Coloring simple hypergraphs

Alan Frieze∗ Dhruv Mubayi†

October 1, 2013

Abstract

Fix an integer $k \geq 3$. A $k$-uniform hypergraph is simple if every two edges share at most one vertex. We prove that there is a constant $c$ depending only on $k$ such that every simple $k$-uniform hypergraph $H$ with maximum degree $\Delta$ has chromatic number satisfying

$$\chi(H) < c \left( \frac{\Delta}{\log \Delta} \right)^{\frac{1}{k-1}}.$$ 

This implies a classical result of Ajtai-Komlós-Pintz-Spencer-Szemerédi and its strengthening due to Duke-Lefmann-Rödl. The result is sharp apart from the constant $c$.

1 Introduction

Hypergraph coloring has been studied for almost 50 years, since Erdős' seminal results on the minimum number of edges in uniform hypergraphs that are not 2-colorable. Some of the major tools in combinatorics have been developed to solve problems in this area, for example, the Local Lemma and the nibble or semirandom method. Consequently, the subject enjoys a prominent place among basic combinatorial questions.

Closely related to coloring problems are questions about the independence number of hypergraphs. An easy extension of Turán’s graph theorem shows that a $k$-uniform hypergraph with $n$ vertices and average degree $d$ has an independent set of size at least $cn/d^{1/(k-1)}$, where $c$ depends only on $k$. If we impose local constraints on the hypergraph, then this bound can be improved. An $i$-cycle in a $k$-uniform hypergraph is a collection of $i$ distinct edges spanned by at most $i(k-1)$ vertices.

Keywords: hypergraph coloring, semi-random method

2010 Mathematics Subject classification: 05C15, 05C65, 05D40
Say that a $k$-uniform hypergraph has girth at least $g$ if it contains no $i$-cycles for $2 \leq i < g$. Call a $k$-uniform hypergraph simple if it has girth at least 3. In other words, every two edges have at most one vertex in common. Throughout this paper we will assume that $k \geq 3$ is a fixed positive integer.

Ajtai-Komlós-Pintz-Spencer-Szemerédi [2] proved the following fundamental result that strengthened the bound obtained by Turán’s theorem above.

**Theorem 1** ([2]) Let $H = (V, E)$ be a $k$-uniform hypergraph of girth at least 5 with maximum degree $\Delta$. Then it has an independent set of size at least

$$cn \left( \frac{\log \Delta}{\Delta} \right)^{1/(k-1)}$$

where $c$ depends only on $k$.

Spencer conjectured that Theorem 1 holds even for simple hypergraphs, and this was later proved by Duke-Lefmann-Rödl [6]. Theorem 1 has proved to be a seminal result in combinatorics, with many applications. Indeed, the result was first proved for $k = 3$ by Komlós-Pintz-Szemerédi [13] to disprove the famous Heilbronn conjecture, that among every set of $n$ points in the unit square, there are three points that form a triangle whose area is at most $O(1/n^2)$. For applications of Theorem 1 to coding theory or combinatorics, see [15] or [14], respectively.

The goal of this paper is to prove a result that is stronger than Theorem 1 (and also the accompanying result of [6]). Since the proof of our result does not use Theorem 1, it gives an alternative proof of all the applications of Theorem 1 as well. Our main result states not only that one can find an independent set of the size guaranteed by Theorem 1, but also that the entire vertex set can be partitioned into independent sets with the average size as in Theorem 1. Recall that the chromatic number $\chi(H)$ of $H$ is the minimum number of colors needed to color the vertex set so that no edge is monochromatic.

**Theorem 2** Fix $k \geq 3$. Let $H = (V, E)$ be a simple $k$-uniform hypergraph with maximum degree $\Delta$. Then

$$\chi(H) < c \left( \frac{\Delta}{\log \Delta} \right)^{1/(k-1)}$$

where $c$ depends only on $k$.

It is shown in [5] that Theorem 2 is sharp apart from the constant $c$. In order to prove Theorem 2 we will first prove the following slightly weaker result. A triangle in a $k$-uniform hypergraph is a 3-cycle that contains no 2-cycle. In other words, it is a collection of three sets $A, B, C$ such that every two of these sets have intersection of size one, and $A \cap B \cap C = \emptyset$. 

2
Theorem 3 Fix $k \geq 3$. Let $H = (V,E)$ be a simple triangle-free $k$-uniform hypergraph with maximum degree $\Delta$. Then

$$\chi(H) < c \left( \frac{\Delta}{\log \Delta} \right)^{\frac{1}{k-1}},$$

where $c$ depends only on $k$.

The proof of Theorem 3 rests on several major developments in probabilistic combinatorics over the past 25 years. Our approach is inspired by Johansson’s breakthrough result on graph coloring, which proved Theorem 3 for $k = 2$.

The proof technique, which has been termed the semi-random, or nibble method, was first used by Rödl (inspired by earlier work in [2, 13]) to confirm the Erdős-Hanani conjecture about the existence of asymptotically optimal designs. Subsequently, Kim [11] (see also Kahn [10]) proved Johansson’s theorem for graphs with girth five and then Johansson proved his result. The approach used by Johansson for the graph case is to iteratively color a small portion of the (currently uncolored) vertices of the graph, record the fact that a color already used at $v$ cannot be used in future on the uncolored neighbors of $v$, and continue this process until the graph induced by the uncolored vertices has small maximum degree. Once this has been achieved, the remaining uncolored vertices are colored using a new set of colors by the greedy algorithm.

In principle our method is the same, but there are several difficulties we encounter. The first, and most important, is that our coloring algorithm is not as simple. A proper coloring of a $k$-uniform hypergraph allows as many as $k-1$ vertices of an edge to have the same color, indeed, to obtain optimal results one must permit this. To facilitate this, we introduce a collection of $k-1$ different hypergraphs at each stage of the algorithm whose edges keep track of coloring restrictions. Keeping track of these hypergraphs requires controlling more parameters during the iteration and dealing with some more lack of independence and this makes the proof more complicated.

In an earlier paper [8], we had carried out this program for $k = 3$. Several technical ideas incorporated in the current proof can be found there. Because the notation in [8] is slightly simpler than that in the current paper, the reader interested in the technical details of our proof may want to familiarize him or herself with [8] first (although this paper is entirely self contained).

The implication Theorem 3 implies Theorem 2 forms a much shorter (but still nontrivial) part of this paper (See Section 2). Our proof uses a recent concentration result of Kim and Vu [12] together with some additional ideas similar to those from Alon-Krivelevich-Sudakov [3]. The approach here is to partition the vertex set of a given simple hypergraph into some number of parts, where the hypergraph induced by each of the parts is triangle-free. Once this has been achieved, each of the parts is colored using Theorem 3.

We end with a conjecture posed in [8], which states that we may replace the hypothesis “simple” with something much weaker.
Conjecture 4 ([8]) Let $F$ be a $k$-uniform hypergraph. There is a constant $c_F$ depending only on $F$ such that every $F$-free $k$-uniform hypergraph with maximum degree $\Delta$ has chromatic number at most $c_F(\Delta/\log\Delta)^{1/(k-1)}$.

Conjecture 4 appears to be out of reach using current methods. For example, the special case $k = 2$ and $F = K_4$ remains open and would imply an old conjecture of [1].

Throughout this paper, we will assume that $\Delta$ is sufficiently large that all implied inequalities hold true. Any asymptotic notation is meant to be taken as $\Delta \to \infty$.

2 Simple hypergraphs

In this section we will prove that Theorem 3 implies Theorem 2.

Let $H = (V, E)$ be a simple $k$-uniform hypergraph. For $v \in V$ let its neighbor set $N_H(v)$ be defined by $N_H(v) = \{x : \exists S \in E \text{ s.t. } \{v, x\} \subset S\}$. Let $d_H(v)$ denote the degree of $v$ so that $|N_H(v)| = (k-1)d_H(v)$.

A pair $x,y \in N_H(v)$ is said to be covered if there exists $S \in E$ that contains both $x$ and $y$ but not $v$. Note that the assumption that $H$ is simple implies that in this case no edge contains all of $v, x, y$.

Recall that $k$ is fixed. Let $\varepsilon = \varepsilon(k)$ be a sufficiently small positive constant depending only on $k$.

Theorem 2 will follow from Theorem 3 and the following two lemmas:

Lemma 5 Fix $k \geq 3$. Let $H = (V, E)$ be a simple $k$-uniform hypergraph with maximum degree $\Delta$. Let $m = \left\lceil \Delta^{\frac{2}{3k-4}} - \varepsilon \right\rceil$. Then there exists a partition of $V$ into subsets $V_1, V_2, \ldots, V_m$ such that each induced subhypergraph $H_i = H[V_i], i = 1, 2, \ldots, m$ has the following properties:

(a) The maximum degree $\Delta_i$ of $H_i$ satisfies $\Delta_i \leq 2\Delta/m^{k-1}$.

(b) If $v \in V_i$ then its $H_i$-neighborhood $N_i(v)$ contains at most $k^2\Delta^2/m^{3k-4}$ covered pairs. (Here we mean covered w.r.t. $H_i$).

Lemma 6 Fix $k \geq 3$ and let $\delta$ be a sufficiently small positive constant depending on $k$. Let $L = (V, E)$ be a simple $k$-uniform hypergraph with maximum degree at most $d$. Suppose that each vertex neighborhood $N_L(v)$ contains at most $d^\delta$ covered pairs. Let $\ell = d^{\frac{1}{k-1}} - \delta$. Then there exists a partition of $V$ into subsets $W_1, W_2, \ldots, W_{\ell_1}, \ell_1 = O(\ell)$ such that for each $1 \leq j \leq \ell_1$, the hypergraph $L_j = L[W_j]$ has the following properties:

(a) The maximum degree $d_j$ of $L_j$ satisfies $d_j \leq 2d/\ell^{k-1}$.

(b) $L_j$ is triangle-free.
2.1 Proof of Theorem 2

Our proof can be thought of as a nibble argument, involving two iterations, given by Lemmas 5 and 6. Suppose that $H$ is a simple $k$-uniform hypergraph with maximum degree $\Delta$ and assume that $\Delta$ is sufficiently large. Apply Lemma 5 to obtain $H_1, \ldots, H_m$ that satisfy the conclusion of the lemma. Now fix $1 \leq i \leq m$ and let $L = H_i$. Lemma 5 part (a) implies that $\Delta(L) \leq \frac{2\Delta}{m^{k-1}}$. Hence we may apply Lemma 6 to $L$ with $d = \frac{2\Delta}{m^{k-1}}$ and $\delta = \epsilon(3k - 4)/(k - 2)$. By Lemma 5 part (b), each neighborhood $N_L(v)$ contains at most $\frac{k^2 \Delta^2}{m^{2k-4}}$ covered pairs. Since $\Delta$ is large,

$$k^2 \frac{\Delta^2}{m^{3k-4}} \leq k^2 \Delta^2 \frac{\epsilon(3k-4)}{m^{k-1}} < d^\delta.$$

We may therefore apply Lemma 6 with $\ell = \frac{d}{d(k-1)}$. Together with Theorem 3 we obtain

$$\chi(L) \leq \sum_{j=1}^{\ell} \chi(L_j) < O \left( \ell \left( \frac{d^{k-1}}{\log(d/k-1)} \right)^{1/k} \right) = O \left( m \left( \frac{\Delta/m^{k-1}}{\log(\Delta/m^{k-1})} \right)^{1/k} \right) = O \left( \frac{\Delta}{\log \Delta} \right)^{1/k}.$$

Since this holds for each $H_i$ we obtain,

$$\chi(H) \leq \sum_{i=1}^{m} \chi(H_i) \leq O \left( \frac{d}{\log d} \right)^{1/k}.$$

2.2 Kim-Vu concentration

We will need the following very useful concentration inequality (1) from Kim and Vu [12]: Let $\mathcal{Y} = (W, F)$ be a hypergraph of rank $s$, meaning that each $f \in F$ satisfies $|f| \leq s$. Let

$$Z = \sum_{f \in F} \prod_{i \in f} z_i$$

where the $z_i, i \in W$ are independent random variables taking values in $[0, 1]$. For $A \subseteq W, |A| \leq s$ let

$$Z_A = \sum_{f \in F, i \in f \setminus A} \prod_{i \in f} z_i.$$

Let $M_A = E(Z_A)$ and $M_j = \max_{A, |A| \geq j} M_A$ for $j \geq 0$. There exist positive constants $a = a_s$ and $b = b_s$ such that for any $\lambda > 0$,

$$P(|Z - E(Z)| \geq a \lambda^{s} \sqrt{M_0 M_1}) \leq b |W|^{s-1} e^{-\lambda}.$$  \hspace{1cm} (1)
2.3 Proof of Lemma 5

We will use the Local Lemma in the form below.

**Theorem 7 (Local Lemma)** Let $A_1, \ldots, A_n$ be events in an arbitrary probability space. Suppose that each event $A_i$ is mutually independent of a set of all the other events $A_j$ but at most $d$, and that $P(A_i) < p$ for all $1 \leq i \leq n$. If $ep(d+1) < 1$, then with positive probability, none of the events $A_i$ holds.

We will partition $V$ randomly into $m$ parts of size $|V|/m$ and use the Local Lemma to show the existence of a partition. We make the partition by assigning a random number in $[m]$ to each $v \in V$.

Fix $v \in V$. To simplify notation, condition on $v \in V_1$. Let $A_v$ be the event that (a) fails at $v$ i.e. that $v$ has degree greater than $2\Delta/m^{k-1}$ in the hypergraph $H_1$.

Let $B_v$ be the event that its neighborhood in $H_1$ contains more than $k^2\Delta^2/m^{3k-4}$ covered pairs. Each of these events is mutually independent of a set of all other events but at most $O(\Delta^4)$. We will show that $P(A_v), P(B_v) = O(\Delta^{-5})$ and this is clearly sufficient for the application of the Local Lemma.

Let $d_v$ be the degree of $v$ in $H_1$. Then $d_v$ has a distribution that is dominated by the binomial distribution $Bin(\Delta, 1/m^{k-1})$. It follows from the Chernoff bounds that

$$P\left(d_v \geq 2\Delta/m^{k-1}\right) \leq e^{-\Delta/(3m^{k-1})} = e^{-\Delta \frac{k-2}{3m^{k-1}}} \leq \Delta^{-5}$$

and this disposes of $A_v$.

Our goal now is to bound $P(B_v)$. For a vertex $x \in N_H(v)$, let $T_v(x)$ denote the unique $(k-1)$-set containing $x$ such that $T_v(x) \cup \{v\} \in E$. A covered pair $x, y \in N_H(v)$ will remain as a covered pair in $N_{H_1}(v)$ iff $S_{x,y} = T_v(x) \cup T_v(y) \cup T \subseteq V_1$ where $T$ is the unique $(k-2)$-set such that $T \cup \{x, y\} \in E$. Let $S_1, S_2, \ldots, S_r$, $r \leq (k-1)^2(\Delta^2)$ be an enumeration of the $(3k-4)$-tuples $S_{x,y}$ as $\{x, y\}$ ranges over the covered pairs in $N_H(v)$.

We will use the concentration inequality (1). The edges of our hypergraph $(W, F)$ are $S_1, S_2, \ldots, S_r$ and if $x \in W$ then $z_x$ is an independent $\{0, 1\}$ Bernoulli random variable with $P(z_x = 1) = 1/m$. Note that $|W| \leq k\Delta^2$.

Let $Z_v$ denote the number of covered pairs in $N_{H_1}(v)$. There is a 1-1 correspondence between covered pairs and the $S_i$. Therefore

$$\mu = E(Z_v) = \frac{r}{m^{3k-4}} \leq \frac{(k-1)^2\Delta^2}{2m^{3k-4}}.$$  \hspace{1cm} (2)

We now have to estimate $M_1$. 

For each set $A \subset W$, let $Y_A$ denote the number of edges of $F$ containing $A$.

**Claim.** $|Y_A| = O(\Delta)$ if $|A| \leq k - 1$ and $|Y_A| = O(1)$ if $|A| \geq k$.

**Proof.** Suppose that $A \subset S \in F$. Then $S$ can be written as $T_v(x) \cup T_v(y) \cup T$, for some $x, y \in N_H(v)$. We will count the number of $S$ containing $A$ by the number of $T_v(x)$’s and $T$’s. First, the number of $S$ where both $T_v(x)$ and $T_v(y)$ have a vertex in $A$ is at most $5k^4$ by the following argument. There are $\binom{|A|}{2} < 5k^2$ choices for the two intersection points, these points uniquely determine $T_v(x)$ and $T_v(y)$, and there are at most $|T_v(y)||T_v(x)| = (k - 1)^2$ possible covered pairs, each of which determines $T$ uniquely (if $T$ exists).

Now suppose that $A \cap T_v(y) = \emptyset$. If $|A| \geq k$, then $A$ must contain a vertex from $T$ and a (different) vertex from $T_v(x)$. There are at most $9k^2$ choices for these two vertices. For each of these choices, $T_v(x)$ is determined uniquely. For each vertex in $T_v(x)$ and the chosen vertex of $T \cap A$, there is at most one choice for $T$ (since $H$ is simple), hence the number of choices for $T$ is at most $k - 1$. Having chosen $T$, there are at most $k - 1$ choices for $T_v(y)$. Altogether, there are at most $9k^4$ choices for $S$. We conclude that if $|A| \geq k$, then

$$|Y_A| \leq 5k^4 + 9k^4 = O(1).$$

If $|A| \leq k - 1$, the argument above still applies unless either $A \subset T_v(x)$ or $A \subset T$ In either case, there are at most $k\Delta$ ways of choosing the other part of $S \setminus T_v(y)$ and at most $k$ ways of choosing $T_v(y)$. Thus $|Y_A| = O(\Delta)$ as claimed. \hfill \Box

The probability of choosing each vertex in $S \setminus A$ is $1/m$, so for given $A$, the probability of a particular $S \supset A$ is $(1/m)^{3k-4-|A|}$. The Claim now implies that for $1 \leq |A| < 3k - 4$,

$$M_A \leq \max\left\{O\left(\frac{\Delta}{m^{2k-3}}\right), O\left(\frac{1}{m}\right)\right\}.$$

When $|A| = 3k - 4$ we have $M_A = 1$. By our choice of $m$, it follows that if $\varepsilon$ is sufficiently small then

$$M_1 = 1.$$

The choice of $m$ also gives

$$M_0 = \max\{\mu, 1\} \leq \frac{k^2\Delta^2}{m^{3k-4}} = k^2\Delta^{(3k-4)}\varepsilon.$$

It follows that if we take $a\lambda^{3k-4} = \frac{k^2\Delta^2}{2m^{3k-4}(M_0M_1)^{1/2}}$ then $\lambda > \Delta\delta_k$ where $\delta_k > 0$. Now (1) implies that

$$P(B_v) \leq P(Z_v - E(Z_v) \geq k^2\Delta^2/2m^{3k-4}) \leq b(k\Delta^2)^3ke^{-\lambda} \leq \Delta^{-5}.$$

This completes the proof of Lemma 5. \hfill \Box
2.4 Proof of Lemma 6

This part follows an approach taken in Alon, Krivelevich and Sudakov [3]. We will first partition $V$ randomly into $\ell$ parts $V_1, V_2, \ldots, V_\ell$ of size $\sim |V|/\ell$ and use the local lemma to show the existence of a partition satisfying certain properties. To simplify notation, condition on $v \in V_1$.

For $v \in V$ let $A_v$ be the event that (a) fails at $v$ i.e. that $v$ has degree greater than $2d/\ell^{k-1}$ in $L_1$. Let $B_v$ be the event that $N_{L_1}(v)$ contains at least $200k^2$ covered pairs w.r.t. $L_1$.

Each of these events is mutually independent of a set of all other events but at most $O(d^4)$. We will show that $P(A_v), P(B_v) = O(d^{-5})$ and this is clearly sufficient for the application of the Local Lemma.

Let $d_v$ be the degree of $v$ in $L_1$. Then $d_v$ has a distribution that is dominated by the binomial distribution $\text{Bin}(d, 1/\ell^{k-1})$. It follows from the Chernoff bounds that $P(d_v \geq 2d/\ell^{k-1}) \leq e^{-d/(3\ell^{k-1})} = e^{-d(k-1)/3} \leq d^{-5}$ and this disproves the $A_v$.

If $B_v$ fails then either

(i) There exists a vertex $w \in N_L(v)$ such that $w$ is in at least $10k$ covered pairs of $N_{L_1}(v)$, or

(ii) $N_{L_1}(v)$ contains at least $10k$ pair-wise disjoint covered pairs.

Now

$$P((i)) \leq kd \left( \frac{d^\delta}{10k} \right) \ell^{-10k} \leq d^{-5}$$

and this disproves the $B_v$.

So, assume that none of the events $A_v, B_v$ occur. We show now that we can partition each $V_j$ into at most $400k^2 + 1$ sets, each of which induces a triangle free hypergraph. Consider the digraph $D_1$ with vertex set $V_1$ and an edge directed from $v \in V_1$ to each vertex of each of the at most $200k^2$ covered pairs in $N_{L_1}(v)$. $D_1$ has maximum out-degree $400k^2$ and so its underlying graph $G_1$ is $400k^2$-degenerate and so it can be properly colored with $400k^2 + 1$ colors. Partition $V_1$ into color classes $W_1, W_2, \ldots, W_{400k^2+1}$. We claim that for each $s$, the hypergraph $L[W_s]$ induced by $W_s$ is triangle-free. Suppose then that there is a triangle $v \cup T_v(x), v \cup T_v(y), T$ inside $L[W_s]$, where $T$ contains both $x$ and $y$. Then $\{x, y\}$ is a covered pair for $v$ and by construction $v$ and $x$ are not in the same $W_s$, contradiction. \[ \square \]
3 Triangle-free hypergraphs

In this section, which forms the bulk of the paper, we will prove Theorem 3.

3.1 Local Lemma

The driving force of our upper bound argument, both in the semi-random phase and the final phase, is the Local Lemma. Note that the Local Lemma immediately implies that every \( k \)-uniform hypergraph with maximum degree \( \Delta \) can be properly colored with at most \( \lceil 4\Delta^{1/(k-1)} \rceil \) colors. Indeed, if we color each vertex randomly and independently with one of these colors, the probability of the event \( A_e \), that an edge \( e \) is monochromatic, is at most \( \frac{1}{4^{k-1} \Delta} \). Moreover \( A_e \) is independent of all other events \( A_f \) unless \( |f \cap e| > 0 \), and the number of \( f \) satisfying this is less than \( k\Delta \). We conclude that there is a proper coloring.

3.2 Coloring Procedure

In the rest of the paper, we will prove the upper bound in Theorem 3. Suppose that \( k \geq 3 \) is fixed and \( H \) is a simple triangle-free \( k \)-uniform hypergraph with maximum degree \( \Delta \).

Let \( V \) be the vertex set of \( H \). As usual, we write \( \chi(H) \) for the chromatic number of \( H \). Let \( \varepsilon \) be a sufficiently small fixed positive constant (depending only on \( k \)). Let

\[
\omega = \varepsilon^2 \log \Delta \times \frac{1}{100 \times k^{2k+1}}
\]

and set

\[
q = \left\lfloor \frac{\Delta^{1/(k-1)}}{\omega^{1/(k-1)}} \right\rfloor.
\]

Note that \( q < c(\Delta/\log \Delta)^{1/(k-1)} \) where \( c \) depends only on \( k \).

We color \( V \) with \( 2q \) colors and therefore show that

\[
\chi(H) \leq 2c \left( \frac{\Delta}{\log \Delta} \right)^{1/(k-1)}.
\]

We use the first \( q \) colors to color \( H \) in rounds and then use the second \( q \) colors to color any vertices not colored by this process.

Our algorithm for coloring in rounds is semi-random. At the beginning of a round certain parameters will satisfy certain properties, (9) – (14) below. We describe a set of random choices for the parameters in the next round and we use the Local Lemma to prove that there is a set of choices that preserves the required properties.

- \( C = \lfloor q \rfloor \) denotes the set of available colors for the semi-random phase.
• $U^{(t)}$: The set of vertices which are currently uncolored. ($U^{(0)} = V$).

• $H^{(t)}$: The sub-hypergraph of $H$ induced by $U^{(t)}$.

• $W^{(t)} = V \setminus U^{(t)}$: The set of vertices that have been colored. We use the notation $\kappa$ to denote the color of an item e.g. $\kappa(w)$, $w \in W^{(t)}$ denotes the color permanently assigned to $w$.

• $H_i^{(t)}$, $2 \leq i \leq k - 1$: An edge-colored $i$-graph with vertex set $U^{(t)}$. There is an edge $u_1 u_2 \cdots u_i \in H_i^{(t)}$ iff there are vertices $u_{i+1}, u_{i+2}, \ldots, u_k \in W^{(t)}$ and an edge $u_1 u_2 \cdots u_k \in H$ with $\kappa(u_{i+1}) = \kappa(u_{i+2}) = \cdots = \kappa(u_k)$. The edge $u_1 u_2 \cdots u_i$ is given the color $\kappa(u_{i+1})$. For a fixed $u_1 u_2 \cdots u_i$, this color is well defined because $H$ is simple. (These hypergraphs are used to keep track of coloring restrictions).

• $p_u^{(t)} \in [0, 1]^C$ for $u \in U^{(t)}$: This is a vector of coloring probabilities. The $c$th coordinate is denoted by $p_u^{(t)}(c)$ and $p_u^{(0)} = (q^{-1}, q^{-1}, \ldots, q^{-1})$.

We can now describe the “algorithm” for computing $U^{(t+1)}, H_i^{(t+1)}, p_u^{(t+1)}$, given $U^{(t)}, H_i^{(t)}, p_u^{(t)}$, for $u \in U^{(t)}$: Let

$$\theta = \frac{\varepsilon}{\omega} = \frac{100 \times k^{2k+1}}{\varepsilon \log \Delta}$$

where we recall that $\varepsilon$ is a sufficiently small positive constant.

For each $u \in U^{(t)}$ and $c \in C$ we tentatively activate $c$ at $u$ with probability $\theta p_u^{(t)}(c)$. A color $c$ is lost at $u \in U^{(t)}$, if either

(i) there is an edge $uu_2 \cdots u \in H^{(t)}$ such that $c$ is tentatively activated at $u, u_3, \ldots, u_k$ or

(ii) there is a $2 \leq i \leq k - 1$ and an edge $e = uu_2 \cdots u \in H_i^{(t)}$ such that $c = \kappa(e)$ and $c$ is tentatively activated at $u, u_3, \ldots, u_i$.

We fix

$$\hat{p} = \frac{1}{\Delta^{1/(k-1)-\varepsilon}}.$$

We keep

$$p_u^{(t)}(c) \leq \hat{p}$$

for all $t, u, c$.

We let

$$B^{(t)}(u) = \left\{ c : p_u^{(t)}(c) = \hat{p} \right\} \quad \text{for all } u \in V.$$

A color in $B^{(t)}(u)$ will not be used at $u$. The role of $B^{(t)}(u)$ is clarified in Section 3.3.

The vertex $u \in U^{(t)}$ is given a permanent color if there is a color tentatively activated at $u$ which is not lost due to (i) or (ii) and not in $B^{(t)}(u)$. If there is a choice, it is made arbitrarily. Then $u$ is placed into $W^{(t+1)}$. 
Let us compute the probability that $c$ is not lost at $u$ in round $t$. Since for each $u \in U^{(t)}$ and $c \in C$, the tentative activation of $c$ at $u$ is done independently of all other tentative activations, the probability that $c$ is not lost at $u$ due to (i) is

$$\prod_{u_2 \cdots u_k \in H^{(t)}} \left(1 - \prod_{j=2}^{k} \theta p_{u_j}^{(t)}(c)\right) = \prod_{u_2 \cdots u_k \in H^{(t)}} \left(1 - \theta^{k-1} \prod_{j=2}^{k} p_{u_j}^{(t)}(c)\right).$$

Similarly the probability that $c$ is not lost at $u$ due to (ii) is

$$\prod_{i=2}^{k-1} \prod_{e = u_2 \cdots u_i \in H_{i+1}^{(t)}} \left(1 - \theta^{i-1} \prod_{j=2}^{i} p_{u_j}^{(t)}(c)\right).$$

Consequently, the probability that $c$ is not lost at $u$ in round $t$ is

$$q_u^{(t)}(c) = \prod_{u_2 \cdots u_k \in H^{(t)}} \left(1 - \theta^{k-1} \prod_{j=2}^{k} p_{u_j}^{(t)}(c)\right) \prod_{i=2}^{k-1} \prod_{e = u_2 \cdots u_i \in H_{i+1}^{(t)}} \left(1 - \theta^{i-1} \prod_{j=2}^{i} p_{u_j}^{(t)}(c)\right).$$

The parameter $q_u^{(t)}(c)$ is of great importance in our proof.

**Coloring Procedure: Round $t$**

**Make tentative random color choices:**

Independently, for all $u \in U^{(t)}$, $c \in C$, let

$$\gamma_u^{(t)}(c) = \begin{cases} 1 & \text{Probability} = \theta p_u^{(t)}(c) \\ 0 & \text{Probability} = 1 - \theta p_u^{(t)}(c) \end{cases}$$

$$\Theta^{(t)}(u) = \{ c : \gamma_u^{(t)}(c) = 1 \} = \text{the set of colors tentatively activated at } u.$$

**Deal with color clashes:**

$$L^{(t)}(u) = \left\{ c : \exists u_2 \cdots u_k \in H^{(t)} \text{ such that } c \in \bigcap_{j=2}^{k} \Theta^{(t)}(u_j) \right\} \cup \left\{ c : \exists 2 \leq i \leq k-1 \text{ and } e = u_2 \cdots u_i \in H_i^{(t)} \text{ such that } \kappa(e) = c \in \bigcap_{j=2}^{i} \Theta^{(t)}(u_j) \right\}$$

is the set of colors lost at $u$ in this round.

**Assign some permanent colors:**

Let

$$\Psi^{(t)}(u) = \Theta^{(t)}(u) \setminus (L^{(t)}(u) \cup B^{(t)}(u)) = \text{set of activated colors that can be used at } u.$$

If $\Psi^{(t)}(u) \neq \emptyset$ then choose $c \in \Psi^{(t)}(u)$ arbitrarily. Let $\kappa(u) = c$. 

11
Update parameters:

(a) \[U^{(t+1)} = U^{(t)} \setminus \left\{ u : \Psi^{(t)}(u) \neq \emptyset \right\} .\]

(b) \[H_i^{(t+1)}, 2 \leq i \leq k - 1\] is the \(i\)-graph with vertex set \(U^{(t+1)}\) and edge set \[\{u_1u_2 \cdots u_i : \exists u_{i+1}, \ldots, u_k \in W^{(t + 1)} \text{ with } u_1 \cdots u_k \in H \text{ and } \kappa(u_{i+1}) = \cdots = \kappa(u_k) = c\}.

Edge \(u_1u_2 \cdots u_i\) has color \(c\). \((H\) simple implies that this color is well-defined).

(c) \(p_u^{(t)}(c)\) is replaced by \(p_u^{(t+1)}(c)\) which is either 0, \(p_u^{(t)}(c)/q_u^{(t)}(c)\), or \(\hat{p}\) (note that the last two are at least \(p_u^{(t)}(c)\)). Furthermore, if \(u \in U^{(t)} \setminus U^{(t+1)}\) then by convention \(p_u^{(t')} = p_u^{(t+1)}\) for all \(t' > t\).

In order to decide which of these three values is taken by \(p_u^{(t+1)}(c)\), we perform a random experiment, where we update \(p_u^{(t)}(c)\). Based on the outcome of this random experiment, we will decide on the value of \(p_u^{(t+1)}(c)\). One of the key properties is

\[E(p_u^{(t+1)}(c)) = p_u^{(t)}(c).\]  

The update rule is as follows: Let \(\eta_u^{(t)}(c) \in \{0, 1\}\) be a random variable with

\[P(\eta_u^{(t)}(c) = 1) = \frac{p_u^{(t)}(c)}{\hat{p}},\]

independently of other variables. Then

\[p_u^{(t+1)}(c) = \begin{cases} 0 & c \in L^{(t)}(u) \\ \frac{p_u^{(t)}(c)}{q_u^{(t)}(c)} & c \notin L^{(t)}(u), \quad \frac{p_u^{(t)}(c)}{q_u^{(t)}(c)} < \hat{p} \\ \eta_u^{(t)}(c)\hat{p} & \frac{p_u^{(t)}(c)}{q_u^{(t)}(c)} \geq \hat{p}. \end{cases}\]  

There will be \(t_0 = \varepsilon^{-1} \log \Delta \log \log \Delta\) rounds.

Before getting into the main body of the proof, we check (5). First observe that \(q_u^{(t)}(c)\) is the probability that \(c \notin L^{(t)}(u)\).

If \(p_u^{(t)}(c)/q_u^{(t)}(c) < \hat{p}\) then

\[E(p_u^{(t+1)}(c)) = q_u^{(t)}(c)\frac{p_u^{(t)}(c)}{q_u^{(t)}(c)} = p_u^{(t)}(c).\]

If \(p_u^{(t)}(c)/q_u^{(t)}(c) \geq \hat{p}\) then

\[E(p_u^{(t+1)}(c)) = \hat{p}\frac{p_u^{(t)}(c)}{\hat{p}} = p_u^{(t)}(c).\]
3.3 The role of \( B^{(t)}(u) \)

Once a color enters \( B^{(t)}(u) \), it will be in \( B^{(t')}(u) \) for all \( t' \geq t \). This is because we update \( p_u(c) \) according to Case B and now \( \mathcal{P}(\eta^{(t)}_u(c) = 1) = 1 \). We arrange things this way, because we want to maintain (5). Then because \( p_u^{(t)}(c) \) cannot exceed \( \hat{p} \), it must actually remain at \( \hat{p} \). This could cause some problems for us if neighbors of \( u \) had been colored with \( c \). There might be an edge \( e = uu_2 \cdots u_k \) where \( u_2, \ldots, u_k \) are (tentatively) colored \( c \). We can’t raise \( p_u^{(t)}(c) \) and to keep it monotone, we can’t allow it to drop to zero. This is why \( B^{(t)}(u) \) is excluded in the definition of \( \Psi^{(t)}(u) \) i.e. we cannot color \( u \) with \( c \in B^{(t)}(u) \).

3.4 Correctness of the coloring

Observe that \( c \in L^{(t)}(x) \) implies that \( p_x^{(t)}(c) \in \{0, \hat{p}\} \). If \( p_x^{(t)}(c) = 0 \), then \( p_x^{(t')}(c) = 0 \) for all \( t' > t \) and \( c \) will never be tentatively activated at \( x \), while if \( p_x^{(t)}(c) = \hat{p} \), then \( c \in B^{(t)}(x) \). Consequently, \( \kappa(x) \neq c \). Suppose that some edge \( u_1 u_2 \cdots u_k \) is improperly colored by the above algorithm. Suppose that \( u_1, u_2, \ldots, u_k \) get colored at times \( t_1 \leq t_2 \leq \cdots \leq t_k \) and that \( \kappa(u_j) = c \) for \( j = 1, 2, \ldots, k \). If \( t_1 = t_2 = \cdots = t_{k-1} = t \) then \( c \in L^{(t)}(u_k) \) and so \( \kappa(u_k) \neq c \). If there exists \( 1 \leq i \leq k-2 \) such that \( t_i < t = t_{i+1} = \cdots = t_{k-1} \) then \( u_{i+1} u_{i+2} \cdots u_k \) is an edge of \( H_{k-1}^{(t)} \), \( \kappa(u_{i+1} u_{i+2} \cdots u_k) = c \) and \( c \) is activated at \( u_{i+1}, \ldots, u_{k-1} \) so \( c \in L^{(t)}(u_k) \) and again \( \kappa(u_k) \neq c \).

3.5 Parameters for the problem

We will now drop the superscript \( (t) \), unless we feel it necessary. It will be implicit i.e. \( p_u(c) = p_u^{(t)}(c) \) etcetera. Furthermore, we use \( t' \) to replace the superscript \( (t + 1) \) i.e. \( p_u^{(t)}(c) = p_u^{(t+1)}(c) \) etcetera. The following are the main parameters that we need in the course of the proof:

In what follows \( u_1 = u \) and \( 2 \leq i \leq k-1 \):

\[
\Xi_e = \sum_{c \in C} \prod_{j=1}^{k} p_{u_j}(c) \quad \text{for edge } e = u_1 u_2 \cdots u_k \text{ of } H^{(t)}.
\]

\[
\Phi_{u,i} = \sum_{c \in C} \sum_{e = u_2 \cdots u_i \in H_i} \prod_{j=1}^{i} p_{u_j}(c)
\]

\[
h_u = - \sum_{c \in C} p_u(c) \log p_u(c) \text{ where } x \log x := 0 \text{ if } x = 0,
\]

\[
d_i(u, c) = | \{ e : u \in e \in H_i \text{ and } \kappa(e) = c \} |
\]

\[
d_i(u) = \sum_{c \in C} d_i(u, c) = \text{degree of } u \text{ in } H_i
\]

\[
d_{H^{(t)}}(u) = | \{ e : u \in e \in H^{(t)} \} | = \text{degree of } u \text{ in } H^{(t)}
\]

\[
d(u) = d_2(u) + d_3(u) + \cdots + d_{k-1} + d_{H^{(t)}}(u)
\]
It will also be convenient to define the following auxiliary parameters:

\[
\Xi_e(c) = \prod_{j=1}^{k} p_{u_j}(c) \quad \text{for edge } e = u_1 u_2 \cdots u_k \text{ of } H^{(t)}.
\]

\[
\Xi_u = \sum_{e = u_1 u_2 \cdots u_k \in H^{(t)}} \Xi_e
\]

\[
\Xi_u(c) = \sum_{u_1 u_2 \cdots u_k \in H^{(t)}} \prod_{j=2}^{k} p_{u_j}(c)
\]

\[
\Phi_{u,i}(c) = \sum_{e = u_1 u_2 \cdots u_i \in H_i \atop \kappa(e) = c} \prod_{j=2}^{i} p_{u_j}(c)
\]

This gives

\[
\Xi_u = \sum_{c \in C} p_u(c) \Xi_u(c)
\]

(7)

\[
\Phi_{u,i} = \sum_{c \in C} p_u(c) \Phi_{u,i}(c).
\]

(8)

### 3.6 Invariants

We define a set of properties such that if they are satisfied at time \( t \) then it is possible to extend our partial coloring and maintain these properties at time \( t + 1 \). These properties are now listed. They are only claimed for \( u \in U \) and they are easily verified for \( t = 0 \). In fact, the reason that \( q \) cannot be lowered (given \( \Delta \) and \( \omega \)) is the second inequality in (10) for \( t = 0 \).

\[
\left| 1 - \sum_c p_u(c) \right| \leq t \Delta^{-\varepsilon}.
\]

(9)

\[
\Xi_e \leq \Xi_e^{(0)} + \frac{t}{\Delta^{1+\varepsilon}}
\]

\[
\leq \frac{\omega}{\Delta} + \frac{t}{\Delta^{1+\varepsilon}}, \quad \forall e \in H^{(t)}.
\]

(10)

\[
\Phi_{u,i} \leq k^{2k-2i} \omega (1-\theta/3k)^t, \quad 2 \leq i \leq k-1.
\]

(11)

\[
h_u \geq h_u^{(0)} - k^{2k} \varepsilon \sum_{\tau=0}^{t} (1-\theta/3k)^\tau.
\]

(12)

\[
d(u) \leq (1-\theta/2k)^t \Delta.
\]

(13)

\[
d_i(u,c) \leq (1+2k\theta)^t \Delta \hat{\rho}^{k-i}, \quad 2 \leq i \leq k-1.
\]

(14)
Equation (13) shows that after $t_0 = \varepsilon^{-1} \log \Delta \log \log \Delta$ rounds we find that the maximum degree in the hypergraph induced by the uncolored vertices satisfies

$$\Delta(H^{(t_0)}) \leq (1 - \theta/2k)^t_0 \Delta$$

$$\leq e^{-\theta t_0/2k} \Delta$$

$$< e^{-100k^2 \log \log \Delta} \Delta$$

$$\leq \Delta \frac{(1 - \theta/2k)^t_0}{(\log \Delta)^{100k^2/2e^2}}. \quad (15)$$

and then the result from Section 3.1 using the Local Lemma will show that the remaining vertices can be colored with a set of $4(\Delta / (\log \Delta)^{100k^2/2e^2})^{1/(k-1)} + 1 < q$ new colors.

The formula for $q_u(c)$ in (3) involves the product of terms of the form $(1 - x)$ for $x \geq 0$. By repeatedly using $(1 - a)(1 - b) \geq 1 - a - b$ for $a, b \geq 0$, and recalling the definitions of $\Xi_u(c)$ and $\Phi_{u,i}(c)$ we see that (3) gives

$$q_u(c) \geq 1 - \theta^{k-1} \Xi_u(c) - \sum_{i=2}^{k-1} \theta^{i-1} \Phi_{u,i}(c). \quad (16)$$

3.7 Dynamics

To prove (9) – (14) we show that we can find updated parameters such that

$$\left| \sum_c p'_u(c) - \sum_c p_u(c) \right| \leq \Delta^{-\varepsilon}. \quad (17)$$

$$\Xi'_e \leq \Xi_e + \Delta^{-1-\varepsilon}. \quad (18)$$

$$\Phi'_{u,i} - \Phi_{u,i} \leq \binom{k-1}{i-1} \theta^{k-i} \Xi_u + \sum_{l=i+1}^{k-1} \binom{l-1}{i-1} \theta^{l-i} \Phi_{u,l} - \theta(1 - 3k^2 \varepsilon) \Phi_{u,i} + \Delta^{-\varepsilon}, \quad 2 \leq i \leq k - 1. \quad (19)$$

The sum $\sum_{i=i+1}^{k-1}$ is vacuous for $i = k - 1$.

$$h_u - h'_u \leq k^2 \varepsilon (1 - \theta/3k)^t. \quad (20)$$

$$d'(u) \leq (1 - \theta/k)d(u) + \Delta^{2/3}. \quad (21)$$

$$d'_i(u, c) \leq d_i(u, c) + 2k \theta (1 + 2k \theta)^t \Delta p^{k-i}, \quad 2 \leq i \leq k - 1. \quad (22)$$

The proofs of (17) to (22) will be given in Section 3.10.
3.8 (17)–(22) imply (9)–(14)

First let us show that (17)–(22) are enough to inductively prove that (9)–(13) hold throughout.

**Property (9):** Trivial, from (17).

**Property (10):** Trivial, from (18).

**Property (11):** Fix $u$ and note that (10) and (13) imply
\[
\Xi_u \leq \left( \frac{\omega}{\Delta} + t \Delta^{-1-\varepsilon} \right) d(u) \leq \omega(1 - \theta/2k)^t + \Delta^{-\varepsilon/2}.
\]

Therefore,
\[
\Phi_{u,i} - \Phi_{u,t} \leq \left( \frac{k-1}{i-1} \right) \theta^{k-i} \omega(1 - \theta/2k)^t + \sum_{l=i+1}^{k-1} \left( \frac{l-1}{i-1} \right) \theta^{l-i} \Phi_{u,l} - \theta(1 - 3k^2 \varepsilon) \Phi_{u,t} + \Delta^{-\varepsilon/3}
\]

from (19) and (23). Thus,
\[
\Phi'_{u,k-1} \leq (k-1) \theta \omega(1 - \theta/2k)^t + (1 - \theta(1 - 3k^2 \varepsilon)) k^2 \omega(1 - \theta/3k)^t + \Delta^{-\varepsilon/3}
\]
\[
\leq k^2(1 - \theta/3k)^{t+1} \omega \left( \frac{\theta(1 - \theta/2k)^t}{k(1 - \theta/3k)^{t+1}} + \frac{1 - \theta(1 - 3k^2 \varepsilon)}{1 - \theta/3k} \right) + \Delta^{-\varepsilon/3}
\]
\[
\leq k^2(1 - \theta/3k)^{t+1} \omega.
\]

Now for $i \leq k - 2$, using $\Phi_{u,t} \leq k^{2k-2i} \omega(1 - \theta/3k)^t$,
\[
\Phi'_{u,i} \leq \left( \frac{k-1}{i-1} \right) \theta^{k-i} \omega(1 - \theta/2k)^t + \frac{k^2}{\theta^i} \omega(1 - \theta/3k)^t \sum_{l=i+1}^{k-1} \left( \frac{l-1}{i-1} \right) \left( \frac{\theta}{k^2} \right)^l
\]
\[
- \theta(1 - 3k^2 \varepsilon) k^{2k-2i} \omega(1 - \theta/3k)^t + \Delta^{-\varepsilon/3}.
\]

Next let $u_l = \left( \frac{l-1}{i-1} \right) \left( \frac{\theta}{k^2} \right)^l$ for $l \in [i-1, k-1]$. Then
\[
\frac{u_{l+1}}{u_l} = \frac{l}{l - i + 1} \frac{\theta}{k^2} < r = \frac{\theta(k-1)}{k^2}.
\]

Because, $\theta = O(1/\log \Delta)$, $\sum_{j=0}^{\infty} r^j$ can be upper bounded by $1 + \theta/k$. Consequently, $\Phi'_{u,i}$ can be upper bounded by
\[
\left( \frac{k-1}{i-1} \right) \theta^{k-i} \omega \left( 1 - \frac{\theta}{2k} \right)^t + \frac{k^2}{\theta^i} \omega \left( 1 - \frac{\theta}{3k} \right)^t k \left( \frac{\theta}{k^2} \right)^{i+1} \left( 1 + \frac{\theta}{k} \right)
\]
\[
- \theta(1 - 3k^2 \varepsilon) k^{2k-2i} \omega \left( 1 - \frac{\theta}{3k} \right)^t + \Delta^{-\varepsilon/3}
\]
\[
= k^{2k-2i} \left( 1 - \frac{\theta}{3k} \right)^{t+1} \omega \left( \frac{k-1}{i-1} \right) \theta^{k-i} \omega \left( \frac{1 - \theta/2k}{1 - \theta/3k} \right)^{t+1} \left( \frac{(\theta/k)(1 + \theta/k) - \theta(1 - 3k^2 \varepsilon)}{1 - \theta/3k} \right) + \Delta^{-\varepsilon/3}.
\]
Now
\[
\left( k - 1 \right) \left( \frac{\theta}{k^2} \right)^{k-i} \frac{(1-\theta/2k)^t}{(1-\theta/3k)^{t+1}} \leq \frac{2^k\theta}{k^2(1-\theta/3k)} = O(\theta),
\]
since \( k \) is constant here, independent of \( \Delta \), and
\[
\frac{(\theta/k)(1+\theta/k) - \theta(1-3k^2\epsilon)}{1-\theta/3k} = O(\theta)
\]
as well. Thus,
\[
\Phi'_{u,i} \leq k^{2k-2i} \left( 1 - \frac{\theta}{3k} \right)^{t+1} \omega \times O(\theta) + \Delta^{-\epsilon/3} \leq k^{2k-2i} \left( 1 - \frac{\theta}{3k} \right)^{t+1} \omega.
\]

Property (12): Trivial.

Property (13): If \( d(u) \leq (1-\theta/2k)^t \Delta \) then from (21) we get
\[
d'(u) \leq \left( 1 - \frac{\theta}{2k} \right)^t \Delta + \Delta^{2/3}
\]
\[
= \left( 1 - \frac{\theta}{2k} \right)^{t+1} \Delta - \frac{\theta}{2k} \left( 1 - \frac{\theta}{2k} \right)^t \Delta + \Delta^{2/3}
\]
\[
\leq \left( 1 - \frac{\theta}{2k} \right)^{t+1} \Delta.
\]

Property (14):
\[
d'_i(u,c) \leq (1 + 2k\theta)^t \Delta \hat{p}^{k-i} + 2k\theta(1 + 2k\theta)^t \Delta \hat{p}^{k-i} = (1 + 2k\theta)^{t+1} \Delta \hat{p}^{k-i}
\]
To complete the proof it suffices to show that there are choices for \( \gamma_u(c), \eta_u(c), u \in U, c \in C \) such that (17)–(22) hold.

In order to help understand the following computations, the reader is reminded that quantities \( \Xi_u, \Phi_{u,i}, \omega, \theta^{-1} \) can all be upper bounded by \( \Delta^{o(1)} \). Note also that in (14), \( (1 + 2k\theta)^{t_0} = \log^{O(1)} \Delta = \Delta^{o(1)} \).

### 3.9 Bad colors

We now put a bound on the weight of the colors in \( B(u) \).

Assume that (9)–(13) hold. It follows from (12) that
\[
h_u^{(0)} - h_u^{(t)} \leq k^{2k} \epsilon \sum_{i=0}^{\infty} (1-\theta/3k)^i = 3k \times k^{2k} \omega = \frac{3\epsilon^2 \log \Delta}{100}.
\]
Since \( p_u^{(0)}(c) = 1/q \) for all \( u, c \) we have

\[
h_u^{(0)} = -\sum_c p_u^{(0)}(c) \log p_u^{(0)}(c)
= -\sum_c p_u^{(t)}(c) \log p_u^{(0)}(c) - (\log 1/q) \sum_c (p_u^{(0)}(c) - p_u^{(t)}(c))
\geq -\sum_c p_u^{(t)}(c) \log p_u^{(0)}(c) - t\Delta^{-\varepsilon} \log \Delta.
\]

where the last inequality uses (9).

Plugging this lower bound on \( h_u^{(0)} \) into (24) gives

\[
\frac{3\varepsilon^2 \log \Delta}{100} \geq h_u^{(0)} - h_u^{(t)}
\geq -\sum_c p_u^{(t)}(c) \log p_u^{(0)}(c) - t\Delta^{-\varepsilon} \log \Delta + \sum_c p_u^{(t)}(c) \log p_u^{(t)}(c)
\]

\[
= \sum_c p_u^{(t)}(c) \log(p_u^{(t)}(c)/p_u^{(0)}(c)) - t\Delta^{-\varepsilon} \log \Delta.
\]

Thus,

\[
\sum_c p_u^{(t)}(c) \log(p_u^{(t)}(c)/p_u^{(0)}(c)) \leq \frac{3\varepsilon^2 \log \Delta}{100} + \Delta^{-\varepsilon/2}.
\]

Now, all terms in (25) are non-negative \( (p_u^{(t)}(c) = 0 \) or \( p_u^{(t)}(c) \geq p_u^{(0)}(c)) \). Thus after dropping the contributions from \( c \notin B(u) \) and using \( p_u^{(t)}(c) = \hat{p} \) for \( c \in B(u) \) and \( p_u^{(0)}(c) = 1/q \) for all colors \( c \), we get

\[
\frac{3\varepsilon^2 \log \Delta}{100} + \Delta^{-\varepsilon/2} \geq \sum_{c \in B(u)} p_u^{(t)}(c) \log(p_u^{(t)}(c)/p_u^{(0)}(c))
= \sum_{c \in B(u)} p_u^{(t)}(c) \log(\hat{p}q) = \sum_{c \in B(u)} p_u^{(t)}(c) \log(\Delta^{\varepsilon-o(1)})
\geq \frac{2}{3}\varepsilon p_u(B(u)) \log \Delta.
\]

So,

\[
p_u(B(u)) \leq \frac{\varepsilon}{10}.
\]

3.10 Verification of Dynamics

Let \( \mathcal{E}_{17}(u) - \mathcal{E}_{22}(u) \) be the events claimed in equations (17) – (22). Let \( \mathcal{E}(u) = \mathcal{E}_{17}(u) \cap \cdots \cap \mathcal{E}_{22}(u) \). We have to show that \( \bigcap_{u \in U} \mathcal{E}(u) \) has positive probability. We use the Local Lemma. Each of the above events depends only on the vertex \( u \) or its neighbors. Therefore, the dependency graph of the \( \mathcal{E}(u), u \in U \) has maximum degree \( \Delta^{O(1)} \) and so it is enough to show that each event
$\mathcal{E}_{17}(u), \ldots, \mathcal{E}_{22}(u), u \in U$ has failure probability $e^{-\Delta u^{(1)}}$. For convenience, we will use the notation \textbf{whp} to stand for \textit{with high probability}, by which we mean with probability $1 - e^{-\Delta u^{(1)}}$.

While parameters $\Xi_u, \Phi_u$ etc. are only needed for $u \in U$ we do not for example consider $\Xi'_u$ conditional on $u \in U'$. We do not impose this conditioning and so we do not have to deal with it. Thus the Local Lemma will guarantee a value for $\Xi_u, u \in U \setminus U'$ and we are free to disregard it for the next round. (We will however face this conditioning for other reasons, see (36)).

In the following we will use two forms of Hoeffding’s inequality for sums of bounded random variables: Suppose first that $X_1, X_2, \ldots, X_m$ are independent random variables and $|X_i| \leq a_i$ for $1 \leq i \leq m$. Let $X = X_1 + X_2 + \cdots + X_m$. Then, for any $t > 0$,

$$\max \{P(X - E(X) \geq t), P(X - E(X) \leq -t)\} \leq \exp \left\{ -\frac{2t^2}{\sum_{i=1}^{m} a_i^2} \right\}. \quad (27)$$

We will also need the following version in the special case that $X_1, X_2, \ldots, X_m$ are independent $[0,1]$ random variables. For $\alpha > 1$ we have

$$P(X \geq L) \leq (3/\alpha)^L \quad (28)$$

for any $L \geq \alpha E(X)$. (We replace $e$ by 3 as the symbol $e$ is over-used in the paper).

For proofs, see for example Alon and Spencer [4], Appendix A and Lugosi [16].

### 3.10.1 Dependencies

In our random experiment, we start with the $p_u(c)$’s and then we instantiate the independent random variables $\gamma_u(c), \eta_u(c), u \in U, c \in C$ and then we compute the $p'_u(c)$ from these values. Observe first that $p'_u(c)$ depends only on $\gamma_v(c), \eta_v(c)$ for $v = u$ or $v$ a neighbor of $u$ in $H$. So $p'_u(c)$ and $p'_v(c^*)$ are independent if $c \neq c^*$, even if $u = v$. We call this \textit{color independence}.

Let

$$N_i(u) = \{\{u_2, u_3, \ldots, u_i\} \subseteq U : \exists e \in H \text{ s.t. } \{u, u_2, \ldots, u_i\} \subseteq e\}.$$  

We shorten $N_2(u)$ to $N(u)$.

If $f = \{u_2, u_3, \ldots, u_i\} \in N_i(u)$ and $l > i$, then $E_{u,f,l} = \{e \in N_l(u) : e \supseteq f \cup \{u\}, e \in H_l\}$.

Next let

$$N_{i,l}(u) = \{f = \{u_2, \ldots, u_i\} \subseteq U : f \in N_i(u) \text{ and } E_{u,f,l} \neq \emptyset\}, \quad 2 \leq i < l \leq k.$$  

In words, $N_{i,l}$ is the collection of $i$-sets containing $u$ that are subsets of edges of $H_l$.

In these definitions $H_k = H^{(t)}$.

For each $v \in N(u)$ we let

$$C_u(v) = \{c \in C : \gamma_u(c) = 1\} \cup L(v) \cup B(v).$$
Note that while the first two sets in this union depend on the random choices made in this round, the set $B(v)$ is already defined at the beginning of the round.

We will later use the fact that if $c^* \notin C_u(v)$ and $\gamma_v(c^*) = 1$ then this is enough to place $c^*$ into $\Psi(v)$ and allow $v$ to be colored. Indeed, we only need to check that $c^* \notin A^{t-1}(v)$ as it then follows that $c^* \notin A(v)$. However, $\gamma_v(c^*) = 1$ implies that $p_v(c^*) \neq 0$ from which it follows that $c^* \notin A^{t-1}(v)$.

Let $Y_v = \sum_{c} p_v(c)1_{c \in C_u(v)} = p_v(C_u(v))$. $C_u(v)$ is a random set and $Y_v$ is the sum of $q$ independent random variables each one bounded by $\hat{p}$. Then by (7), (8) and (16),

$$\mathbb{E}(Y_v) \leq \sum_{c \in C} p_v(c)\mathbb{P}(\gamma_u(c) = 1) + \sum_{c \in C} p_v(c)(1 - q_v(c)) + p_v(B(v))$$

$$\leq \theta \sum_{c \in C} p_u(c)p_v(c) + \theta^{k-1}\Xi_v + \sum_{i=2}^{k-1} \theta^{i-1}\Phi_{v,i} + p_v(B(v)).$$

Now let us bound each term separately:

$$\theta \sum_{c \in C} p_u(c)p_v(c) \leq \theta q \rho^2 < \theta \Delta^{1/(k-1)} \Delta^{2\varepsilon - 2/(k-1)} \leq \varepsilon/3.$$ 

Using (10) we obtain

$$\theta^{k-1}\Xi_v < \omega \theta^{k-1} + \varepsilon \theta^{k-1} \Delta^{-\varepsilon} \leq \varepsilon \theta^{k-1} + \varepsilon \theta^{k-1} \Delta^{-\varepsilon} < \varepsilon/6 + \varepsilon/6 = \varepsilon/3.$$

Using (11) we obtain

$$\sum_{i=2}^{k-1} \theta^{i-1}\Phi_{v,i} \leq \sum_{i=2}^{k-1} \theta^{i-1}k^{2k-2i} \omega (1 - \theta/3k)^t \leq k^{2k-1}\varepsilon.$$ 

Together with $\mathbb{P}(B(v)) \leq \varepsilon/10$ we get

$$\mathbb{E}(Y_v) \leq (k^{2k-1} + 1)\varepsilon.$$ 

Hoeffding’s inequality then gives

$$\mathbb{P}(Y_v \geq \mathbb{E}(Y_v) + \rho) \leq \exp \left\{ -\frac{2\rho^2}{\rho^2} \right\} < e^{-2\rho^2 \Delta^{1/k}}.$$ 

Taking $\rho = \Delta^{-1/2k}$ say, it follows that

$$\mathbb{P}(p_v(C_u(v)) \geq (k^{2k-1} + 2)\varepsilon) = \mathbb{P}(Y_v \geq (k^{2k-1} + 2)\varepsilon) \leq e^{-\Delta^{1/2k}}. \quad (29)$$ 

Let $\mathcal{E}_{(29)}$ be the event $\{p_v(C_u(v)) \leq (k^{2k-1} + 2)\varepsilon\}$.

Now consider some fixed vertex $u \in U$. It will sometimes be convenient to condition on the values $\gamma_x(c), \eta_x(c)$ for all $c \in C$ and all $x \notin N(u)$ and for $x = u$. This conditioning is needed to obtain independence. We let $\mathcal{C}$ denote these conditional values.
Remark 8 Note that \( C \) determines the set \( C_{u}(v) \), and hence it also determines whether or not \( E_{(29)} \) occurs. Indeed, if \( \gamma_{u}(c) = 1 \), then \( c \in C_{u}(v) \). On the other hand, if \( \gamma_{u}(c) = 0 \) then whether or not \( c \in L(v) \) depends only on colors tentatively assigned to vertices not in \( N(u) \). This uses the simplicity and triangle-freeness of \( H \).

Given the conditioning \( C \), simplicity and triangle-freeness imply that the events \( \{v \not\in U'\} \), \( \{w \not\in U'\} \) for \( v, w \in N(u) \) are independent provided \( u, v, w \) are not part of an edge of \( H \). Indeed, triangle-freeness implies that in this case, there is no edge containing both \( v \) and \( w \). Therefore the random choices at \( w \) will not affect the coloring of \( v \) (and vice versa). Thus random variables \( p'_{v}(c), p'_{w}(c) \) will become (conditionally) independent under these circumstances. We call this conditional neighborhood independence.

3.10.1.1 Some expectations

Let us fix a color \( c \) and an edge \( u_{1}u_{2} \cdots u_{k} \in H \) (here we mean \( H \) and not \( H^{(t)} \)). In this subsection we will estimate the expectation of \( \mathbb{E} \left( \prod_{j=1}^{k} p'_{u_{j}}(c) \right) \) for \( 2 \leq i \leq k \) in two distinct situations.

Case 1: \( i = k \) and \( u_{1}u_{2} \cdots u_{k} \in H^{(t)} \).

Our goal is to prove that

\[
\mathbb{E} \left( \prod_{j=1}^{k} p'_{u_{j}}(c) \right) \leq (1 + 2k\theta^2 \hat{p}^2) \prod_{j=1}^{k} p_{u_{j}}(c)
\]  

(30)

If \( c \in \bigcup_{j=1}^{k} A^{(t-1)}(u_{j}) \) then \( \prod_{j=1}^{k} p'_{u_{j}}(c) = 0 \). Assume then that \( c \notin \bigcup_{j=1}^{k} A^{(t-1)}(u_{j}) \). If Case B of (6) occurs for any of \( u_{1}, u_{2}, \ldots, u_{k} \) e.g. \( u_{k} \) then

\[
\mathbb{E} \left( \prod_{j=1}^{k} p'_{u_{j}}(c) \bigg| \text{Case B for } k \right) = \mathbb{E} \left( \prod_{j=1}^{k-1} p'_{u_{j}}(c) \right) p_{u_{k}}(c).
\]

(31)

This is because in Case B the value of \( \eta_{u_{k}}(c) \) is independent of all other random variables and we may use (5). One can see then that we have to prove something slightly more general than (30). So we now aim to show that

\[
\mathbb{E} \left( \prod_{j=1}^{i} p'_{u_{j}}(c) \right) \leq (1 + 2k\theta^2 \hat{p}^2) \prod_{j=1}^{i} p_{u_{j}}(c)
\]

(32)

assuming that \( 1 \leq i \leq k \) and that there is an edge \( u_{1}u_{2} \cdots u_{k} \in H^{(t)} \) and that Case A of (6) happens for \( u_{j}, c, 1 \leq j \leq i \). The case \( i = 1 \) follows from (5) and so we assume that \( i \geq 2 \). By simplicity, \( u_{i+1}, \ldots, u_{k} \) are determined by \( u_{1}, u_{2}, \ldots, u_{i} \).

Now \( \prod_{j=1}^{i} p'_{u_{j}}(c) = 0 \) unless \( c \notin \bigcup_{j=1}^{i} L(u_{j}) \). Consequently,

\[
\mathbb{E} \left( \prod_{j=1}^{i} p'_{u_{j}}(c) \right) = \prod_{j=1}^{i} \frac{p_{u_{j}}(c)}{q_{u_{j}}(c)} \times \mathbb{P} \left( c \notin \bigcup_{j=1}^{i} L(u_{j}) \right).
\]

(33)
Furthermore,
\[
\Pr\left( c \notin \bigcup_{j=1}^{i} L(u_j) \mid \gamma_{u_j}(c) = 0, 1 \leq j \leq k \right) = \prod_{j=1}^{i} \left( q_{u_j}(c) \left( 1 - \theta^{k-1} \prod_{j' \neq j} p_{u_{j'}}(c) \right)^{-1} \right)
\leq (1 + 2k\theta^{k-1}p^{k-1}) \prod_{j=1}^{i} q_{u_j}(c).
\]

On the other hand we will show that
\[
\Pr\left( c \notin \bigcup_{j=1}^{i} L(u_j) \mid \exists 1 \leq j \leq k : \gamma_{u_j}(c) = 1 \right) \leq \Pr\left( c \notin \bigcup_{j=1}^{i} L(u_j) \mid \gamma_{u_j}(c) = 0, 1 \leq j \leq k \right). \tag{34}
\]

This is intuitively clear, since color \( c \) is at least as likely to be lost at \( u_j \) if it is tentatively activated at some \( u_{j'} \). Indeed, to see this formally, partition the probability space \( \Omega \) of outcomes of the \( \gamma \)'s and \( \eta \)'s into the sets \( \Omega_{\varepsilon_1, \ldots, \varepsilon_k} \) in which \( \gamma_{u_j}(c) = \varepsilon_j \in \{0, 1\} \) for \( 1 \leq j \leq k \). Let \( \Omega'_{\varepsilon_1, \ldots, \varepsilon_k} \) be the set of outcomes in \( \Omega_{\varepsilon_1, \ldots, \varepsilon_k} \) in which \( c \notin \bigcup_{j=1}^{i} L(u_j) \). Now consider the map \( f : \Omega_{\varepsilon_1, \ldots, \varepsilon_k} \to \Omega'_{0, \ldots, 0} \) which just sets \( \gamma_{u_j}(c) \) to 0 for \( 1 \leq j \leq k \). Then if \( \pi_j = \theta p_{u_j}(c) \) and \( \pi_j^0 = 1 - \pi_j \)
\[
\frac{\Pr(\Omega_{\varepsilon_1, \ldots, \varepsilon_k})}{\Pr(\Omega'_{0, \ldots, 0})} = \prod_{j=1}^{i} \frac{\pi_j^0}{\pi_j} = \frac{\Pr(\Omega'_{\varepsilon_1, \ldots, \varepsilon_k})}{\Pr(f(\Omega'_{\varepsilon_1, \ldots, \varepsilon_k}))}.
\]

If \( c \notin \bigcup_{j=1}^{i} L(u_j) \) and \( \exists 1 \leq j \leq k \) such that \( \gamma_{u_j}(c) = 1 \), then we still have \( c \notin \bigcup_{j=1}^{i} L(u_j) \) if we change \( \gamma_{u_j}(c) \) to 0 for \( 1 \leq j \leq k \) and make no other changes. Consequently, \( f(\Omega'_{\varepsilon_1, \ldots, \varepsilon_k}) \subseteq \Omega'_{0, \ldots, 0} \) and we have
\[
\frac{\Pr(\Omega'_{0, \ldots, 0})}{\Pr(\Omega_{0, \ldots, 0})} \geq \frac{\Pr(f(\Omega'_{\varepsilon_1, \ldots, \varepsilon_k})))}{\Pr(\Omega_{\varepsilon_1, \ldots, \varepsilon_k})} \cdot \frac{\Pr(\Omega_{\varepsilon_1, \ldots, \varepsilon_k})}{\Pr(\Omega_{0, \ldots, 0})} = \frac{\Pr(\Omega'_{\varepsilon_1, \ldots, \varepsilon_k})}{\Pr(\Omega_{\varepsilon_1, \ldots, \varepsilon_k})},
\]
which is (34).

It follows that
\[
\Pr\left( c \notin \bigcup_{j=1}^{i} L(u_j) \right) \leq (1 + 2k\theta^2p^2) \prod_{j=1}^{i} q_{u_j}(c). \tag{35}
\]
and in combination with (33) this proves (32) and hence (30).

Case 2: \( e = u_1u_2 \cdots u_i \in H_1, \kappa(e) = c \).

Our goal is now to prove
\[
E\left( \prod_{j=1}^{i} p'_{u_j}(c) \times 1_{u_2 \in U'} \right) \leq (1 - \theta(1 - 2k\varepsilon)) \prod_{j=1}^{i} p_{u_j}(c). \tag{36}
\]
Suppose that $p'_{u_j}(c)$ is determined by Case A of (6) for $1 \leq j \leq l$ and by Case B otherwise. We factor out $\prod_{j=l+1}^{l} p_{u_j}(c)$ as in (31). We let $\mathcal{L} = \{c \notin L(u_1) \cup \cdots \cup L(u_l)\}$ and concentrate on bounding

$$
E \left( \prod_{j=1}^{l} p'_{u_j}(c) \times 1_{u_2 \in U'} \right) = \prod_{j=1}^{l} \frac{p_{u_j}(c)}{q_{u_j}(c)} \times P(\mathcal{L} \land (u_2 \in U'))
$$

$$
\leq \prod_{j=1}^{l} \frac{p_{u_j}(c)}{q_{u_j}(c)} \times P(\mathcal{L}) \times P(u_2 \in U' | \mathcal{L})
$$

$$
\leq \prod_{j=1}^{l} \frac{p_{u_j}(c)}{q_{u_j}(c)} \times P(\mathcal{L} | \gamma_{u_1}(c) = \cdots = \gamma_{u_l}(c) = 0) \times P(u_2 \in U' | \mathcal{L}) \quad (37)
$$

$$
\leq \prod_{j=1}^{l} p_{u_j}(c) \times (1 - \theta \hat{p})^{-l} \times P(u_2 \in U' | \mathcal{L}). \quad (38)
$$

$$
\leq (1 + k \theta \hat{p}) \prod_{j=1}^{l} p_{u_j}(c) \times P(u_2 \in U' | \mathcal{L}).
$$

**Explanations:** Equation (37) follows as for (34). Equation (38) now follows because the events $c \notin L(u_j)$ become conditionally independent. And then $P(c \notin L(u_j) \mid \gamma_{u_j}(c) = 0)$ gains a factor $(1 - \theta^{j-1} \prod_{j' \neq j} p_{u_j}(c))^{-1} \leq (1 - \theta \hat{p})^{-1}$.

Equation (36) will follow once we prove

$$
P(u_2 \in U' \mid \mathcal{L}) \leq 1 - \theta (1 - k^2 \varepsilon). \quad (39)
$$

**Proof of (39):**

$$
P(u_2 \in U' \mid \mathcal{L}) = P(u_2 \in U' \land \gamma_{u_2}(c) = 1 \mid \mathcal{L}) + P(u_2 \in U' \land \gamma_{u_2}(c) = 0 \mid \mathcal{L})
$$

$$
\leq P(\gamma_{u_2}(c) = 1 \mid \mathcal{L}) + \frac{P(u_2 \in U' \land \mathcal{L} \mid \gamma_{u_2}(c) = 0) P(\gamma_{u_2}(c) = 0)}{P(\mathcal{L})} \quad (40)
$$

$$
\leq P(\gamma_{u_2}(c) = 1) + \frac{P(u_2 \in U' \mid \gamma_{u_2}(c) = 0) P(\mathcal{L} \mid \gamma_{u_2}(c) = 0) P(\gamma_{u_2}(c) = 0)}{P(\mathcal{L})} \quad (41)
$$

$$
\leq P(\gamma_{u_2}(c) = 1) + P(u_2 \in U' \mid \gamma_{u_2}(c) = 0)
$$

$$
\leq P(\gamma_{u_2}(c) = 1) + \frac{P(u_2 \in U')}{P(\gamma_{u_2}(c) = 0)}
$$

$$
\leq \theta \hat{p} + \frac{P(u_2 \in U')}{1 - \theta \hat{p}}. \quad (42)
$$

**Explanation:** To go from (40) to 41 we have used the following:

(i) $P(\gamma_{u_2}(c) = 1 \mid \mathcal{L}) \leq P(\gamma_{u_2}(c) = 1)$, which follows from the FKG inequality. $\mathcal{L}$ is monotone decreasing in the $\gamma$’s.
(ii) If $\gamma_{u_2}(c) = 0$ then $u_2 \in U'$ is independent of $L$.

The vertex $u_2$ is colored (i.e., not in $U'$) if and only if for some color $d \not\in B(u_2)$, $\gamma_{u_2}(d) = 1$ and $d \not\in L(u_2)$. Let $R_d$ denote the event that $\gamma_{u_2}(d) = 1$ and $d \not\in L(u_2)$.

$$P(u_2 \not\in U') = P \left( \bigcup_{d \not\in B(u_2)} R_d \right)$$
$$\geq \sum_{d \not\in B(u_2)} P(R_d) - \sum_{d,d' \not\in B(u_2)} P(R_d)P(R_{d'})$$
$$= \sum_{d \not\in B(u_2)} \theta p_{u_2}(d)q_{u_2}(d) - \sum_{d,d' \not\in B(u_2)} \theta^2 p_{u_2}(d)p_{u_2}(d')q_{u_2}(d)q_{u_2}(d')$$
$$\geq \theta \sum_{d \in C} p_{u_2}(d)q_{u_2}(d) - \theta \sum_{d \in B(u_2)} p_{u_2}(d)q_{u_2}(d) - \theta^2 \sum_{d,d' \not\in B(u_2)} p_{u_2}(d)p_{u_2}(d')$$
$$\geq \theta \sum_{d \in C} p_{u_2}(d) \left( 1 - \theta^{k-1} \Xi_{u_2}(d) - \sum_{i=2}^{k-1} \theta^i \Phi_{u,i}(d) \right)$$
$$\geq \theta \sum_{d \in C} p_{u_2}(d) \left( 1 - k \Xi_{u_2}(d) - \sum_{i=2}^{k-1} \theta^i k^2 \Phi_{u,i}(d) \right)$$
$$\geq \theta - \theta^k \Xi_{u_2} - \sum_{i=2}^{k-1} \theta^i \Phi_{u_2,i} - \frac{\theta \varepsilon}{10} - 2\theta^2$$

after using (16)

$$= \theta - \theta^k \Xi_{u_2} - \sum_{i=2}^{k-1} \theta^i \Phi_{u_2,i} - \frac{\theta \varepsilon}{10} - 2\theta^2$$

after using (9) and (26)

$$\geq \theta - \theta^k (\omega + \Delta^{-\varepsilon/2}) - \sum_{i=2}^{k-1} \theta^i k^2 \omega - \frac{\theta \varepsilon}{10} - 2\theta^2$$

after using (11) and (23).

Going back to (42) we see that this implies

$$P(u_2 \notin U' \mid L) \leq \theta \hat{p} + \left( 1 - \theta + \theta^k (\omega + \Delta^{-\varepsilon/2}) + \sum_{i=2}^{k-1} \theta^i k^2 \omega + \frac{\theta \varepsilon}{10} + 2\theta^2 \right) (1 + 2\hat{p})$$
$$\leq \theta \hat{p} + \left( 1 - \theta + 2\theta^{k-1} \varepsilon + k^2 \theta \varepsilon + \frac{\theta \varepsilon}{10} + 2\theta^2 \right) (1 + 2\hat{p})$$
$$\leq 1 - \theta (1 - k^2 \varepsilon)$$

which is (39).

### 3.10.2 Proof of (17)

Given the $p_u(c)$ we see that if $Z' = \sum_{c \in C} P'_u(c)$ then $E(Z') = \sum_{c \in C} p_u(c)$. This follows on using (5). By color independence $Z'$ is the sum of $q$ independent non-negative random variables each
bounded by $\hat{p}$. Applying (27) we see that
\[
P(|Z' - E(Z')| \geq \rho) \leq 2 \exp \left\{-\frac{2\rho^2}{q\hat{p}^2} \right\} = 2e^{-2\rho^2\Delta^1(k-1) - 2\epsilon - o(1)}.
\]

We take $\rho = \Delta^{-\epsilon}$ to see that $\mathcal{E}_{17}(u)$ holds whp.

### 3.10.3 Proof of (18)

Given the $p_u(c)$ we see that by (30), $\Xi'_e$ has expectation no more than $\Xi_e(1 + 2k^2\hat{p}^2)$ and is the sum of $q$ independent non-negative random variables, each of which is bounded by $\hat{p}^k$. We have used color independence again here. Applying (27) we see that
\[
P(\Xi'_e \geq \Xi_e(1 + 2k^2\hat{p}^k) + \rho/2) \leq \exp \left\{-\frac{\rho^2}{2q\hat{p}^k} \right\} \leq e^{-\rho^2\Delta^2(2k-1)/(k-1) - 2k\epsilon - o(1)}.
\]

We also have
\[
k\Xi_e\theta^2\hat{p}^2 \leq k \left(\frac{\omega}{\Delta} + \frac{t}{\Delta^{1+\epsilon}}\right) \hat{p}^2 < \frac{1}{2\Delta^{1+\epsilon}}.
\]

We take $\rho = \Delta^{-1-\epsilon}$ to obtain
\[
P(\Xi'_e \geq \Xi_e + \Delta^{-1-\epsilon}) \leq e^{-\Delta^{O(1)}}
\]
and so $\mathcal{E}_{18}(u)$ holds whp.

### 3.10.4 Proof of (19)

Throughout this section $u_1 = u$. Recall that
\[
\Phi'_{u,i} = \sum_{c \in C} \sum_{e = u_{i-1}u_i \in H'_i} 1_{\kappa'(e) = c} \prod_{j=1}^{i} p'_{u_j}(c).
\]

If $e \in H_i$ and $\kappa(e) = c$ then $e \in H'_i$ is equivalent to $\kappa'(e) = c$. If $\kappa(e) \neq c$ but $\kappa'(e) = c$ then the edge of $H$ containing $u, u_2, \ldots, u_i$ has some other vertices in $U$ that will be colored with $c$ in the current round. Consequently, the above expression is
\[
D_1 + \sum_{l=i+1}^{k} D_{2,l}
\]

25
where

\[ D_1 = \sum_{c \in C} \sum_{\kappa(e) = c} 1_{\kappa'(e) = c} \prod_{j=1}^{i} p'_{u_j}(c) \]

\[ D_{2,k} = \sum_{c \in C} \sum_{\{u_2, \ldots, u_{i}\} \in N_{i,k}(u)} 1_{\kappa'(u_2 \cdots u_{i}) = c} \prod_{j=1}^{i} p'_{u_j}(c) \]

\[ D_{2,l} = \sum_{c \in C} \sum_{\{u_2, \ldots, u_{i}\} \in N_{i,l}(u)} 1_{\kappa'(u_2 \cdots u_{i}) = c} \prod_{j=1}^{i} p'_{u_j}(c) \quad i + 1 \leq l \leq k - 1. \]

We bound \( E(D_1) \) and \( E(D_{2,i+1}), \ldots, E(D_{2,k}) \) separately.

\( E(D_1) \):

We write

\[ D_1 \leq \hat{D}_1 = \sum_{c \in C} \sum_{\kappa(e) = c} \prod_{j=1}^{i} p'_{u_j}(c) \times 1_{u_2 \in U'}. \]

and then we can use (36) to show

\[ E(\hat{D}_1) \leq (1 - \theta(1 - 2k^2 \varepsilon)) \Phi_{u,i}. \quad (43) \]

\( E(D_{2,k}) \):

Recall that

\[ D_{2,k} = \sum_{c \in C} \sum_{\{u_2, \ldots, u_{i}\} \in N_{i,k}(u)} 1_{\kappa'(u_2 \cdots u_{i}) = c} \prod_{j=1}^{i} p'_{u_j}(c). \]

Instead of summing over sets in \( N_{i,k}(u) \), we may sum over edges \( u_2 \cdots u_{k} \in H^{(t)} \), and then over subsets of these edges that lie in \( N_{i,k}(u) \). Thus

\[ D_{2,k} = \sum_{c \in C} \sum_{u_2 \cdots u_{k} \in H^{(t)}} \sum_{f \subseteq \{u_2, \ldots, u_{k}\}, |f| = i-1} 1_{\kappa'(f \cup \{u\}) = c} \prod_{u_j \in f \cup \{u\}} p'_{u_j}(c). \]

Fix an edge \( u_2 \cdots u_{k} \in H^{(t)} \). If \( u_{i+1}, \ldots, u_{k} \) are colored with \( c \) in this round, then certainly \( c \)
Recall that must have been tentatively activated at these vertices. Therefore,

\[
\mathbb{E} \left( \prod_{j=1}^{i} p'_{u_j}(c) \right) \leq \prod_{j=1}^{k} \gamma_{u_j}(c) \prod_{j=1}^{i} p'_{u_j}(c)
\]

\[
\leq \theta^{k-i} \prod_{j=1}^{k} p_{u_j}(c) \prod_{j=1}^{i} p'_{u_j}(c) \mathbb{P} \left( c \notin \bigcup_{j=1}^{i} L(u_j) \bigcap_{j=i+1}^{k} (\gamma_{u_j}(c) = 1) \right)
\]

\[
\leq \theta^{k-i} \prod_{j=1}^{k} p_{u_j}(c) \prod_{j=1}^{i} p'_{u_j}(c) \mathbb{P} \left( c \notin \bigcup_{j=1}^{i} L(u_j) \right) \quad (44)
\]

\[
\leq \theta^{k-i} \prod_{j=1}^{k} p_{u_j}(c)(1 + 2k\theta^2p^2). \quad (45)
\]

It follows that

\[
\mathbb{E}(D_{2,k}) \leq \binom{k-1}{i-1} \theta^{k-i} \Xi_u(1 + 2k\theta^2p^2). \quad (46)
\]

We use the argument for (34) to obtain (44) and (35) to obtain (45).

It follows that

\[
\mathbb{E}(D_{2,l}) \leq \binom{l-1}{i-1} \theta^{l-i} \Phi_u(1 + 2k\theta^2p^2).
\]

We first deal with \(D_1\). For each color \(c\), let \(\mathcal{D}_c\) be the event that \(\gamma_v(c) = 1\) for at most \(d = \max \{d_i(u, c)\rho, \Delta^c\} \) vertices \(v \in N_i(u, c) = \{w : \exists e \in H_i such that u, w \in e and \kappa(e) = c\} \).

Since \(\mathbb{P} \left( \gamma_v(c) = 1 \right) \leq \hat{\rho}\theta\),

\[
\mathbb{P}(\mathcal{D}_c) \leq \left( \frac{(i-1)d_i(u, c)}{d} \right) (\theta\hat{\rho})^d \leq \left( \frac{ke\theta}{\rho} \right)^d (\hat{\rho}\theta)^d = (ke\theta)^d < e^{-\Delta^c}.
\]

Let \(\mathcal{D}\) denote the event that \(\mathcal{D}_c\) holds for all \(c\). By the union bound,

\[
\mathbb{P}(\mathcal{D}) \leq q e^{-\Delta^c}.
\]
We now deal with the equation (50) is a direct application of the Azuma-Hoeffding concentration inequality. Let $\prod_{j=1}^{i} p_{u,j}(c) \times 1_{u_2 \in U'}$. For $d \neq c$, $\prod_{j=1}^{i} p_{u,j}(d) \times 1_{u_2 \in U'}$ only if $\gamma_{u_2}(c) = 1$; this is because if $\gamma_{u_2}(c) = 0$, the trials for color $c$ have no impact on whether or not $u_2 \in U'$. Thus, given $D$, changing the values in $T_c$ can change $\hat{D}_1$ by at most $d_i(u,c)\hat{p}^i + 2d_i(u,c)\hat{p}^{i+1} + 2\Delta^c \hat{p}^i$.

Let $\pi(t_i) = P(T_i = t_i \mid D)$ for $i = 1, 2, \ldots, q$ and let $\delta(t_i, t_{i+1}, \ldots, t_q) = \pi(t_i)\pi(t_{i+1}) \cdots \pi(t_q) = P(T_j = t_j, j = i, i+1, \ldots, q \mid D)$.

Here we use the fact that conditioning on $D$ still leaves the choices $t_1, t_2, \ldots, t_q$ for the distinct sets of colors $T_1, T_2, \ldots, T_q$ independent of each other. Thus,

$$\sum_{t_{c+1}, \ldots, t_q} [\hat{D}_1(t_1, \ldots, c-1, c, c+1, \ldots, t_q) - \hat{D}_1(t_1, \ldots, c-1, t_c', c+1, \ldots, t_q)]\delta(t_{c+1}, \ldots, t_q) \leq 3d_i(u,c)p^i + \Delta^c \hat{p}^i \leq 3(1 + 2k\theta)^{l_0} \Delta p^k + \Delta^c \hat{p}^i$$

on using (14)

$$\leq \Delta p^k \log^{O(1)} \Delta + \Delta^c \hat{p}^i \leq \Delta^{(k+1)e^{-l_1/(k-1)}}$$

Let $\delta_c$ denote the maximum over $t_1, t_2, \ldots, t_c, t_c'$ of (49).

$$P(\hat{D}_1 > (1 - \theta(1 - 2k^{2k}\varepsilon))\Phi(u,c) + \Delta^{-1/2k})$$

$$\leq P(\hat{D}_1 > E(\hat{D}_1) + \Delta^{-1/2k})$$

$$\leq P(\hat{D}_1 > E(\hat{D}_1 \mid D) + \Delta^{-1/2k} - 2q\Delta e^{-\Delta^c})$$

$$\leq \exp \left\{ -\frac{\Delta^{-1/k}}{2\sum_{c} \delta_c^2} \right\} + q^2 \Delta e^{-\Delta^c} \leq e^{-\Delta^c/2}. (51)$$

Equation (50) is a direct application of the Azuma-Hoeffding concentration inequality.

We now deal with the $D_{2,l}$. There is a minor problem in that the $D_{2,l}$ are sums of random variables for which we do not have a sufficiently small absolute bound. These variables do however have a
small bound which holds with high probability. There are several ways to use this fact. We proceed as follows: First assume \( l \leq k - 1 \) and let

\[
D_{2,l,c} = \sum_{\{u_2, u_3, \ldots, u_l\} \in N_{i,l}(u)} 1_{\kappa(u_2, u_3, \ldots, u_l) = c} \prod_{j=1}^{i} p'_{u_j}(c)
\]

which we re-write as

\[
D_{2,l,c} = \sum_{e=uu_2, u_3, \ldots, u_l \in H_l} Z_e,
\]

where

\[
Z_{uu_2, \ldots, u_l} = \sum_{S \subseteq \{u_2, u_3, \ldots, u_l\}} 1_{\kappa(S \cup \{u\}) = c} \prod_{u_j \in S \cup \{u\}} p'_{u_j}(c).
\]

Then we let

\[
\hat{D}_{2,l} = \min_{c \in C} \left\{ (1 + 2k \theta)^l \Delta \hat{p}^k, D_{2,l,c} \right\}.
\]

Observe that \( \hat{D}_{2,l} \) is the sum of \( q \) independent random variables each bounded by \( (1 + 2k \theta)^l \Delta \hat{p}^k \). So, for \( \rho > 0 \),

\[
P(\hat{D}_{2,l} - E(\hat{D}_{2,l}) \geq \rho) \leq \exp \left\{ -\frac{2\rho^2}{\Delta^2 + o(1) \hat{p}^2k} \right\} \leq e^{-\rho^2 \Delta^{1/(k-1)} - 2k \epsilon}.
\]

We take \( \rho = \Delta^{-1/2k} \) to see that

\[
P(\hat{D}_{2,l} \geq E(\hat{D}_{2,l}) + \Delta^{-1/2k}) \leq e^{-\epsilon}.
\]

(52)

We must of course compare \( D_{2,l} \) and \( \hat{D}_{2,l} \). Now \( D_{2,l} \neq \hat{D}_{2,l} \) only if there exists \( c \) such that \( D_{2,l,c} > (1 + 2k \theta)^l \Delta \hat{p}^k \). For each \( c \), \( D_{2,l,c} \) is the sum of the \( d_i(u, c) \leq (1 + 2k \theta)^l \Delta \hat{p}^{k-l} \) variables \( Z_e, e \in H_l \). Each \( Z_e \) is bounded above by \( \binom{l-1}{i-1} \hat{p}^i \) and \( E(Z_e) \leq \binom{l-1}{i-1} \theta^l \hat{p}^i \). This is because \( Z_e \) is bounded by the sum of \( \binom{l-1}{i-1} \) variables \( Z_{e,S} \), each taking the value 0 or \( \hat{p} \). Here \( Z_{e,S} \) corresponds to some \( S = \{u_2, u_3, \ldots, u_l\} \subseteq \{u_2, u_3, \ldots, u_l\} \). Furthermore, \( P(Z_{e,S} = \hat{p}^i) \leq (\theta \hat{p})^{l-i} \) because this will happen only if the vertices in \( S \) tentatively choose \( c \).

\( H \) being simple and triangle free, if we condition on \( C \) then the random variables \( Z_e \) become independent.

Now put \( X_e = Z_e/(\binom{l-1}{i-1} \hat{p}^i) \) and \( X = \sum_e X_e \). We see that \( 0 \leq X_e \leq 1 \) and \( E(X_e) \leq (\theta \hat{p})^{l-i} \).

We now use (28) with \( \alpha = 1/(\binom{l-1}{i-1} \theta^l) \) and \( E(X) \leq (1 + 2k \theta)^l \Delta \hat{p}^{k-l} \times (\theta \hat{p})^{l-i} = \binom{l+2k \theta}{l} \hat{p}^k / \alpha \binom{l}{i} \hat{p}^i \). This gives

\[
P(\hat{D}_{2,l,c} \geq (1 + 2k \theta)^l \Delta \hat{p}^k \mid C) \leq P \left( X \geq \frac{(1 + 2k \theta)^l \Delta \hat{p}^k}{\binom{l}{i} \hat{p}^i} \mid C \right) \leq \left( 3 \left( \frac{l}{i} \right) \theta^l \hat{p} \right)^{(1+2k \theta)^l \Delta \hat{p}^{k-l} / \binom{l}{i}}
\]
Therefore
\[ P(D_{2,l} \neq \hat{D}_{2,l}) \leq \sum_c P(\exists c : D_{2,l,c} \geq (1 + 2k\theta)^i \Delta \hat{\theta}^k | C)P(C) \]
\[ \leq \sum_c q \left( \binom{l}{i} \theta^{l-i} \right)^{(1+2k\theta)^i \Delta \hat{\theta}^{k-i}/(i)} P(C) \]
\[ \leq e^{-\Delta^\epsilon}. \quad (53) \]

It follows from (53) and \( \hat{D}_{2,l} \leq D_{2,l} \leq \Delta \)
that
\[ |E(D_{2,l}) - E(\hat{D}_{2,l})| \leq \Delta P(D_{2,l} \neq \hat{D}_{2,l}) \leq \Delta q e^{-\Delta^\epsilon} < \Delta^{-1/2k}. \]

Applying (52) and (53) we see that
\[ P(D_{2,l} \geq E(D_{2,l}) + 2\Delta^{-1/2k}) \leq P(\hat{D}_{2,l} \geq E(\hat{D}_{2,l}) + \Delta^{-1/2k}) + P(D_{2,l} \neq \hat{D}_{2,l}) \leq 2e^{-\Delta^\epsilon}. \quad (54) \]

We must now deal with the case of \( l = k \) i.e.
\[ D_{2,k,c} = \sum_{\{u_1, u_2, \ldots, u_i\} \in N_{i,k}(u)} 1_{k'(uu_2 \ldots u_i) = c} \prod_{j=1}^i p'_{u_j}(c) \]
and
\[ \hat{D}_{2,k} = \sum_{c \in C} \min \left\{ \Delta \hat{\theta}^k, D_{2,k,c} \right\}. \]

We re-write
\[ D_{2,k,c} = \sum_{S \in N_{i,k}(u)} W_S \]
where for \( S = \{u_2, u_3, \ldots u_i\}, \)
\[ W_S = \sum_{e \supset S, e \in H^{(l)}} 1_{k'(uu_2 \ldots u_i) = e} \prod_{j=1}^i p'_{u_j}(c). \]

Now we view \( D_{2,k,c} \) as the sum of at most \( \Delta \) random variables, each of which is bounded by \( \binom{k}{i} \hat{\theta}^i \)
and has expectation bounded by \( \binom{k}{i} \theta^{k-i} \hat{\theta}^k \). We now simply follow the argument for \( l < k \) by taking \( l = k \) to show that
\[ P(D_{2,k} \geq E(D_{2,k}) + 2\Delta^{-1/2k}) \leq 2e^{-\Delta^\epsilon}. \quad (55) \]

Indeed, (52) holds with \( l = k \). Then
\[ P(D_{2,k} \neq \hat{D}_{2,k}) \leq q P\left( Bin\left(\Delta, (\hat{\theta})^{k-i}\right) \geq \Delta \hat{\theta}^{k-i} \right) \leq q \left( 3^{\theta^{k-i}} \right) \Delta^{\hat{\theta}^{k-i}} \leq e^{-\Delta^\epsilon}. \]
Combining (54) and (55) with (51) we see that \( \text{whp} \),

\[
\Phi'_{u,i} - \Phi_{u,i} \leq -\theta(1 - 2k^{2\varepsilon})\Phi_{u,i} + \binom{k-1}{i-1}\theta^{k-i}\Xi_u + \sum_{l=i+1}^{k-1} \binom{l}{i-1}\theta^{l-i}\Phi_{u,l} + \\
+2k\Delta^{-1/2k} + 2k\theta^2\hat{p}^2 \left( \binom{k-1}{i-1}\theta^{k-i}\Xi_u + \sum_{l=i+1}^{k-1} \binom{l}{i-1}\theta^{l-i}\Phi_{u,l} \right) \\
\leq \binom{k-1}{i-1}\theta^{k-i}\Xi_u + \sum_{l=i+1}^{k-1} \binom{l}{i-1}\theta^{l-i}\Phi_{u,l} - \theta(1 - 3k^{2\varepsilon})\Phi_{u,i} + \Delta^{-\varepsilon}.
\]

This confirms (19).

### 3.10.5 Proof of (20)

Fix \( c \) and write \( p' = p'_u(c) = p\beta \). We consider two cases, but in both cases \( E(\beta) = 1 \) and \( \beta \) takes two values, 0 and \( 1/P(\beta > 0) \). Then we have

\[
E(-p' \log p') = -p \log p - p \log(1/P(\beta > 0)).
\]

(i) \( p = p_u(c) \) and \( \beta = \gamma_u(c)/q_u(c) \) and \( \gamma_u(c) \) is a \( \{0, 1\} \) random variable with \( P(\beta > 0) = q_u(c) \).

(ii) \( p = p_u(c) = \hat{p} \) and \( \beta \) is a \( \{0, 1\} \) random variable with \( P(\beta > 0) = p_u(c)/\hat{p} \geq q_u(c) \).

Thus in both cases

\[
E(-p' \log p') \geq -p \log p - p \log 1/q_u(c).
\]

Observe next that \( 0 \leq a, b \leq 1 \) implies that \((1 - ab)^{-1} \leq (1 - a)^{-b} \) and \(-\log(1 - x) \leq x + x^2 \) for \( 0 \leq x \ll 1 \). So, from (3),

\[
\log 1/q_u(c) \leq -\Xi_u(c) \log(1 - \theta^{k-1}) - \sum_{i=2}^{k-1} \Phi_{u,i}(c) \log(1 - \theta^{i-1}) \\
\leq (\theta^{k-1} + \theta^{2k-2})\Xi_u(c) + \sum_{i=2}^{k-1} (\theta^{i-1} + \theta^{2i-2})\Phi_{u,i}(c).
\]
Now

\[ E(h_u - h'_u) \leq - \sum_c p_u(c) \log p_u(c) - E \left( \sum_c -p'_u(c) \log p'_u(c) \right) \]
\[ \leq \sum_c -p_u(c) \log p_u(c) - \left( \sum_c -p_u(c) \log p_u(c) - p_u(c) \log 1/q_u(c) \right) \]
\[ = \sum_c p_u(c) \log 1/q_u(c) \]
\[ \leq (\theta^{k-1} + \theta^{2k-2}) \sum_c p_u(c) \Xi_u(c) + \sum_c \sum_{i=2}^{k-1} (\theta^{i-1} + \theta^{2i-2}) p_u(c) \Phi_{u,i}(c) \]
\[ = (\theta^{k-1} + \theta^{2k-2}) \Xi_u + \sum_{i=2}^{k-1} (\theta^{i-1} + \theta^{2i-2}) \Phi_{u,i} \]
\[ \leq (\theta^{k-1} + \theta^{2k-2})(\omega + t\Delta^{-\varepsilon})(1 - \theta/2k)^t + \sum_{i=2}^{k-1} (\theta^{i-1} + \theta^{2i-2})k^{2k-2i}\omega(1 - \theta/3k)^t \]
\[ \leq k^{2k-3}\varepsilon(1 - \theta/3k)^t. \]

Given the \( p_u(c) \) we see that \( h'_u \) is the sum of \( q \) independent non-negative random variables with values bounded by \(-\hat{p}\log\hat{p} \leq \Delta^{-1/(k-1)+o(1)}\). Here we have used color independence. So,

\[ P(h_u - h'_u \geq k^{2k-3}\varepsilon(1 - \theta/3k)^t + \rho) \leq \exp \left\{ -\frac{2\rho^2}{q(\hat{p}\log\hat{p})^2} \right\} = e^{-2\rho^2\Delta^{1/k}}. \]

We take \( \rho = \varepsilon(1 - \theta/3k)^t \geq (\log \Delta)^{-O(1)} \) to see that \( h_u - h'_u \leq k^{2k}\varepsilon(1 - \theta/3k)^t \) holds \textit{whp}.

3.10.6 Proof of (21)

Fix \( u \) and condition on the values \( \gamma_{w}(c), \eta_{w}(c) \) for all \( c \in C \) and all \( w \notin N(u) \) and for \( w = u \). Now write \( u \sim v \) to mean that \{\( u, v \}\} lies in an edge of \( H^{(t)} \) or some \( H_i \). Then write

\[ Z_u = d(u) - d'(u) \geq \frac{1}{k-1} \sum_{u \sim v} Z_{u,v} \text{ where } Z_{u,v} = 1_{v \in U'}. \]

Now, for \( e = uu_2 \cdots u_k \in H^{(t)} \) let \( Z_{u,e} = \sum_{j=2}^{k} Z_{u,u_j} \) and if \( e = uu_2 \cdots u_i \in H_i \) let \( Z_{u,e} = \sum_{j=2}^{i} Z_{u,u_j} \). Conditional neighborhood independence implies that the collection \( Z_{u,e} \) constitute an independent set of random variables. Applying (27) to \( Z_u = \sum_e Z_{u,e} \) we see that

\[ P(Z_u \leq E(Z_u) - \Delta^{2/3}) \leq \exp \left\{ -\frac{2\Delta^{4/3}}{(k-1)^2\Delta} \right\} = e^{-2\Delta^{1/3}/(k-1)^2}. \]

(56)

and so we only have to estimate \( E(Z_u) \).
Fix $v \sim u$. Let $C_u(v)$ be as in (29). Condition on $C$. The vertex $v$ is a member of $U'$ if none of the colors $c \notin C_u(v)$ are tentatively activated. The activations we consider are done independently and so

$$
P(v \in U' \mid C) \leq \prod_{c \notin C_u(v)} (1 - \theta \rho_v(c))$$

$$\leq \exp \left\{ - \sum_{c \notin C_u(v)} \theta \rho_v(c) \right\}$$

$$\leq \exp \{ -\theta(1 - t\Delta^{-\varepsilon}) + \theta \rho_v(C_u(v)) \}$$

(57)

If $E_{(29)}$ occurs then $p_v(C_u(v)) \leq k^2 \varepsilon$. Consequently,

$$P(v \notin U') \geq \sum_{C : E_{(29)} \text{ occurs}} \left( 1 - \exp \left\{ -\theta(1 - \Delta^{-\varepsilon}) + k^2 \varepsilon \theta \right\} \right) P(C),$$

where the sum is well-defined due to Remark 8. Since $\theta \to 0$ as $\Delta \to \infty$, and $\varepsilon$ is sufficiently small,

$$1 - \exp \left\{ -\theta(1 - \Delta^{-\varepsilon}) + k^2 \varepsilon \theta \right\} > 1 - e^{-\theta(1 - 2k^2 \varepsilon)} > \theta(1 - 3k^2 \varepsilon) > \theta(1 - 1/k^2).$$

Recall that (29) shows that

$$P(E_{(29)} \text{ fails}) \leq e^{-\Delta^{1/2k}} < 1/k^2.$$ 

Therefore

$$P(v \notin U') \geq \theta(1 - 1/k^2) \sum_{C : E_{(29)} \text{ occurs}} P(C) > \theta(1 - 1/k^2)^2 > \theta(1 - 1/k).$$

This gives

$$E(Z_u) \geq \frac{1}{k} \theta d(u)$$

and (21).

3.10.7 Proof of (22)

Observe that if $e = uu_2 \cdots u_i \in H'_i \setminus H_i$ and $\kappa'(e) = c$ then either

(i) there exists $1 \leq j \leq k - i - 1$ and vertices $u_{i+1}, \ldots, u_{i+j}$ and an edge $uu_2 \cdots u_{i+j} \in H_{i+j}$ such that $u_{i+1}, \ldots, u_{i+j}$ get colored in Step $t$ with $c$ and so $\gamma_{u_{i+1}}(c) = \cdots = \gamma_{u_{i+j}}(c) = 1$ or

(ii) there exists $uu_2 \cdots u_k \in H(t)$ such that $u_{i+1}, \ldots, u_k$ all receive the color $c$ and so $\gamma_{u_{i+1}}(c) = \cdots = \gamma_{u_k}(c) = 1$. Hence,

$$d'_i(u) - d_i(u) \leq \sum_{j=1}^{k-i} Z_j$$

where for $j \leq k - i - 1$, $Z_j \leq Bin((1 + 2k\theta)^j \Delta \tilde{\rho}^{k-i-j}, (k-i) (\theta \tilde{p})^j)$ and $Z_{k-i} \leq Bin(\Delta, (k-i) (\theta \tilde{p})^{k-i}).$
If \( i < k - 1 \), then the Chernoff bound
\[
\Pr(\text{Bin}(n,p) \geq 2np) \leq e^{-np/3}
\]
implies that for \( 1 \leq j < k - i \),
\[
P \left( Z_j \geq 2(1 + 2k\theta)^{t} {k-i \choose j} \theta^j \Delta^{k-i} \right) \leq e^{-\Delta \epsilon}.
\]
Similarly,
\[
P(Z_{k-i} \geq 2(1 + 2k\theta)^{t} \theta^{k-i} \Delta^{k-i}) \leq e^{-\Delta \epsilon}.
\]
Therefore \textbf{whp}
\[
d'_i(u,c) - d_i(u,c) \leq 2(1 + 2k\theta)^{t} \Delta^{k-i} \sum_{j=1}^{k-i} {k-i \choose j} \theta^j
\]
\[
= 2(1 + 2k\theta)^{t} \Delta^{k-i} ((1 + \theta)^{k-i} - 1) \leq 2k\theta(1 + 2k\theta)^{t} \Delta^{k-i}.
\]

4 Acknowledgments

We thank Jeff Cooper for pointing out an error in an earlier draft of this paper and for helpful subsequent discussions on correcting it. Many thanks also to the referees for their careful reading and detailed comments which improved the presentation.
