (1 + \frac{2}{d})|Q_j|^2 \varepsilon_j + \frac{2}{d}|Q_j|^4 \varepsilon_j^2 Q_j^2 \varepsilon_j, \Lambda Q_j) = 2\langle \varepsilon_{j,1}, Q \rangle + 2\langle \varepsilon_{j,2}, (\beta_j \cdot y - \frac{\gamma_j}{4}|y|^2) Q \rangle
\]
(4.34)
\[+ \gamma_j \langle \Lambda \varepsilon_{j,2}, \Lambda Q \rangle - 2\beta_j \langle \nabla \varepsilon_{j,2}, \Lambda Q \rangle - 2\gamma_j \langle \varepsilon_{j,2}, \Lambda Q \rangle + 2\beta_j \langle \varepsilon_{j,2}, \nabla Q \rangle.
\]
Moreover, we see that
\[
-\gamma_j \text{Im}(\Lambda \varepsilon_j, \Lambda Q_j) = -\gamma_j \langle \Lambda \varepsilon_{j,2}, \Lambda Q \rangle + O(P^2\|R\|_{L^2}),
\]
and by the almost orthogonality (4.13),
\[
\text{Im}(\Lambda \varepsilon_j, \nabla Q_j) = \text{Im}(\nabla \varepsilon_j, \Lambda Q_j) + \text{Im}(\varepsilon_j, \nabla Q_j) = \text{Im}(\nabla \varepsilon_j, \Lambda Q_j) + O(e^{-\frac{4\sqrt{\tau}}{\tau}}\|R\|_{L^2}),
\]
which yields that
\[
2\beta_j \text{Im}(\Lambda \varepsilon_j, \nabla Q_j) = 2\beta_j \text{Im}(\nabla \varepsilon_j, \Lambda Q_j) + O(e^{-\frac{4\sqrt{\tau}}{\tau}}\|R\|_{L^2})
\]
(4.36)
\[= 2\beta_j \langle \nabla \varepsilon_{j,2}, \Lambda Q \rangle + O((P^2 + e^{-\frac{4\sqrt{\tau}}{\tau}})\|R\|_{L^2}).
\]
Thus, we conclude from (4.33), (4.34), (4.36) and the almost orthogonality (4.13) that
\[
\text{Re}(\Delta \varepsilon_j - \varepsilon_j + (1 + \frac{2}{d})|Q_j|^2 \varepsilon_j + \frac{2}{d}|Q_j|^4 \varepsilon_j^2 Q_j^2 \varepsilon_j, \Lambda Q_j) - \gamma_j \text{Im}(\Lambda \varepsilon_j, \Lambda Q_j) + 2\beta_j \text{Im}(\Lambda \varepsilon_j, \nabla Q_j)
\]
(4.37)
\[= 2\langle \varepsilon_{j,1}, Q \rangle + 2\langle \varepsilon_{j,2}, (\beta_j \cdot y - \frac{\gamma_j}{4}|y|^2) Q \rangle - 2\gamma_j \langle \varepsilon_{j,2}, \Lambda Q \rangle + 2\beta_j \langle \varepsilon_{j,2}, \nabla Q \rangle
\]
\[+ O((P^2 + e^{-\frac{4\sqrt{\tau}}{\tau}})\|R\|_{L^2}).
\]
This along with (4.32) yields that
\[
\lambda_j^2 \times (\text{L.H.S. of (1.18)}) = -\frac{1}{4}\|yQ\|^2_2 (\lambda_j^2 \gamma_j + \gamma_j^2) + 2\text{Re}(R_j, U_j)
\]
(4.38)
\[+ O((\text{Mod} + P^2 + e^{-\frac{4\sqrt{\tau}}{\tau}})\|R\|_{L^2} + \text{Mod}\|\beta_j\|).
\]
Then, combining (1.23) and (4.38) we obtain that for each \( 1 \leq j \leq K \),
\[
|\lambda_j^2 \gamma_j + \gamma_j^2| \leq C(\text{Mod}(P + \|R\|_{L^2} + e^{-\frac{4\sqrt{\tau}}{\tau}}) + |\text{Re}(R_j, U_j)| + (e^{-\frac{4\sqrt{\tau}}{\tau}} + P^{\nu+1})(1 + \|R\|_{L^2})
\]
(4.39)
\[+ P^2\|R\|_{L^2} + \|R\|^2_{L^2} + \|R\|^2_{\beta_j}).
\]
Similar arguments apply also to the remaining four modulation equations. Actually, taking the inner products of equation (4.11) with \( i(x - \alpha_j)U_j, \ i|x - \alpha_j|^2U_j, \ \nabla U_j, \ g_j \), respectively, then taking the real parts and using analogous arguments as above, we can obtain the same bounds for \( |\lambda_j \dot{\alpha}_j - 2\beta_j|, \ |\lambda_j \dot{\lambda}_j + \gamma_j|, \ |\lambda_j^2 \dot{\beta}_j + \beta_j \gamma_j| \) and \( |\lambda_j^2 \dot{\theta}_j - 1 - |\beta_j|^2| \), respectively. We then get

\[
Mod_j(t) \leq C \left( \text{Mod}(P + \|R\|_{L^2} + e^{-\frac{\delta}{T}}) + \sum_{j=1}^{K} |\text{Re}(R_j, U_j)| + (e^{-\frac{\delta}{T}} + P^\nu + 1)(1 + \|R\|_{L^2}) + P^2 \|R\|_{L^2} + \|R\|_{H^1}^2 \right).
\]  

(4.40)

Therefore, taking \( T \) possibly even smaller such that

\[
(1 + C)(P + \sup_{t^* \leq t \leq T^*} \|R(t)\|_{H^1} + e^{-\frac{\delta}{T}}) \leq \frac{1}{2}
\]

and then summing over \( j \) we obtain (4.8) and finish the proof. \( \square \)

5. Bootstrap estimates

This section is mainly devoted to the bootstrap type estimates of the remainder \( R \) and the modulation parameters \( P \), which are the key ingredients in the construction of multibubble blow-up solutions in Section 6 later. The main result is formulated in Theorem 5.1 below.

**Theorem 5.1 (Bootstrap).** Let \( \varepsilon^* > 0 \) be sufficiently small, \( 0 < \zeta < \frac{1}{12} \). For any \( \varepsilon \in (0, \varepsilon^*], \) let \( T = T(M) \) be small enough, satisfying (5.5), and fix \( T^* \in (0, T^*) \). Suppose that there exists \( t^* \in (0, T^*) \) such that \( u \) admits the unique geometrical decomposition (4.1) on \([t^*, T^*]\) and the following estimates hold for \( \kappa := \nu^* - 3(\geq 2) \):

(i) For the reminder term,

\[
\|\nabla R(t)\|_{L^2} \leq (T - t)^\kappa, \quad \|R(t)\|_{L^2} \leq (T - t)^{\kappa + 1}.
\]

(ii) For the modulation parameters, \( 1 \leq j \leq K \),

\[
|\lambda_j(t) - \omega_j(T - t)| + |\gamma_j(t) - \omega_j^2(T - t)| \leq (T - t)^{\kappa + 1 + \zeta},
\]

\[
|\alpha_j(t) - x_j| + |\beta_j(t)| \leq (T - t)^{\frac{3}{2} + 1 + \zeta},
\]

\[
|\theta_j(t) - (\omega_j^2(T - t)^{-1} + \theta_j)| \leq (T - t)^{\kappa - 1 + \zeta}.
\]

Then, there exists \( t_* \in [0, t^*] \) such that (4.11) holds on the larger interval \([t_*, T_*)\) and the coefficients in estimates (5.1)-(5.4) can be refined to \( 1/2 \), i.e., for any \( t \in [t_*, T_*] \), \( 1 \leq j \leq K \),

\[
\|\nabla R(t)\|_{L^2} \leq \frac{1}{2} (T - t)^\kappa, \quad \|R(t)\|_{L^2} \leq \frac{1}{2} (T - t)^{\kappa + 1},
\]

\[
|\lambda_j(t) - \omega_j(T - t)| + |\gamma_j(t) - \omega_j^2(T - t)| \leq \frac{1}{2} (T - t)^{\kappa + 1 + \zeta},
\]

\[
|\alpha_j(t) - x_j| + |\beta_j(t)| \leq \frac{1}{2} (T - t)^{\frac{3}{2} + 1 + \zeta},
\]

\[
|\theta_j(t) - (\omega_j^2(T - t)^{-1} + \theta_j)| \leq \frac{1}{2} (T - t)^{\kappa - 1 + \zeta}.
\]

In order to prove Theorem 5.1, we may take \( t_* \in [0, t^*] \), sufficiently close to \( t^* \), such that \( u \) still has the geometrical decomposition (4.11) on the larger interval \([t_*, T_*]\) (this is possible because the Jacobian of transformation is continuous in time). Moreover, by
virtue of the local well-posedness theory and the $C^1$-regularity of modulation parameters, taking $t_*$ possibly closer to $t^*$, we have that for any $t \in [t_*, t_n]$,

\begin{align}
(5.9) \quad \|\nabla R(t)\|_{L^2} & \leq 2(T - t)^\kappa, \quad \|R(t)\|_{L^2} \leq 2(T - t)^{\kappa + 1}, \\
(5.10) \quad |\lambda_j(t) - \omega_j(T - t)| + |\gamma_j(t) - \omega_j^2(T - t)| & \leq 2(T - t)^{\kappa + 1 + \zeta}, \\
(5.11) \quad |\alpha_j(t) - x_j| + |\beta_j(t)| & \leq 2(T - t)^{\frac{1}{2} + 1 + \zeta}, \\
(5.12) \quad |\theta_j(t) - (\omega_j^{-2}(T - t)^{-1} + \vartheta_j)| & \leq 2(T - t)^{\kappa - 1 + \zeta}.
\end{align}

By (5.10) and (5.12), we may also take $T$ sufficiently small such that (5.3) holds, and thus Lemma 5.4 is applicable below.

**Remark 5.2.** We infer from (5.10) that for $T$ small enough, $\lambda_j, \gamma_j, P$ are comparable with $T - t$, i.e.,

\begin{equation}
(5.13) \quad C_1(T - t) \leq \lambda_j, \gamma_j, P \leq C_2(T - t).
\end{equation}

where $C_1, C_2$ are positive constants independent of $\varepsilon$.

By virtue of Proposition 4.3 and Proposition 5.6 below, we have the refined estimate for the modulation parameters below.

**Lemma 5.3.** Assume estimates (5.1) - (5.4) to hold with $T$ sufficiently small. Then, there exists $C > 0$ such that

\begin{equation}
(5.14) \quad \text{Mod}(t) \leq C(T - t)^{\kappa + 3}, \quad \forall t \in [t_*, T_*].
\end{equation}

Moreover, by equation (2.11), the remainder $R$ satisfies the equation

\begin{equation}
(5.15) \quad i\partial_t R + \Delta R + (f(u) - f(U)) + b \cdot \nabla R + cR = -\eta,
\end{equation}

where

\begin{equation}
(5.16) \quad \eta = i\partial_t U + \Delta U + f(U) + b \cdot \nabla U + cU.
\end{equation}

The estimates of $U_j, R$ and $\eta$ are contained in Lemmas 5.4 and 5.5 below.

**Lemma 5.4.** Assume estimates (5.1) - (5.4) to hold and let $\varepsilon_j$ be defined in (4.10). Then, there exists $C > 0$ such that for all $t \in [t_*, T_*], 1 \leq j \leq K$,

\begin{align}
\|\varepsilon_j(t)\|_{L^2} = \|R_j(t)\|_{L^2} & \leq C(T - t)^{\kappa + 1}, \quad \lambda_j^{-1}\|\nabla \varepsilon_j(t)\|_{L^2} = \|\nabla R_j(t)\|_{L^2} \leq C(T - t)^{\kappa}, \\
\|U_j(t)\|_{L^2} = \|Q\|_{L^2}, \quad \|\nabla U_j(t)\|_{L^2} & + \frac{x_j - \alpha_j(t)}{\lambda_j(t)} \cdot \nabla U_j(t)\|_{L^2} \leq C(T - t)^{-1}.
\end{align}

**Lemma 5.5.** Assume estimates (5.1) - (5.4) to hold with $T$ sufficiently small. Then, there exists a constant $C > 0$ such that for $t \in [t_*, T_*]$ and multi-index $\nu$ with $|\nu| \leq 2$,

\begin{equation}
(5.17) \quad \|\partial^\nu \eta(t)\|_{L^2} \leq C(T - t)^{\kappa + 1 - |\nu|}.
\end{equation}

The proof is postponed to the Appendix for simplicity.

The remainder of Section 5 is devoted to the proof of Theorem 5.1. We first derive the estimates of the localized mass and energy in Subsection 5.1, and then in Subsection 5.2 we derive the key monotonicity property of the generalized energy, involving a Morawetz type term and localized function, which actually constitutes the most technical part of this section. The detailed proof of Theorem 5.1 is then given in Subsection 5.3. We shall assume estimates (5.1) - (5.4) to hold on $[t_*, T_*] \subseteq [0, T)$ with $T$ small enough and satisfying (3.5) throughout Subsections 5.1-5.3.
5.1. Estimates of localized mass and energy.

**Proposition 5.6** (Estimate of localized mass). There exists $C > 0$ such that for any $t \in [t_*, T_*]$ and $1 \leq j \leq K$,

\[(5.18) \quad 2\text{Re} \int \overline{u} R_j dx + \int |R(t)|^2 \Phi_j dx = O((T - t)^{2\kappa + 2}),\]

where $R_j := R \Phi_j$ with $\Phi_j$ the local functions defined in (3.2).

**Remark 5.7.** (i) The estimate (5.18) allows us to control the scalar product along the direction $Q$ when applying the localized coercivity in Corollary 3.4.

(ii) It should be mentioned that, the proof of (5.18) relies on the analysis of the localized mass $\int |u|^2 \Phi_j dx$, instead of the usual whole mass $\|u\|_{L^2}$. This is quite different from the single bubble case in [55, 58].

**Proof of Proposition 5.6.** Using (4.1) and Lemma 3.1 we have that for some $\delta > 0$,

\[
\int |u|^2 \Phi_j dx = \int |U|^2 \Phi_j dx + \int |R|^2 \Phi_j dx + 2\text{Re} \int \overline{U} R \Phi_j dx
\]

which yields that

\[
|2\text{Re} \int (\overline{U} R_j)(t) dx + \int |R(t)|^2 \Phi_j dx| \leq | \int |u(t)|^2 \Phi_j dx - \int |u(T_*)|^2 \Phi_j dx |
\]

\[
+ | \int |u(T_*)|^2 \Phi_j dx - \int |U(t)|^2 \Phi_j dx | + C e^{-\frac{\delta}{T - t}} \|R\|_{L^2}.
\]

(5.19)

For the first term on the right-hand side of (5.19), we use equation (2.11) to get

\[
\frac{d}{dt} \int |u|^2 \Phi_j dx = \text{Im} \int (2\pi \nabla u + b|u|^2) \cdot \nabla \Phi_j dx
\]

(5.20)

where $\sigma$ is given by (3.1). By (5.11), we may take $t_*$ close to $T_*$ such that $|x_1(t) - \alpha_1(t)| \leq \sigma$ for any $t \in [t_*, T_*]$, $1 \leq i \leq K$. This along with (3.8) and (4.11) yields that

\[
| \frac{d}{dt} \int |u|^2 \Phi_j dx | \leq C \int [x - \alpha_i(t)]^2 \|U + R\|_{L^2} \|\nabla U + \nabla R\|_{L^2} + \|U + R\|^2 dx
\]

\[
\leq C(\|R\|_{L^2}^2 + \|R\|_{L^2}^2 \|\nabla R\|_{L^2} + \sum_{i=1}^{K} (\int |Q|^2 dy)^{\frac{1}{2}} \|\nabla R\|_{L^2}
\]

\[
+ \sum_{i=1}^{K} \int |Q|^2 + \lambda_i^{-2} |\nabla Q_i|^2 dy)
\]

\[
\leq C(\|R\|_{L^2}^2 + \|R\|_{L^2}^2 \|\nabla R\|_{L^2} + e^{-\frac{\delta}{T - t}}),
\]

where $\delta > 0$. Hence, we obtain that for some $\delta > 0$,

\[
| \int |u(t)|^2 \Phi_j dx - \int |u(T_*)|^2 \Phi_j dx |
\]

(5.21)

\[
\leq C \int_{T_*}^{T_*} \|R(s)\|_{L^2}^2 + \|R(s)\|_{L^2} \|\nabla R(s)\|_{L^2} ds + Ce^{-\frac{\delta}{T - t}}.
\]
Regarding the second term on the right-hand side of (5.19), we apply Lemma 3.1 to extract the main blow-up profile $U_j$

$$\int |U(t)|^2\Phi_j dx = \int |U_j(t)|^2\Phi_j dx + O(e^{-\frac{4}{T-t}}).$$

Since

$$\int |U_j(t)|^2\Phi_j dx = \int |Q|^2 dy + \int |Q(y)|^2(\Phi_j(\lambda_j(t)y + \alpha_j(t)) - 1)dy,$$

and for some $\delta > 0$,

$$\int |Q(y)|^2(1 - \Phi_j(\lambda_j(t)y + \alpha_j(t)))dy \leq \int_{|y| \geq \frac{\alpha_j(t)}{\lambda_j(t)}} Q^2(y)dy \leq Ce^{-\frac{4}{T-t}},$$

we infer that

$$\int |U(t)|^2\Phi_j dx = \|Q\|_{L^2}^2 + O(e^{-\frac{4}{T-t}}).$$

Similarly, we have

$$\int |u(T_*)|^2\Phi_j dx = \int \sum_{i=1}^{K} S_i(T_*)|^2\Phi_j dx = \|Q\|_{L^2}^2 + O(e^{-\frac{4}{T-t}}).$$

We infer from (5.22) and (5.23) that

$$|\int |u(T_*)|^2\Phi_j dx - \int |U(t)|^2\Phi_j dx | \leq Ce^{-\frac{4}{T-t}}.$$

Therefore, plugging (5.21) and (5.24) into (5.19) we obtain

$$|2Re\int (U_j R_j)(t) dx + \int |R(t)|^2\Phi_j dx| \leq C(\int_{t}^{T_*} \|R\|_{L^2}^2 + \|\nabla R\|_{L^2}^2 ds + e^{-\frac{4}{T-t}}),$$

which along with (5.9) yields (5.18) for $T$ small enough and finishes the proof. \(\square\)

Theorem 5.8 below contains the estimate of the variation of energy. Unlike the deterministic case, the energy (1.6) is no longer conserved and the corresponding variation plays an important role in the derivation of the refined estimate of the modulation parameter $\beta$ later (see Lemma 5.14 below).

**Proposition 5.8 (Variation of the energy).** There exists $C > 0$ such that for any $t \in [t_*, T_*]$, \n
$$|E(u(t)) - E(u(T_*))| \leq C(T - t)^{\kappa + 1}.$$  

**Proof.** The proof is quite similar to that of [58, Theorem 5.6], based on the Gagliardo-Nirenberg inequality (3.28) and the estimate (4.23) of the spatial functions of noises under Assumption (A1). Actually, as in [58, (5.20)], we have

$$\frac{d}{dt} E(u_n) = -2 \sum_{k=1}^{N} B_k \Re \int \nabla^2 \phi_k(\nabla u_n, \nabla u_n) dx + \frac{1}{2} \sum_{k=1}^{N} B_k \int \Delta^2 \phi_k |u_n|^2 dx$$

$$+ \frac{2}{d+2} \sum_{k=1}^{N} B_k \int \Delta \phi_k |u_n|^2 dx - \sum_{j=1}^{d} \Im \int \nabla (\sum_{k=1}^{N} \partial_j \phi_k B_k) \cdot \nabla u_n \overline{u_n} dx.$$  

25
This yields that
\[
\left| \frac{d}{dt} E(u_n) \right| \leq C \|R\|_{H^1}^2 + C \sum_{k=1}^{K} \sum_{j=1}^{d} \left( \int (|\nabla^2 \phi_k| + |\Delta \phi_k| + |\partial_j \phi_k \nabla \partial_j \phi_k|)(|\nabla U|^2 + |U|^{2+\frac{2}{d}})dx \right)
\]
\[+ \int \left( |\Delta^2 \phi_k| + |\partial_j \phi_k \nabla \partial_j \phi_k| \right)|U|^2 dx, \]
which, via the change of variables, can be further bounded by, up to some constant,
\[
\|R\|_{H^1}^2 + \sum_{k,l=1}^{K} \int (T - t)^{-2} \sum_{|\nu| \leq 2} |\partial^\nu \phi_k|(|\lambda y + \alpha_l|)|\nabla Q_l|^2 + |Q_l|^{2+\frac{2}{d}} + \sum_{|\nu| \leq 2} |\partial^\nu \phi_k|(|\lambda y + \alpha_l|)|Q|^2 dy.
\]
Thus, using (4.23) and (5.9) we obtain
\[
\left| \frac{d}{dt} E(u_n) \right| \leq C(T - t)^\epsilon,
\]
which immediately yields (5.25), thereby finishing the proof. □

5.2. Monotonicity of generalized energy. This subsection is mainly devoted to the monotonicity property of a new generalized energy, which is the key ingredient in the proof of the bootstrap estimate (5.5) of the remainder.

It should be mentioned that, unlike the single blow-up point case in [55, 58], the new generalized energy (5.28) below includes also the localized functions in an appropriate way, such that the different profiles can be decoupled completely and the key monotonicity property is still preserved.

More precisely, let \( \chi(x) = \psi(|x|) \) be a smooth radial function on \( \mathbb{R}^d \), where \( \psi \) satisfies \( \psi'(r) = r \) if \( r \leq 1 \), \( \psi'(r) = 2 - e^{-r} \) if \( r \geq 2 \), and
\[
|\psi''(r)| \leq C, \quad \frac{\psi'(r)}{r} - \psi''(r) \geq 0 .
\]

Let \( \chi_A(x) := A^2 \chi(\frac{x}{A}) \), \( A > 0 \), \( f(u) := |u|^2 u \), and \( F(u) := \frac{d}{2d+1}|u|^{2+\frac{2}{d}} \). We shall also use the notations \( f'(U, R) \cdot R \) and \( f''(U, R) \cdot R^2 \) as in (3.18) and (3.19), respectively.

We define the generalized energy by
\[
I(t) := \frac{1}{2} \int |\nabla R|^2 dx + \frac{1}{2} \sum_{j=1}^{K} \int \frac{1}{\lambda_j^2} |R_j|^2 \Phi_j dx - \text{Re} \int F(u) - F(U) - f(U) R dx
\]
\[+ \sum_{j=1}^{K} \frac{\gamma_j}{2 \lambda_j} \text{Im} \int (\nabla \chi_A) \left( \frac{x - \alpha_j}{\lambda_j} \right) \cdot R R \Phi_j dx.
\]

The key monotonicity property of the generalized energy is formulated in Theorem 5.9 below.

**Theorem 5.9.** There exist \( C_1, C_2(A), C_3 > 0 \) such that for any \( t \in [t_*, T_*] \)
\[
\frac{dI}{dt} \geq C_1 \sum_{j=1}^{K} \frac{1}{\lambda_j} \int (|\nabla R_j|^2 + \frac{1}{\lambda_j^2} |R_j|^2) e^{-\frac{|x - \alpha_j|}{A \lambda_j}} dx - C_2(A)(T - t)^{2\epsilon} - C_3 \epsilon^* (T - t)^{2\kappa - 1}.
\]

**Remark 5.10.** Theorem 5.9 yields that the derivative of the generalized energy is almost positive, up to some error terms, and thus the generalized energy is almost monotone. We also mention that, the error term of order \( (T - t)^{2\kappa - 1} \) corresponds to the frequencies
\( \{ \omega_j \}_{j=1}^K \), and the small coefficient \( \varepsilon^* \) is important later in the derivation of the bootstrap estimate \([5.3]\) of the remainder \( R \), and also in the iteration arguments in the proof of uniqueness.

In order to prove Theorem \([5.9]\) we separate \( I \) into two parts \( I = I^{(1)} + I^{(2)} \), where

\[
I^{(1)} := \frac{1}{2} \int |\nabla R|^2 \, dx + \frac{1}{2} \sum_{j=1}^K \int \frac{1}{\lambda_j^2} |R|^2 \Phi_j \mathit{dx} - \text{Re} \int F(u) - F(U) - f(U)R \mathit{dx},
\]

\[
(5.30)
\]

\[
I^{(2)} := \sum_{j=1}^K \frac{\gamma_j}{2\lambda_j} \text{Im} \int (\nabla \chi_A)(\frac{x - \alpha_j}{\lambda_j}) \cdot \nabla R \Phi_j \mathit{dx}.
\]

Below we treat \( I^{(1)} \) and \( I^{(2)} \) separately in Lemmas \([5.11]\) and \([5.12]\). Let us first show the estimate of \( I^{(1)} \).

**Lemma 5.11.** Consider the situations as in Theorem \([5.9]\). Then, for every \( t \in [t_*, T] \) we have that for some \( C_1, C_2 > 0 \),

\[
\frac{dI^{(1)}}{dt} \geq \sum_{j=1}^K \frac{\gamma_j}{\lambda_j^2} |R_j|^2 - \sum_{j=1}^K \frac{\gamma_j}{\lambda_j^2} \text{Re} \int (1 + \frac{2}{d})|U_j|^2 |R_j|^2 + \frac{2}{d}|U_j|^4 |R_j|^2 \mathit{dx}
\]

\[
- \sum_{j=1}^K \frac{\gamma_j}{\lambda_j^2} \text{Re} \int \left( \frac{x - \alpha_j}{\lambda_j} \right) \cdot \nabla U_j \left\{ \frac{2}{d} (1 + \frac{2}{d})|U_j|^2 |R_j|^2 + \frac{1}{d} (\frac{2}{d} - 1)|U_j|^4 |R_j|^2 \right\} \mathit{dx}
\]

\[
(5.32)
\]

- \( C_1(T - t)^{2\varepsilon} - C_2\varepsilon^* (T - t)^{2\varepsilon - 1} \).

**Proof.** Using the identities

\[
\partial_t F(u) = \text{Re} \left( f(u) \partial_t \overline{U} \right), \quad \partial_t f(U) = \partial_x f(U) \partial_t U + \partial_x f(U) \partial_t \overline{U},
\]

and the expansion \([3.21]\) we have

\[
\frac{dI^{(1)}}{dt} = \text{Im} \langle \Delta R + f(u) - f(U), i\partial_t R \rangle - \lambda_j^{-2} \text{Im} \langle R_j, i\partial_t R \rangle - \lambda_j^{-3} \int |R|^2 \Phi_j \mathit{dx} - \text{Re} \langle f''(U, R) \cdot R^2, \partial_t U \rangle.
\]

Then, in view of \([5.15]\), we obtain

\[
\frac{dI^{(1)}}{dt} = - \sum_{j=1}^K \lambda_j \lambda_j^{-3} \text{Im} \int |R|^2 \Phi_j \mathit{dx} - \sum_{j=1}^K \lambda_j^{-2} \text{Im} \langle f'(U) \cdot R, R_j \rangle
\]

\[
- \text{Re} \langle f''(U, R) \cdot R^2, \partial_t U \rangle - \sum_{j=1}^K \lambda_j^{-2} \text{Im} \langle R \nabla \Phi_j, \nabla R \rangle
\]

\[
- \sum_{j=1}^K \lambda_j^{-2} \text{Im} \langle f''(U, R) \cdot R^2, R_j \rangle - \text{Im} \langle \Delta R - \sum_{j=1}^K \lambda_j^{-2} R_j + f(u) - f(U), \eta \rangle
\]

\[
(5.33)
\]

- \( \text{Im} \langle \Delta R - \sum_{j=1}^K \lambda_j^{-2} R_j + f(u) - f(U), b \cdot \nabla R + c R \rangle =: \sum_{j=1}^7 I^{(1)}_{j} \),

where \( \eta \) is given by \([5.16]\).
As we shall see below, the main orders of \( \frac{dI_{1}^{(1)}}{dt} \) are contributed by the first three terms \( I_{1,1}^{(1)} \), \( I_{1,2}^{(1)} \) and \( I_{1,3}^{(1)} \), the fourth term will contribute the error of order \((T-t)^{2\kappa-1}\) for which we shall treat Case (I) and Case (II) separately, while the remaining three terms are of the negligible order \((T-t)^{2\kappa}\).

(i) Estimate of \( I_{1,1}^{(1)} \). Since by (5.14), \( \frac{\lambda_{1} \alpha_{j} + \gamma_{j}}{\lambda_{j}^{2}} \leq C \frac{\text{Mod}}{\lambda_{j}^{2}} \leq C(T-t)^{\kappa-1} \), it follows from (5.1) that

\[
I_{1,1}^{(1)} = \sum_{j=1}^{K} \frac{\gamma_{j}}{\lambda_{j}^{2}} \int |R|^2 \Phi_{j} dx - \frac{\lambda_{j} \alpha_{j} + \gamma_{j}}{\lambda_{j}^{2}} \int |R|^2 \Phi_{j} dx
\]

\[
= \sum_{j=1}^{K} \frac{\gamma_{j}}{\lambda_{j}^{2}} \int |R|^2 \Phi_{j} dx + O((T-t)^{2\kappa})
\]

(5.34)

\[
\geq \sum_{j=1}^{K} \frac{\gamma_{j}}{\lambda_{j}^{2}} \|R_{j}\|_{L^2}^2 - C(T-t)^{2\kappa},
\]

where we also used the inequality \( \Phi_{j} \geq \Phi_{j}^2 \) in the last step.

(ii) Estimates of \( I_{1,2}^{(1)} \) and \( I_{1,3}^{(1)} \). We apply Lemma 3.1 to decouple different blow-up profiles to obtain

\[
I_{1,2}^{(1)} + I_{1,3}^{(1)} = -\sum_{j=1}^{K} \frac{1}{\lambda_{j}^{2}} \text{Im} \int \frac{2}{d} |U_{j}|^{\frac{4}{d}} - 2 U_{j}^{2} R_{j}^{2} dx - \sum_{j=1}^{K} \text{Re} \int j''(U_{j}, R_{j}) \cdot R_{j}^{2} \partial_{t} U_{j} dx + O(e^{-\frac{\rho}{d}}).
\]

Then, for each \( 1 \leq j \leq K \), straightforward computations show that (see also the proof of [58] (5.46),(5.49))

\[
I_{1,2}^{(1)} + I_{1,3}^{(1)} = -\sum_{j=1}^{K} \frac{\gamma_{j}}{\lambda_{j}^{2}} \text{Re} \int \left(1 + \frac{2}{d}\right) |U_{j}|^{\frac{4}{d}} |R_{j}|^{2} + \frac{2}{d} |U_{j}|^{\frac{4}{d} - 2} \nabla U_{j}^{2} R_{j}^{2}
\]

\[
- \sum_{j=1}^{K} \frac{\gamma_{j}}{\lambda_{j}^{2}} \text{Re} \int \left(\frac{x - \alpha_{j}}{\lambda_{j}}\right) \cdot \nabla U_{j} \left(\frac{2}{d} \left(1 + \frac{2}{d}\right) |U_{j}|^{\frac{4}{d} - 2} |R_{j}|^{2}\right)
\]

\[
+ \frac{1}{d} \left(1 + \frac{2}{d}\right) |U_{j}|^{\frac{4}{d} - 2} \nabla U_{j} R_{j}^{2} + \frac{2}{d} |R_{j}|^{4} - \frac{4}{d} |U_{j}|^{\frac{4}{d} - 2} \nabla U_{j} R_{j}^{2}\right) dx + O((T-t)^{2\kappa}).
\]

(5.35)

(iii) Estimate of \( I_{1,4}^{(1)} \). We consider Case (I) and Case (II) separately. First, in Case (I), since \( \sum_{j=1}^{K} \nabla \Phi_{j}(x) = 0 \), we see that

\[
|I_{1,4}^{(1)}| = \sum_{j=1}^{K} \left(\frac{1}{\lambda_{j}^{2}} - \frac{1}{\omega^2(T-t)^{2}}\right) \text{Im} \langle R \nabla \Phi_{j}, \nabla R \rangle
\]

\[
\leq \sum_{j=1}^{K} \frac{|\lambda_{j} - \omega(T-t)||\lambda_{j} + \omega(T-t)|}{\lambda_{j}^{2} \omega^2(T-t)^{2}} \|R \nabla \Phi_{j}\|_{L^2} \|\nabla R\|_{L^2}
\]

\[
\leq \sum_{j=1}^{K} \frac{|\lambda_{j} - \omega(T-t)||\lambda_{j} + \omega(T-t)|}{\lambda_{j}^{2} \omega^2(T-t)} \left( \frac{\|R\|_{L^2}^2}{(T-t)^2} + \|\nabla R\|_{L^2}^2 \right).
\]
Since $|\omega - \omega_j| \leq \epsilon^*$ for any $1 \leq j \leq K$, using (5.10) and (5.13) we see that
\[
|\lambda_j - \omega(T - t)||\lambda_j + \omega(T - t)|
\leq \frac{|\lambda_j - \omega_j(T - t)| + |(\omega_j - \omega)(T - t)||\lambda_j + \omega(T - t)|}{\lambda_j^2\omega^2(T - t)}
\leq C((T - t)^{\kappa - 1} + \epsilon^*(T - t)^{-1}).
\]
This along with (5.9) yields that
\[
|I_{t,4}^{(1)}| \leq C((T - t)^{3\kappa - 1} + \epsilon^*(T - t)^{2\kappa - 1}) \leq C((T - t)^{2\kappa} + \epsilon^*(T - t)^{2\kappa - 1}).
\]
In Case (II), we see that
\[
|I_{t,4}^{(1)}| \leq \frac{K}{\sum_{j=1}^K \chi_j^2} \|\nabla \phi_j\|_{L^\infty} \|R\|_{L^2} \|\nabla R\|_{L^2}.
\]
Since $|\nabla \phi_j| \leq C\sigma^1 \leq C\epsilon^*$ in Case (II), using (5.9) and (5.13) we have
\[
|I_{t,4}^{(1)}| \leq C(T - t)^{-1} (\|R\|_{L^2}^2 + \|\nabla R\|_{L^2}^2) \leq C\epsilon^*(T - t)^{-1}.
\]
(iv) Estimate of $I_{t,5}^{(1)}$. Since
\[
|U(t)| \leq C(T - t)^{-\frac{d}{2}},
\]
using (3.23), (3.28), (3.29) and (5.9) we get
\[
|I_{t,5}^{(1)}| \leq C(T - t)^{-2} (\int |U|^\frac{d}{2} - 1 |R|^3 dx + \|R\|_{L^2}^{\frac{d+2}{2}})
\leq C(T - t)^{-2} ((T - t)^{-2 + \frac{d}{2}} \|R\|_{L^2}^{\frac{d}{2}} \|\nabla R\|_{L^2}^{\frac{d}{4}} + \|R\|_{H^1}^{\frac{d}{4} + 2}) \leq C(T - t)^{2\kappa}.
\]
(v) Estimate of $I_{t,6}^{(1)}$. Regarding $I_{t,6}^{(1)}$, since by (3.20) and (3.22),
\[
|f(u) - f(U)| = |f'(U, R) \cdot R| \leq C(|U|^\frac{d}{4} + |R|^\frac{d}{4}) \|R\| \leq C((T - t)^{-2} + |R|^\frac{d}{4}) \|R\|,
\]
using the integration by parts formula, (3.20), (5.9) and the estimate (5.17) of $\eta$, we obtain
\[
|I_{t,6}^{(1)}| \leq C(\|\nabla \eta\|_{L^2} \|\nabla R\|_{L^2} + (T - t)^{-2} \|R\|_{L^2} \|\eta\|_{L^2} + \|R\|^{\frac{d}{4} + 1} \|\eta\|_{L^2})
\leq C(T - t)^{-2\kappa}.
\]
(vi) Estimate of $I_{t,7}^{(1)}$. The last term $I_{t,7}^{(1)}$ can be estimated similarly as in the proof of [55] Lemma 5.10. Precisely, using the explicit expressions (2.12) of $b$, $\sup_{0 \leq t \leq T} |B_k| < \infty$, a.s., $1 \leq k \leq N$, and integration by parts formula we have
\[
\text{Im} \langle \Delta R - \lambda_j^{-2} R_j + f(u) - f(U), b \cdot \nabla R \rangle
\leq C \sum_{k=1}^N \left( |\int \nabla^2 \phi_k(\nabla \overline{R}, \nabla R) dx| + \int \Delta \phi_k |\nabla R|^2 dx + (T - t)^{-2} \|R\|_{L^2}^2
+ \int |R|^{\frac{d}{4} + 1} |\nabla \phi_k \cdot \nabla \overline{R}| dx + \int (f(u) - f(U) - |R|^\frac{d}{4} R) \nabla \phi_k \cdot \nabla \overline{R} dx \right)
\leq C(T - t)^{2\kappa} + C \sum_{k=1}^N \int (f(u) - f(U) - |R|^\frac{d}{4} R) \nabla \phi_k \cdot \nabla \overline{R} dx\]
where in the last step we also used Hölder’s inequality and the inequality

\[(5.43) \quad \|R\|_{L^p} \leq C\|R\|_{L^2}^{p-d-\frac{1}{2}dp} \|\nabla R\|_{L^2}^{\frac{1}{2}dp-d} \leq C(T-t)^{kp+d-\frac{1}{2}dp}, \quad \forall p \geq 2.\]

Moreover, by Lemma 3.1, the last term in (5.42) is bounded by

\[C \sum_{k=1}^{4/d} \sum_{j=1}^{K} \int |R^k U_j^{1+\frac{1}{2}-k} \nabla \phi_k \cdot \nabla R_j| dx + C e^{-\frac{4}{\tau-t}} \]

\[\leq C \sum_{j=1}^{4/d} \sum_{k=1}^{K} \int \lambda_j^d (R^k U_j^{1+\frac{1}{2}-k} \nabla \phi_k \cdot \nabla R_j)(\lambda_j y + \alpha_j) dy + C e^{-\frac{4}{\tau-t}}. \]

which, via (4.23) and (5.43), can be further bounded by

\[C \sum_{j=1}^{4/d} \sum_{k=1}^{K} (T-t)^{-\frac{d}{2}(1+\frac{1}{2}-k)+\nu} \|R\|_{H^1} \|R\|_{L^{2k}}^{k} + C e^{-\frac{4}{\tau-t}} \leq C(T-t)^{2\nu}. \]

Hence, we obtain

\[(5.44) \quad \text{Im}(\Delta R - \lambda_j^{-2} R_j + f(u) - f(U), b \cdot \nabla R) | \leq C(T-t)^{2\nu}. \]

Similarly, since \(|U(t)| \leq C(T-t)^{-\frac{4}{3}}\) and \(\|e\|_{L^\infty(t, T; L^\infty)} < \infty,\) using (5.9) and (5.43) we get

\[\text{Im}(\Delta R - \lambda_j^{-2} R_j + f(u) - f(U), cR) | \leq \|R\|_{H^1}^2 + (T-t)^{-2} \|R\|_{L^2}^2 + \sum_{k=1}^{1+\frac{1}{2}} (T-t)^{-\frac{4}{3}(1+\frac{1}{2}-k)} \|R\|_{L^{2k+1}}^{k+1} \]

\[(5.45) \quad \leq C(T-t)^{2\nu}. \]

Thus, we conclude from (5.44) and (5.45) that

\[(5.46) \quad |I_{t, T}^{(1)}| \leq C(T-t)^{2\nu}. \]

Therefore, plugging estimates (5.32), (5.35), (5.36), (5.38), (5.40), (5.41) and (5.46) into (5.33) we obtain (5.32) and finish the proof of Lemma 5.11. \(\square\)

**Lemma 5.12.** For all \(t \in [t_*, T_*],\) we have that for some \(C(A) > 0,\)

\[\frac{d I^{(2)}}{dt} \geq -\sum_{j=1}^{K} \frac{\gamma_j}{4 \lambda_j^3} \int \Delta^2 \chi_A(\frac{x - \alpha_j}{\lambda_j}) |R_j|^2 dx + \sum_{j=1}^{K} \frac{\gamma_j}{\lambda_j^2} \int \nabla^2 \chi_A(\frac{x - \alpha_j}{\lambda_j}) \nabla R_j \cdot \nabla R_j dx \]

\[+ \sum_{j=1}^{K} \frac{\gamma_j}{\lambda_j} \sum_{j=1}^{K} \gamma_j \frac{\beta_j}{\lambda_j} \int \nabla \chi_A(\frac{x - \alpha_j}{\lambda_j}) \cdot \nabla U_j \left\{ \frac{2}{d} (1 + \frac{2}{d}) |U_j|^{\frac{4}{d} - 2} |U_j^d | R_j^2 \right\} \]

\[+ \frac{1}{d} (1 + \frac{2}{d}) |U_j|^{\frac{4}{d} - 2} U_j R_j^2 + \frac{1}{d} (\frac{2}{d} - 1) |U_j|^{\frac{4}{d} - 4} U_j R_j^2 \]

\[(5.47) \quad dx - C(A)(T-t)^{2\nu}. \]

**Remark 5.13.** The difficulty in the proof of Lemma 5.12 lies in the analysis of the interactions between the remainders, of which the perturbation order is of only polynomial type. This is different from the situation in Lemma 5.11, where the interactions involving \(U_j\) are very weak, because of the exponential decay of the ground state. The point here is to gain additional decays from the functions \(\partial^n \chi_A,\) where \(|n| \geq 2.\)
Proof of Lemma 5.12. Straightforward computations show that
\[
\frac{dI^{(2)}}{dt} = - \sum_{j=1}^{K} \frac{\lambda_j \gamma_j - \lambda_j \dot{\gamma}_j}{2\lambda_j^2} \text{Im}(\nabla \chi_A \frac{x - \alpha_j}{\lambda_j} \cdot \nabla R, R_j)
\]
\[+ \sum_{j=1}^{K} \frac{\gamma_j}{2\lambda_j} \text{Im}(\partial_t(\nabla \chi_A \frac{x - \alpha_j}{\lambda_j}) \cdot \nabla R, R_j) + \sum_{j=1}^{K} \frac{\gamma_j}{2\lambda_j^2} \text{Im}(\Delta \chi_A \frac{x - \alpha_j}{\lambda_j} R_j, \partial_t R)
\]
\[+ \sum_{j=1}^{K} \frac{\gamma_j}{2\lambda_j} \text{Im}(\nabla \chi_A \frac{x - \alpha_j}{\lambda_j} \cdot (\nabla R_j + \nabla R(\Phi_j), \partial_t R)
\]
(5.48) =: \sum_{j=1}^{K} (I_{t,j1}^{(2)} + I_{t,j2}^{(2)} + I_{t,j3}^{(2)} + I_{t,j4}^{(2)}).

We shall estimate \(I_{t,jk}^{(2)}\), \(1 \leq k \leq 4\), separately. The main contributions come from the last two terms \(I_{t,j3}^{(2)}\) and \(I_{t,j4}^{(2)}\), which requires a delicate analysis of the interactions between remainders.

(i) Estimate of \(I_{t,j1}^{(2)}\) and \(I_{t,j2}^{(2)}\). Since \(\sup_y |\nabla^2 \chi_A(y)(1 + |y|)| \leq C(A)\), by Lemmas 5.3 and 5.4
\[
|\partial_t(\nabla \chi_A \frac{x - \alpha_j}{\lambda_j})| = |\nabla^2 \chi_A \frac{x - \alpha_j}{\lambda_j} \cdot \left(\left(\frac{x - \alpha_j}{\lambda_j}\right) \cdot \frac{\lambda_j \dot{\gamma}_j + \dot{\gamma}_j}{\lambda_j^2} - \left(\frac{x - \alpha_j}{\lambda_j} \cdot \frac{\gamma_j}{\lambda_j^2} + \frac{\lambda_j \dot{\gamma}_j + \dot{\gamma}_j}{\lambda_j^2} + \frac{2\beta_j}{\lambda_j^2}\right)\right)|
\]
(5.49) \(\leq C(A)\lambda_j^{-2}(\text{Mod}_j + P_j) \leq C(A)(T - t)^{-1}\).

Taking into account \(\frac{\lambda_j \gamma_j - \lambda_j \dot{\gamma}_j}{2\lambda_j^2} \leq C \frac{\text{Mod}_j(t)}{\lambda_j^2} \leq C(T - t)^{\kappa}\) and (5.50) we obtain
\[
|I_{t,j1}^{(2)} + I_{t,j2}| \leq C(A)((T - t)^{\kappa}||\nabla R||_{L^2}||R||_{L^2} + (T - t)^{-1}||\nabla R||_{L^2}||R||_{L^2})
\]
(5.50) \(\leq C(A)(T - t)^{2\kappa}\).

(ii) Estimate of \(I_{t,j3}^{(2)}\). We claim that
\[
I_{t,j3}^{(2)} = -\frac{\gamma_j}{4\lambda_j^4} \text{Re} \int \Delta^2 \chi_A \frac{x - \alpha_j}{\lambda_j} |R_j|^2 dx + \frac{\gamma_j}{2\lambda_j^2} \text{Re} \int \Delta \chi_A \frac{x - \alpha_j}{\lambda_j} \nabla R_j |^2 dx
\]
(5.51)
\[-\frac{\gamma_j}{2\lambda_j^2} \text{Re}(\Delta \chi_A \frac{x - \alpha_j}{\lambda_j} R_j, f'(U_j) \cdot R_j) + O((T - t)^{2\kappa}).
\]

In order to prove (5.51), we infer from (3.21) and equation (5.15) that
(5.52)
\[
I_{t,j3}^{(2)} = -\frac{\gamma_j}{2\lambda_j^2} \text{Re}(\Delta \chi_A \frac{x - \alpha_j}{\lambda_j} R_j, \Delta R + f'(U) \cdot R + f''(U, R) \cdot R^2 + (b \cdot \nabla + c)R + \eta).
\]

The main contributions come from the terms involving \(\Delta R\) and \(f'(U) \cdot R\).

First, since for any \(j \neq l\), \(|x - \alpha_j| \geq 4\sigma\) on the support of \(R_l\), taking \(t_*\) close to \(T\) we may let \(|x_j - \alpha_j| \leq \sigma\), and thus \(|x - \alpha_j| \geq 3\sigma\) on the support \(R_l\). By the integration by
parts formula, for $1 \leq j \neq l \leq K$,
\begin{align*}
\frac{\gamma_j}{2\lambda_j^2} \text{Re} \int \Delta \chi_A(\frac{x - \alpha_j}{\lambda_j}) R_j \Delta R_l \, dx &\leq \frac{\gamma_j}{2\lambda_j^2} \text{Re} \int_{|x - \alpha_j| \geq 3\sigma} \Delta \chi_A(\frac{x - \alpha_j}{\lambda_j}) \nabla R_j \cdot \nabla R_l \, dx \\
&+ \frac{\gamma_j}{2\lambda_j^2} \text{Re} \int_{|x - \alpha_j| \geq 3\sigma} \nabla \Delta \chi_A(\frac{x - \alpha_j}{\lambda_j}) \cdot \nabla R_l R_j \, dx \\
&=: K_1 + K_2.
\end{align*}

(5.53)

The key observation here is that, because of the decay of $\partial^n \chi_A$, $|\nu| \geq 2$, the different remainders $R_j$ and $R_l$ have weak interactions of order $(T - t)^{2\kappa}$, which is important for the bootstrap estimate of the remainder.

To be precise, since
\[ \Delta \chi(y) = \psi''(|y|) + (d - 1)\psi'(|y|)|y|^{-1} \leq C|y|^{-1}, \quad \text{if } |y| \geq 2, \]
we have
\[ K_1 \leq C \frac{\gamma_j \lambda_j A}{\lambda_j^2 (3\sigma)} \| R \|_{H^1}^2 \leq C A (T - t)^{2\kappa}. \]

(5.54)

Similarly, since
\[ \partial_j \Delta \chi(y) = \psi'''(|y|) \frac{y_j}{|y|} + (d - 1)(\psi''(|y|) \frac{y_j}{|y|}^2 - \psi'(|y|) \frac{y_j^2}{|y|^3}) \leq C|y|^{-2}, \quad \text{if } |y| \geq 2, \]
we get
\[ K_2 \leq C \frac{\gamma_j \lambda_j A^2}{\lambda_j^2 (3\sigma)} \| \nabla R \|_{L^2}^2 \| R_j \|_{L^2} \leq C (T - t)^{2\kappa + 1}. \]

(5.55)

Hence, plugging (5.54) and (5.55) into (5.53) we conclude that the interactions between different remainders $R_j$ and $R_l$ have the negligible order $(T - t)^{2\kappa}$, i.e.,
\[ \frac{\gamma_j}{2\lambda_j^2} \text{Re} \int \Delta \chi_A(\frac{x - \alpha_j}{\lambda_j}) R_j \Delta R_l \, dx \leq C(T - t)^{2\kappa}. \]

This along with the integration by parts formula yields that
\begin{align*}
-\frac{\gamma_j}{2\lambda_j^2} \text{Re} \langle \Delta \chi_A(\frac{x - \alpha_j}{\lambda_j}) R_j, \Delta R \rangle &=- \frac{\gamma_j}{4\lambda_j^4} \text{Re} \int \Delta^2 \chi_A(\frac{x - \alpha_j}{\lambda_j}) |R_j|^2 \, dx \\
&+ \frac{\gamma_j}{2\lambda_j^2} \text{Re} \int \Delta \chi_A(\frac{x - \alpha_j}{\lambda_j}) |\nabla R_j|^2 \, dx + O((T - t)^{2\kappa}).
\end{align*}

(5.56)

We also apply Lemma 3.1 to obtain
\[ \text{Re} \langle \Delta \chi_A(\frac{x - \alpha_j}{\lambda_j}) R_j, f'(U) \cdot R \rangle = \text{Re} \langle \Delta \chi_A(\frac{x - \alpha_j}{\lambda_j}) R_j, f'(U_j) \cdot R_j \rangle + O(e^{-\frac{\delta}{T - t}}). \]

Moreover, since by (3.23) and (5.39),
\[ |f''(U, R) \cdot R^2| \leq C(|U|^\frac{4}{T} + |R|^\frac{4}{T - 1}) |R|^2 \leq C((T - t)^{-2 + \frac{4}{T}} + |R|^\frac{4}{T - 1}) |R|^2, \]

32
using (5.31), (5.5) and (5.43) we have

\[ \frac{\gamma_j}{2 \lambda_j} Re(\Delta \chi_A(\frac{x - \alpha_j}{\lambda_j})R_j, f''(U, R) \cdot R^2) \]

\[ \leq C(A) \int (T - t)^{-1}((T - t)^{-\frac{\delta}{2}} + |R|^2)|R|dx \]

(5.58)

\[ \leq C(A)(T - t)^{-\frac{3\delta}{2}}\|R\|_L^3 + (T - t)^{-1}\|R\|_L^2 \leq C(A)(T - t)^{2\epsilon}. \]

Furthermore, using Hölder’s inequality, (5.49) and (5.57) we have

\[ \frac{\gamma_j}{2 \lambda_j} Re(\Delta \chi_A(\frac{x - \alpha_j}{\lambda_j})R_j, (b \cdot \nabla + c)R + \eta) \]

\[ \leq C(A)(T - t)^{-1}(\|R\|_L^2\|\nabla R\|_L^2 + \|R\|_L^2) + C(A)(T - t)^{-1}\|\eta\|_L^2\|R\|_L^2 \]

(5.59)

\[ \leq C(A)(T - t)^{2\epsilon}. \]

Hence, plugging (5.56), (5.57), (5.58) and (5.59) into (5.52) we obtain (5.51), as claimed.

(i) Estimate of \( I_{t,j}^{(2)} \). We claim that

\[ I_{t,j}^{(2)} = \frac{\gamma_j}{\lambda_j} Re(\Delta \chi_A(\frac{x - \alpha_j}{\lambda_j})R_j, \nabla R_j)dx - \frac{\gamma_j}{2 \lambda_j} Re(\Delta \chi_A(\frac{x - \alpha_j}{\lambda_j})\nabla R_j^2)dx \]

\[ - \frac{\gamma_j}{\lambda_j} Re(\nabla \chi_A(\frac{x - \alpha_j}{\lambda_j}) \cdot \nabla R_j, f'(U_j) \cdot R_j) + O((T - t)^{2\epsilon}). \]

(5.60)

For this purpose, we infer from equation (5.15) and Lemma 3.1 that

\[ I_{t,j}^{(2)} = - \frac{\gamma_j}{2 \lambda_j} Re(\nabla \chi_A(\frac{x - \alpha_j}{\lambda_j}) \cdot (\nabla R_j + \nabla R\Phi_j), \Delta R) \]

\[ \Delta R + f'(U_j) \cdot R_j + f''(U, R) \cdot R^2 + (b \cdot \nabla + c)R + \eta) + O(e^{-\frac{\delta}{2}t}). \]

(5.61)

We first show that

(5.62) \[ - Re(\nabla \chi_A(\frac{x - \alpha_j}{\lambda_j}) \cdot (\nabla R_j + \nabla R\Phi_j), \Delta R) \]

\[ = Re \frac{2}{\lambda_j} \nabla^2 \chi_A(\frac{x - \alpha_j}{\lambda_j})(\nabla R_j, \nabla R_j) - \frac{1}{\lambda_j} \Delta \chi_A(\frac{x - \alpha_j}{\lambda_j})|\nabla R_j|^2dx + O((T - t)^{2\epsilon}). \]

In order to prove (5.62), using integration by parts formula we see that

\[ - Re(\nabla \chi_A(\frac{x - \alpha_j}{\lambda_j}) \cdot \nabla R_j, \Delta R) \]

\[ = Re \frac{1}{\lambda_j} \nabla^2 \chi_A(\frac{x - \alpha_j}{\lambda_j})(\nabla R_j, \nabla R) - \frac{1}{\lambda_j} \Delta \chi_A(\frac{x - \alpha_j}{\lambda_j})\nabla R_j \cdot \nabla Rdx \]

(5.63)

\[ - \sum_{1 \leq k, l \leq d} Re \int \partial_k \chi_A(\frac{x - \alpha_j}{\lambda_j})\partial_l R_j \partial_{kl} Rdx. \]
Then, as in the proof of (5.56), using the decay of $\partial_\nu \chi_A$ with $|\nu| = 2$ we obtain that the interactions between different remainders have negligible contributions and thus

$$- \Re \langle \nabla \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \cdot \nabla R_j, \Delta R \rangle$$

$$= \Re \int \frac{1}{\lambda_j} \nabla^2 \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) (\nabla R_j, \nabla \overline{R}) - \frac{1}{\lambda_j} \Delta \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) |\nabla R_j|^2 dx$$

$$= \Re \sum_{1 \leq k, l \leq d} \Re \int \partial_k \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \partial_l R_j \partial_k \overline{R} dx + \mathcal{O}(\langle T - t \rangle^{2\kappa}). \tag{5.64}$$

Similarly, we have

$$- \Re \langle \nabla \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \cdot \nabla R \Phi_j, \Delta R \rangle$$

$$= \Re \int \frac{1}{\lambda_j} \nabla^2 \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) (\nabla R, \nabla \overline{R}) \Phi_j + \Re \sum_{1 \leq k, l \leq d} \partial_k \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \partial_k R \partial_l \overline{R} \Phi_j dx$$

$$+ \Re \int (\nabla \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \cdot \nabla R)(\nabla \overline{R} \cdot \nabla \Phi_j) dx$$

$$= \Re \int \frac{1}{\lambda_j} \nabla^2 \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) (\nabla R_j, \nabla \overline{R}) + \Re \sum_{1 \leq k, l \leq d} \partial_k \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \partial_k \overline{R} \Phi_j dx$$

$$+ \mathcal{O}(\langle T - t \rangle^{2\kappa}). \tag{5.65}$$

Moreover, for the two terms involving $\partial_k \overline{R}$ in (5.64) and (5.65), we see that the cancellation appears and the integration by parts formula and (5.1) give

$$\Re \int \partial_k \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \partial_h \overline{R} \partial_l \Phi_j - \partial_k \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \partial_l R_j \partial_h \Phi_j dx$$

$$= - \Re \int \partial_k \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \partial_l R \partial_k \Phi_j dx$$

$$= \Re \int \frac{1}{\lambda_j} \Delta \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \partial_l R \partial_k \Phi_j + \partial_k \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \partial_l \Phi_j \partial_l R \partial_k \Phi_j dx$$

$$+ \Re \int \partial_k \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \partial_k \Phi_j \partial_l R \Phi_j dx = \mathcal{O}(\langle T - t \rangle^{2\kappa}). \tag{5.66}$$

Thus, plugging (5.64) - (5.66) into (5.63) we obtain (5.62), as claimed.

We also apply Lemma 3.1 to decouple different profiles between $\{U_j\}$ and $\{R_j\}$ to obtain that, similarly to (5.57),

$$\frac{\gamma_j}{2\lambda_j} \Re \langle \nabla \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \cdot (\nabla R_j + \nabla R \Phi_j), f'(U) \cdot R \rangle$$

$$= \frac{\gamma_j}{2\lambda_j} \Re \langle \nabla \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \cdot (\nabla R_j + \nabla R \Phi_j), f'(U_j) \cdot R_j \rangle + \mathcal{O}(e^{-\frac{x}{\sigma_j}}).$$

Since $|x - \alpha_j| \geq 3\sigma$ on the support of $1 - \Phi_j$, we have the exponential decay of $U_j$ that $|U_j(x)| \leq C\lambda_j^{-\frac{3}{2}} e^{-\frac{3|x|}{2\lambda_j}}$, and thus

$$\Re \langle \nabla \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \cdot \nabla R \Phi_j, f'(U_j) \cdot R_j \rangle = \Re \langle \nabla \chi_A \left( \frac{x - \alpha_j}{\lambda_j} \right) \cdot \nabla R, f'(U_j) \cdot R_j \rangle + \mathcal{O}(e^{-\frac{x}{\sigma_j}}).$$
Hence, we obtain
\begin{equation}
\frac{\gamma_j}{2\lambda_j} \text{Re}(\nabla \chi A \frac{x - \alpha_j}{\lambda_j}) \cdot (\nabla R_j + \nabla R\Phi_j) + f'(U) \cdot R_j + O(e^{-\frac{x}{\lambda_j}}).
\end{equation}

Moreover, using Hölder’s inequality, (5.9) and (5.17) we easily get
\begin{equation}
\frac{\gamma_j}{2\lambda_j} \text{Re}(\nabla \chi A \frac{x - \alpha_j}{\lambda_j}) \cdot (\nabla R_j + \nabla R\Phi_j) + f''(U) \cdot R^2 + (b \cdot \nabla + c)R + \eta_j) \leq C(T - t)^{2\kappa}.
\end{equation}

Hence, we conclude from (5.62), (5.67) and (5.68) that (5.60) holds.

Now, putting the estimates (5.50), (5.61) and (5.64) altogether we obtain
\begin{equation}
\frac{d\mathcal{I}(t)}{dt} = -\sum_{j=1}^{K} \frac{\gamma_j}{\lambda_j} \int \Delta^2 \chi A \frac{x - \alpha_j}{\lambda_j} |R_j|^2 dx + \sum_{j=1}^{K} \frac{\gamma_j}{\lambda_j} \text{Re} \int \nabla^2 \chi A \frac{x - \alpha_j}{\lambda_j} (\nabla R_j, \nabla R_j) dx
\end{equation}
\begin{equation}
- \sum_{j=1}^{K} \text{Re} \frac{\gamma_j}{2\lambda_j^2} \Delta \chi A \frac{x - \alpha_j}{\lambda_j} R_j + \frac{\gamma_j}{\lambda_j} \nabla \chi A \frac{x - \alpha_j}{\lambda_j} \cdot \nabla R_j, f'(U_j) \cdot R_j + O((T - t)^{2\kappa}).
\end{equation}

Because the profiles are decoupled completely, we can treat each profile individually by using similar computations as in the proof of [58, Lemma 5.11] and thus obtain that the third term on the right-hand-side above is equal to
\begin{equation}
\sum_{j=1}^{K} \frac{\gamma_j}{\lambda_j} \text{Re} \int \nabla \chi A \frac{x - \alpha_j}{\lambda_j} \cdot \nabla U_j \left\{ \frac{2}{d}(1 + \frac{2}{d}) |U_j|^4 - 2 |U_j|^2 |R_j|^2 \right\} dx,
\end{equation}
\begin{equation}
+ \frac{1}{d}(1 + \frac{2}{d}) |U_j|^4 - 2 |U_j|^2 R_j^2 + \frac{1}{d}(d - 1) |U_j|^4 - 4 U_j^3 R_j^2 \right\} dx,
\end{equation}
which immediately yields (5.47), thereby finishing the proof of Lemma 5.12 \(\square\)

We are now ready to prove Theorem 5.9.

Proof of Theorem 5.9. At this stage, the blow-up profiles are decoupled in (5.32) and (5.47), up to the acceptance order \(O((T - t)^{2\kappa})\), and thus we are able to treat each profile separately by using similar arguments as in the proof of [58, Theorem 5.8]. For the reader’s convenience, we sketch the proof below.

Combining (5.32) and (5.47) altogether and then using the renormalized variable \(\varepsilon_j\) in (4.10) we obtain that for all \(t \in [t_*, T_*]\),
\begin{equation}
\frac{d\mathcal{I}}{dt} \geq \sum_{j=1}^{K} \frac{\gamma_j}{\lambda_j} \int \nabla^2 \chi \frac{y}{A} (\nabla \varepsilon_j, \nabla \bar{\varepsilon}_j) dy + \int |\varepsilon_j|^2 dy - \int (1 + \frac{4}{d}) Q^4 \varepsilon_{j,1}^2 + Q^4 \varepsilon_{j,2}^2 dy
\end{equation}
\begin{equation}
- \frac{1}{4A^2} \int \Delta^2 \chi \frac{y}{A} |\varepsilon_j|^2 dy
\end{equation}
\begin{equation}
+ \sum_{j=1}^{K} \frac{\gamma_j}{\lambda_j} \int \frac{A \nabla \chi \frac{y}{A}}{y} - y \cdot \nabla QQ^{\frac{1}{2}} ((1 + \frac{4}{d}) \varepsilon_{j,1}^2 + \varepsilon_{j,2}^2) dy
\end{equation}
\begin{equation}
- C \varepsilon^* (T - t)^{2\kappa - 1} - C(A)(T - t)^{2\kappa},
\end{equation}
where \(\varepsilon_{j,1}\) and \(\varepsilon_{j,2}\) denote the real and imaginary parts of \(\varepsilon_j\), respectively.
Then, since
\[ \int \nabla^2 \chi \left( \frac{y}{A} \right) (\nabla \epsilon_j, \nabla \epsilon_j) dy \geq \int \psi'' \left( \frac{y}{A} \right) |\nabla \epsilon_j|^2 dy, \]
applying Corollary 3.4 with \( \phi := \psi''(|x|) \), Lemma 4.4 and Proposition 5.6 and using the estimate \( \text{Scal}(\epsilon_j) \leq C(T - t)^{2\kappa + 4} \) we obtain for some \( \tilde{C} > 0 \)
\[ \frac{dI}{dt} \geq \tilde{C} \sum_{j=1}^{K} \frac{\gamma_j}{\lambda_j^2} \int \psi'' \left( \frac{y}{A} \right) (|\epsilon_j|^2 + |\nabla \epsilon_j|^2) dy - \sum_{j=1}^{K} \frac{1}{4A^2} \frac{\gamma_j}{\lambda_j^2} \int \Delta^2 \chi \left( \frac{y}{A} \right) |\epsilon_j|^2 dy \]
\[ + \sum_{j=1}^{K} \frac{2}{d} \frac{\gamma_j}{\lambda_j^2} \int (A \nabla \chi \left( \frac{y}{A} \right) - y) \cdot \nabla Q \sqrt{t}^{-1} ((1 + \frac{4}{d}) \epsilon_j^2 + \epsilon_j^2) dy \]
\[ - C \epsilon^*(T - t)^{2\kappa - 1} - C(A)(T - t)^{2\kappa}. \]
(5.71)

Taking into account that for \( A \) large enough,
\[ \frac{1}{4A^2} |\Delta^2 \chi \left( \frac{y}{A} \right) | \leq \frac{1}{4} \tilde{C} \psi'' \left( \frac{y}{A} \right), \]
and
\[ \frac{2}{d} (2 + \frac{4}{d}) |A \nabla \chi \left( \frac{y}{A} \right) - y| |\nabla Q \sqrt{t}^{-1}| \leq \frac{1}{4} \tilde{C} \psi'' \left( \frac{y}{A} \right), \]
we arrive at
\[ \frac{dI}{dt} \geq \frac{1}{2} \tilde{C} \sum_{j=1}^{K} \frac{\gamma_j}{\lambda_j^2} \int \psi'' \left( \frac{y}{A} \right) (|\epsilon_j|^2 + |\nabla \epsilon_j|^2) dy - C \epsilon^*(T - t)^{2\kappa - 1} - C(A)(T - t)^{2\kappa}. \]

Therefore, as \( \psi''(r) \geq \delta e^{-r} \) for some \( \delta > 0 \), we obtain (5.29) and finish the proof. \( \Box \)

5.3. **Proof of bootstrap estimates.** In this subsection we prove the crucial bootstrap estimates in Theorem 5.1. To begin with, we first obtain the refined estimate for the modulation parameter \( \beta \).

**Lemma 5.14 (Refined estimate for \( \beta \)).** There exists \( C > 0 \) such that for all \( t \in [t_*, T_*] \),
\[ \sum_{j=1}^{K} |\beta_j(t)|^2 \leq C \sum_{j=1}^{K} |\omega_j^2 \lambda_j^2(t) - \gamma_j^2(t)| + C(T - t)^{\kappa + 3}. \]
(5.72)

**Remark 5.15.** Unlike single bubble case in [58], the proof of Lemma 5.14 requires the localized mass in Proposition 5.6 and also a delicate treatment of the localized function \( \Phi_j \) and the radial function \( \phi_A \) in Corollary 3.4 in order to derive the coercivity of energy.

**Proof of Lemma 5.14.** Using the expansion (5.27) of \( F(u) = \frac{d}{2d+4} |u|^{2+\frac{4}{d}} \) we have
\[ E(u) = \frac{1}{2} \int |\nabla U|^2 dx - \frac{d}{2d+4} \int |U|^{2+\frac{4}{d}} dx - \text{Re} \int (\Delta U + |U|^{\frac{4}{d}} U) \overline{U} dx \]
\[ + \frac{1}{2} \text{Re} \int |\nabla R|^2 - (1 + \frac{2}{d}) |U|^{\frac{4}{d}}|R|^2 - \frac{2}{d} |U|^{\frac{4}{d} - 2} U^2 \overline{R}^2 dx + o(\|R\|_{H^1}^2). \]
(5.73)
Note that, by Lemma 3.1 and the explicit expression (4.3) of \( U_j \),
\[
\frac{1}{2} \int |\nabla U|^2 dx - \frac{d}{2d+4} \int |U|^{2+\frac{4}{d}} dx \\
= \sum_{j=1}^{K} \frac{1}{2} \int |\nabla U_j|^2 dx - \frac{d}{2d+4} \int |U_j|^{2+\frac{4}{d}} dx + O(e^{-\frac{d}{T-t}})
\]
(5.74)
\[
= \sum_{j=1}^{K} \left( \frac{|\beta_j|^2}{2\lambda_j^4} \|Q\|_{L^2}^2 + \frac{\gamma_j^2}{8\lambda_j^2} \|yQ\|_{L^2}^2 \right) + O(e^{-\frac{d}{T-t}}),
\]
and
\[
\int (\Delta U + |U|^\frac{d}{2} U) R dx = \sum_{j=1}^{K} \int (\Delta U_j + |U_j|^\frac{d}{2} U_j) R_j dx + O(e^{-\frac{d}{T-t}} \|R\|_{L^2}).
\]
(5.75)

Taking into account Proposition 5.6 and rearranging the terms according to the orders of \( R \) we obtain that for \( T \) small enough,
\[
E(u) = E(u) + \sum_{j=1}^{K} \frac{1}{\lambda_j^2} \Re \int U_j R_j + \frac{1}{2} \|R\|^2 \Phi_j dx + O((T-t)^{2\kappa})
\]
\[
= \sum_{j=1}^{K} \left( \frac{|\beta_j|^2}{2\lambda_j^4} \|Q\|_{L^2}^2 + \frac{\gamma_j^2}{8\lambda_j^2} \|yQ\|_{L^2}^2 \right) - \sum_{j=1}^{K} \Re \int (\Delta U_j - \frac{1}{\lambda_j^2} U_j + |U_j|^\frac{d}{2} U_j) R_j dx \\
+ \frac{1}{2} \Re \int |\nabla R|^2 + \sum_{j=1}^{K} \frac{1}{\lambda_j^2} |R_j|^2 \Phi_j - (1 + \frac{2}{d}) |U|^\frac{d}{2} |R|^2 - \frac{2}{d} |U|^\frac{d}{2} - 2U^2 R^2 dx
\]
(5.76)
+ \mathcal{O}((T-t)^{2\kappa}).

On one hand, using the identity (4.28) and the change of variables we get
\[
\Re \int (\Delta U_j - \frac{1}{\lambda_j^2} U_j + |U_j|^\frac{d}{2} U_j) R_j dx
\]
(5.77)
\[
= \frac{1}{\lambda_j^2} \Im \int (\gamma_j A Q_j - 2\beta_j \cdot \nabla Q_j) e_j dx + \frac{1}{\lambda_j^2} \Re \int |\beta_j - \frac{\gamma_j}{2} yQ_j e_j|^2 dx,
\]
which along with the almost orthogonality in Lemma 4.4 and (5.11) yields that
\[
\sum_{j=1}^{K} \Re \int (\Delta U_j - \frac{1}{\lambda_j^2} U_j + |U_j|^\frac{d}{2} U_j) R_j dx \leq C \|R\|_{L^2} \leq C(T-t)^{2\kappa+1}.
\]
(5.78)

On the other hand, we claim that there exist \( \tilde{c}, C > 0 \) such that for the quadratic terms of \( R \) on the right-hand side of (5.76),
\[
E_2(u) := \Re \int |\nabla R|^2 + \sum_{j=1}^{K} \frac{1}{\lambda_j^2} |R_j|^2 \Phi_j - (1 + \frac{2}{d}) |U|^\frac{d}{2} |R|^2 - \frac{2}{d} |U|^\frac{d}{2} - 2U^2 R^2 dx
\]
\[
\geq \tilde{c} \int |\nabla R|^2 + \sum_{j=1}^{K} \frac{1}{\lambda_j^2} |R_j|^2 \Phi_j dx
\]
(5.79)
\[- C((T-t)^{-1} \|R\|_{L^2}^2 + e^{-\frac{d}{T-t}} \|R\|_{H^1}^2 + (T-t)^{2\kappa+2}).
\]
(Note that, this does not follow directly from Corollary 3.4, because the localized function \(\Phi_j\) does not satisfy the conditions there.)

For this purpose, using the partition of unity and Lemma 3.1 we have

\[
E_2(u) = \sum_{j=1}^{K} \Re \int \left( (|\nabla R|^2 + \frac{1}{\lambda_j^2} |R|^2) \phi_j - \left(1 + \frac{2}{d}\right)|U_j|^\frac{4}{d}|R|^2 - \frac{2}{d}|U_j|^\frac{4}{d-2} U_j^2 \right) dx \\
+ \mathcal{O}(e^{-\frac{\delta}{\lambda_j^2}} \|R\|_{L^2}^2).
\]

In order to obtain the coercivity of the energy, we use \(\phi_{A,j}(x) := \phi_A\left(\frac{x - \alpha_j}{\lambda_j}\right)\) with \(\phi_A(x)\) as in Corollary 3.3 and the renormalized variable \(\tilde{\varepsilon}_j\) defined by

\[
R(t, x) = \lambda_j^{-\frac{d}{2}} \tilde{\varepsilon}_j(t, \frac{x - \alpha_j}{\lambda_j}) e^{\theta_j},
\]

to reformulate \(E_2(u)\) as follows

\[
E_2(u) = \sum_{j=1}^{K} \Re \int \left( (|\nabla R|^2 + \frac{1}{\lambda_j^2} |R|^2) \phi_{A,j} - \left(1 + \frac{2}{d}\right)|U_j|^\frac{4}{d}|R|^2 - \frac{2}{d}|U_j|^\frac{4}{d-2} U_j^2 \right) dx \\
+ \sum_{j=1}^{K} \int \left( (|\nabla R|^2 + \frac{1}{\lambda_j^2} |R|^2) (\Phi_j - \phi_{A,j}) \right) dx + \mathcal{O}(e^{-\frac{\delta}{\lambda_j^2}} \|R\|_{L^2}^2)
\]

\[
= \sum_{j=1}^{K} \Re \int \left( (|\nabla \tilde{\varepsilon}_j|^2 + |\tilde{\varepsilon}_j|^2) \phi_A - \left(1 + \frac{2}{d}\right) Q \frac{4}{d} |\tilde{\varepsilon}_j|^2 - \frac{2}{d} Q \frac{4}{d-2} Q_{\tilde{\varepsilon}}^2 \tilde{\varepsilon}_j^2 \right) dy \\
+ \sum_{j=1}^{K} \Re \int \left( (|\nabla \tilde{\varepsilon}_j|^2 + |\tilde{\varepsilon}_j|^2) (\Phi_j(\lambda_j y + \alpha_j) - \phi_A(y)) \right) dy + \mathcal{O}(e^{-\frac{\delta}{\lambda_j^2}} \|R\|_{L^2}^2)
\]

(5.80)

Since \(Q_j = Q + \mathcal{O}(P(y)^2 Q)\), the localized coercivity in Corollary 3.3, the estimate \(\text{Scal}(\tilde{\varepsilon}_j) \leq C(T - t)^{2\varepsilon + 1}\) and (5.1) yield immediately that there exists \(\tilde{c}_j > 0\) such that

\[
E_{21,j} \geq \frac{1}{\lambda_j^2} \Re \int \left( (|\nabla \tilde{\varepsilon}_j|^2 + |\tilde{\varepsilon}_j|^2) \phi_A - \left(1 + \frac{2}{d}\right) Q \frac{4}{d} |\tilde{\varepsilon}_j|^2 - \frac{2}{d} Q \frac{4}{d-2} Q_{\tilde{\varepsilon}}^2 \tilde{\varepsilon}_j^2 \right) dy - C(T - t)^{-1} \|R\|_{L^2}^2 \\
\geq \tilde{c}_j \int \left( (|\nabla R|^2 + \frac{1}{\lambda_j^2} |R|^2) \phi_{A,j} dx - C \frac{1}{\lambda_j^2} \text{Scal}(\tilde{\varepsilon}_j) - C(T - t)^{-1} \|R\|_{L^2}^2
\]

(5.81)

Moreover, set \(\bar{c} := \min\left\{\frac{1}{2}, 1 \leq j \leq K\right\} > 0\). Since \(\Phi_j(\lambda_j y + \alpha_j) - \phi_A(y) \geq 0\) if \(|y \cdot \mathbf{v}_1| \leq \frac{\delta}{\lambda_j^2}\), we get

\[
E_{22,j} \geq \frac{\bar{c}}{\lambda_j^2} \int_{|y \cdot \mathbf{v}_1| \leq \frac{\delta}{\lambda_j^2}} \left( (|\nabla \tilde{\varepsilon}_j|^2 + |\tilde{\varepsilon}_j|^2) (\Phi_j(\lambda_j y + \alpha_j) - \phi_A(y)) \right) dy \\
+ \frac{1}{\lambda_j^2} \int_{|y \cdot \mathbf{v}_1| \geq \frac{\delta}{\lambda_j^2}} \left( (|\nabla \tilde{\varepsilon}_j|^2 + |\tilde{\varepsilon}_j|^2) (\Phi_j(\lambda_j y + \alpha_j) - \phi_A(y)) \right) dy.
\]
By the positivity of $\Phi_j$ and the exponential decay of $\phi_A$, the second term on the right-hand side above is bounded from below by

$$
\geq \frac{c}{\lambda_j^2} \int_{|y| \geq 2\lambda_j} (|\nabla \bar{\varepsilon}_j|^2 + |\varepsilon_j|^2)(\Phi_j(\lambda_j y + \alpha_j) - \phi_A(y))dy - \frac{1 - c}{\lambda_j^2} \int_{|y| > 2\lambda_j} (|\nabla \bar{\varepsilon}_j|^2 + |\varepsilon_j|^2)\phi_A dy
$$

$$
\geq \frac{c}{\lambda_j^2} \int_{|y| \geq 2\lambda_j} (|\nabla \bar{\varepsilon}_j|^2 + |\varepsilon_j|^2)(\Phi_j(\lambda_j y + \alpha_j) - \phi_A(y))dy - \frac{1 - c}{\lambda_j^2} e^{-\frac{3\lambda_j}{y^2}}\|\varepsilon_j\|_{H^1}.
$$

This yields that for $t$ close to $T$,

$$E_{22,j} \geq \frac{c}{\lambda_j^2} \int (|\nabla \bar{\varepsilon}_j|^2 + |\varepsilon_j|^2)(\Phi_j(\lambda_j y + \alpha_j) - \phi_A(y))dy - \frac{1 - c}{\lambda_j^2} e^{-\frac{3\lambda_j}{y^2}}\|\varepsilon_j\|_{H^1}$$

(5.82)

$$
\geq \int (|\nabla R|^2 + \frac{1}{\lambda_j^2}R^2)(\Phi_j - \phi_A)dx - Ce^{-\frac{3\lambda_j}{y^2}}\|R\|_{H^1}^2.
$$

Then, plugging (5.81) and (5.82) into (5.80) we obtain (5.79), as claimed.

Therefore, taking into account $u(T_*) = S_T(T_*)$ we have

$$
E(u(T_*)) = \frac{1}{2} \int \sum_{j=1}^K \nabla S_j(T_*)^2 dx - \frac{d}{2d+4} \int \sum_{j=1}^K S_j(T_*)^{2+\frac{4}{d}} dx
$$

$$
= \sum_{j=1}^K \frac{\omega_j^2}{8} \|yQ\|_{L^2}^2 + O(e^{-\frac{c\lambda_j}{y^2}}),
$$

and then plugging (5.78) and (5.79) into (5.76) we arrive at

$$
\sum_{j=1}^K \frac{1}{2\lambda_j^2} \beta_j(t)^2 \|Q\|_{L^2}^2 \leq \sum_{j=1}^K \frac{1}{8\lambda_j^2} \|yQ\|_{L^2}^2 \|\omega_j^2 \lambda_j^2(t) - \gamma_j^2(t)\|_{L^2}^2 + E(u(t)) - E(u)(T_*) + O((T - t)^{2n}),
$$

which, via Theorem 5.8 and (5.13), yields (5.72) and finishes the proof. □

We are now ready to prove the bootstrap estimates in Theorem 5.4.

**Proof of Theorem 5.4**

(i) Estimate of $R$. On one hand, by (3.27),

$$I = \int |\nabla R|^2 + \frac{1}{2} \sum_{j=1}^K \text{Re} \left( \int \frac{1}{\lambda_j^2} |R|^2 \Phi_j - (1 + \frac{2}{d})|U|^\frac{4}{d} |R|^2 - \frac{2}{d} |U|^\frac{4}{d} - 2U^2 R^2 dx \right)
$$

$$+ O((T - t)^{2+\frac{4}{d}}) \sum_{k=3}^{\frac{\lambda_j^2}{2}} \|R\|_{H^k}^k + O(\|R\|_{L^2}^2 \|\nabla R\|_{L^2}),
$$

which, via (5.13) and (5.79), yields that for some $0 < \tilde{c} < 1$,

$$I \geq \tilde{c} \|\nabla R\|_{L^2}^2 + \frac{1}{(T - t)^2} \|R\|_{L^2}^2
$$

$$- C(e^{-\frac{c\lambda_j}{y^2}} \|R\|_{H^1}^2 + (T - t)^{-1} \|R\|_{L^2}^2 + (T - t)^{\frac{4}{d}} \|R\|_{H^1}^2 + \|R\|_{L^2}^2 \|\nabla R\|_{L^2}).
$$

Then, taking $T$ small enough we get that

$$I(t) \geq \frac{1}{2} \tilde{c} \|\nabla R\|_{L^2}^2 + \frac{1}{(T - t)^2} \|R\|_{L^2}^2.
$$

(5.83)
On the other hand, Theorem 5.9 yields that for any \( t \in [t_*, T_*] \),
\[
\frac{dI}{dt} \geq -C(A)(T - t)^{2\kappa} - C\varepsilon^*(T - t)^{2\kappa - 1}.
\]

Thus, combining (5.83) and (5.84) and using the fundamental theorem of calculus we obtain that for any \( t \in [t_*, T_*] \),
\[
\frac{1}{2} \varepsilon^2(\|\nabla R(t)\|_{L^2}^2 + \frac{1}{(T - t)^2}\|R(t)\|_{L^2}^2) \leq I(T_*) + \int_t^{T_*} C\varepsilon^*(T - r)^{2\kappa - 1} + C(A)(T - r)^{2\kappa} dr.
\]

Taking into account \( I(T_*) = 0 \) we obtain
\[
\frac{1}{2} \varepsilon^2(\|\nabla R(t)\|_{L^2}^2 + \frac{1}{(T - t)^2}\|R(t)\|_{L^2}^2) \leq \frac{C\varepsilon^*}{k\kappa}(T - t)^{2\kappa} + \frac{2C(A)}{(2\kappa + 1)c}(T - t)^{2\kappa + 1},
\]
which yields (5.5) immediately, as long as \( \varepsilon^* \) and \( T \) are sufficiently small such that
\[
\frac{C}{k\kappa}\varepsilon^* + \frac{2C(A)}{(2\kappa + 1)c}T \leq \frac{1}{8}.
\]

(ii) Estimates of \( \lambda_j \) and \( \gamma_j \). Since \( (\frac{2}{\lambda_j})(T_*) = \omega_j \) and by (5.14),
\[
|\frac{d}{dt}\left(\frac{\gamma_j}{\lambda_j}\right)| = \left|\frac{\lambda_j^2\gamma_j - \lambda_j\gamma_j^2}{\lambda_j^3}\right| \leq 2\frac{\text{Mod}}{\lambda_j^3} \leq C(T - t)^\kappa,
\]
we infer that for \( T \) small enough such that \( CT^\kappa \leq \frac{1}{2} \),
\[
|\frac{\gamma_j}{\lambda_j}(t) - \omega_j(t)| \leq \int_t^T |\frac{d}{dr}\left(\frac{\gamma_j}{\lambda_j}\right)| dr \leq C(T - t)^{\kappa + 1} \leq \frac{1}{2}(T - t)^{\kappa + 6\kappa}.
\]

This along with (5.14) yields that
\[
|\frac{d}{dt}(\lambda_j - \omega_j(T - t))| = |\dot{\lambda}_j + \frac{\gamma_j}{\lambda_j} + \omega_j - \frac{\gamma_j^2}{\lambda_j^2}| \leq \frac{\text{Mod}}{\lambda_j} + \frac{1}{2}(T - t)^{\kappa + 6\kappa} \leq C(T - t)^{\kappa + 6\kappa},
\]
which implies that for \( T \) possibly smaller such that \( CT^\kappa \leq \frac{1}{2} \),
\[
|\lambda_j - \omega_j(T - t)| \leq \int_t^T |\frac{d}{dr}(\lambda_j - \omega_j(T - r))| dr \leq \frac{1}{2}(T - t)^{\kappa + 1 + 5\kappa},
\]
thereby yielding the estimate of \( \lambda_j \) in (5.6).

Similarly, by (5.14) and (5.87),
\[
|\frac{d}{dt}(\gamma_j - \omega_j^2(T - t))| = |\dot{\gamma}_j + \frac{\gamma_j^2}{\lambda_j^2} + \omega_j - \frac{\gamma_j^2}{\lambda_j^2}| \leq \frac{\text{Mod}}{\lambda_j^2} + C|\omega_j - \frac{\gamma_j}{\lambda_j}| \leq C(T - t)^{\kappa + 6\kappa},
\]
which along with \( \gamma_j(T_*) = \omega_j^2(T - T_*) \) yields that
\[
|\gamma_j(t) - \omega_j^2(T - t)| \leq \int_t^{T_*} |\frac{d}{dr}(\gamma_j(r) - \omega_j^2(T - r))| dr \leq C(T - t)^{\kappa + 1 + 6\kappa}.
\]

Hence, for \( T \) very small such that \( CT^\kappa \leq \frac{1}{2} \) we obtain
\[
|\gamma_j - \omega_j^2(T - t)| \leq \frac{1}{2}(T - t)^{\kappa + 5\kappa},
\]
which yields the estimate of \( \gamma_j \) in (5.6).
(iii) Estimates of $\beta_j$ and $\alpha_j$. We use the refined estimate of $\beta_j$ in Lemma 5.14 to get
\begin{equation}
|\beta_j|^2 \leq C \sum_{j=1}^{K} |\omega_j^2 \lambda_j^2 - \gamma_j^2| + C(T-t)^{\kappa+3} \leq C \sum_{j=1}^{K} (\lambda_j^2 |\omega_j - \frac{\gamma_j}{\lambda_j}| + \lambda_j^\kappa + 3),
\end{equation}
which along with (5.13) and (5.87) yields that for $T$ small enough,
\begin{equation}
|\beta_j| \leq C \sum_{j=1}^{K} (\lambda_j |\omega_j - \frac{\gamma_j}{\lambda_j}| + \lambda_j^{\kappa+3}) \leq C(T-t)^{\frac{\kappa}{2} + 3\zeta} \leq \frac{1}{2}(T-t)^{\frac{\kappa}{2} + 2\zeta}.
\end{equation}
Moreover, since $\alpha_j(T_*) = x_j$ and by (5.14) and (5.91),
\begin{equation}
|\dot{\alpha}_j| = \left| \frac{\lambda_j \dot{\alpha}_j - 2 \beta_j}{\lambda_j} + \frac{2 \beta_j}{\lambda_j} \right| \leq \frac{\text{Mod}}{\lambda_j} + \frac{2|\beta_j|}{\lambda_j} \leq C(T-t)^{\frac{\kappa}{2} + 2\zeta},
\end{equation}
we infer that for sufficiently small $T$,
\begin{equation}
|\alpha_j(t) - x_j| \leq \int_t^{T_*} |\dot{\alpha}_j(r)|dr \leq C|T-t|^\frac{\kappa}{2} + 2\zeta \leq \frac{1}{2}(T-t)^{\frac{\kappa}{2} + 2\zeta},
\end{equation}
which yields (5.7).

(iv) Estimate of $\theta_j$. By (5.13), (5.88) and (5.91),
\begin{equation}
\left| \frac{d}{dt}(\theta_j - \omega_j^{-2}(T-t)^{-1} + \vartheta_j) \right| = \left| \frac{\lambda_j^2 \dot{\theta}_j - 1 - |\beta_j|^2}{\lambda_j^2} \right| \leq \frac{\text{Mod}}{\lambda_j^2} + \frac{|\beta_j|^2}{\lambda_j^2} + \frac{1}{\omega_j^2} \left( \frac{1}{(T-t)^2} \right).
\end{equation}
which yields that for $t$ sufficiently small,
\begin{equation}
|\theta_j - (\omega_j^{-2}(T-t)^{-1} + \vartheta_j)| \leq \int_t^{T_*} \left| \frac{d}{dr}(\theta - \omega_j^{-2}(T-r)^{-1} + \vartheta_j) \right|dr \leq C(T-t)^{\kappa - 1 + 5\zeta} \leq \frac{1}{2}(T-t)^{\kappa - 1 + 4\zeta},
\end{equation}
thereby yielding (5.8). The proof of Theorem 5.1 is complete. \hfill \Box

6. Existence of multi-bubble solutions

In this section, we shall fix $\varepsilon^* > 0$ to be sufficiently small, and for any $0 < \varepsilon \leq \varepsilon^*$, take $\tau^*$ to be very small such that for a large universal constant $C$,
\begin{equation}
C(1 + \max_{1 \leq j \leq K} |x_j|) \tau^* \leq \frac{1}{2}.
\end{equation}
For any $T \in (0, \tau^*)$, take any increasing sequence $\{t_n\}$ converging to $T$ and consider the approximating solutions $u_n$ satisfying the equation
\begin{equation}
\begin{cases}
i \dot{t} u_n + \Delta u_n + |u_n|^4 u_n + (b \cdot \nabla + c) u_n = 0, \\
u_n(t_n) = \sum_{j=1}^{K} S_j(t_n),
\end{cases}
\end{equation}
where the coefficients $b, c$ are given by (2.12) and (2.13) respectively, and $S_j$ are the pseudo-conformal blow-up solutions defined in (2.5), $1 \leq j \leq K$. We also note that for each $n \geq 1$, $t_n$ plays the same role as $T_*$ in the previous sections.
We first have the uniform estimates of approximating solutions in Theorem 6.1 below.

**Theorem 6.1 (Uniform estimates).** For \( n \) large enough, \( u_n \) admits the unique geometrical decomposition \( u_n = \omega_n + R_n \) on \([0, t_n]\) as in (4.1), and estimates (5.1)-(5.4) hold on \([0, t_n] \).

Moreover, we have

\[
\sup_{t \in [0, t_n]} \|xu_n(t)\|_{L^2} \leq C, \tag{6.2}
\]

and for any \( t \in [0, t_n] \),

\[
\|R_n(t)\|_{\Sigma} \leq C(T - t)^\alpha. \tag{6.3}
\]

**Proof.** The proof of (5.1)-(5.4) is quite similar to that of [58, Theorem 5.1], mainly based on the bootstrap estimate in Theorem 5.1 and the abstract bootstrap principle (see, e.g., [60, Proposition 1.21]). For simplicity, the details are omitted here.

Below we prove estimates (6.2) and (6.3). Let \( \varphi(x) \in C^1(\mathbb{R}^d, \mathbb{R}) \) be a radial cutoff function such that \( \varphi(x) = 0 \) for \( |x| \leq r \), and \( \varphi(x) = (|x| - r)^2 \) for \( |x| > r \), where \( r = 2 \max_{1 \leq j \leq K} \{|x_j|, 1\} \). Note that, \( |\nabla \varphi| \leq C \varphi^{1/2} \).

Using integration by parts formula we have for some constant \( C > 0 \) independent of \( n \),

\[
\frac{d}{dt} \int |u_n|^2 \varphi dx = |\text{Im} \int (2\overline{u_n} \nabla u_n + b|u_n|^2) \cdot \nabla \varphi dx| \leq C \int |\nabla u_n|^2 \varphi dx + |u_n|^2 \varphi^{1/2} dx \tag{6.4}
\]

By (4.1) and the exponential decay of the ground state,

\[
|\int_{|x-x_j| \geq 1, 1 \leq j \leq K} |u_n(t)|^2 + |\nabla u_n(t)|^2 dx| \leq C(\|R_n(t)\|_{H^1}^2 + e^{-\frac{4}{\kappa}}). \tag{6.5}
\]

Thus, taking into account the uniform estimate (5.1) we get

\[
\frac{d}{dt} \int |u_n(t)|^2 \varphi dx \leq C(\|R_n(t)\|_{H^1} + e^{-\frac{4}{\kappa}})(\int |u_n(t)|^2 \varphi dx)^{1/2} \leq C(T - t)^\alpha (\int |u_n(t)|^2 \varphi dx)^{1/2}. \tag{6.6}
\]

Moreover, using the boundary condition \( u_n(t_n) = \sum_{j=1}^{K} S_j(t_n) \) and \( R_n(t_n) = 0 \) we have

\[
|\int |u_n(t_n)|^2 \varphi dx| \leq Ce^{-\frac{4}{\kappa} t_n}, \tag{6.7}
\]

Thus, integrating from \( t \) to \( t_n \) we get for \( t \in [0, t_n] \),

\[
\int |u_n(t)|^2 \varphi dx \leq C(T - t)^{2\kappa+2} + Ce^{-\frac{4}{\kappa} t} \leq C(T - t)^{2\kappa+2}, \tag{6.8}
\]

which yields that

\[
\int |R_n(t)|^2 \varphi dx \leq C(\int |U_n(t)|^2 \varphi dx + \int |u_n(t)|^2 \varphi dx) \leq C(T - t)^{2\kappa+2} + Ce^{-\frac{4}{\kappa} t} \leq C(T - t)^{2\kappa+2}. \tag{6.9}
\]
Moreover, since the uniform estimates (6.10)-(6.11) hold on \[0, t\] and its right neighborhood, to some extent, we infer that for any \(t \in [0, t_n]\) the following statements hold:

\[
\int |x u_n(t)|^2 \, dx \leq C \left( \int |u_n(t)|^2 \varphi \, dx + \int |u_n(t)|^2 \, dx \right) \leq C,
\]

and

\[
\int |x R_n(t)|^2 \, dx \leq C \left( \int |R_n(t)|^2 \varphi \, dx + \int |R_n(t)|^2 \, dx \right) \leq C(T - t)^{2k + 2}.
\]

Therefore, taking into account (5.1) we obtain (6.2) and (6.3) and finish the proof. □

**Proof of Theorem 2.14.** Let \(\tau^*, \varepsilon^*\) be as in Theorem 6.1 and let \(T \in (0, \tau^*], \varepsilon \in (0, \varepsilon^*]\) be fixed below. By virtue of Theorem 6.1, we have the geometrical decomposition

\[
u_n = U_n + R_n, \quad \forall t \in [0, t_n],
\]

where \(U_n = \sum_{j=1}^{K} u_{n,j}\) is as in (4.12) with the modulation parameters \(\mathcal{P}_{n,j}\) satisfying

\[
\mathcal{P}_{n,j}(t) := (\lambda_{n,j}(t_n), \alpha_{n,j}(t_n), \beta_{n,j}(t_n), \gamma_{n,j}(t_n), \theta_{n,j}(t_n)) = (\omega_j(T - t_n), x_j, 0, \omega_j^2(T - t_n), \omega_j^{-2}(T - t_n)^{-1} + \vartheta_j).
\]

and \(S_j\) are the pseudo-conformal blow-up solutions given by (2.6), \(1 \leq j \leq K\). Moreover, the uniform estimates (5.1)-(5.4) hold on \([0, t_n]\).

In particular, \(\{u_n(0)\}\) are uniformly bounded in \(\Sigma\), and thus \(u_n(0)\) converges weakly to some \(u_0 \in \Sigma\).

We claim that \(u_n(0)\) indeed converges strongly in \(L^2\), i.e.,

\[
u_n(0) \to u_0, \quad \text{in} \quad L^2, \quad \text{as} \quad n \to \infty.
\]

This follows immediately from the uniform integrability of \(\{u_n(0)\}\), that is, by (6.2),

\[
\sup_{n \geq 1} \|u_n(0)\|_{L^2(|x| > A)} \leq \frac{1}{A} \sup_{n \geq 1} \|x u_n(0)\|_{L^2(|x| > A)} \leq \frac{C}{A} \to 0, \quad \text{as} \quad A \to \infty.
\]

Thus, by virtue of (6.15) and the \(L^2\) local well-posedness theory (see, e.g., [4]) we obtain a unique \(L^2\)-solution \(u\) to (6.1) on \([0, T]\) satisfying \(u(0) = u_0\), and

\[
\lim_{n \to \infty} \|u_n - u\|_{C([0,t];L^2)} = 0, \quad t \in [0, T).
\]

Moreover, since \(u_0 \in H^1\), using the \(H^1\) local well-posedness result (see, e.g., [3]) we also have \(u \in C([0,t];H^1)\) for any \(0 < t < T\). Such solution is indeed the desirable blow-up solution that explodes at the given \(K\) points \(\{x_j\}_{j=1}^K\).

As a matter of fact, let

\[
(\lambda_{0,j}, \alpha_{0,j}, \beta_{0,j}, \gamma_{0,j}, \theta_{0,j}) := (\omega_j(T - t), x_j, 0, \omega_j^2(T - t), \omega_j^{-2}(T - t)^{-1} + \vartheta_j),
\]
and \( Q_{0,j}(t, y) := Q(y)e^{i(\beta_{0,j}(t)y - \frac{\gamma_{0,j}(t)}{4}|y|^2)} \). Since

\[
U_{n,j} - S_j = (\lambda_{n,j}^{-\frac{d}{2}} - \lambda_{0,j}^{-\frac{d}{2}}) Q_{n,j}(t, \frac{x - x_{n,j}}{\lambda_{n,j}}) e^{i\theta_{n,j}}
+ \lambda_{n,j}^{-\frac{d}{2}}(Q_{n,j}(t, \frac{x - x_{n,j}}{\lambda_{n,j}}) - Q_{n,j}(t, \frac{x - x_{0,j}}{\lambda_{0,j}})) e^{i\theta_{n,j}}
\]

(6.20)

\[
+ \lambda_{0,j}^{-\frac{d}{2}}(Q_{n,j}(t, \frac{x - x_{0,j}}{\lambda_{0,j}}) - Q_{0,j}(t, \frac{x - x_{0,j}}{\lambda_{0,j}})) e^{i\theta_{n,j}}
\]

using the change of variables and (5.13) we infer that, if \( \lambda_{n,j} \) is a universal constant, independent of \( (U_n - \nabla n, t, M, T) \),

\[
\|x(U_n - S_T)\|_{L^2} \leq \lambda_{n,j}^{-\frac{d}{2}} \|x|((Q_{n,j}(t, \frac{x - x_{n,j}}{\lambda_{n,j}}) - Q_{n,j}(t, \frac{x - x_{0,j}}{\lambda_{0,j}}))\|_{L^2}
+ \lambda_{n,j}^{-\frac{d}{2}} \|x|((Q_{n,j}(t, \frac{x - x_{0,j}}{\lambda_{0,j}}) - Q_{0,j}(t, \frac{x - x_{0,j}}{\lambda_{0,j}}))\|_{L^2}
\]

(6.19)

\[
+ CM \left( \|\lambda_{n,j}^{-\frac{d}{2}} - \lambda_{0,j}^{-\frac{d}{2}}\|_{\lambda_{n,j}} + |\theta_{n,j} - \theta_{0,j}| \right) \|Q\|_{L^2}.
\]

Then, taking into account the uniform estimates (5.2)-(5.4) of the modulation parameters and the well localized property of \( Q \) we get that for \( T \) small enough such that \( MT \leq 1 \),

\[
\|x(U_n - S_T)\|_{L^2} \leq CM \sum_{j=1}^{K} \left( |\lambda_{n,j}^{-\frac{d}{2}} - 1| + |\frac{x_{n,j} - x_{0,j}}{\lambda_{n,j}}| + |\beta_{n,j} - \beta_{0,j}| + |\gamma_{n,j} - \gamma_{0,j}| + |\lambda_{n,j}^{-\frac{d}{2}} - \lambda_{0,j}^{-\frac{d}{2}}| + |\theta_{n,j} - \theta_{0,j}| \right)
\]

\[
\leq CM(T - t)^{\frac{d}{2} + \epsilon} \leq C(T - t)^{\frac{d}{2} - 1 + \epsilon},
\]

where \( C \) is a universal constant, independent of \( n, t, M, T \).

Similarly, we have (see also the proof of [58, Theorem 2.12])

\[
\|U_n - S_T\|_{L^2} \leq CM \sum_{j=1}^{K} \left( \lambda_{n,j}^{-\frac{d}{2}} - 1 + |\frac{x_{n,j} - x_{0,j}}{\lambda_{n,j}}| + |\gamma_{n,j} - \gamma_{0,j}| + |\lambda_{n,j}^{-\frac{d}{2}} - \lambda_{0,j}^{-\frac{d}{2}}| + |\theta_{n,j} - \theta_{0,j}| \right) \leq C(T - t)^{\frac{d}{2} + \epsilon},
\]

and

\[
\|\nabla U_n - \nabla S_T\|_{L^2} \leq CM \sum_{j=1}^{K} \left( \frac{1}{\lambda_{n,j}} |\lambda_{n,j}^{-\frac{d}{2}} - 1| + |\frac{x_{n,j} - x_{0,j}}{\lambda_{n,j}^{\frac{d}{2}}}| + |\lambda_{n,j}^{-\frac{d}{2}} - \lambda_{0,j}^{-\frac{d}{2}}| + |\theta_{n,j} - \theta_{0,j}| \right) \leq C(T - t)^{\frac{d}{2} - 1 + \epsilon}.
\]

Hence, we conclude that

(6.20) \[ \|U_n(t) - S_T(t)\|_{\Sigma} \leq C(T - t)^{\frac{d}{2} - 1 + \epsilon}. \]
This along with \((5.1)\) and \((6.12)\) yields that
\[
\|u_n(t) - S_T(t)\|_\Sigma \leq \|U_n(t) - S_T(t)\|_\Sigma + \|R_n(t)\|_\Sigma \leq C(T-t)^{\frac{1}{2}-1+\xi},\]
where \(C\) is independent of \(n\).

Hence, in view of \((6.17)\), we infer that for some subsequence (still denoted by \(\{n\}\)),
\[
u_n(t) - S_T(t) \rightarrow u(t) - S_T(t), \quad \text{weakly in } \Sigma, \quad \text{as } n \rightarrow \infty,
\]
which yields that
\[
\|u(t) - S_T(t)\|_\Sigma \leq \liminf_{n \rightarrow \infty} \|u_n(t) - S_T(t)\|_\Sigma \leq C(T-t)^{\frac{1}{2}-1+\xi}.
\]

Therefore, the proof of Theorem 7.5.1 is complete. \(\square\)

### 7. Uniqueness of multi-bubble solutions

#### 7.1. Geometrical decomposition

In this subsection we obtain the geometrical decomposition and uniform estimates for the blow-up solution constructed in the proof of Theorem 7.5.1 which, actually, are inherited from those of the approximating solutions.

Let us start with the boundedness of the remainders in the more regular space \(H^\frac{3}{2}\), which will be used in Theorem 7.5.3 later to derive the key monotonicity formula of the generalized functional defined on the difference.

Below we use the same notations \(u, u_n, R_n\) and \(t_n\) as in Section 6 We also set \(M := \max_{1 \leq j \leq K} |x_j| + 1\) and keep using the notation \(\kappa := \nu_* - 3\).

**Proposition 7.1.** Assume (A0) and (A1) with \(\nu_* \geq 5\). Then, for \(T\) small enough such that
\[
C(1 + \max_{1 \leq j \leq K} |x_j|)T^{\frac{3}{2}} \leq \frac{1}{2},
\]
where \(C\) is a large universal constant, independent of \(\varepsilon, T, n\), we have
\[
\|R_n(t)\|_{H^\frac{3}{2}} \leq (T-t)^{\kappa-2}, \quad t \in [0, t_n).
\]

**Proof.** We rewrite the equation \((5.15)\) of \(R_n\) as follows
\[
i\partial_t R_n + \Delta R_n + b \cdot \nabla R_n + c R_n = -\eta_n - f(R_n) - (f(u_n) - f(U_n) - f(R_n)),
\]
with \(R_n(t_n) = 0\) and \(\eta_n\) as in \((5.16)\), where \(U\) is replaced by \(U_n\) given by \((6.12)\). Then, applying the operator \(\langle \nabla \rangle^{\frac{3}{2}}\) to both sides of \((7.3)\) we obtain
\[
i\partial_t (\langle \nabla \rangle^{\frac{3}{2}} R_n) + \Delta (\langle \nabla \rangle^{\frac{3}{2}} R_n) + (b \cdot \nabla + c) (\langle \nabla \rangle^{\frac{3}{2}} R_n)
\]
\[
= [b \cdot \nabla + c, (\langle \nabla \rangle^{\frac{3}{2}} R_n - (\langle \nabla \rangle^{\frac{3}{2}} f(R_n) - (\langle \nabla \rangle^{\frac{3}{2}} f(u_n) - f(U_n) - f(R_n)),
\]
where \([b \cdot \nabla + c, (\langle \nabla \rangle^{\frac{3}{2}}]\) is the commutator \((b \cdot \nabla + c) (\langle \nabla \rangle^{\frac{3}{2}} - \langle \nabla \rangle^{\frac{3}{2}} (b \cdot \nabla + c)\). We regard \((7.4)\) as the equation for the unknown \(\langle \nabla \rangle^{\frac{3}{2}} R_n\) and apply the Strichartz estimates and local smoothing estimates (see \([64]\) Theorem 2.13)) to get
\[
\|R_n\|_{C([t_n, T]; H^{\frac{3}{2}})} \leq C(\|b \cdot \nabla + c, (\langle \nabla \rangle^{\frac{3}{2}} R_n\|_{L^2(t_n, T; H^{\frac{3}{2}})} + \|\langle \nabla \rangle^{\frac{3}{2}} f(R_n)\|_{L^2(t_n, T; L^{\frac{4}{3}+}\sigma)}
\]
\[
+ \|\langle \nabla \rangle^{\frac{3}{2}} (f(u_n) - f(U_n) - f(R_n))\|_{L^2(t_n, T; H^{\frac{3}{2}})} =: \sum_{j=1}^4 R_j.
\]

Below we estimate each term \(R_j, 1 \leq j \leq 4\), separately.
(i) Estimate of $R_1$. Since by Assumption (A0), $|\partial^\nu b| + |\partial^\nu c| \leq C(x)^{-\frac{2}{2}}$ for any multi-index $\nu$, using the calculus of pseudo-differential operators (see, e.g., (6.1) and (5.1)) we get

$$(7.6) \quad R_1 \leq C \|R_n\|_{L^2(t,t_n;H^1)} \leq C(T-t)^{\frac{3}{2} + \frac{d}{2} + d} \|R_n\|_{C\{t,t_n;H^1\}} \leq C(T-t)^{\kappa + \frac{1}{2}}.$$ 

(ii) Estimate of $R_2$. Using (4.14) and (5.10) we have the pointwise estimate of $\eta_n$ that for any multi-index $\nu$ with $|\nu| \leq 2$ and for $y := \frac{x - \gamma_{n,j}}{\lambda_{n,j}}$,

$$|\partial^\nu y \eta_n(x)| \leq \sum_{j=1}^{K} \lambda_{n,j}^{-\frac{4}{2} - 2} |\partial^\nu y((\lambda_{n,j} \tilde{b} \cdot \nabla + \lambda_{n,j}^2 \tilde{c}) Q_{n,j})| + \sum_{j=1}^{K} \lambda_{n,j}^{-\frac{4}{2} - 2} Mod_n(y)^2 \sum_{|\nu| \leq |\nu| + 1} \partial_y^\nu Q_{n,j}$$

$$= : \sum_{j=1}^{K} \eta_{1,j} + \eta_{2,j},$$

where $\tilde{b}$ and $\tilde{c}$ are as in (4.22). Note that, for $p := \frac{4+2d}{4+d}$, by (4.23),

$$\|\eta_{1,j}\|_{L^p} \leq \sum_{j=1}^{K} \lambda_{n,j}^{-\frac{1}{2} - \frac{4}{2} - 4} \lambda_{n,j}^\nu |\partial_y^\nu((\lambda_{n,j} \tilde{b} \cdot \nabla + \lambda_{n,j}^2 \tilde{c}) Q_{n,j})| \|\|\|_{L^p}$$

$$\leq \sum_{j=1}^{K} \lambda_{n,j}^{-\frac{1}{2} - \frac{4}{2} - 4} \lambda_{n,j}^\nu \leq (T-t)^{\kappa + \frac{d}{2^+}}.$$ 

Moreover, by (5.14),

$$\|\eta_{2,j}\|_{L^p} \leq C(T-t)^{d(\frac{1}{p} - \frac{1}{2}) - 4} Mod_n \leq C(T-t)^{\kappa - \frac{d}{d^+}}.$$

Hence, we obtain that for any multi-index $\nu$ with $|\nu| \leq 2$,

$$\|\partial^\nu \eta_n\|_{L^p} \leq C(T-t)^{\kappa - \frac{d}{d^+}}.$$ 

This yields that

$$(7.7) \quad R_2 \leq \|\eta_n\|_{L^{\frac{4+2d}{4+d}}(t,t_n;W^{\frac{4+2d}{4+d}})} \leq C(T-t)^{\frac{4+2d}{4+d} + \kappa - \frac{d}{d^+}} \leq C(T-t)^{\kappa}.$$ 

(iii) Estimate of $R_3$. Using the product rule in Lemma 3.6, (3.29) and (5.1) we get

$$\|\langle \nabla \rangle^{\frac{3}{2}}(f(R_n))\|_{L^{\frac{4+2d}{4+d}}} \leq C\|\langle \nabla \rangle^{\frac{3}{2}} R_n\|_{L^2} \|R_n\|_{L^{\frac{4+2d}{4+d}}}$$

$$(7.8) \quad \leq C\|R_n\|_{H^{\frac{3}{2}}} \|R_n\|_{H^1} \leq C(T-t)^{\frac{3}{2}\kappa} \|R_n\|_{H^{\frac{3}{2}}},$$

which yields that

$$(7.9) \quad R_3 \leq C(T-t)^{\frac{3}{2}\kappa + \frac{4+2d}{4+d}} \|R_n\|_{C\{t,t_n;H^{\frac{3}{2}}\}}.$$ 

(iv) Estimate of $R_4$. We first see that

$$R_4 \leq C\|\langle x \rangle f(u_n) - f(U_n) - f(R_n)\|_{L^2(t,t_n;H^1)}$$

$$\leq C \sum_{j=1}^{4/d} (\|\langle x \rangle U_n\|^{1+\frac{d}{2}} R_n\|_{L^2(t,t_n;L^2)} + \|\langle x \rangle \nabla U_n\| U_n\|^{1+\frac{d}{2}} R_n\|_{L^2(t,t_n;L^2)}$$

$$+ \|\langle x \rangle U_n\|^{1+\frac{d}{2}} \nabla R_n\| R_n\|^{1-1}_L L^2(t,t_n;L^2))$$

$$(7.10) \quad = \sum_{j=1}^{4/d} (R_{4,j1} + R_{4,j2} + R_{4,j3}).$$
Since $|\alpha_j| \leq |x_j - \alpha_j| + |x_j| \leq M$, $1 \leq j \leq K$, and $\sup_{y \in \mathbb{R}^d} \langle y \rangle Q(y) < \infty$, we infer that
\begin{equation}
\|\langle x \rangle U_n(t)\|_{L^\infty} \leq \sum_{j=1}^{K} \sup_{y \in \mathbb{R}^d} \langle \lambda_j y + \alpha_j \rangle \lambda_j^{-\frac{d}{2}} Q(y) \leq CM(T - t)^{-\frac{d}{4}},
\end{equation}
which along with (3.43) yields that
\begin{equation}
R_{4,j1} \leq CM(T - t)^{-\frac{d}{4}(1+\frac{d}{4}-j)+\frac{1}{2}} \| R_n \|_{C([t,t_n];L^2)}^{j} \leq CM(T - t)^{\kappa - \frac{d}{2}}.
\end{equation}
Moreover, since for any $1 < p < \infty$,
\begin{equation}
\|\langle x \rangle \nabla U_n\|_{L^p} \leq CM(T - t)^{\frac{d}{4}(j-1)-3+\frac{d}{4}},
\end{equation}
using Hölder’s inequality and (5.43) we get that
\begin{equation}
R_{4,j2} \leq C \|\langle x \rangle \nabla U_n\|_{L^2}^{\frac{d}{4}-j} \| R_n \|_{C([t,t_n];L^2)}^{j} \leq CM(T - t)^{\kappa - \frac{d}{4}},
\end{equation}
where $p, q$ are any positive numbers such that $\frac{1}{p} + \frac{1}{q} = \frac{1}{2}$.
It remains to treat the last term $R_{4,j3}$. In the case where $j = 1$ we have
\begin{equation}
R_{4,j3} \leq CM(T - t)^{-\frac{d}{2}} \| \nabla R_n \|_{C([t,t_n];L^2)} \leq CM(T - t)^{\kappa - \frac{d}{4}}.
\end{equation}
In the case where $d = 1$ and $2 \leq j \leq \frac{4}{3}$, using Sobolev’s embedding $H^1(\mathbb{R}) \hookrightarrow L^\infty(\mathbb{R})$ we get
\begin{equation}
R_{4,j3} \leq CM(T - t)^{-\frac{d}{4}(1+\frac{d}{4}-j)+\frac{1}{2}} \| R_n \|_{C([t,t_n];H^1)} \leq CM(T - t)^{2\kappa - 1}.
\end{equation}
Furthermore, in the case where $d = 2$ and $2 \leq j \leq \frac{4}{3}$, using the Sobolev embedding $H^{\frac{d}{2}}(\mathbb{R}^2) \hookrightarrow L^{\frac{2d}{d-2}}(\mathbb{R}^2)$ instead we get
\begin{equation}
R_{4,j3} \leq CM(T - t)^{-\frac{d}{4}(1+\frac{d}{4}-j)+\frac{1}{2}} \| R_n \|_{C([t,t_n];L^{2d})}^{j} \| R_n \|_{C([t,t_n];W^{1,\frac{2d}{d-2}})} \leq CM(T - t)^{2\kappa - 2} \| R_n \|_{C([t,t_n];H^\frac{d}{2})}.
\end{equation}
Hence we conclude that
\begin{equation}
R_{4,j3} \leq CM((T - t)^{\kappa - \frac{d}{4}} \| R_n \|_{C([t,t_n];H^\frac{d}{2})} + (T - t)^{\kappa - \frac{d}{4}}).
\end{equation}
Thus, plugging (7.12) into (7.10) we obtain
\begin{equation}
R_4 \leq CM((T - t)^{\kappa - \frac{d}{4}} + (T - t)^{\kappa - \frac{d}{4}} \| R_n \|_{C([t,t_n];H^\frac{d}{2})}).
\end{equation}
Therefore, plugging the estimates (7.3), (7.7), (7.9) and (7.16) into (7.3) we obtain
\begin{equation}
\| R_n \|_{C([t,t_n];H^\frac{d}{2})} \leq CM((T - t)^{\kappa - \frac{d}{4}} + (T - t)^{\kappa - \frac{d}{4}} \| R_n \|_{C([t,t_n];H^\frac{d}{2})}).
\end{equation}
Hence, taking $T$ very small such that (7.11) holds, we obtain (7.2) and finish the proof. □

Proposition 7.2 below shows that, in the case where $\kappa \geq 3$ (i.e., $\nu_* \geq 6$), one may enhance the approximation (2.15) of $u$ and $u_n$ in the space $\dot{H}^\frac{d}{2}$.

**Proposition 7.2.** Consider the situation as in Proposition 7.1 but with $\nu_* \geq 6$. Then, we have
\begin{equation}
\| u_n(t) - S_T(t) \|_{\dot{H}^\frac{d}{2}} \leq C(T - t)^{\frac{d}{2}(\kappa-3)+\zeta},
\end{equation}
where \( \zeta \in (0, \frac{1}{12}) \). In particular, for the blow-up solution \( u \) constructed in Theorem \( 2.14 \)

\[
(7.18) \quad \|u(t) - S_T(t)\|_{H^\frac{3}{2}} \leq C(T - t)^{\frac{1}{2}(\kappa - 3) + \zeta},
\]

and we also have the strong \( H^1 \) convergence that for any \( t \in (0, T) \),

\[
(7.19) \quad \|u_n - u\|_{C([0,t];H^1)} \to 0, \text{ as } n \to \infty.
\]

**Proof.** Since

\[
\|u_n(t) - \sum_{j=1}^{K} S_j(t)\|_{H^\frac{3}{2}} \leq \|R_n(t)\|_{H^\frac{3}{2}} + \sum_{j=1}^{K} \|U_{n,j}(t) - S_j(t)\|_{H^\frac{3}{2}},
\]

in view of Proposition \( 7.1 \) we only need to prove that for each \( 1 \leq j \leq K \),

\[
(7.20) \quad \|U_{n,j}(t) - S_j(t)\|_{H^\frac{3}{2}} \leq C(T - t)^{\frac{1}{2}(\kappa - 3) + \zeta}.
\]

For this purpose, we let \((\lambda_{0,j}, \alpha_{0,j}, \beta_{0,j}, \gamma_{0,j}, \theta_{0,j})\) and \( Q_{0,j}(t, y) \) be as in the proof of Theorem \( 2.14 \). Then, as in \( 6.19 \), we decompose

\[
U_{n,j} - S_j = (\lambda_{n,j} - \lambda_{0,j})Q_{n,j}(t, x_n - \alpha_{0,j} = (\lambda_{n,j} - \lambda_{0,j})Q_{n,j}(t, x_n - \alpha_{0,j}) - Q_{n,j}(t, x_n - \alpha_{0,j}))e^{i \theta_{n,j}}
\]

\[
+ \lambda_{0,j} (Q_{0,j}(t, x_n - \alpha_{0,j}) - Q_{0,j}(t, x_n - \alpha_{0,j}))e^{i \theta_{0,j}} + \lambda_{0,j} (Q_{0,j}(t, x_n - \alpha_{0,j}))e^{i \theta_{0,j}} - e^{i \theta_{0,j}}
\]

\[
=: T_1 + T_2 + T_3 + T_4.
\]

Note that

\[
\|T_1\|_{H^\frac{3}{2}} = (\lambda_{n,j} - \lambda_{0,j})\lambda_{n,j}^{\frac{1}{2}} \|Q\|_{H^\frac{3}{2}} \leq C(T - t)^{\frac{1}{2}(\kappa - 3) + \zeta}.
\]

Moreover, for \( T_2 \), we have

\[
\|T_2\|_{H^\frac{3}{2}} = \lambda_{0,j}^{\frac{1}{2}} \xi \|e^{-i \alpha_{0,j} \xi} \xi \|_{L^2} \leq C(T - t)^{\frac{1}{2}(\kappa - 3) + \zeta}.
\]

Regarding \( T_3 \) and \( T_4 \) we have the bounds

\[
\|T_3\|_{H^\frac{3}{2}} \leq C \lambda_{0,j}^{\frac{1}{2}} (|\beta_{n,j} - \beta_{0,j}| + |\gamma_{n,j} - \gamma_{0,j}|) \leq C(T - t)^{\frac{1}{2}(\kappa - 1) + \zeta},
\]

and

\[
\|T_4\|_{H^\frac{3}{2}} = \lambda_{0,j}^{\frac{1}{2}} |\theta_{n,j} - \theta_{0,j}| \|Q\|_{H^\frac{3}{2}} \leq C(T - t)^{\frac{1}{2}(\kappa - 3) + \zeta}.
\]

Thus, putting the estimates above altogether we obtain \( 7.20 \), and thus \( 7.17 \) follows.

In view of \( 6.17 \) and \( 7.17 \), we also infer that

\[
(7.21) \quad u_n(t) - S_T(t) \to u(t) - S_T(t), \text{ weakly in } \dot{H}^\frac{3}{2}, \text{ as } n \to \infty,
\]

which yields \( 7.18 \) immediately. Moreover, the strong convergence \( 7.19 \) in \( H^1 \) follows from the strong \( L^2 \) convergence \( 6.17 \), the uniform \( H^\frac{3}{2} \) boundedness \( 7.2 \) and standard interpolation arguments. Therefore, the proof is complete. \( \square \)

Below we show that the constructed blow-up solution \( u \) indeed admits the geometrical decomposition as in Proposition \( 7.1 \) on the maximal existing time interval \([0, T)\).

For each \( 0 < t < T \) fixed, Lemma \( 5.3 \) yields that the derivatives of modulation parameters \( P_n \) are uniformly bounded on \([0, t]\), and thus \( P_n \) are equicontinuous on \([0, t]\), \( n \geq 1 \). Then, by the Arzelà-Ascoli Theorem, \( P_n \) converges uniformly on \([0, t]\) up to some subsequence (which may depend on \( t \)). But, using the diagonal arguments one may extract a universal subsequence (still denoted by \( \{n_j\} \) such that for some \( \mathcal{P} := (P_1, \ldots, P_K) \),
where \( P_j := (\lambda_j, \alpha_j, \beta_j, \gamma_j, \theta_j) \in C([0, t]; R^{2d+3}), 1 \leq j \leq K \), and for every \( t \in (0, T) \), one has

\[
(7.22) \quad P_n \to P \text{ in } C([0, t]; R^{(2d+3)K}).
\]

Then, taking into account the uniform estimates \([5.1]-[5.4]\) we obtain that for each \( t \in [0, T) \) and for \( 1 \leq j \leq K \),

\[
(7.23) \quad |\lambda_j(t) - \omega_j(T - t)| + |\gamma_j(t) - \omega_j^2(T - t)| \leq (T - t)^{\kappa+1+\epsilon},
\]

\[
(7.24) \quad |\alpha_j(t) - x_j| + |\beta_j(t)| \leq (T - t)^{\kappa+1+\epsilon},
\]

\[
(7.25) \quad |\theta_j(t) - (\omega_j^{-2}(T - t)^{-1} + \vartheta_j)| \leq (T - t)^{\kappa-1+\epsilon}.
\]

In particular, as in Remark \([5.2]\) \( \lambda_j, \gamma_j, P \) are comparable to \( T - t \), i.e., there exist \( C_1, C_2 \geq 0 \), independent of \( \epsilon, T \), such that

\[
(7.26) \quad C_1(T - t) \leq \lambda_j, \gamma_j, P \leq C_2(T - t), \quad \forall 0 \leq t < T.
\]

Let

\[
(7.27) \quad U(t, x) := \sum_{j=1}^{K} \lambda_j^{-d} Q_j(t, \frac{x - \alpha_j}{\lambda_j}) e^{i\theta_j} (:= \sum_{j=1}^{K} U_j(t, x)),
\]

with

\[
(7.28) \quad Q_j(t, y) := Q(y) e^{i(\beta_j(t) y - \frac{1}{4} \gamma_j(t)|y|^2)},
\]

define \( \varrho_j \) as in \([4.6]\), and define the remainder \( R \) by

\[
(7.29) \quad R(t, x) := u(t, x) - U(t, x), \quad 0 \leq t < T, x \in \mathbb{R}^d.
\]

Then, for each \( 0 < t < T \), using the explicit expression \((7.27)\) of \( U \) and the convergence \((7.22)\) of modulation parameters, we infer that \( \langle x \rangle^2 U_n \to \langle x \rangle^2 U \) in \( C([0, t]; H^1) \), \( U_n \to U \) in \( C([0, t]; H^\frac{1}{2}) \), \( \nabla U_n \to \nabla U \) in \( C([0, t]; L^2) \), and \( \varrho_{n, j} \to \varrho_j \) in \( C([0, t]; L^2) \). Then, in view of \([6.4] \) and \([7.21]\), we obtain that \( R_n \to R \) in \( C([0, t]; L^2) \) and \( R_n(t) \to R(t) \) weakly in \( H^\frac{1}{2}, \) which by interpolation yields that \( R_n(t) \to R(t) \) in \( H^1 \).

Hence, in view of \([5.1]\) and Proposition \([7.1]\) we get that for \( T = T(M) \) small enough satisfying \((7.1)\) and for any \( t \in [0, T) \),

\[
(7.30) \quad \|R(t)\|_{L^2} \leq (T - t)^{\kappa+1}, \quad \|R(t)\|_{H^1} \leq (T - t)^{\kappa}, \quad \|R(t)\|_{H^\frac{1}{2}} \leq (T - t)^{\kappa-2}.
\]

Furthermore, the following orthogonality conditions hold on \([0, T]\) for each \( 1 \leq j \leq K \):

\[
(7.31) \quad \text{Re} \int (x - \alpha_j) U_j \overline{R} dx = 0, \quad \text{Re} \int |x - \alpha_j|^2 U_j \overline{R} dx = 0,
\]

\[
\text{Im} \int \nabla U_j \overline{R} dx = 0, \quad \text{Im} \int \Lambda U_j \overline{R} dx = 0, \quad \text{Im} \int \varrho_j \overline{R} dx = 0.
\]

We also see that the modulation parameters in \( P \) are \( C^1 \) functions. Actually, similar arguments as in the proof of Proposition \([5.3]\) show that the modulation equations \( Mod_n \) can be expressed in terms of the inner products of polynomials of \( \partial^\nu U_n \) and \( R_n \), where \( |\nu| \leq 2 \). Hence, the convergence of \( \partial^\nu U_n \) and \( R_n \) also yields that of \( P_n \), which in turn yields the desirable \( C^1 \)-regularity of the modulation parameter \( P \).

Thus, similarly to Lemma \([5.3]\) we have

**Lemma 7.3.** There exists \( C > 0 \) such that

\[
(7.32) \quad \text{Mod}(t) \leq C(T - t)^{\kappa+3}, \quad t \in [0, T).
\]
7.2. Energy estimate of the difference. Below we assume Assumption (A1) with \( \nu_* \geq 11 \). Let \( v \) be any blow-up solution to (2.11) satisfying (2.10), i.e.,

\[
\|v(t) - \sum_{j=1}^{K} S_j(t)\|_{H^1} \leq C(T - t)^{3+\zeta}, \quad 0 < t < T.
\]

Set

\[
w := v - u = \sum_{j=1}^{K} w_j, \quad \text{with} \quad w_j := w\Phi_j,
\]

where the localization functions \( \Phi_j \) are given by (3.2), \( 1 \leq j \leq K \). Since \( \kappa := \nu_* - 3 \geq 8 \), it follows from (2.16) and (7.33) that

\[
\|w(t)\|_{H^1} \leq C(T - t)^{3+\zeta}.
\]

For \( 1 \leq j \leq K \), define the renormalized variable \( \epsilon_j \) by

\[
w_j(t, x) := \lambda_j(t)^{-\frac{4}{3}} \epsilon_j(t, \frac{x - \alpha_j(t)}{\lambda_j(t)}) e^{i\theta_j(t)}.
\]

Set

\[
D(t) := \|\nabla w(t)\|_{L^2}^2 + \sum_{j=1}^{K} \frac{\|w_j(t)\|_{L^2}^2}{\lambda_j^2(t)}.
\]

We note that

\[
\|w_j(t)\|_{L^2} \leq C(T - t)\sqrt{D(t)}, \quad \|w_j(t)\|_{H^1} \leq C\sqrt{D(t)}, \quad 1 \leq j \leq K.
\]

Moreover, as in (3.15), we set \( \text{Scal}_j(t) := \text{Scal}(\epsilon_j) \), i.e., for \( \epsilon_{j,1} := \text{Re}\epsilon_j, \epsilon_{j,2} := \text{Im}\epsilon_j \),

\[
\text{Scal}_j(t) := \langle \epsilon_{j,1}, Q \rangle^2 + \langle \epsilon_{j,1}, yQ \rangle^2 + \langle \epsilon_{j,1}, |y|^2Q \rangle^2 + \langle \epsilon_{j,2}, \nabla Q \rangle^2 + \langle \epsilon_{j,2}, \Lambda Q \rangle^2 + \langle \epsilon_{j,2}, \rho \rangle^2,
\]

which actually measures the deviations of the remainder term \( \epsilon_j \) with respect to the six instable directions of the linearized operator \( L \).

By equation (2.11), \( w \) satisfies the equation

\[
i\partial_tw + \Delta w + f(u + w) - f(u) + b \cdot \nabla w + cw = 0, \quad t \in (0, T),
\]

and \( \lim_{t \to T} \|w(t)\|_{H^1} = 0 \), due to (7.35).

The strategy to prove that \( w \equiv 0 \) is to show that \( D \equiv 0 \). As in the proof of the bootstrap estimate of remainder in Section 5 above, such result will be derived from the estimate of a generalized energy. This leads to the definition of \( \tilde{I} \) below

\[
\tilde{I} := \frac{1}{2} \int |\nabla w|^2 dx + \frac{1}{2} \sum_{j=1}^{K} \frac{1}{\lambda_j^2} \int |w|^2 \Phi_j dx - \text{Re} \int F(u + w) - F(u) - f(u)\overline{w} dx
\]

\[
+ \sum_{j=1}^{K} \frac{\gamma_j}{2\lambda_j} \text{Im} \int \langle \nabla \chi \Lambda \rangle (\frac{x - \alpha_j}{\lambda_j}) \cdot \nabla w \overline{w} \Phi_j dx.
\]

Note that, \( u \) and \( w \) play similar roles as \( U \) and \( R \) in (5.28), respectively.

Lemma 7.3 relates the generalized energy \( \tilde{I}(t) \) and the two quantities \( D(t) \) and \( \text{Scal}_j(t) \).
Lemma 7.4. For \( t \in [0, T) \), there exist \( C_1, C_2, C_3 > 0 \) such that

\[
C_1 D(t) - C_2 \sum_{j=1}^{K} \frac{\text{Scal}_j(t)}{\lambda_j^2} \leq \tilde{I}(t) \leq C_3 D(t).
\]

Proof. We first show that, in the formulation of the generalized energy \( \tilde{I} \), one may replace the blow-up solution \( u \) with the main blow-up profile \( U \) given by (7.27), at the cost of the error \( \mathcal{O}((T - t)D(t)) \), i.e.,

\[
\text{Re} \int F(u + w) - F(u) - f(u)w dx = \text{Re} \int F(U + w) - F(U) - f(U)w dx + \mathcal{O}((T - t)D(t)).
\]

In order to prove (7.43), using Taylor’s expansion (3.21) we see that

\[
\text{Re} \int F(u + w) - F(u) - f(u)w dx
\]

\[
= \text{Re} \int F(U + w) - F(U) - f(U)w dx + \mathcal{O}\left(\|U\|^{\frac{4}{3} - 1} + \|w\|^{\frac{4}{3} - 1} + |R|^{\frac{4}{3} - 1}|R|\|w\|^2 dx\right).
\]

By (3.29), (5.39) and (7.30),

\[
\int |U|^{\frac{4}{3} - 1}|R||w|^2 dx \leq C(T - t)^{-\frac{4}{3}(\frac{4}{3} - 1)}\|R\|_{L^2}^2\|w\|^2_{H^1} \leq C(T - t)\|w\|^2_{H^1}.
\]

Moreover, by (3.29), (7.30) and (7.35),

\[
\int (|w|^{\frac{4}{3} - 1} + |R|^{\frac{4}{3} - 1})|R||w|^2 dx \leq C\|R\|_{H^1}\|w\|^{\frac{4}{3} + 1}_{H^1} + \|R\|^{\frac{4}{3}}_{H^1}\|w\|^2_{H^1} \leq C(T - t)\|w\|^2_{H^1}.
\]

Hence, plugging (7.45) and (7.46) into (7.44) and using (7.38) we obtain (7.43), as claimed.

Next we analyze the right-hand-side of (7.44). Note that, by (3.21),

\[
\text{Re}(F(U + w) - F(U) - f(U)w) = \frac{1}{2} \int \left(1 + \frac{2}{d} |U|^{\frac{4}{3}} |w|^2 + \frac{1}{d} |U|^{\frac{4}{3} - 2} \text{Re}(U^2\overline{w})^2\right) dx + \mathcal{O}((|U|^{\frac{4}{3} - 1} + |w|^2)|w|^3).
\]

Note that

\[
\int (|U|^{\frac{4}{3} - 1} + |w|^{\frac{4}{3} - 1})|w|^3 dx \leq C(T - t)^{-2}\|w\|^3_{H^1} + \|w\|^2_{H^1} \leq C(T - t)D(t).
\]

Moreover, a direct application of Hölder’s inequality also shows that the last term on the right-hand-side of (7.44) is bounded by

\[
C\|w\|_{L^2}\|
abla w\|_{L^2} \leq C(T - t)D(t).
\]

Thus, we conclude from (7.43), (7.47), (7.48) and (7.49) that

\[
\tilde{I} = \frac{1}{2} \text{Re} \int |\nabla w|^2 + \sum_{j=1}^{K} \frac{1}{\lambda_j^2} |w|^2 \Phi_j - (1 + \frac{2}{d}) |U|^{\frac{4}{3}} |w|^2 - \frac{2}{d} |U|^{\frac{4}{3} - 2} U^2 \overline{w}^2 dx + \mathcal{O}((T - t)D(t)).
\]

(7.50)
Arguing as in the proof of (5.79) we have that for some $C_1, C_2 > 0$,

\[
\tilde{I} \geq C_1 \left( \int |\nabla w|^2 + \sum_{j=1}^K \lambda_j^{-2} |w|^2 \Phi_j dx \right) - C_2 ((T-t)D + (T-t)^{-1} \|w\|_{L^2}^2 + \sum_{j=1}^K \lambda_j^{-2} Scal_j + e^{-\frac{A}{\lambda_j^2}} \|w\|_{H^1}^2). \]

Then, taking $T$ small enough such that $C_2 (2(T-t) + e^{-\frac{A}{\lambda_j^2}}) \leq \frac{1}{2} C_1$, $\forall t \in [0, T]$, and taking into account (7.37) and $\Phi_j \geq \Phi_j^2$, we get

\[
\tilde{I} \geq C_1 \left( \int |\nabla w|^2 + \sum_{j=1}^K \lambda_j^{-2} |w|^2 \Phi_j dx \right) - \frac{1}{2} C_1 D(t) - C_2 \sum_{j=1}^K \lambda_j^{-2} Scal_j(t) \geq \frac{1}{2} C_1 D(t) - C_2 \sum_{j=1}^K \lambda_j^{-2} Scal_j(t).
\]

But, since $|U(t)| \leq C(T-t)^{-\frac{d}{2}}$, using Hölder’s inequality, (7.37) and (7.50) we also have

\[
\tilde{I}(t) \leq CD(t).
\]

Therefore, combining two estimates together we obtain (7.42) and finish the proof. □

Similarly to Theorem 5.9 we have the monotonicity property of $\frac{dI}{dt}$.

**Theorem 7.5.** There exist $C_1, C_2, C_3 > 0$ such that for any $t \in [0, T)$,

\[
\frac{dI}{dt} \geq \sum_{j=1}^K \frac{C_1}{\lambda_j} \int \left( |\nabla w_j|^2 + \frac{1}{\lambda_j^2} |w_j|^2 \right) e^{-\frac{|x-a_j|}{\lambda_j}} dx - C(D(t) + \sum_{j=1}^K \frac{Scal_j(t)}{\lambda_j^3(t)}) - C_3 \varepsilon^* \frac{D(t)}{T-t}.
\] (7.51)
Proof. Similarly to (5.33) and (5.48), using equation (7.40) we compute

\[
\frac{d\tilde{T}}{dt} = -\sum_{j=1}^{K} \frac{\lambda_j}{\lambda_j^2} \text{Im} \int |w|^2 \Phi_j dx - \sum_{j=1}^{K} \frac{1}{\lambda_j} \text{Im} \langle f'(u) \cdot w, w_j \rangle - \text{Re} \langle f''(u, w) \cdot w^2, \partial_t u \rangle - \sum_{j=1}^{K} \frac{1}{\lambda_j} \text{Im} \langle w^2 \Phi_j, \nabla w \rangle - \sum_{j=1}^{K} \frac{1}{\lambda_j} \text{Im} \langle f''(u, w) \cdot w^2, w_j \rangle - \sum_{j=1}^{K} \text{Im} \langle \Delta w - \frac{1}{\lambda_j^2} w_j + f(u + w) - f(u), b \cdot \nabla w + cw \rangle - \sum_{j=1}^{K} \frac{\lambda_j \gamma_j - \lambda_j \gamma_j}{2\lambda_j^2} \text{Im} \langle \nabla \chi_A(\frac{x - \alpha_j}{\lambda_j}) \cdot \nabla w, w_j \rangle - \sum_{j=1}^{K} \frac{\gamma_j}{2\lambda_j} \text{Im} \langle \partial_t \chi_A(\frac{x - \alpha_j}{\lambda_j}) \cdot \nabla w, \partial_t w \rangle + \sum_{j=1}^{K} \text{Im} \langle \gamma_j \frac{\lambda_j}{2\lambda_j^2} \nabla \chi_A(\frac{x - \alpha_j}{\lambda_j}) \nabla w_j + \frac{\gamma_j}{2\lambda_j} \nabla \chi_A(\frac{x - \alpha_j}{\lambda_j}) \cdot (\nabla w_j + \nabla w \Phi_j), \partial_t w \rangle
\]

(7.52) \[= \sum_{j=1}^{K} \tilde{T}_{t,j}. \]

Below we replace the each appearance of \( u \) by the blow-up profile \( U \) in the terms \( \tilde{T}_{t,2}, \tilde{T}_{t,3}, \tilde{T}_{t,5}, \tilde{T}_{t,6} \) and \( \tilde{T}_{t,9} \).

(i) Estimate of \( \tilde{T}_{t,2} \). Since by (5.18),

\[
|f'(u) \cdot w - f'(U) \cdot w| \leq C(|U|^\frac{1}{2} - 1 + |R|^\frac{1}{2} - 1 + |w|^\frac{1}{2} - 1)|R||w|,
\]

using Lemma 5.1 we get

\[
\text{Im} \langle f'(U) \cdot w, w_j \rangle \leq C \sum_{j=1}^{K} \frac{1}{\lambda_j^2} \int (|U|^\frac{1}{2} - 1 + |R|^\frac{1}{2} - 1 + |w|^\frac{1}{2} - 1)|R||w||w_j| dx.
\]

By Hölder’s inequality, (3.28), (3.39), (5.43) and (7.30), we have that for \( \frac{1}{p} + \frac{1}{q} = \frac{1}{2} \),

\[
\frac{1}{\lambda_j^2} \int |U|^\frac{1}{2} - 1 |R||w||w_j| dx \leq (T - t)^{-4 + \frac{d}{p}} |R||L_p||w||L_p||w_j||L_2 \leq (T - t)^{-3 + \frac{d}{p} + \frac{d}{p'} + \frac{d}{p''}} |w||L^{\frac{2}{d}}_2||\nabla w||L_2^\frac{2}{d}.
\]

Then, by Young’s inequality \( ab \leq a^p + \frac{b^p}{p'} \) with \( p' = \frac{2p}{d}, \frac{1}{p} + \frac{1}{p'} = 1 \) and \( 0 < \frac{d}{p'} < 1 \),

\[
\frac{1}{\lambda_j^2} \int |U|^\frac{1}{2} - 1 |R||w||w_j| dx \leq (T - t)^{\frac{\delta - 3}{2}} |w||L^2_p| + \|\nabla w_j\|_{L^2} \leq CD(t).
\]

Moreover, by (3.24) and (7.30),

\[
\frac{1}{\lambda_j} \int |R|^\frac{1}{2} |w_j| |w| dx \leq C(T - t)^{-2} |R||H^\frac{1}{2}||H^\frac{1}{2}||w||H^1 \leq C |w||H^1 \leq CD(t),
\]

and

\[
\frac{1}{\lambda_j} \int |w|^\frac{1}{2} |R||w_j| dx \leq C(T - t)^{-2} |R||L^2||w||H^{1 + \frac{d}{2}} \leq C |w||H^{2} \leq CD(t).
\]
Hence, we conclude that

$$\tilde{I}_{t,2} = - \sum_{j=1}^{K} \frac{1}{\lambda_j^2} \text{Im} \langle f'(U) \cdot w, w_j \rangle + \mathcal{O}(D(t)).$$

(ii) Estimate of $\tilde{I}_{t,3}$. Since by (7.29),

$$\text{Re} \langle f''(u, w) \cdot w^2, \partial_t u \rangle = \text{Re} \langle f''(u, w) \cdot w^2, \partial_t U \rangle + \text{Re} \langle f''(u, w) \cdot w^2, \partial_t R \rangle,$$

we shall treat the two terms on the right-hand side separately below.

First, using (3.19) we see that

$$|f''(u, w) \cdot w^2 - f''(U, w) \cdot w^2| \leq C(|U|^\frac{4}{5} - 2 + |R|^\frac{4}{5} - 2 + |w|^\frac{4}{5} - 2)|R||w|^2,$$

which yields that

$$|\text{Re} \langle f''(u, w) \cdot w^2, \partial_t U \rangle - \text{Re} \langle f''(U, w) \cdot w^2, \partial_t U \rangle|$$

$$\leq C \sum_{j=1}^{K} \|\partial_t U_j\|_{L^\infty} \int (|U|^\frac{4}{5} - 2 + |R|^\frac{4}{5} - 2 + |w|^\frac{4}{5} - 2)|R||w|^2 dx.$$

Note that, by (4.14), \(\|\partial_t U_j\|_{L^\infty} \leq C(T-t)^{-\frac{4}{5} - \frac{q}{2}}\), and by Gagliardo-Nirenberg’s inequality (5.28),

$$\|\partial_t U_j\|_{L^\infty} \int |U|^\frac{4}{5} - 2 |R||w|^2 dx \leq C(T-t)^{-\frac{4}{5} + \frac{q}{2}}\|R\|_{L^2} \|w\|_{L^4}^2 \leq C(T-t)^{\frac{1}{2} - \frac{4}{5} + \frac{q}{2}}\|w\|_{L^2}^2 \|\nabla w\|_{L^2}^\frac{4}{5},$$

which, via Young’s inequality \(ab \leq \frac{a^p}{p} + \frac{b^q}{q}\) with \(p = \frac{4}{3 - \sigma}\) and \(q = \frac{4}{3}\), can be bounded by

$$C(T-t)^{(\frac{1}{2} + \frac{2}{5} - \frac{4}{5})\frac{4}{5}}\|w\|_{L^2}^2 + \|\nabla w\|_{L^2}^2 \leq C(T-t)^{-\frac{2}{5}}\|w\|_{L^2}^2 + \|\nabla w\|_{L^2}^2 \leq CD(t).$$

Moreover, by Hölder’s inequality, (5.31), (5.33), (7.30) and (7.35),

$$\|\partial_t U_j\|_{L^\infty} \int (|R|^\frac{4}{5} - 2 + |w|^\frac{4}{5} - 2)|R||w|^2 dx \leq C(T-t)^{-2\frac{4}{5}}(\|R\|^\frac{1}{L^\frac{4}{5} - 2} \|w\|_{H^1}^2 + \|R\|_{L^2} \|w\|_{H^\frac{4}{5}}^2)$$

$$\leq C\|w\|_{H^1}^2 \leq CD(t).$$

Hence, we obtain

$$\text{Re} \langle f''(u, w) \cdot w^2, \partial_t U \rangle = \text{Re} \langle f''(U, w) \cdot w^2, \partial_t U \rangle + \mathcal{O}(D(t)).$$

Next we show that

$$\text{Re} \langle f''(u, w) \cdot w^2, \partial_t R \rangle = \mathcal{O}(D(t)).$$

For this purpose, using equation (5.13) we get

$$|\text{Re} \langle f''(u, w) \cdot w^2, \partial_t R \rangle| = |\text{Im} \langle f''(u, w) \cdot w^2, \Delta R + f(U) - f(U) + b \cdot \nabla R + cR + \eta \rangle|.$$

Note that, by (5.30),

$$|\text{Im} \langle f''(u, w) \cdot w^2, \Delta R \rangle| \leq C\|R\|_{\dot{H}^\frac{4}{5}} \|f''(u, w) \cdot w^2\|_{\dot{H}^\frac{4}{5}}$$

$$\leq C(T-t)^{-\frac{2}{5}}\|f''(u, w) \cdot w^2\|_{\dot{H}^\frac{4}{5}}.$$
Using (5.32), (7.30) and $\|U(t)\|_{H^1} \leq C(T-t)^{-1}$ we get

$$\|f''(u, w) \cdot w^2\|_{H^2_{\pm}} \leq C \sum_{j=2}^{1+\frac{4}{t}} \|w\|^1_{H^1} \|w\|^j_{H^1} \leq C \sum_{j=2}^{1+\frac{4}{t}} (\|U\|_{H^1}^{1+\frac{j}{t}} + \|R\|_{H^1}^{1+\frac{j}{t}}) \|w\|^2_{H^1}$$

$$\leq C \sum_{k=2}^{1+\frac{4}{t}} ((T-t)^{(1+\frac{j}{t})} + (T-t)^{(1+\frac{j}{t})}) (T-t)^{(3+\kappa)(j-2)} \|w\|^2_{H^1}$$

(7.60)

which along with (7.59) and $\kappa \geq 8$ yields that

(7.61)

$$\text{Im} \langle f''(u, w) \cdot w^2, \Delta R \rangle \leq C \|w\|^2_{H^1} \leq CD(t).$$

Moreover, since

(7.62)

$$\|f(u) - f(U)\| \leq C (\|U\|^\frac{1}{t} + |R|^\frac{1}{t}) |R|,$$

and

(7.63)

$$\|f''(u, w) \cdot w^2\| \leq C (\|U\|^\frac{1}{t} + |R|^\frac{1}{t} + |w|^\frac{1}{t}) |w|^2,$$

by (3.31) and (7.30) we get

(7.64)

$$\text{Im} \langle f''(u, w) \cdot w^2, f(u) - f(U) + b \cdot \nabla R + cR \rangle \leq C \|w\|^2_{H^1} \leq CD(t).$$

Furthermore, using (3.31), (5.17) and (7.63) again we also have

$$\text{Im} \langle f''(u, w) \cdot w^2, \eta \rangle \leq C ((T-t)^{-2} |R|^\frac{1}{t} + |w|^\frac{1}{t} \|\eta\|_{L^2}) \|w\|^2_{H^1}$$

(7.65)

$$\leq C \|w\|^2_{H^1} \leq CD(t).$$

Thus, combining estimates (7.61), (7.64) and (7.65) we obtain (7.58), as claimed. Therefore, we infer from (7.57) and (7.65) that

(7.66)

$$\tilde{I}_{t,3} = \text{Re} \langle f''(U, w) \cdot w^2, \partial_t U \rangle + O(D(t)).$$

(iii) Estimate of $\tilde{I}_{t,5}$. Using (7.55) we have

$$\tilde{I}_{t,5} + \sum_{j=1}^{K} \frac{1}{\lambda_j} \text{Im} \langle f''(U, w) \cdot w^2, w_j \rangle \leq C(T-t)^{-2} \int (\|U\|^\frac{1}{t} - \|R\|^\frac{1}{t} + |w|^\frac{1}{t}) |R| |w|^2 |w_j| dx.$$

By Hölder’s inequality, (3.29), (5.39), (7.30) and (7.35),

$$(T-t)^{-2} \int (\|U\|^\frac{1}{t} - \|R\|^\frac{1}{t} + |w|^\frac{1}{t}) |R| |w|^2 |w_j| dx \leq (T-t)^{-2} \|R\|^\frac{1}{t} \|w\|^2_{H^1} \leq CD(t).$$

Similarly, using (3.29), (7.30) and (7.35) we also have

$$(T-t)^{-2} \int (\|R\|^\frac{1}{t} - |w|^\frac{1}{t}) |R| |w|^2 |w_j| dx \leq C(T-t)^{-2} (\|R\|^\frac{1}{t} \|w\|^2_{H^1} + \|R\|^3_{L^2} \|w\|^\frac{3}{t} + 1) \leq CD(t).$$

Hence, we obtain

(7.67)

$$\tilde{I}_{t,5} = - \sum_{j=1}^{N} \frac{1}{\lambda_j} \text{Im} \langle f''(U, w) \cdot w^2, w_j \rangle + O(D(t)).$$
(iv) Estimate of $\tilde{I}_{t,6}$. Since by (3.20),

\[
|f(u + w) - f(u) - (f(U + w) - f(U))| \leq C(|U|^\frac{1}{2} + |w|^\frac{1}{2} + |R|^\frac{1}{2}|R||w|, \tag{7.68}
\]

taking into account (3.29) we infer that

\[
\text{Im}(f(u + w) - f(u) - (f(U + w) - f(U)), (b \cdot \nabla + c)w) \\
\leq C \int (|U|^\frac{1}{2} + |w|^\frac{1}{2} + |R|^\frac{1}{2}|R||w||(b \cdot \nabla + c)w| dx \\
\leq C[(T - t)^{\frac{1}{2}} + ||w||^\frac{1}{2} + ||R||^\frac{1}{2}|R||H^1||w||H^1||(b \cdot \nabla + c)w||_{L^2} \\
\leq C||w||_{H^1}^\frac{1}{2} \leq CD(t).
\]

This yields that

\[
\tilde{I}_{t,6} = -\sum_{j=1}^{K} \text{Im}(\Delta w - \frac{1}{\lambda_j}w_j + f(U + w) - f(U), b \cdot \nabla w + cw) + O(D(t)). \tag{7.69}
\]

(v) Estimate of $\tilde{I}_{t,9}$. The arguments are similar to those in the previous cases (i) and (iv). Actually, using equation (7.40) we infer that

\[
\tilde{I}_{t,9} = \text{Im}(\frac{\gamma_j}{2\lambda_j^2}\Delta \chi_{\lambda} \frac{x - \alpha_j}{\lambda_j}w_j + \frac{\gamma_j}{2\lambda_j^2}\nabla \chi_{\lambda} \frac{x - \alpha_j}{\lambda_j} \cdot (\nabla w_j + \nabla \Phi_j), \\
i\Delta w + i(f(u + w) - f(u)) + i(b \cdot \nabla) + c)w).
\]

Then, in view of (7.68) we see that

\[
\begin{align*}
&\left|\left(\frac{\gamma_j}{2\lambda_j^2}\Delta \chi_{\lambda} \frac{x - \alpha_j}{\lambda_j}w_j + \frac{\gamma_j}{2\lambda_j^2}\nabla \chi_{\lambda} \frac{x - \alpha_j}{\lambda_j} \cdot (\nabla w_j + \nabla \Phi_j), i(f(u + w) - f(u))\right) \\
&\quad - \left(\frac{\gamma_j}{2\lambda_j^2}\Delta \chi_{\lambda} \frac{x - \alpha_j}{\lambda_j}w_j + \frac{\gamma_j}{2\lambda_j^2}\nabla \chi_{\lambda} \frac{x - \alpha_j}{\lambda_j} \cdot (\nabla w_j + \nabla \Phi_j), i(f(U + w) - f(U))\right)| \\
&\leq C(A) \int (T - t)^{-1}|w_j||(|U|^\frac{1}{2} + |w|^\frac{1}{2} + |R|^\frac{1}{2})||R||w| dx \\
&\quad + C(A) \int |\nabla w_j + \nabla \Phi_j||(|U|^\frac{1}{2} + |w|^\frac{1}{2} + |R|^\frac{1}{2})||R|||w| dx.
\end{align*}
\]

Arguing as in the proof of (7.54) and (7.69), respectively, we can also bound the two integrations on the right-hand side above by $CD(t)$. This yields that

\[
\tilde{I}_{t,9} = \text{Im}(\frac{\gamma_j}{2\lambda_j^2}\Delta \chi_{\lambda} \frac{x - \alpha_j}{\lambda_j}w_j + \frac{\gamma_j}{2\lambda_j^2}\nabla \chi_{\lambda} \frac{x - \alpha_j}{\lambda_j} \cdot (\nabla w_j + \nabla \Phi_j), \\
i\Delta w + i(f(U + w) - f(U)) + i(b \cdot \nabla) + c)w) + O(D(t)). \tag{7.70}
\]

At this stage, we have replaced $u$ by the blow-up profile $U$ in (7.52). Then, arguing as in the proof of Theorem 5.9 with $R$ replaced by $\omega$ and using (7.35) we obtain (7.51) and thus finish the proof. \[\square\]

As a consequence of Lemma 7.4 and Theorem 7.5 we have

**Theorem 7.6.** For $t \in [0, T)$, we have that

\[
\sup_{t \leq s < T} D(s) \leq C \left( \sum_{j=1}^{K} \frac{\text{Scal}_j(s)}{\lambda_j^2} + \int_{t}^{T} \sum_{j=1}^{K} \frac{\text{Scal}_j(s)}{\lambda_j^2} + \varepsilon^{*} \frac{D(s)}{T - s} ds \right). \tag{7.71}
\]
Proof. By Lemma 7.4 and Theorem 7.5 for \( t < \tilde{t} < T \),

\[
C_1 D(t) \leq \tilde{I}(t) + C_2 \sum_{j=1}^{K} \frac{\text{Scal}_j(t)}{\lambda_j^2(t)} = \tilde{I}(\tilde{t}) + C_2 \sum_{j=1}^{K} \frac{\text{Scal}_j(t)}{\lambda_j^2(t)} - \int_t^{\tilde{t}} \frac{dI(s)}{ds} ds
\]

which yields that

\[
\sup_{t \leq s \leq \tilde{t}} D(s) \leq C(D(\tilde{t})) + \sum_{j=1}^{K} \sup_{t \leq s \leq \tilde{t}} \frac{\text{Scal}_j(s)}{\lambda_j^2(s)} + (\tilde{t} - t) \sup_{t \leq s \leq \tilde{t}} D(s) + \int_t^{\tilde{t}} \sum_{j=1}^{K} \frac{\text{Scal}_j(s)}{\lambda_j^2(s)} + \varepsilon s \frac{D(s)}{T - s} ds.
\]

By (7.33), \( D(\tilde{t}) \to 0 \) as \( \tilde{t} \to T \). Hence, letting \( \tilde{t} \to T \) and taking \( T \) sufficiently small we obtain (7.71) and finish the proof.

7.3. Control of the null space. In view of Theorem 7.6, the last step is to control the scalar products in \( \text{Scal}_j \), that is, the growth along six unstable directions in the null space. The key result is formulated in Theorem 7.7 below. Then, at the end of this subsection, we finish the proof of the main uniqueness result.

Theorem 7.7. For \( T \) small enough and for \( 1 \leq j \leq K \), there exist \( C > 0, \zeta \in (0, 1) \) such that

\[
\text{Scal}_j(t) \leq C(T - t)^{2+\zeta} \sup_{t \leq s < T} D(s).
\]

To begin with, we first treat the estimate of the scalar product \( \text{Re}\langle U_j, w \rangle \).

Proposition 7.8. For \( 1 \leq j \leq K \), we have

\[
|\text{Re} \int U_j(t) \overline{\nu}(t) dx| \leq C(T - t)^{4+\zeta} \sup_{t \leq s < T} \sqrt{D(s)}.
\]

Remark 7.9. One may also use equation (7.88) below to obtain the bound

\[
|\text{Re} \int U_j(t) \overline{\nu}(t) dx| = |\text{Re} \int Q e_j(t) dy| \leq C(T - t)^{3+\zeta} \sup_{t \leq s < T} \sqrt{D(s)},
\]

where \( e_j \) is defined in (7.82) below. Estimate (7.74) improves (7.73) by a factor \( (T - t) \), by exploring the conservation law of mass.

Proof of Proposition 7.8. We first note from (7.34), \( v = u + w \), that

\[
\int |v(t)|^2 \Phi_j dx = \int |u(t)|^2 \Phi_j dx + \int |w(t)|^2 \Phi_j dx + 2 \text{Re}\langle w_j, u \rangle.
\]

Taking into account \( u = U + R \), Lemma 8.1, (7.30) and (7.35) we get, for \( T \) small enough,

\[
\text{Re}\langle w_j, u \rangle = \text{Re}\langle w, U_j \rangle + \text{Re}\langle w_j, R \rangle + O(e^{-\frac{t}{T}} \|w\|_{L^2}) = \text{Re}\langle U_j, w \rangle + O((T - t)^{\zeta+1}\|w\|_{L^2})
\]

57
Hence, taking into account (7.35) and $\kappa \geq 3$ we obtain
\[
\text{Re}\langle U_j(t), w(t)\rangle = \frac{1}{2} \left( \int |v(t)|^2 \Phi_j \, dx - \int |u(t)|^2 \Phi_j \, dx \right) \\
- \frac{1}{2} \int |w(t)|^2 \Phi_j \, dx + O((T-t)^{\kappa+1}||w(t)||_{L^2})
\]
(7.75)
\[
= \frac{1}{2} \left( \int |v(t)|^2 \Phi_j \, dx - \int |u(t)|^2 \Phi_j \, dx \right) + O((T-t)^{3+\zeta}||w(t)||_{L^2}).
\]

In order to estimate the first term on the right-hand side above, we note that for $\tilde{t} \in (t, T)$,
\[
\int |v(t)|^2 \Phi_j \, dx - \int |u(t)|^2 \Phi_j \, dx = \int_{\tilde{t}}^t \left( \frac{d}{ds} \int |v|^2 \Phi_j \, dx - \frac{d}{ds} \int |u|^2 \Phi_j \, dx \right) ds
\]
(7.76)
\[
+ \left( \int |v(\tilde{t})|^2 \Phi_j \, dx - \int |u(\tilde{t})|^2 \Phi_j \, dx \right).
\]
Similarly to (5.20), we have
\[
\frac{d}{dt} \int |v|^2 \Phi_j \, dx = \text{Im} \int (2\overline{v} \nabla v + b|v|^2) \cdot \nabla \Phi_j \, dx.
\]
Similar equation also holds for $u$. Then, taking into account $v = u + w$ and $u = U + R$ we get
\[
\frac{d}{dt} \int |v|^2 \Phi_j \, dx - \frac{d}{dt} \int |u|^2 \Phi_j \, dx = \text{Im} \int (2\overline{w} \nabla u + \overline{w} \nabla w) + 2\overline{w} \nabla w + b(\overline{w} u + \overline{w} w + |w|^2) \cdot \nabla \Phi_j \, dx
\]
\[
= \text{Im} \int_{|x-x_0| \leq 4\sigma, t \leq T} (2\overline{v} \nabla U + \overline{U} \nabla w) + b(\overline{w} U + \overline{U} w) \cdot \nabla \Phi_j \, dx
\]
(7.77)
\[
+ \text{Im} \int (2\overline{R} \nabla R + \overline{R} \nabla w) + 2\overline{w} \nabla w + b(\overline{R} R + \overline{R} w + |w|^2) \cdot \nabla \Phi_j \, dx,
\]
which along with Lemma 5.1 integration by parts formula, Hölder’s inequality and (7.30) yields that
\[
\left| \frac{d}{dt} \int |v|^2 \Phi_j \, dx - \frac{d}{dt} \int |u|^2 \Phi_j \, dx \right| \leq C(||R||_{H^1} + ||w||_{H^1} + e^{-\frac{1}{T-t}})||w||_{L^2}
\]
(7.78)
\[
\leq C(T-t)^{3+\zeta} ||w||_{L^2},
\]
and thus
\[
\left| \int_{\tilde{t}}^t \left( \frac{d}{ds} \int |v|^2 \Phi_j \, dx - \frac{d}{ds} \int |u|^2 \Phi_j \, dx \right) ds \right| \leq C(T-t)^{4+\zeta} \sup_{t \leq s \leq \tilde{t}} ||w(s)||_{L^2}.
\]
(7.79)

Moreover, taking into account (7.33) we have
\[
\lim_{\tilde{t} \to T} \left| \int |v(\tilde{t})|^2 \Phi_j \, dx - \int |u(\tilde{t})|^2 \Phi_j \, dx \right| = 0.
\]
(7.80)

Therefore, plugging (7.79) and (7.80) into (7.76) and passing to the limit $\tilde{t} \to T$ we arrive at
\[
\left| \int |v(t)|^2 \Phi_j \, dx - \int |u(t)|^2 \Phi_j \, dx \right| \leq C(T-t)^{4+\zeta} \sup_{t \leq s \leq T} ||w(s)||_{L^2},
\]
(7.81)
which along with (7.38) and (7.75) yields (7.73), thereby finishing the proof. □
Below we estimate the growth in the remaining five unstable directions associated to the null space of the operator $L$.

We define the renormalized variables $\tilde{e}_j$ and $e_j$ by

$$w(t, x) = \lambda_j(t)^{-\frac{2}{d}} \tilde{e}_j(t, x - \alpha_j(t)) e^{i\beta_j(t)}, \quad \text{with } \tilde{e}_j(t, y) = e_j(t, y) e^{i(\beta_j(t) y - \frac{1}{4} \gamma_j(t) |y|^2)},$$

and let $e_{j,1} := \text{Re} e_j$ and $e_{j,2} := \text{Im} e_j$, where $1 \leq j \leq K$. Note that, the renormalized variable $e_j$ is different from the previous one $\tilde{e}_j$ in (7.30). The advantage to introduce $e_j$ and $\tilde{e}_j$ can be seen in Proposition 7.12 below, where the estimates of the unstable directions can be diagonalized in some sense.

Using the Taylor expansions (3.20), (3.21) we have

$$f(u + w) - f(u) = f'(U) \cdot w + G_1,$$

where

$$G_1 := (\partial_{x} f)'(U, R) \cdot Rw + (\partial_{x} f)'(U, R) \cdot Rw + f''(u, w) \cdot w^2.$$

We further split $f'(U; w)$ into three parts below

$$f'(U) \cdot w = f'(U_j) \cdot w + \sum_{l \neq j} f'(U_l) \cdot w + [f'(U) \cdot w - \sum_{l=1}^{K} f'(U_l) \cdot w]$$

$$(7.85) \quad =: f'(U_j) \cdot w + G_2 + G_3.$$ 

Note that, $G_2$ contains the blow-up profiles different from $U_j$, and $G_3$ contains the interactions between different blow-up profiles.

Moreover, let $G_4$ denote the lower order perturbations

$$G_4 := b \cdot \nabla w + cw,$$

where $b, c$ are given by (2.12), (2.13), respectively.

Then, plugging (7.83), (7.85) and (7.86) into equation (7.40) we reformulate the equation of $w$ as follows

$$i\partial_t w + \Delta w + f'(U_j) \cdot w = - \sum_{l=1}^{4} G_l.$$ 

The equation of renormalized variable $e_j$ is contained in Lemma 7.10 below, which is, actually, a consequence of several algebraic cancellations.

**Lemma 7.10.** For every $1 \leq j \leq K$, $e_j$ satisfies the equation

$$i\lambda_j^2 \partial_t e_j + \Delta e_j - e_j + (1 + \frac{2}{d}) Q^4 e_j + \frac{2}{d} Q^4 e_j = - \sum_{l=1}^{4} H_l + \mathcal{O}((|\beta_j|^2 |e_j| + |\gamma_j| |\nabla e_j|) \mod j),$$

where

$$H_l(t, y) = \lambda_j^{2+\frac{2}{d}} e^{-i\beta_j} e^{-i(\beta_j y - \frac{1}{4} \gamma_j |y|^2)} G_l(t, \lambda_j y + \alpha_j), \quad 1 \leq l \leq 4.$$ 

**Proof.** Using the identity

$$\partial_t \tilde{e}_j = \partial_t e_j e^{i(\beta_j y - \frac{1}{4} \gamma_j |y|^2)} + i(\beta_j \cdot y - \frac{1}{4} \gamma_j |y|^2) \tilde{e}_j,$$
which along with (4.7) yields that
\[ \lambda_j^{-2-\frac{\beta}{4}}e^{i\theta_j}(\lambda_j \partial_t \vec{e}_j + \lambda_j^2 \partial_t \vec{e}_j e^{i(\beta_j \cdot y - \frac{1}{4}\gamma_j |y|^2)} + i\lambda_j^2 \beta_j \cdot \vec{e}_j - \frac{1}{4} i\lambda_j^2 \gamma_j |y|^2 \vec{e}_j - \lambda_j \partial_t \vec{e}_j - \lambda_j \lambda_j y \cdot \nabla \vec{e}_j + i\lambda_j^2 \beta_j \vec{e}_j) , \]
which along with (4.7) yields that
\[ i\partial_t w = \lambda_j^{-2-\frac{\beta}{4}}e^{i\theta_j}(i\gamma_j \Lambda \vec{e}_j + i\lambda_j^2 \partial_t \vec{e}_j e^{i(\beta_j \cdot y - \frac{1}{4}\gamma_j |y|^2)} + \gamma_j \beta_j \cdot \vec{e}_j - \frac{1}{4} \gamma_j^2 |y|^2 \vec{e}_j - 2i\beta_j \cdot \nabla \vec{e}_j - \vec{e}_j - |\beta_j|^2 \vec{e}_j + O((|y|^2|\vec{e}_j| + |y| |\nabla \vec{e}_j|) \text{Mod}_j) \).

Then, taking into account the identities, similarly to (4.29) and (4.30),
\[ \Lambda \vec{e}_j = (\Lambda e_j + i(\beta_j \cdot y - \frac{1}{2} \gamma_j |y|^2 e_j))e^{i(\beta_j \cdot y - \frac{1}{4}\gamma_j |y|^2)} , \]
\[ \nabla \vec{e}_j = (\nabla e_j + i(\beta_j - \frac{1}{2} \gamma_j y) e_j))e^{i(\beta_j \cdot y - \frac{1}{4}\gamma_j |y|^2)} , \]
we come to
\[ i\partial_t w = \lambda_j^{-2-\frac{\beta}{4}}e^{i\theta_j}(i\lambda_j^2 \partial_t e_j + i\gamma_j \Lambda e_j + |\beta_j - \frac{1}{2} \gamma_j y|^2 e_j - 2i\beta_j \cdot \nabla e_j - e_j + \Delta e_j - i\gamma_j \Lambda e_j - |\beta_j - \frac{1}{2} \gamma_j y|^2 e_j + 2i\beta_j \cdot \nabla e_j) e^{i(\beta_j \cdot y - \frac{1}{4}\gamma_j |y|^2)} . \]

Moreover, by (7.82), direct computations show that
\[ \Delta \vec{e}_j = (\Delta e_j - i\gamma_j \Lambda e_j - |\beta_j - \frac{1}{2} \gamma_j y|^2 e_j + 2i\beta_j \cdot \nabla e_j) e^{i(\beta_j \cdot y - \frac{1}{4}\gamma_j |y|^2)} . \]

Thus, combing (7.92) and (7.93) altogether we obtain that, after algebraic cancellations,
\[ i\partial_t w + \Delta w = \lambda_j^{-2-\frac{\beta}{4}}e^{i\theta_j}(i\lambda_j^2 \partial_t e_j - e_j + \Delta e_j + O((|y|^2|\vec{e}_j| + |y| |\nabla \vec{e}_j|) \text{Mod}_j) , \]
which along with (7.87) yields (7.88) and thus finishes the proof.

The contributions of the error terms $H_i$, $1 \leq l \leq 4$, are actually negligible, which is the content of Lemma 7.11 below.

**Lemma 7.11.** Let $E$ belong to the generalized kernels of the linearized operator $L$, i.e., $E \in \{ Q, yQ, |y|^2Q, \nabla Q, \Lambda Q, \rho \}$. Then, there exists $C > 0$, $\zeta, \delta \in (0, 1)$ such that
\[ \int |H_1(t, y)||E(y)|dy \leq C(T - t)^{3+\zeta} \|w\|_{L^2} , \]
\[ \int (|H_2(t, y)| + |H_3(t, y)|)|E(y)|dy \leq C e^{-\frac{\delta}{T - t}} \|w\|_{L^2} , \]
\[ |\int H_4(t, y)E(y)dy| \leq C(T - t)^{\nu + 1} \|w\|_{L^2} , \]
where $\nu$ is the flatness index of the spatial functions of noise in Assumption (A1).

**Proof.** We first see that, by (7.89),
\[ \int |H_1(t, y)||E(y)|dy \leq C(T - t)^{2-\frac{\beta}{4}} \int |G_1(t, x)E(x)\delta(t - x)\|dx. \]

Since by (3.18), (3.19) and (7.54),
\[ |G_1| \leq C(|U|^{\frac{\alpha_j}{2}} + |R|^{\frac{1}{2}})|R|w| + C(|U|^{\frac{1}{2}} + |R|^{\frac{1}{2}} + |w|^{\frac{1}{2}})|w|^2 , \]
Hence, similarly to (7.99), we get that for some \( \delta \) and thus (7.95) follows.

Moreover, since by (3.25), (7.82) and (7.85),

\[
|G_2(t,x)| \leq \sum_{l \neq j} |f'(U_l) \cdot w| \leq (T-t)^{-2-\frac{d}{2}}Q\left(\frac{x-\alpha_l}{\lambda_1}\right)|e_j(t, \frac{x-\alpha_j}{\lambda_j})|,
\]

we see from (7.89) that

\[
|H_2(t,y)| \leq C \sum_{l \neq j} Q\left(\frac{\lambda_j}{\lambda_l}y + \frac{\alpha_j - \alpha_l}{\lambda_l}\right)|e_j(t,y)|.
\]

This yields that

\[
\int |H_2(t,y)||E(y)|dy \leq C \sum_{l \neq j} \int Q\left(\frac{\lambda_j}{\lambda_l}y + \frac{\alpha_j - \alpha_l}{\lambda_l}\right)|e_j(y)||E(y)|dy
\]

\[
\leq C \sum_{l \neq j} e^{-\frac{\delta}{T-t}}\|e_j\|L^2 \leq Ce^{-\frac{\delta}{T-t}}\|w\|L^2,
\]

where \( \delta \in (0,1) \), and the second inequality is due to the exponential decay of the ground state \( Q \) and \( E \).

Similarly, by the definition of \( G_3 \) and (5.39), 1 \( \leq l \leq K \),

\[
|G_3(t,x)| \leq C(T-t)^{-2-\frac{d}{2}} \sum_{l \neq h} Q\left(\frac{x-\alpha_l}{\lambda_l}\right)Q\left(\frac{x-\alpha_h}{\lambda_h}\right)|e_j(t, \frac{x-\alpha_j}{\lambda_j})|,
\]

which along with (7.89) yields that

\[
|H_3(t,y)| \leq C \sum_{l \neq j} Q\left(\frac{\lambda_j}{\lambda_l}y + \frac{\alpha_j - \alpha_l}{\lambda_l}\right)|e_j(t,y)|.
\]

Hence, similarly to (7.99), we get that for some \( \delta \in (0,1) \),

\[
\int |H_3(t,y)||E(y)|dy \leq Ce^{-\frac{\delta}{T-t}}\|w\|L^2
\]

and thus (7.95) follows.

Regarding \( H_4 \), in view of (7.86), (7.89) and (7.91), we obtain

\[
H_4(t,y) = \lambda_j \tilde{b} \cdot (\nabla e_j + i(\beta_j - \frac{1}{2}\gamma_jy)e_j) + \lambda_j^2 \tilde{c}e_j,
\]

where \( \tilde{b}(t,y) = b(t, \lambda_jy + \alpha_j), \tilde{c}(t,y) = c(t, \lambda_jy + \alpha_j) \). Using integration by parts formula we have

\[
\int \tilde{b} \cdot \nabla e_j Edy = - \int \text{div} \tilde{b} E e_j dy - \int \tilde{b} \cdot \nabla E e_j dy,
\]

then using Hölder’s inequality, (2.12), (2.13) and (4.23) we obtain (7.96) and finish the proof.

By virtue of the identities in (3.11) and Lemmas 7.10 and 7.11 we are now able to control the growth of \( e_j \) along the remaining five unstable directions as stated in Proposition 7.12 below.
Proposition 7.12. Let $e_j$ be as in (7.82) and $e_{j,1} := \text{Re} e_j$, $e_{j,2} := \text{Im} e_j$. Then, for $1 \leq j \leq K$ and for $T$ small enough we have

\begin{align}
(7.100) \quad & \frac{d}{dt} \langle e_{j,2}, \Lambda Q \rangle = 2\lambda_j^{-2} \langle e_{j,1}, Q \rangle + O((T-t)^{2+\varsigma} \sqrt{D(t)}), \\
(7.101) \quad & \frac{d}{dt} \langle e_{j,1}, |y|^2 Q \rangle = -4\lambda_j^{-2} \langle e_{j,2}, \Lambda Q \rangle + O((T-t)^{2+\varsigma} \sqrt{D(t)}), \\
(7.102) \quad & \frac{d}{dt} \langle e_{j,2}, \rho \rangle = \lambda_j^{-2} \langle e_{j,1}, |y|^2 Q \rangle + O((T-t)^{2+\varsigma} \sqrt{D(t)}), \\
(7.103) \quad & \frac{d}{dt} \langle e_{j,2}, \nabla Q \rangle = O((T-t)^{2+\varsigma} \sqrt{D(t)}), \\
(7.104) \quad & \frac{d}{dt} \langle e_{j,1}, y \rangle = -2\lambda_j^{-2} \langle e_{j,2}, \nabla Q \rangle + O((T-t)^{2+\varsigma} \sqrt{D(t)}),
\end{align}

Proof. Let us take $\frac{d}{dt} \langle e_{j,2}, \Lambda Q \rangle$ as an example to illustrate the arguments. Using equation (7.88) we have

\begin{equation}
\frac{d}{dt} \langle e_{j,2}, \Lambda Q \rangle = \lambda_j^{-2} \text{Re} \int \Lambda Q (\Delta e_j - e_j + (1 + \frac{2}{d})Q \nabla e_j + \frac{2}{d} \rho e_j - \frac{2}{d} Q e_j) dy \\
+ \lambda_j^{-2} \sum_{l=1}^{4} O(\int \Lambda Q H_l dy) + \lambda_j^{-2} \text{Mod}_j O(\int \Lambda Q (\langle y \rangle^2 |\nabla e_j| + \langle y \rangle |\nabla \tilde{e}_j|) dy). 
\end{equation}

Note that, by the definition (3.9) of the operator $L$, the integration by parts formula and the identity $L_+ \Lambda Q = -2Q$ in (3.11),

\begin{equation}
\text{Re} \int \Lambda Q (\Delta e_j - e_j + (1 + \frac{2}{d})Q \nabla e_j + \frac{2}{d} \rho e_j - \frac{2}{d} Q e_j) dy = - \int \Lambda Q L_+ e_{j,1} dy = 2 \int Q e_{j,1} dy.
\end{equation}

Moreover, using Lemma (7.11) and (7.38) we infer that for each $1 \leq l \leq 4$,

\begin{equation}
\lambda_j^{-2} \left| \int \Lambda Q H_l dy \right| \leq C(T-t)^{1+\varsigma} \|w\|_{L^2} \leq C(T-t)^{2+\varsigma} \sqrt{D(t)}.
\end{equation}

We also note from Lemma (7.3) that $\text{Mod}(t) \leq C(T-t)^{\kappa+3} \leq C(T-t)^{3+\varsigma}$. Then, using Hölder’s inequality, the boundedness of $\|\langle y \rangle^2 \Lambda Q\|_{L^2}$ and

\begin{equation}
\|\tilde{e}_j\|_{L^2} + \|\nabla \tilde{e}_j\|_{L^2} \leq C(\|w\|_{L^2} + \lambda_j \|\nabla w\|_{L^2}) \leq C(T-t) \sqrt{D(t)},
\end{equation}

we get

\begin{equation}
\lambda_j^{-2} \text{Mod}_j \left| \int \Lambda Q (\langle y \rangle^2 |\nabla e_j| + \langle y \rangle |\nabla \tilde{e}_j|) dy \right| \leq C(T-t)^{1+\varsigma} \|\langle y \rangle^2 \Lambda Q\|_{L^2} (\|\tilde{e}_j\|_{L^2} + \|\nabla \tilde{e}_j\|_{L^2}) \\
\leq C(T-t)^{2+\varsigma} \sqrt{D(t)}.
\end{equation}

Thus, plugging (7.106)-(7.108) into (7.105) yields immediately (7.102). For simplicity, the details are omitted here.

We are now ready to prove the key estimate (7.72) in Theorem 7.7.

Proof of Theorem 7.7. Similarly to (7.39), we define the growth quantity associated to $e_j$ by

\begin{equation}
\text{Scal}_j(t) := \langle e_{j,1}, Q \rangle^2 + \langle e_{j,1}, y Q \rangle^2 + \langle e_{j,1}, |y|^2 Q \rangle^2 + \langle e_{j,2}, \nabla Q \rangle^2 + \langle e_{j,2}, \Lambda Q \rangle^2 + \langle e_{j,2}, \rho \rangle^2.
\end{equation}

As we shall see below, the two renormalized variables $\epsilon_j$ and $\tilde{\epsilon}_j$ defined in (7.36) and (7.82) respectively are almost the same up to the negligible error of order $O(P + e^{-\frac{\delta}{T-t}})$, and thus the two quantities $\text{Scal}_j$ and $\tilde{\text{Scal}}_j$ should be close to each other.

We first claim that for some $\zeta > 0$,

$$\tilde{\text{Scal}}_j(t) = \frac{C}{(T-t)^{2+\zeta}} \sup_{t \leq s < T} D(s).$$  (7.110)

To this end, we use Proposition 7.8 and the change of variables to get

$$|\langle e_{j,1}, Q \rangle| \leq \frac{C}{(T-t)^{2+\zeta}} \sup_{t \leq s < T} \sqrt{D(s)},$$  (7.111)

which along with (7.100) yields that

$$|\frac{d}{dt} \langle e_{j,2}, \Lambda Q \rangle| \leq \frac{C}{(T-t)^{2+\zeta}} \sup_{t \leq s < T} \sqrt{D(s)}.$$  (7.112)

Since by (7.35), $\lim_{t \to T} \|w(t)\|_{H^1} = 0$, we infer that

$$\lim_{t \to T} \langle e_{j,1}(t), \Lambda Q \rangle = 0.$$  (7.113)

This yields that

$$|\langle e_{j,2}, \Lambda Q \rangle| \leq \int_t^T |\frac{d}{ds} \langle e_{j,2}, \Lambda Q \rangle| ds \leq \frac{C}{(T-t)^{3+\zeta}} \sup_{t \leq s < T} \sqrt{D(s)}.$$  (7.114)

Then, plugging (7.113) into (7.101) yields

$$|\langle e_{j,1}, |y|^2Q \rangle| \leq \frac{C}{(T-t)^{2+\zeta}} \sup_{t \leq s < T} \sqrt{D(s)},$$  (7.115)

which along with (7.102) yields

$$|\langle e_{j,2}, \rho \rangle| \leq \frac{C}{(T-t)^{1+\zeta}} \sup_{t \leq s < T} \sqrt{D(s)}.$$  (7.116)

We also see from (7.103) that

$$|\langle e_{j,2}, \nabla Q \rangle| \leq \frac{C}{(T-t)^{3+\zeta}} \sup_{t \leq s < T} \sqrt{D(s)},$$  (7.117)

which along with (7.104) yields that

$$|\langle e_{j,1}, yQ \rangle| \leq \frac{C}{(T-t)^{2+\zeta}} \sup_{t \leq s < T} \sqrt{D(s)}.$$  (7.118)

Thus, combining estimates (7.111)-(7.117) altogether we obtain (7.110), as claimed.

Next we show that there exist $C, \delta > 0$ such that

$$\text{Scal}_j(t) = \frac{C}{(T-t)^{2+\zeta}} \sup_{t \leq s < T} D(s).$$  (7.119)

Then, taking into account (7.23), (7.38) and (7.110) we obtain (7.72).

It remains to prove (7.118). For this purpose, by (7.2) (7.34), (7.82) and the change of variables,

$$\text{Re} \langle e_j, Q \rangle = \text{Re} \langle w, U_j \rangle = \text{Re} \langle w_j, U_j \rangle + \sum_{l \neq j} \text{Re} \langle w_l, U_j \rangle.$$  (7.120)

Using Lemma 3.1 to decouple $w_l$ and $U_j$, $l \neq j$, and then using (7.36) we get

$$\text{Re} \langle e_j, Q \rangle = \text{Re} \langle w_j, U_j \rangle + O(e^{-\frac{\delta}{T-t}} \|w\|_{L^2}) = \text{Re} \langle e_j, Q_j \rangle + O(e^{-\frac{\delta}{T-t}} \|w\|_{L^2}),$$  (7.121)
where \( Q_j \) is given by (7.28). Then, using the fact

\[
Q_j = Q + O(P(y)^2 Q),
\]

we arrive at

\[
\text{Re}(\epsilon_j, Q) = \text{Re}(\epsilon_j, Q) + O(P + e^{-\frac{s}{T}})\|w\|_{L^2}.
\]

Similar arguments with slight modifications also yield that

\[
\text{Re}(\epsilon_j, yQ) = \text{Re}(\epsilon_j, yQ) + O(P + e^{-\frac{s}{T}})\|w\|_{L^2},
\]

\[
\text{Re}(\epsilon_j, |y|^2 Q) = \text{Re}(\epsilon_j, |y|^2 Q) + O(P + e^{-\frac{s}{T}})\|w\|_{L^2},
\]

and taking into account \( \rho_j = \rho + O(P(y)^2 \rho) \) we also have

\[
\text{Re}(\epsilon_j, \rho) = \text{Re}(\epsilon_j, \rho) + O(P + e^{-\frac{s}{T}})\|w\|_{L^2}.
\]

Regarding \( \text{Im}(\Lambda Q, \epsilon_j) \), using the change of variables and the identity (4.29) we have

\[
\text{Im}(\epsilon_j, \Lambda Q) = \text{Im} \int \overline{\epsilon_j \Lambda Q} e^{i(\beta_j y - \frac{1}{2} y_j |y|^2)} dy
\]

\[
= \text{Im} \int w(\Lambda U_j + i(\beta_j \cdot \left( \frac{x - \alpha_j}{\lambda_j} \right) - \frac{1}{2} \gamma_j \left| \frac{x - \alpha_j}{\lambda_j} \right|^2 \overline{U_j}) dx
\]

\[
= \text{Im} \int w_j(\Lambda U_j + i(\beta_j \cdot \left( \frac{x - \alpha_j}{\lambda_j} \right) - \frac{1}{2} \gamma_j \left| \frac{x - \alpha_j}{\lambda_j} \right|^2 \overline{U_j}) dx + O(e^{-\frac{s}{T}})\|w\|_{L^2},
\]

where in the last step we also used Lemma 3.1 to decouple the different profiles \( w_j \) and \( U_j \), \( l \neq j \), which merely contribute the exponentially small error. Then, using again (4.29), \( (7.36) \), the change of variables and (7.119) we obtain

\[
\text{Im}(\epsilon_j, \Lambda Q) = \text{Im} \int \overline{\epsilon_j \Lambda Q} e^{i(\beta_j y - \frac{1}{2} y_j |y|^2)} dy + O(e^{-\frac{s}{T}})\|w\|_{L^2})
\]

\[
= \text{Im}(\epsilon_j, \Lambda Q) + O(P + e^{-\frac{s}{T}})\|w\|_{L^2}.
\]

Using similar arguments, but with the identity (4.30) instead, we also have

\[
\text{Im}(\epsilon_j, \nabla Q) = \text{Im} \int \overline{\epsilon_j \nabla Q} e^{i(\beta_j y - \frac{1}{2} y_j |y|^2)} dy + O(P + e^{-\frac{s}{T}})\|w\|_{L^2}.
\]

Therefore, combining estimates (7.120), (7.121), (7.122), (7.123), (7.124) and (7.125) altogether we obtain (7.118) and thus finish the proof of Theorem 7.7. \( \Box \)

**Proof of Theorem 2.7** First take any \( \varepsilon \in (0, \varepsilon^*) \), where \( \varepsilon^* \) is sufficiently small and is to be specified later. Then, let \( T \) be sufficiently small and satisfy (7.1). We shall use iteration arguments to show that \( D \equiv 0 \).

By Theorem 7.6 we have for any \( t \in [0, T) \),

\[
\sup_{t \leq s < T} D(s) \leq C_1 \sup_{t \leq s < T} \sum_{j=1}^{K} \frac{Scal_j(s)}{\lambda_j^2(s)} + C_1 \int_{t}^{T} \sum_{j=1}^{K} \frac{Scal_j(s)}{\lambda_j^2(s)} + \varepsilon^* D(s) \frac{T}{T - s} ds.
\]

Then, in view of Theorem 7.4 and (7.35) we obtain that for some \( \zeta > 0 \),

\[
\sup_{t \leq s < T} D(s) \leq C_2(T - t)^{\zeta} \sup_{t \leq s < T} D(s) + C_2 \varepsilon^* \int_{t}^{T} \frac{D(s)}{T - s} ds,
\]

\[ \tag{7.127} \]
where $C_2$ is independent of $\varepsilon^*$. This yields that for $T$ even smaller such that $C_2T^\zeta \leq \frac{1}{2}$,

\begin{equation}
(7.128) \quad \sup_{t \leq s < T} D(s) \leq 2C_2\varepsilon^* \int_t^T \frac{D(s)}{T-s} ds.
\end{equation}

We also infer from (7.35) and (7.37) that

\begin{equation}
(7.129) \quad D(s) \leq C_3(T-s)^{4+\zeta},
\end{equation}

where we may take $C_3 \geq 1$, independent of $\varepsilon^*$.

Then, plugging this into (7.128) we get

\begin{equation}
(7.130) \quad \sup_{t \leq s < T} D(s) \leq 2C_2C_3\varepsilon^* (T-t)^{4+\zeta}.
\end{equation}

But, plugging (7.129) into (7.128) again we can obtain the refined estimate

\begin{equation}
(7.131) \quad \sup_{t \leq s < T} D(s) \leq \left(\frac{2C_2C_3\varepsilon^*}{4+\zeta}\right)^k (T-t)^{4+\zeta}.
\end{equation}

Thus, iterating similar arguments we infer that for any $k \geq 1$,

\begin{equation}
(7.132) \quad \sup_{t \leq s < T} D(s) \leq \left(\frac{2C_2C_3\varepsilon^*}{4+\zeta}\right)^k (T-t)^{4+\zeta} \leq \left(\frac{2C_2C_3\varepsilon^*}{4+\zeta}\right)^k,
\end{equation}

where $C_2, C_3 > 0$ are independent of $\varepsilon^*$ and $k$.

Therefore, taking $\varepsilon^*$ small enough such that $\frac{2C_2C_3\varepsilon^*}{4+\zeta} < 1$ and using the arbitrariness of $k$ we infer that $D(t) = 0$ for any $t \in [0, T)$, which yields immediately that $w \equiv 0$, and thus $v \equiv u$. The proof of Theorem 2.7 is complete. \hfill \Box

8. Appendix

Proof of Lemma 3.1. First, using (3.4) and the separation of $\{x_j\}_{j=1}^K$ we have that for any $t^* \leq t < T^*$,

\begin{equation}
(8.1) \quad |(\alpha_j(t) - \alpha_l(t)) \cdot \nu_1| \geq 10\sigma, \quad j \neq l,
\end{equation}

where $\sigma$ is given by (3.1). Note that

\begin{equation}
(8.2) \quad \max_{1 \leq j \neq l \leq K} \frac{\lambda_j(t)}{\lambda_l(t)} \leq c_* := 4 \max_{1 \leq j \neq l \leq K} \frac{\omega_j}{\omega_l}, \quad \max_{1 \leq j \neq l \leq K} |\alpha_j - \alpha_l| \leq 2M := 2(1 + \max_{1 \leq j \leq K} |x_j|).
\end{equation}

In order to prove (3.6), we note that

\begin{align*}
&\int_{\mathbb{R}^d} |x - \alpha_l|^n \partial^\nu G_l(t) ||x - \alpha_l|^m G_j(t)| dx \\
\leq &\ C(T-t)^{-|\nu|+m+n-d} \int_{\mathbb{R}^d} |x - \alpha_l|^n \frac{x - \alpha_j}{\lambda_j} \partial^\nu g_l(t, \frac{x - \alpha_l}{\lambda_l}) ||g_l(t, \frac{x - \alpha_j}{\lambda_j})| dx \\
\leq &\ C(T-t)^{-|\nu|+m+n} \int |\frac{\lambda_j y + \alpha_j - \alpha_l}{\lambda_l} y^n \partial^\nu g_l(t, \frac{\lambda_j y + \alpha_j - \alpha_l}{\lambda_l}) ||g(y)| dy.
\end{align*}

Using (7.1) we have

\begin{equation}
|\frac{\lambda_j y + \alpha_j - \alpha_l}{\lambda_l} y^n | \leq C( |y^n + (T-t)^{-n}M^n |) \leq C(T-t)^{-2n} |y|^n.
\end{equation}
It follows that

$$\left| \int_{\mathbb{R}^d} |x - \alpha_i|^n |\partial^\nu g(t) ||x - \alpha_j|^m |G_j(t)| \, dx \right|$$

$$\leq C(T - t)^{-|\nu| + m - n} \left( \int_{|y \cdot \nu_1| \leq \frac{5\sigma}{\epsilon + \lambda_i y} \nu} + \int_{|y \cdot \nu_1| \geq \frac{5\sigma}{\epsilon + \lambda_i y}} \right) (y)^{m+n} |\partial^\nu g(t, \frac{\lambda_i y + \alpha_j - \alpha_i}{\lambda_i}) ||g(y)|| \, dy.$$  

On one hand, in the region \( \{ y \in \mathbb{R}^d : |y \cdot \nu_1| \leq \frac{5\sigma}{\epsilon + \lambda_i y} \} \), by (8.1) and (8.2),

$$\frac{\lambda_i y + \alpha_j - \alpha_i}{\lambda_i} \geq \frac{(\alpha_j - \alpha_i) \cdot \nu_1}{\lambda_i} - \frac{\lambda_i (y \cdot \nu_1)}{\lambda_i} \geq \frac{5\sigma}{\lambda_i} \to \infty, \text{ as } T \to 0.$$  

Then, in view of the exponential decay of \( \partial_v g \), we obtain that

$$\left( T - t \right)^{-|\nu| + m - n} \int_{|y \cdot \nu_1| \geq \frac{5\sigma}{\epsilon + \lambda_i y}} (y)^{m+n} |\partial^\nu g(t, \frac{\lambda_i y + \alpha_j - \alpha_i}{\lambda_i}) ||g(y)|| \, dy$$

$$\leq C(T - t)^{-|\nu| + m - n} e^{-\frac{\delta_1}{T^\nu}} \| (y)^{m+n} g \|_{L^1} \leq C e^{-\frac{\delta_1}{T^\nu}},$$

where \( \delta_1 > 0 \), and we also used \( \sup_{T > \sigma} r^{-|\nu| + m - n} e^{-\frac{\delta_1}{r}} < \infty \) in the last step. On the other hand, in the region \( \{ y : |y \cdot \nu_1| \geq \frac{5\sigma}{\epsilon + \lambda_i y} \} \), \( |y| \geq |y \cdot \nu_1| \geq \frac{5\sigma}{\epsilon + \lambda_i y} \to \infty, \) as \( t \to T \). Using the change of variables and the exponential decay of \( g \) we get

$$\left( T - t \right)^{-|\nu| + m - n} \int_{|y \cdot \nu_1| \geq \frac{5\sigma}{\epsilon + \lambda_i y}} (y)^{m+n} |\partial^\nu g(t, \frac{\lambda_i y + \alpha_j - \alpha_i}{\lambda_i}) ||g(y)|| \, dy$$

$$\leq C(T - t)^{-|\nu| + m - n} e^{-\frac{\delta_2}{T^\nu}} \| (y)^{m+n} g \|_{L^1} \| \partial^\nu g \|_{L^1} \leq C e^{-\frac{\delta_2}{T^\nu}},$$

where \( \delta_2 > 0 \). Thus, combining the estimates above we obtain (3.6).

Regarding (3.7), since for \( j \neq l \), \( |(x - x_l) \cdot \nu_1| \geq 3\sigma \) on the support of \( \Phi_j \), we infer from (3.4) that \( |(x - \alpha_l) \cdot \nu_1| \geq 3\sigma \). Then, using the change of variables and the inequality

$$\left| \frac{\lambda_i y + \alpha_j - \alpha_i}{\lambda_j} \right|^m \leq C M (T - t)^{-m} \langle y \rangle^m \leq C(T - t)^{-2m} \langle y \rangle^m$$

we get

$$\left| \int_{\mathbb{R}^d} |x - \alpha_l|^n |\partial^\nu g(t) ||x - \alpha_j|^m |h| \Phi_j \, dx \right|$$

$$\leq C(T - t)^{-|\nu| + m + n - \frac{d}{2}} \int_{|(x-x_l) \cdot \nu_1| \geq 4\sigma} \frac{|x - \alpha_l|^n |\partial^\nu g(t, \frac{x - \alpha_j}{\lambda_j})|}{\lambda_i} \frac{x - \alpha_j}{\lambda_j} |h(x)| \, dx$$

$$\leq C(T - t)^{-|\nu| - m + n + \frac{d}{2}} \int_{|y \cdot \nu_1| \geq \frac{5\sigma}{\epsilon + \lambda_i y}} (y)^{m+n} |\partial^\nu g(t, y)||h(\lambda_i y + \alpha_i)| \, dy. \quad (8.3)$$

Then, using Cauchy’s inequality and the exponential decay of \( \partial^\nu g \) again we obtain that for \( t \) close to \( T \), the right-hand-side of (8.3) is bounded by

$$C(T - t)^{-|\nu| - m + n + \frac{d}{2}} e^{-\frac{\delta_3}{T^\nu}} \| (y)^{m+n} |\partial^\nu g| \|_{L^1} \| h \|_{L^2} \leq C e^{-\frac{\delta_3}{T^\nu}} \| h \|_{L^2},$$

$$
\begin{align*}
C(T - t)^{-|\nu| - m + n + \frac{d}{2}} & e^{-\frac{\delta_3}{T^\nu}} \| (y)^{m+n} |\partial^\nu g| \|_{L^1} \| h \|_{L^2} \\
& \leq C e^{-\frac{\delta_3}{T^\nu}} \| h \|_{L^2},
\end{align*}
$$

66
where $\delta_3 > 0$ and in the last step we also used $\sup_{r > 0} r^{-|\nu| - m + n} e^{-\frac{\delta_3}{r}} < \infty$. One can also bound the right-hand-side of (8.3) by

$$C(T - t)^{-|\nu| - m + n} e^{-\frac{\delta_3}{t}} \|y\|^{m+n} |\partial^\nu g_l|\frac{1}{2} \|L^\infty \int h(\lambda_l + \alpha_l) dy$$

$$\leq C(T - t)^{-|\nu| - m + n} e^{-\frac{\delta_3}{t}} \|y\|^{m+n} |\partial^\nu g_l|\frac{1}{2} \|L^\infty \|h\|_{L^1} \leq C e^{-\frac{\delta_3}{t}} \|h\|_{L^1}.$$

Hence, combining the two estimates together we obtain (3.7), thereby finishing the proof of Lemma 3.1.\Box

**Proof of Corollary 3.4.** Let $\tilde{f} := f \phi_A^\frac{1}{2}$. Since $\nabla f \phi_A^\frac{1}{2} = \nabla \tilde{f} - \frac{\nabla \phi_A}{\phi_A} \tilde{f}$, we have

$$\int (|\nabla f|^2 + |f|^2) \phi_A - (1 + \frac{4}{d}) Q^\frac{2}{d} f_1^2 - Q^\frac{2}{d} f_2^2 dx$$

$$= \int |\nabla \tilde{f}|^2 + |\tilde{f}|^2 - (1 + \frac{4}{d}) Q^\frac{2}{d} f_1^2 - Q^\frac{2}{d} f_2^2 dx$$

$$- \int (1 - \phi_A)((1 + \frac{4}{d}) Q^\frac{2}{d} f_1^2 + Q^\frac{2}{d} f_2^2) dx$$

$$+ \frac{4}{4} \int |\nabla \phi_A| |\tilde{f}|^2 dx - \text{Re} \int \frac{\nabla \phi_A}{\phi_A} \cdot \nabla \tilde{f} dx =: \sum_{i=1}^4 K_i.$$

Using Corollary 3.3, we have

$$K_1 \geq C_1' \|\tilde{f}\|_{L^1}^2 - C_2' \text{Scal}(\tilde{f}),$$

where $C_1', C_2' > 0$. Moreover, we claim that there exist $C, \delta > 0$ such that

$$\text{Scal}(\tilde{f}) \leq \text{Scal}(f) + C e^{-\delta A} \|\tilde{f}\|_{L^2}^2.$$

To this end, we see that

$$\langle \tilde{f}_1, Q \rangle = \langle f_1, Q \rangle + \langle \tilde{f}_1 \phi_A^{-\frac{1}{2}} (\phi_A^{-\frac{1}{2}} - 1), Q \rangle.$$  

Since on the support of $\phi_A^\frac{1}{2} - 1$, $|x| \geq A$, by the exponential decay of $Q$ we have that for some $\delta' > 0$

$$|\phi_A^{-\frac{1}{2}}(x) Q^\frac{1}{2}(x)| \leq C e^{-\frac{\delta}{|x|} (\delta' - A - 1)} \leq C e^{-\frac{\delta}{\delta'} A}, \quad |x| \geq A,$$

where we also took $A$ large enough such that $\delta' - A - 1 \geq \frac{1}{2} A$. It follows that

$$|\langle f_1 \phi_A^{-\frac{1}{2}} (\phi_A^{-\frac{1}{2}} - 1), Q \rangle| \leq C \|\tilde{f}\|_{L^2} \|\phi_A^{-\frac{1}{2}} Q^\frac{1}{2} \|_{L^\infty (|x| \geq A)} \|Q^\frac{1}{2} \|_{L^2} \leq C e^{-\frac{\delta}{\delta'} A} \|\tilde{f}\|_{L^2},$$

which yields that

$$|\langle \tilde{f}_1, Q \rangle - \langle f_1, Q \rangle| \leq C e^{-\frac{\delta}{\delta'} A} \|\tilde{f}\|_{L^2}.$$

Similar arguments apply also to the remaining five scalar products in $\text{Scal}(f)$, and thus we obtain (8.6), as claimed.

Hence, we infer from (8.5) and (8.6) that for $C_1, C_2 > 0$,

$$K_1 \geq C_1 \|\tilde{f}\|_{L^1}^2 - C_2 \text{Scal}(f).$$

Regarding the second term $K_2$, we see that

$$K_2 = \int (1 - \phi_A) \phi_A^{-\frac{1}{2}} ((1 + \frac{4}{d}) Q^2 f_1^2 + Q^2 f_2^2) dx \leq C \|\phi_A^{-1} Q^2 \|_{L^\infty (|x| \geq A)} \|\tilde{f}\|_{L^2}.$$
Similar arguments as in the proof of (8.7) yield that for $A$ large enough $\|\phi_A^{-1}Q^2\|_{L^\infty(|x|\geq A)} \leq C e^{-\delta A}$, where $C, \delta > 0$. This implies that for $A$ large enough

$$K_2 \leq Ce^{-\delta A}\|\tilde{f}\|_{L^2}.$$  

We also note that, since $|\sum_{\phi_A}\phi_A| \leq CA^{-1}$, by Hölder’s inequality,

$$K_3 + K_4 \leq \frac{C}{A}\|\tilde{f}\|_{H^1}^2.$$  

Thus, plugging (8.8), (8.10) and (8.11) into (8.4), we obtain that for $A$ large enough

$$\int (|\nabla f|^2 + |f|^2)\phi_A - (1 + \frac{4}{d})Q^2 f_1^2 - Q^2 f_2^2 \geq \frac{C}{2}\|\tilde{f}\|_{H^1}^2 - C2 Scal(f).$$

It remains to show that for $A$ large enough,

$$\frac{C_1}{2}\|\tilde{f}\|_{H^1}^2 \geq \frac{C_1}{8} \int (|\nabla f|^2 + |f|^2)\phi_A dx.$$  

To this end, since $\nabla \tilde{f} = \nabla f\phi_A + \sum_{\phi_A} \nabla \phi_A \tilde{f}$ we have

$$\frac{C_1}{2}\|\tilde{f}\|_{H^1}^2 = \frac{C_1}{2} \int |f|^2 \phi_A dx + \frac{C_1}{2} \int |\nabla f\phi_A + \frac{1}{2}\phi_A \tilde{f}|^2 dx$$

$$= \frac{C_1}{2} \int (|f|^2 + |\nabla f|^2)\phi_A dx + \frac{C_1}{2} \int \text{Re}(\nabla f\phi_A + \frac{\nabla \phi_A}{\phi_A} \tilde{f}) dx + \frac{C_1}{8} \int \frac{|\nabla \phi_A |}{\phi_A} \tilde{f}^2 dx.$$  

Note that, by Hölder’s inequality and $|\sum_{\phi_A}\phi_A| \leq CA^{-1}$,

$$|\frac{C_1}{2} \int \text{Re}(\nabla f\phi_A + \frac{\nabla \phi_A}{\phi_A} \tilde{f}) dx| \leq \frac{C_1}{2} \int |\nabla f|^2 \phi_A dx + \frac{C_1 C}{2A} \int \frac{|\nabla \phi_A|^2}{\phi_A} \tilde{f}^2 dx + \frac{4C_1 C^2}{A^2} \int |f|^2 \phi_A dx.$$  

We also have

$$\frac{C_1}{8} \int \frac{|\nabla \phi_A |}{\phi_A} \tilde{f}^2 dx \leq \frac{C_1 C^2}{2A^2} \int |f|^2 \phi_A dx.$$  

Therefore, combining (8.12)-(8.16) and taking $A$ large enough such that $\frac{4C^2}{A^2} + \frac{C^2}{2A^2} \leq \frac{1}{8}$ we obtain (8.13), as claimed. This along with (8.12) yields (8.17).  

**Proof of Lemma 5.5** Using (4.14) and (5.16) we have

$$\|\partial^\nu \eta\|_{L^2} \leq C(T - t)^{-2 - |\nu|} Mod + \sum_{j=1}^K \|\partial^\nu (b \cdot \nabla U_j + c U_j)\|_{L^2} + \|\partial^\nu (f(U) - \sum_{j=1}^K f(U_j))\|_{L^2}.$$  

Note that,

$$\|\partial^\nu (b \cdot \nabla U_j)\|_{L^2} = \sum_{\nu_1 + \nu_2 = \nu} \|\partial^{\nu_1} b \cdot \partial^{\nu_2} \nabla U_j\|_{L^2}$$

$$\leq C(T - t)^{-|\nu_1|-1} \sum_{j=1}^K \left( \int |(\partial^{\nu_1} b)(\lambda_j y + \alpha_j)\partial^{\nu_2} \nabla Q_j(y)|^2 dy \right)^{\frac{1}{2}}.$$  

Since by (2.12) and (4.23),

$$|\partial^{\nu_1} b(\lambda_j y + \alpha_j)| \leq C(T - t)^{\nu_1 - |\nu_1|} \langle y \rangle^{\nu_1 + 1}.$$
This yields that
\[
(8.18) \quad \| \partial^\nu (b \cdot \nabla U_j) \|_{L^2} \leq C(T-t)^{\nu_*-|\nu|-1}.
\]

Similarly, using (2.13) and (4.23) again we also have
\[
(8.19) \quad \| \partial^\nu (cU_j) \|_{L^2} \leq C(T-t)^{\nu_*-|\nu|-1}.
\]

Moreover, we have that for $T$ small enough,
\[
(8.20) \quad \| \partial^\nu (f(U) - \sum_{j=1}^K f(U_j)) \|_{L^2} \leq C(T-t)^{-\frac{3}{2} + \frac{d}{2}} \sum_{k \neq l} \int |U_k||U_l| dx \leq C(T-t)^{\nu_*-|\nu|-1}.
\]

Therefore, plugging (8.18), (8.19) and (8.20) into (8.17) we arrive at
\[
\| \partial^\nu \eta \|_{L^2} \leq C(T-t)^{-2-|\nu| \text{ Mod} + C(T-t)^{\nu_*-|\nu|-1},
\]
which, via (5.14) and $\nu_* = \kappa + 3$, yields (5.17) immediately. The proof is complete. \qed

ACKNOWLEDGEMENTS

The authors would like to thank Prof. Daomin Cao and Prof. Michael R"ockner for valuable comments to improve the manuscript. Y. Su is supported by NSF C (No. 11601482) and D. Zhang is supported by NSFC (No. 11871337). Financial support by the Key Laboratory of Scientific and Engineering Computing (Ministry of Education) is also gratefully acknowledged.
