The citrus leafminer, Phyllocnistis citrella Stainton (Lepidoptera: Gracillariidae), was first detected in Florida in 1993 and quickly spread throughout the state (Heppner 1995). Leaf mining causes a decline in leaf photosynthesis and increased susceptibility to citrus canker (Graham et al. 2004; Gottwald et al. 2007). Incidence and severity of P. citrella (CLM) damage have increased in Florida recently, possibly due to resurgence of leafminer populations resulting from intensified spray programs directed against the Asian citrus psyllid (Diaphorina citri). Consequent increases in canker are especially notable in young trees and susceptible varieties such as grapefruit and early season oranges (Dewdney & Graham 2012).

One of the most common methods to monitor CLM abundance is to use a pheromone lure to attract the adult moth. Ando et al. (1985) reported attraction of male P. citrella in Japan to (Z,Z)-7,11-hexadecadienal (diene). Elsewhere, including Florida, the diene alone did not attract males (Jacas & Peña 2002). Leal et al. (2006) identified two additional aldehydes from pheromone glands of female P. citrella from Brazil, (Z,Z,E)-7,11,13-hexadecatrienal (triene) and (Z)-7-hexadecenal (monoene), in a ratio of 30:10:1 triene:diene:monoene. However, inclusion of the mononene in a ternary blend did not increase trap catch of males in Florida compared with a 3:1 triene:diene blend (Lapointe et al. 2006). Moreira et al. (2006) also identified the triene and diene compounds from P. citrella populations in California, USA, and reported an optimal ratio of 3:1 triene: diene to attract males. The 3:1 ratio was confirmed as optimal in Florida (Lapointe et al. 2009). Recently, the presence of a congeneric leafminer native to Florida, P. insignis (Frey & Boll), was observed in sticky traps baited with P. citrella lures loaded with the 3:1 blend (Keathley et al. 2013). Here we provide evidence that the 3:1 blend of (Z,Z,E)-7,11,13-hexadecatrienal and (Z,Z)-7,11-hexadecenal attracts multiple unrelated and genetically distinct species of Phyllocnistis in southern Florida.

Recent research in Florida has focused on the use of pheromone traps to determine optimal application timing of insecticides, efficacy of insecticides, optimal trap density, correlation between CLM damage and adult trap counts, and number of CLM generations per year (Jones, unpublished). The traps (Great Lakes IPM, IPS-G004) containing an insecticide dispenser (Vaportape™ II, Great Lakes IPM, HC-8500-25) and a lure loaded with a 3:1 blend of (Z,Z,E)-7,11,13-hexadecatrienal and (Z,Z)-7,11-hexadecadienal (IT203 ISCA lure-Citrella, ISCA Technologies, Riverside, California) were monitored weekly between Feb and Nov (2011 and 2012), and bi-weekly from Jan through Dec. Trap locations included large commercial citrus groves in Collier, Hendry, Lee, and St. Lucie Counties, Florida, the U.S. Horticultural Research Laboratory at Ft. Pierce, Florida and a 35,000 acre unmanaged natural area in Okalacoochee Slough State Forest (Table 1). The latter is a habitat characterized by marsh, cypress, wet prairie, pine flatwoods, oak hammocks, and oak-palm hammocks straddling southwestern Hendry and northwestern Collier counties. A single trap was centrally located in the upper canopy of trees of each selected citrus grove, and 12 traps were placed in the slough at varying distances (1.6, 3.2, 4.8, and 6.4 km) from known citrus. Pheromone lures were replaced every 6 to 8 weeks.

Moths were separated by morpho type and specimens of each type were sequenced for the 658 bp “barcode region” of the mitochondrial cytochrome c oxidase I (COI) gene following our published techniques (e.g., Kawahara et al. 2013; Kawahara & Rubinoff 2013; Rubinoff et al. 2012). The COI sequences generated were combined with known Phyllocnistis COI sequences from GenBank (www.ncbi.org) and BOLD (www.boldsystems.org). We included 4 gracillariid outgroups, Acrocercops astericola, Cameraria ohridella, Phyllonorycter acerifoliella and P. junoniella. Sequences were assembled, edited, and aligned using Geneious 5.4 (Biomatters). We applied the “Genious Alignment” option with default settings and manually checked the alignment. As we have done previously in our
Phyllocnistis citrella, P. insignis, P. vitegenella and 2 unidentified congeners were obtained from traps baited with ISCA lure Citrella™ lures at locations in Collier, Hendry, Lee, and St. Lucie Counties. Based on COI sequence data, at least 5 genetically divergent Phyllocnistis species were attracted to the lure. Two unidentified species (circles 4 and 5, Fig. 1) share a separate origin from P. citrella and constitute a genetically distinct group from P. citrella and P. insignis. Because this preliminary study was conducted at a limited number of sites in Central Florida, it is possible that additional species in the genus might be attracted to the major components of the P. citrella pheromone. Species in the genus often appear morphologically similar based on wing pattern (Kawahara et al. 2009; De Prins & Kawahara 2009; Davis & Wagner 2011), therefore it is likely that past surveys overlooked the presence of multiple Phyllocnistis species in traps. The morphological similarity of these leaf miner species implies that estimates of P. citrella infestation in citrus groves might be influenced by non-P. citrella species, and therefore caution is required when making estimates on damage based on the number of moths attracted to lures.

This study was a preliminary investigation of Phyllocnistis species attracted to pheromone lures. We sequenced only one gene for this initial screening, and we plan to sequence additional samples and loci in the future. A study that utilizes a combination of morphology and multiple molecular markers (e.g., Mitter et al. 2010) will be necessary to conclusively determine the true identities of the clusters we observed from the COI barcode region alone.

### SUMMARY

The citrus leafminer, Phyllocnistis citrella Stainton, is a major pest of citrus throughout the world. The larval stage of the moth mines leaves and reduces photosynthesis and increases the incidence and severity of citrus canker disease. A lure comprised of 2 aldehyde compounds isolated from pheromone glands of female P. citrella is widely used to monitor field populations. We conducted a preliminary morphological and molecular analysis to examine candidate species of Phyllocnistis that are attracted to pheromone lures containing the 2 major components of P. citrella. Our results demonstrated that several species of Phyllocnistis, including P. insignis and P. vitegenella, are attracted to the 2 major pheromone components of P. citrella.

Key Words: citrus leafminer, citrus canker, lure, molecular phylogeny, Phyllocnistinae

### RESUMEN

El minador de los cítricos, Phyllocnistis citrella Stainton, es una de las plagas principales de los cítricos en el mundo, ya que causa daño a las hojas por sus galerías, que reduce la capacidad...
la fotosintética de las hojas y aumenta la incidencia y la gravedad de la enfermedad del cáncro de los cítricos. Un señuelo hecho de 2 compuestos de aldehído aislado de las glándulas de feromonas de la hembra de *P. citrella* es ampliamente utilizado para monitorear las poblaciones en el campo. Se realizó un análisis molecular preliminar utilizando la región de código de barras 658 pb del gen mitocondrial citocromo c oxidasa I (COI) para examinar especies candidatas de *Phyllocnistis* que son atraídas a la feromona señuelo que contiene los 2 componentes principales de la feromona sexual de *P. citrella*. Nuestros resultados demostraron que los grupos genéticamente divergentes de los individuos son atraídos a los 2 principales componentes de la feromona de *P. citrella*.

**Fig. 1.** Preliminary maximum likelihood molecular phylogeny of *P. citrella* and relatives based on COI alone. The 5 tentative clusters collected from traps baited with a 3:1 blend of (Z,Z,E)-7,11,13-hexadecatrienal and (Z,Z)-7,11-hexadecadienal are indicated with thick lines, with circles denoting their origin. Numbers above or beside branches are bootstrap values.
Palabras Clave: minador de los cítricos, el cancro cítrico, señuelo, filogenia molecular, Phyllocnistinae

ACKNOWLEDGMENTS

We thank Carlos Lopez-Vaamonde and Paul Hebert for providing access to the BOLD database. Donald R. Davis provided useful suggestions that improved this paper. Cassandra Romero, Matthew Standridge, Jillian Sullivan, Lei Xiao, and Minjia Zhong helped prepare samples for COI sequencing. We thank Matthew Conley, Zach Lahey, Katiria Perez, Robert Riefer (SWFREC, Immokalee, FL), Denis Willett and Larry Markle (USD-A, ARS, Ft. Pierce, Florida) for collecting and processing trap catches.
