**Keywords**: Gram-negative, rod-shaped, non-sporulating, non-motile, mesophile, strictly anaerobic, chemoorganotrophic, *Rikenellaceae*, GEBA

*Alistipes finegoldii* Rautio et al. 2003 is one of five species of *Alistipes* with a validly published name: family *Rikenellaceae*, order *Bacteroidetes*, class *Bacteroidia*, phylum *Bacteroidetes*. This rod-shaped and strictly anaerobic organism has been isolated mostly from human tissues. Here we describe the features of the type strain of this species, together with the complete genome sequence, and annotation. *A. finegoldii* is the first member of the genus *Alistipes* for which the complete genome sequence of its type strain is now available. The 3,734,239 bp long single replicon genome with its 3,302 protein-coding and 68 RNA genes is part of the *Genomic Encyclopedia of Bacteria and Archaea* project.

**Introduction**

Strain AHN2437\(^T\) (= DSM 17242 = CCUG 46020 = JCM 16770) is the type strain of *Alistipes finegoldii* [1,2]. This strain is one of several strains with similar properties [3] that were isolated mainly from pediatric patients with inflamed, gangrenous or non-inflamed appendices [4,5]. Though the type strain AHN2437\(^T\) resembled members of the *Bacteroides fragilis* group in bile-resistance and positive indole reaction, it was found, together with the type strain of *Bacteroides putredinis*, to form a separate phylogenetic lineage apart from authentic *Bacteroides* species [1]. The genus *Alistipes* was established to accommodate these two species and has subsequently been enlarged to encompass three additional species with validly published names and one with an effectively published name [6,7]. According to the position in the ‘The All-Species Living Tree’ 16S rRNA gene sequence dendrogram [8], the genus *Alistipes* is a sister clade of *Rikenella microfusus*, formerly *Bacteroides microfusus* [9,10], the two genera constituting the family *Rikenellaceae* [11,12]. Here we present a summary classification and a set of features for *A. finegoldii* AHN2437\(^T\) together with the description of the complete genomic sequencing and annotation.
Classification and features

16S rDNA gene sequence analysis

A representative genomic 16S rRNA gene sequence of *A. finegoldii* AHN2437T was compared using NCBI BLAST [13,14] under default settings (e.g., considering only the high-scoring segment pairs (HSPs) from the best 250 hits) with the most recent release of the Greengenes database [15] and the relative frequencies of taxa and keywords (reduced to their stem [16]) were determined, weighted by BLAST scores. The most frequently occurring genera were *Alistipes* (84.4%) and *Bacteroides* (15.6%) (19 hits in total). Regarding the three hits to sequences from members of the species, the average identity within HSPs was 98.7%, whereas the average coverage by HSPs was 98.0%. Regarding the nine hits to sequences from other members of the genus, the average identity within HSPs was 96.5%, whereas the average coverage by HSPs was 100.1%. Among all other species, the one yielding the highest score was *Alistipes shahii* (AB554233), which corresponded to an identity of 97.2% and an HSP coverage of 100.0%. (Note that the Greengenes database uses the INSDC (= EMBL/NCBI/DDBJ) annotation, which is not an authoritative source for nomenclature or classification.) The highest-scoring environmental sequence was AY643083 (Greengenes short name 'Isolation finegoldii blood two patients colon cancer *Alistipes finegoldii*; clone 3'), which showed an identity of 100.0% and an HSP coverage of 99.4%. The most frequently occurring keywords within the labels of all environmental samples which yielded hits were 'human' (11.5%), 'fecal' (11.5%), 'intestin' (5.5%), 'biopsi' (4.2%) and 'mucos' (4.0%) (231 hits in total). The most frequently occurring keywords within the labels of those environmental samples which yielded hits of a higher score than the highest scoring species were 'finegoldii' (18.2%), 'alistip, blood, cancer, colon, isol, patient, two' (9.1%) and 'fecal, human' (9.1%) (2 hits in total). These keywords are in accordance with the original isolation source of *A. finegoldii*.

Figure 1 shows the phylogenetic neighborhood of *A. finegoldii* in a 16S rRNA gene based tree. The sequences of the two 16S rRNA gene copies in the genome differ from each other by ten nucleotides, and differ by up to ten nucleotides from the previously published 16S rRNA gene sequence (AY643083).

Morphology and physiology

Most members of *A. finegoldii* were isolated on *Bacteroides*-bile-esculin (BBE) agar, others on kanamycin/vancomycin laked blood agar. Cells stain Gram-negative, and are non-spor forming and rod-shaped with rounded ends (0.2 x 0.8 to 2 μm), mostly occurring singly, though longer filaments are observed occasionally (Figure 2). After 4 days growth on *Brucella* sheep blood agar colonies are 0.3–1.0 mm in diameter, circular, gray, translucent or opaque and weakly β-hemolytic. On laked rabbit blood agar colonies are light brown after 4 days incubation, turning reddish or chocolate brown after 10 days [1,3]. Growth temperature is 37°C [31]. The organism is strictly anaerobic, indole-positive, catalase-negative and grows in peptone-yeast extract-glucose containing 20% bile [1,3]. Nitrate is not reduced to nitrite, gelatin is liquefied and esculin hydrolysis is negative. Metabolism is fermentative, however, due to scanty growth on agar media and in liquid media, carbohydrate metabolism is difficult to evaluate. In PYG broth, succinic acid is the major end product, while acetic and propionic acids are minor products; isovaleric and lactic acids are sometimes produced in very small amounts. Acid- and alkaline phosphatases, N-acetyl-β-glucosaminidase, esterase, esterase lipase, α- and β-galactosidases, and α-glucosidase are detected in the API ZYM (bioMérieux) gallery, while no activity is detected for lipase C4, leucine/valine/cystine arylamidases, trypsin, β-glucuronidase, β-glucosidase or α-mannosidase. In addition, using Rosco diagnostic tablets (Rosco, Taastrup, Denmark), α-fucosidase is detected, but not β-xilosidase or trypsin. Strains are resistant to vancomycin (5 μg), kanamycin (1,000 μg), and colistin (10 μg). Susceptibility to penicillin varies and some strains produce β-lactamase (reaction for the type strain has not been specified) [1,3].

Strain AHN2437T was isolated from a human appendiceal tissue sample. The habitat is not known but strains are probably members of the microflora of the human gut [1]. *A. finegoldii*-type organisms were identified by molecular methods as part of the microbiota of chicken guts [32] and they were detected in blood cultures from colon cancer patients [33].
**Alistipes finegoldii** type strain (AHN2437T)

### Chemotaxonomy

The major cellular fatty acid of strain AHN2437\(^T\) is iso-C\(_{15:0}\); smaller amounts (with 5 to 10% occurrence) are anteiso-C\(_{15:0}\), C\(_{15:0}\), C\(_{16:0}\), iso-C\(_{17:0}\), and one or both of C\(_{17:0}\) iso-3OH/C\(_{18:2}\) DMA. The mol% G+C of DNA is 57 [1,3]. No information is available for the peptidoglycan composition, isoprenoid composition, polar lipids or whole cell sugars.

### Genome sequencing and annotation

#### Genome project history

This organism was selected for sequencing on the basis of its phylogenetic position [34], and is part of the *Genomic Encyclopedia of Bacteria and Archaea* project [35]. The genome project is deposited in the Genomes OnLine Database [23] and the complete genome sequence is deposited in GenBank. Sequencing, finishing and annotation were performed by the DOE Joint Genome Institute (JGI) using state of the art sequencing technology [46]. A summary of the project information is shown in Table 2.

#### Growth conditions and DNA isolation

*A. finegoldii* strain AHN2437\(^T\), DSM 17242, was grown anaerobically in DSMZ medium 104 (PYG, supplemented with vitamin solution (see DSMZ medium 131)) [36] at 37°C. DNA was isolated from 1-1.5 g of cell paste using MasterPure Gram-positive DNA purification kit (Epicentre MGP04100) following the standard protocol as recommended by the manufacturer with modification st/LALM for cell lysis as described in Wu *et al*. 2009 [35]. DNA is available through the DNA Bank Network [37].

---

**Figure 1.** Phylogenetic tree highlighting the position of *A. finegoldii* relative to the type strains of the other species within the family *Rikenellaceae*. The tree was inferred from 1,432 aligned characters [17,18] of the 16S rRNA gene sequence under the maximum likelihood (ML) criterion [19]. Rooting was done initially using the midpoint method [20] and then checked for its agreement with the current classification (Table 1). The branches are scaled in terms of the expected number of substitutions per site. Numbers adjacent to the branches are support values from 1,000 ML bootstrap replicates [21] (left) and from 1,000 maximum-parsimony bootstrap replicates [22] (right) if larger than 60%. Lineages with type strain genome sequencing projects registered in GOLD [23] are labeled with one asterisk, those also listed as 'Complete and Published' with two asterisks. See also the species the not yet validly published names described together with their genome sequences in [6].
Genome sequencing and assembly

The genome was sequenced using a combination of Illumina and 454 sequencing platforms. All general aspects of library construction and sequencing can be found at the JGI website [38]. Pyrosequencing reads were assembled using the Newbler assembler (Roche). The initial Newbler assembly consisting of 103 contigs in four scaffolds was converted into a phrap [39] assembly by making fake reads from the consensus, to collect the read pairs in the 454 paired end library. Illumina GAii sequencing data (500.5 Mb) was assembled with Velvet [40] and the consensus sequences were shredded into 2.0 kb overlapped fake reads and assembled together with the 454 data. The 454 draft assembly was based on 160.8 Mb 454 draft data and all of the 454 paired end data. Newbler parameters are -consed -a 50 -l 350 -g -m -ml 20. The Phred/Phrap/Consed software package [39] was used for sequence assembly and quality assessment in the subsequent finishing process. After the shotgun stage, reads were assembled with parallel phrap (High Performance Software, LLC). Possible mis-assemblies were corrected with gapResolution [38], Dupfinisher [41], or sequencing cloned bridging PCR fragments with subcloning. Gaps between contigs were closed by editing in Consed, by PCR and by Bubble PCR primer walks (J.-F. Chang, unpublished). A total of 696 additional reactions and 2 shatter libraries were necessary to close gaps and to raise the quality of the finished sequence. Illumina reads were also used to correct potential base errors and increase consensus quality using a software Polisher developed at JGI [42]. The error rate of the completed genome sequence is less than 1 in 100,000. Together, the combination of the Illumina and 454 sequencing platforms provided 161.1 × coverage of the genome. The final assembly contained 324,940 pyrosequence and 13,793,104 Illumina reads.

Genome annotation

Genes were identified using Prodigal [43] as part of the DOE-JGI genome annotation pipeline [47], followed by a round of manual curation using the JGI GenePRIMP pipeline [44]. The predicted CDSs were translated and used to search the National Center for Biotechnology Information (NCBI) non-redundant database, UniProt, TIGR-Fam, Pfam, PRIAM, KEGG, COG, and InterPro databases. Additional gene prediction analysis and functional annotation was performed within the Integrated Microbial Genomes - Expert Review (IMG-ER) platform [45].
Alistipes finegoldii type strain (AHN2437T)

**Genome properties**
The genome statistics are provided in Table 3 and Figure 3. The genome consists of one circular chromosome with a total length of 3,734,239 bp and a G+C content of 56.6%. Of the 3,302 genes predicted, 3,234 were protein-coding genes, and 68 RNAs; 121 pseudogenes were also identified. The majority of the protein-coding genes (62.0%) were assigned a putative function while the remaining ones were annotated as hypothetical proteins. The distribution of genes into COGs functional categories is presented in Table 4.

**Table 1. Classification and general features of A. finegoldii AHN2437T according to the MIGS recommendations [24].**

| MIGS ID | Property | Term | Evidence code |
|---------|----------|------|---------------|
| MIGS-12 | Reference for biomaterial | Rautio et al., 2003 | TAS [1] |

Acknowledgements

We would like to gratefully acknowledge the help of Sabine Welnitz for growing *A. finegoldii* cultures, and Evelyne-Marie Brambilla for DNA extraction and quality control (both at DSMZ). This work was performed under the auspices of the US Department of Energy Office of Science, Biological and Environmental Research Program, and by the University of California, Lawrence Berkeley National Laboratory under contract No. DE-AC02-05CH11231, Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344, and Los Alamos National Laboratory under contract No. DE-AC02-06NA25396, UT-Battelle and Oak Ridge National Laboratory under contract DE-AC05-00OR22725.
