PRETERM PRELABOUR RUPTURE OF MEMBRANE: 1 YEAR STUDY
Th. Digel Singh¹, Ratana Usham², Helen Kamei³

ABSTRACT: OBJECTIVE: This study was conducted to find out the incidence, aetiology and maternal and fetal outcome of preterm prelabour rupture of membrane during a period of one year

METHODS: This prospective study was conducted during a period of one year from July 2006 to June 2007 among those patients admitted in the labour room with preterm prelabour rupture of membrane (PPROM) in a tertiary care center. RESULTS: The present study shows the incidence of PPROM was 2.01%. PPROM occurs most commonly in unbooked patients (75%). Incidence is more in primigravidas (60%). Anemia was found to be the most common associated medical disorder. CONCLUSION: Preterm prelabour rupture of membrane is an important problem in the developing world. It is one of the most common causes of perinatal mortality. Incidence and associated complications can be reduced with improve socioeconomic status and regular antenatal checkup.

KEYWORDS: PPROM, perinatal mortality, incidence.

INTRODUCTION: The average length of pregnancy is 40 weeks. But many babies are born well before term. The shorter the gestation the greater is the risk of perinatal morbidity and mortality. Prelabour rupture of membrane (PROM) is defined as rupture of membrane before the onset of labour. Preterm prelabour rupture of membrane (PPROM) is defined as the spontaneous rupture of membrane from viability to 37 weeks of gestation and prior to the onset of labour.¹

PPROM occurs in approx 0.7% to 2% of all pregnancies and is responsible for 1/3 rd of all preterm births.² It is more common in women with previous PPROM, previous history of repeated abortions. Preterm neonates contribute to only 8-10% of live births, but accounts for 90% of neonatal deaths. There is a substantial increase in the survival rate of preterm infants due to creation of specialised neonatal and obstetrics care centres. Maternal complications include the risk of chorioamnionitis, higher incidence of operative deliveries, psychological and lactational problems.

MATERIAL AND METHODS: This prospective study was carried out on women attending labour room with complain of watery discharge with gestational age between 28 weeks to 36 completed weeks. The other inclusion criteria were cervical dilatation less than 3cm and confirmation by per speculum examination

Patients with bleeding P/V and IUFD were excluded.

RESULTS: Of the total 9120 deliveries 184 were diagnosed as case of PPROM (2%). Of the 184 cases 139(75%) were unbooked. Most of the patients were from low socioeconomic status (77%) and primigravida (60.8%). Majority of patients were in the age group of 20-30 years.

HOW TO CITE THIS ARTICLE: Th. Digel Singh, Ratana Usham, Helen Kamei. "Preterm Prelabour Rupture of Membrane: 1 Year Study". Journal of Evolution of Medical and Dental Sciences 2015; Vol. 4, Issue 49, June 18; Page: 8495-8498, DOI: 10.14260/jemds/2015/1232
Anemia was found to be the most common associated medical disorders followed by UTI.

Most of the cases presenting with PPROM had spontaneous vaginal delivery. Most common cause for intervention was fetal distress.

Hyperbilirubinemia was the most common perinatal complication.

Neonatal deaths were more if the birth weights were less than 1500gms.
Table 5: Gestational age and perinatal mortality

| Gestational age | No. of babies delivered | No. of babies died | Mortality rate (%) |
|-----------------|------------------------|--------------------|-------------------|
| 28-29           | 13                     | 10                 | 77                |
| 30-31           | 37                     | 8                  | 21                |
| 32-33           | 70                     | 5                  | 7                 |
| 34-35           | 46                     | 1                  | 2                 |
| <37             | 18                     | 0                  | 0                 |

The lesser the gestational age the greater the perinatal mortality rate.

Only two patients who had undergone LSCS had wound infection. No other significant maternal morbidity and mortality were noted in the study.

DISCUSSION: PPROM remains an important problem in obstetrics causing 20-30% of preterm labour and 19% of perinatal mortality. The incidence of PPROM in the present study was 2%. Obi SN et al (2007) observe 2.5% incidence, Smith G et al (2005) noted 2.3% incidence of PPROM. Incidence varies from country to country due to effects of socioeconomic status, environmental factors, and percentage of antenatal checkup.

Inadequate antenatal care has 3.11 times chance of PPROM. Gosserlink CA (1993) and Phupong Voru et al (2002) found association between inadequate antenatal care and PPROM as in our study which had an incidence of 75% PPROM in unbooked cases.

The study shows the incidence of PPROM was more in low socioeconomic status groups (77%). Similar finding was found in study conducted by Tahir S et al (2002).

Primigravidas were found to have higher incidence of PPROM in the study (60.8%). Similar observation was found in study conducted by Tahir S et al (2002). in contrast Dars S et al (2002) found PPROM to be more common in multigravidas.

In this study the commonest associated medical disorders were found to be anemia. This is similar to data from NFHS, 2003 survey which found the incidence of anemia in pregnant women in Assam to be 60%. Another common medical disorders associated with PPROM was UTI. Davison J et al (1995) found the incidence of asymptomatic bacteriuria in pregnancy to be 2-10% and symptomatic UTI complicates 4% of pregnancy.

Neonatal hyperbilirubinemia was the most common perinatal complication in the study. 24% of babies delivered of PPROM suffered from neonatal jaundice. This observation was much lower than the incidence observed by Maherban Singh which was 60.7%.the present study observed rate of RDS was 5%. A study by Maherban Singh observed the rate of RDS to be 5.7%. JD steinfield et al (1999) observed 2.8 % of RDS.

Cox and Leveno et al and Tahir S et al showed caesarean section rate of 12% and 14% respectively which was comparable with our study which shows caesarean section rate of 9%. However in some studies caesarean section rate was as high as 34 % (Muller H; 1994). The differences may be due to exclusion of PPROM cases between 24-28 weeks in the present study. The other reason may be that due to availability of facilities for testing lung maturity and advance treatment facilities, many institutions go for LSCS in preterm babies.
CONCLUSIONS: Preterm prelabour rupture of membranes is an important obstetric problem in developed and developing countries. The present study shows the incidence of preterm prelabour rupture of membrane was 2.01%. The most important factors associated with PPROM were low socioeconomic factors and absence of antenatal checkup. The other risk factors which may be associated with PPROM were preterm delivery and abortions. The most common perinatal complication was hyperbilirubinemia and the second most common complication was birth asphyxia. Routine antibiotics decrease the chance of maternal and fetal infections. Although this condition is not totally preventable, good antenatal care, improved socioeconomic and well equipped neonatal care center will help a lot for this problem.
