Abstract

Recently deep learning models have been shown to be capable of making remarkable performance in sentences and documents classification tasks. In this work, we propose a novel framework called AC-BLSTM for modeling sentences and documents, which combines the asymmetric convolution neural network (ACNN) with the Bidirectional Long Short-Term Memory network (BLSTM). Experiment results demonstrate that our model achieves state-of-the-art results on all six tasks, including sentiment analysis, question type classification, and subjectivity classification.

1 Introduction

Deep neural models recently have achieved remarkable results in computer vision (Krizhevsky et al., 2012; Szegedy et al., 2015a; Simonyan and Zisserman, 2014; He et al., 2015), and a range of NLP tasks such as sentiment classification (Kim, 2014; Zhou et al., 2015; Kalchbrenner et al., 2014), and question-answering (Sukhbaatar et al., 2015). Convolutional neural networks (CNNs) and recurrent neural networks (RNNs) especially Long Short-term Memory Network (LSTM), are used wildly in natural language processing tasks. With increasing data, these two methods can reach considerable performance by requiring only limited domain knowledge and easy to be finetuned to specific applications at the same time.

CNNs, which have the ability of capturing local correlations of spatial or temporal structures, have achieved excellent performance in computer vision and NLP tasks. And recently the emerge of some new techniques, such as Inception module (Szegedy et al., 2015b), Batchnorm (Ioffe and Szegedy, 2015) and Redual Network (He et al., 2015) have also made the performance even better. For sentence modeling, CNNs perform excellently in extracting n-gram features at different positions of a sentence through convolutional filters.

RNNs, with the ability of handling sequences of any length and capturing long-term dependencies, have also achieved remarkable results in sentence or document modeling tasks. LSTMs (Hochreiter and Schmidhuber, 1997) were designed for better remembering and memory accesses, which can also avoid the problem of gradient exploding or vanishing in the standard RNN. Be capable of incorporating context on both sides of every position in the input sequence, BLSTMs introduced in (Graves et al., 2005; Graves and Schmidhuber, 2005) have reported to achieve great performance in Handwriting Recognition (Liwicki et al., 2007), and Machine Translation (Peris and Casacuberta, 2015) tasks.

In this paper, We proposed an end-to-end architecture named AC-BLSTM by combining the ACNN with the BLSTM for sentences and documents modeling. Instead of using the normal convolution, we apply the technique proposed in (Szegedy et al., 2015b) which employs a 1 \times n convolution followed by a n \times 1 convolution by spatial factorizing the n \times n convolution. And we use the pretrained word2vec vectors (Mikolov et al., 2013) as the ACNN input, which were trained on 100 billion words of Google News to learn the higher-level representations of n-grams. The outputs of the ACNN are organized as the sequence window feature to feed into the BLSTM. So our model does not rely on any other extra domain specific knowledge and complex preprocess, e.g. word segmentation, part of speech tagging and so on. We evaluate AC-BLSTM on sentence-level and document-level tasks including sentiment analysis, question type classification, and subjectivity classification. Experimental results demonstrate the effectiveness of our approach compared with other state-of-the-art methods.

The rest of the paper is organized as follows. Section 2 presents a brief review of related work. Section 3 discusses the architecture of our model. Section...
Figure 1: Illustration of the AC-BLSTM architecture. The input is represented as a matrix where each row is a d-dimensional word vector. Then the ACNN is applied to obtain the feature maps, we apply three parallel asymmetric convolution operation on the input in our model, where $k_1$, $k_2$ and $k_3$ stand for the length of the filter. And then the features with the same convolution window index from different convolution layer (different color) are concatenated to generate the input sequence of BLSTM. Finally all the hidden units of BLSTM are concatenated then apply a softmax layer to obtain the prediction output.

4 presents the experiments result with comparison analysis. Section 5 concludes the paper.

2 Related Work

Deep learning models have made remarkable progress in various NLP tasks recently. For example, word embeddings (Mikolov et al., 2013; Pennington et al., 2014), question answering (Sukhbaatar et al., 2015), sentiment analysis (Tang et al., 2015; Chen et al., 2016a,b), machine translation (Sutskever et al., 2014) and so on. CNNs and RNNs are two wildly used architectures amongst these models. The success of deep learning models for NLP mostly relates to the progress in learning distributed word representations (Mikolov et al., 2013; Pennington et al., 2014). In these methods, instead of using one-hot vectors by indexing words into a vocabulary, each word is modeled as a low dimensional and dense vector which encodes both semantic and syntactic informations of words.

Our model mostly relates to (Kim, 2014) which combines CNNs of different filter lengths and either static or fine-tuned word vectors, and (Zhou et al., 2015) which stacks CNN and LSTM in a unified architecture with static word vectors. Other than employing the normal convolutional operation, we borrow the idea of asymmetric convolution introduced in (Szegedy et al., 2015b), which can reduce the number of the parameters, and increase the representation ability of the model by adding more nonlinearity. Then we stack the BLSTM, which is capable of analyzing the future as well as the past of every position in the sequence, on top of the ACNN. The experiment results also demonstrate the effectiveness of our model.

3 AC-BLSTM Model

In this section, we will introduce our AC-BLSTM architecture in detail. We first describe the ACNN which takes the word vector represented matrix of the sentence as input and produces higher-level representation of word features. Then we introduce the
the input matrix which factorize the

k 

tion operation inspired by (Szegedy et al., 2015)

and Zhou et al., 2015), we apply the asymmetric convolu-
k 

tion into 1

Then instead of employing the

ply pad them with space.

L 

\[ \sum \]

if

k 

\text{max}

where

f

is element-wise multiplication,

b

is a bias

term and

f

is a non-linear function such as the sig-

moid, hyperbolic tangent, etc. In our case, we choose

ReLU (Nair and Hinton, 2010) as the nonlinear func-
tion. Then we get the feature map

\[ m^i = [m^i_1, m^i_2, ..., m^i_L]. \]

(3)

After that, the second convolution operation of the
asymmetric convolution layer corresponding to the

k \times 1

convolution with filter

\[ w^i_2 \in \mathbb{R}^{k_i} \]

is applied to a window of

k 

features in the feature map

m^i

to produce the new feature

\[ c^i_j = f(w^i_2 \circ m^i_{j:j+k_i-1} + b). \]

(4)

with

c^i \in \mathbb{R}^{L-k_i+1}.

As shown in Figure 1, we simultaneously apply three
asymmetric convolution layers to the input matrix,
which all have the same number of filters denoted
as

n.

Thus the output of the asymmetric con-

volution layer has

n

feature maps. To generate the input

sequence of the BLSTM, for each output sequence
of the second convolution operation in the asymmet-
ric convolution layer, we slice the feature maps by
channel then obtained sequence of

L-k_i+1

new features

\[ c^i_t \in \mathbb{R}^n \]

for

t \in \{1, 2, ..., L-k_i+1\}.

Then we concatanate

\[ c^i_1, c^i_2, ..., c^i_{L-k_i+1} \]

for each time step

\[ c_t = [c^i_1, c^i_2, c^i_3]. \]

(6)

where

\[ c_t \in \mathbb{R}^{3n} \]

for

t \in \{1, 2, ..., L-\hat{k}+1\}

and

\[ \hat{k} = \text{max} k_i. \]

In general, those

\[ c^i_t \]

where

\[ k_i < \hat{k} \]

and

\[ t > L-\hat{k}+1 \]

must be dropped in order to maintain the same
sequence length, which will cause the loss of some
information. In our model, instead of simply cutting
the sequence, we use a simple trick to obtain the same
sequence length without losing the useful information
as shown in Figure 2. For each output sequence

\[ c^i_t \]

obtained from the second convolution operation with
filter length

k_i,

we take those

\[ c^i_t \]

where

\[ t >= L-\hat{k}+1 \]

then apply a fullyconnected layer to get a new feature,
which has the same dimension of

\[ c^i_t, \]

to replace the

(L-\hat{k}+1)-th feature in the origin sequence.

3.2 Bidirectional Long Short-Term Memory Network

First introduced in (Hochreiter and Schmidhuber,
1997), and shown as a successful model recently,
LSTM is a RNN architecture specifically designed to
bridge long time delays between relevant input and

BLSTM which can incorporate context on both sides
of every position in the input sequence. Finally, we
introduce the techniques to avoid overfitting in our
model. An overall illustration of our architecture is
shown in Figure 1.

3.1 Asymmetric Convolution

Let

\[ x_j \in \mathbb{R}^d \]

be the

d-dimensional word vector correspon-
ding to the

j-th

word in the sentence and

L

be the

maximum length

of the sentence in the dataset. Then the sentence with
length

L

is represented as

\[ x_{1:L} = [x_1, x_2, ..., x_L]. \]

(1)

For those sentences that are shorter than

L,

we simply pad them with space.

In general, let

k_i

in which

i \in \{1, 2, 3\}
be the length
of convolution filter. Then instead of employing the

k \times d

convolution operation described in (Kim, 2014;
Zhou et al. 2015), we apply the asymmetric convolu-
tion operation inspired by (Szegedy et al. 2015b) to
the input matrix which factorize the

k \times d

convolution into

1 \times d

convolution followed by a

k_i \times 1

convolution. And in experiments, we found that employ
this technique can improve the performance. The fol-
lowing part of this subsection describe how we define
the asymmetric convolution layer.

First, the convolution operation corresponding to
the

1 \times d

convolution with filter

\[ w^i_1 \in \mathbb{R}^d \]

is applied to each word

x_j

in the sentence and generates corre-
sponding feature

\[ m^i_j = f(w^i_1 \circ x_j + b). \]

(2)

Figure 2: Illustration of how to deal with the incos-
tence output sequence length by compression.
target events, making it suitable for problems where long range context is required, such as handwriting recognition, machine translation and so on.

For many sequence processing tasks, it is useful to analyze the future as well as the past of a given point in the series. Whereas standard RNNs make use of previous context only, BLSTM (Graves et al., 2005) is explicitly designed for learning long-term dependencies of a given point on both side, which has also been shown to outperform other neural network architectures in framewise phoneme recognition (Graves and Schmidhuber, 2005).

Therefore we choose BLSTM on top of the ACNN to learn such dependencies given the sequence of higher-level features. Finally, we concatenate all hidden state of all the time step of BLSTM to obtain final representation of the text and we add a softmax layer on top of the model for classification.

3.3 Regularization

For model regularization, we employ two commonly used techniques to prevent overfitting during training: dropout (Srivastava et al., 2014) and batch normalization (Ioffe and Szegedy, 2015). In our model, we apply dropout to the input feature of the BLSTM, and the output of BLSTM before the softmax layer. And we apply batch normalization to outputs of each convolution operation just before the relu activation. We also provide a L2-normalization of gradients during the training process.

4 Experiments

4.1 Datasets

We evaluate our model on various benchmarks. Stanford Sentiment Treebank (SST) is a popular sentiment classification dataset introduced by (Socher et al., 2013). The sentences are labeled in a fine-grained way (SST-1): very negative, negative, neutral, positive, very positive. The dataset has been split into 8,544 training, 1,101 validation, and 2,210 testing sentences. By removing the neutral sentences, SST can also be used for binary classification (SST-2), which has been split into 6,920 training, 872 validation, and 1,821 testing. Since the data is provided in the format of sub-sentences, we train the model on both phrases and sentences but only test on the sentences as in several previous works (Socher et al., 2013; Kalchbrenner et al., 2014).

Movie Review Data (MR) proposed by (Pang and Lee, 2005) is another dataset for sentiment analysis of movie reviews. The dataset consists of 5,331 positive and 5,331 negative reviews, mostly in one sentence. We follow the practice of using 10-fold cross validation to report the result.

Furthermore, we apply AC-BLSTM on the subjectivity classification dataset (SUBJ) released by (Pang and Lee, 2004). The dataset contains 5,000 subjective sentences and 5,000 objective sentences. We also follow the practice of using 10-fold cross validation to report the result.

We also benchmark our system on question type classification task (TREC) (Li and Roth, 2002), where sentences are questions in the following 6 classes: abbreviation, entity, description, location, numeric. The entire dataset consists of 5,452 training examples and 500 testing examples.

For document-level dataset, we use the sentiment classification dataset Yelp 2013 (YELP13) with user and product information, which is built by (Tang et al., 2015). The dataset has been split into 62,522 training, 7,773 validation, and 8,671 testing documents. But in the experiment, we neglect the user and product information to make it consistent with the above experiment settings.

4.2 Training and Implementation Details

We implement our model based on Mxnet (Chen et al., 2015) - a C++ library, which is a deep learning framework designed for both efficiency and flexibility. In order to benefit from the efficiency of parallel computation of the tensors, we train our model on a Nvidia GTX 1070 GPU. Training is done through stochastic gradient descent over shuffled mini-batches with the optimizer RMSprop (Tieleman and Hinton, 2012). For all experiments, we simultaneously apply three asymmetric convolution operation with the second filter length \( k \) of 2, 3, 4 to the input, set the dropout rate to 0.5 before feeding the feature into BLSTM, and set the initial learning rate to 0.0001. But there are some hyper-parameters that are not the same for all datasets, which are listed in table 2.

4.3 Word Vector Initialization

We use the publicly available word2vec vectors that were trained on 100 billion words from Google News. The vectors have dimensionality of 300 and were trained using the continuous bag-of-words architecture (Mikolov et al., 2013). Words not present in the set of pre-trained words are initialized from the uniform distribution \([-0.25, 0.25]\). We fix the word

4.4 Results and Discussion

We used standard train/test splits for those datasets that had them. Otherwise, we performed 10-fold cross validation. We repeated each experiment 10 times and report the mean accuracy. Results of our models against other methods are listed in table 1. To the best of our knowledge, AC-BLSTM achieves the best results on all six tasks.

Compared to [Kim, 2014] and [Zhou et al., 2015], which inspired our model mostly, AC-BLSTM can achieve better performance but with more complex architecture. By just employing the word2vec vectors, our model can achieve better results than [Zhang et al., 2016b] which combines multiple word embedding methods such as word2vec [Mikolov et al., 2013], glove [Pennington et al., 2014] and Syntactic embedding.

The experiment results show that the number of the convolution filter and the lstm memory dimention should keep the same for our model. Also the configuration of hyper-parameters: number of the convolution filter, the lstm memory dimention and the lstm layer are quiet stable across datasets. If the task is simple, e.g. TREC, we just set number of convolution filter to 100, lstm memory dimention to 100 and lstm layer to 1. And as the task becomes complicated, we
simply increase the lstm layer from 1 to 4. The SST-2 is a special case, we find that if we set the number of convolution filter and lstm memory dimension to 300 can get better result. And the dropout rate before softmax need to be tuned.

5 Conclusions

In this paper we have proposed AC-BLSTM: a novel framework that combines asymmetric convolutional neural network with bidirectional long short-term memory network. The asymmetric convolutional layers are able to learn phrase-level features. Then output sequences of such higher level representations are fed into the BLSTM to learn long-term dependencies of a given point on both side. To the best of our knowledge, the AC-BLSTM model achieves top performance on standard sentiment classification, question classification and document categorization tasks. In future work, we plan to explore the combination of multiple word embeddings which are described in (Zhang et al., 2016b).
