A Lower Bound on Inelasticity in Pion-Pion Scattering

André Martin\(^1\) and S. M. Roy\(^2\)

\(^1\)Theoretical Physics Division, CERN, Geneva
\(^2\)HBCSE, Tata Institute of Fundamental Research, Mumbai

(Dated: 5 Oct. 2017)

Assuming that the pion-pion scattering amplitude and its absorptive part are analytic inside an ellipse in \(t\)-plane with foci \(t = 0, u = 0\) and right extremity \(t = 4m^2 \pi + \epsilon\), except for cuts prescribed by Mandelstam representation for \(t \geq 4m^2 \pi, u \geq 4m^2 \pi\), and bounded by \(s^N\) on the boundary of this domain, we prove that for \(s \to \infty\),

\[
\sigma_{\text{inel}}(s) > \frac{\text{Const}}{s^{5/2}} \exp\left[-\frac{\sqrt{s}}{4}(N + 5/2) \ln s\right].
\]

I. Introduction.

It is well known that if there is no inelasticity, the scattering amplitude must be zero. However, there is no quantitative estimate of the amount of inelasticity required. This is what we try to do. There are various proofs of the fact that the scattering amplitude must be zero if there is no inelasticity. A very appealing attempt has been made by Cheung and Toll [1]. Their idea is to use repeatedly elastic unitarity at all energies to the point where they get an absurd analyticity domain much too large. However, even after the enlargement of the pion-pion analyticity domain by one of us in 1966 [2], it is not obvious that they have really succeeded. Alexander Dragt [3] has a proof which is nice but not quite complete: it uses the fact that partial wave amplitudes for very large angular momenta are dominated by the nearest singularities in the crossed channel. He needs more analyticity than what has been proved from field theory [2]. For instance, if \(\epsilon = 12\) (corresponding to the full \(t\)-channel elastic strip), we must have inelasticity for \(s > 22\).

For simplicity, we look first at \(\pi^0\pi^0\) scattering amplitude \(F(s,t)\) where \(\pi^0\) is a fictitious iso-spin zero neutral pseudoscalar particle. It has the partial wave expansion,

\[
F(s,t) = \sum_{l=0}^{\infty} (2l + 1) f_l(s) P_l(1 + \frac{2t}{s-4});
\]

\[
f_l(s) = a_l(s)/\rho(s); \quad \rho(s) \equiv \frac{2k}{\sqrt{s}} = \sqrt{\frac{s-4}{s}} \quad (1)
\]

with the unitarity constraint

\[
\text{Im} a_l(s) = |a_l(s)|^2, 4 \leq s \leq 16; \quad \text{Im} a_l(s) \geq |a_l(s)|^2, s \geq 16. \quad (2)
\]
The optical theorem gives,
\[
\sigma_{\text{tot}} = \frac{8\pi}{k^2} \sum_{l=0}^{\infty} (2l + 1) \text{Im} \sigma_l(s) = \frac{16\pi}{k^2} \text{F}_s(s,0),
\]  
(3)

where \( F_s(s,t) \) denotes the \( s \)-channel absorptive part \( \text{Im} F(s,t) \). Similar unitarity conditions hold in the \( t \) and \( u \) channels. The normalization specified by the above choice of \( \rho(s) \) corresponds to \( F(4,0) = S \)-wave scattering length \( a_0 \). For the generalization to real pions of iso-spin 1, we shall use the same normalizations as above, with \( F(s,t), f_i(s), a_i(s), \sigma_{\text{tot}}, A_s(s,0), F(4,0), a_0 \) being replaced respectively by the corresponding quantities with superscript \( I \), e.g. \( F^I(s,t), a^I_0 \).

Our strategy will be the following, we write the partial-wave amplitudes as well as their imaginary parts as contour integrals along the ellipse mentioned above, and add the contribution of the cuts (see fig. 1). Then we try to get an upper bound on the partial wave amplitude \( f_i \) for which we need an upper bound \( B(s) \) on the whole ellipse. We also seek a lower bound on it’s imaginary part \( \text{Im} f_i \), for which we need a bound on the discontinuity of the absorptive part which is not just the Mandelstam double spectral function. In fact this is what is missing in the work of Dragt. This will be done in the next section.

**Domain of Positivity of the Double Spectral Function and a Lower Bound** In the first part, we recall the results of Mahoux and of one of us \( @ \) on the domain of positivity of the double spectral function.

For \( s > 20 \), the absorptive part in the \( s \)-channel has a cut beginning at
\[
t = 4 + \frac{64}{s - 16}.
\]  
(4)

From \( t = 4 \) to \( t = 4 + \epsilon < 16 \), the discontinuity across the cut is given by the Mandelstam form of the \( t \)-channel elastic unitarity condition on one of the double spectral functions \( \rho_{st}(s,t) \),
\[
\rho_{st}(s,t) = \frac{2\rho(t)}{\pi} \int \int \frac{dz_1dz_2}{\sqrt{H(z,z_1,z_2)}} F_s(s_1,t)F_s(s_2,t)^*,
\]  
(5)

where
\[
\rho(t) = \sqrt{\frac{4t}{t-4}}, \quad z = 1 + \frac{2s}{t-4}, \quad z_0 = 1 + \frac{t}{t-4}, \quad z_i = 1 + (2s_i)/(t-4), \quad i = 1,2
\]  
(6)

and
\[
H(z,z_1,z_2) = z^2 + z_1^2 + z_2^2 - 1 - 2z z_1 z_2
= (z - z_+)(z - z_-).
\]  
(7)

with
\[
z_{\pm} = z_1 z_2 \pm \sqrt{(z_1^2 - 1)(z_2^2 - 1)}.
\]  
(8)

The domain of integration in the \( z_1, z_2 \) plane is bounded by the three lines,
\[
z_1 > z_0, \quad z_2 > z_0, \quad , z > z_+.
\]  
(9)

If we define
\[
z = \cosh \theta; \quad z_i = \cosh \theta_i, \quad i = 0,1,2,
\]  
(10)

then, the region \((9)\) becomes just a triangle in the \( \theta_1, \theta_2 \) plane bounded by the lines, (see Fig. 2)
\[
\theta_0 \leq \theta_1, \quad \theta_0 \leq \theta_2, \quad \theta_1 + \theta_2 \leq \theta.
\]  
(11)

These inequalities imply that for \( i = 1,2 \), \( \theta_0 \leq \theta_i \leq \theta - \theta_0 \), i.e.
\[
z_0 \leq z_i \leq zz_0 - \sqrt{(z^2 - 1)(z_0^2 - 1)}.
\]  
(12)

They also imply that \( \theta \geq 2\theta_0 \) which gives the boundary curve of the spectral region
\[
s \geq \frac{16t}{t-4}.
\]  
(13)

It will be crucial to recall the observation of Mahoux and Martin that when \( \theta \leq 3\theta_0 \), the inequalities \((11)\) imply that only values of \( \theta_i \leq 2\theta_0 \) for \( i = 1,2 \), i.e. only values of \( F_s(s_i,t) \) outside the spectral region for \( i = 1,2 \) are needed to compute the double spectral function. In this region, the convergent partial wave expansion,
\[
F_s(s_i,t) = \sum_{l=0}^{\infty} (2l + 1)\text{Im} f_i(s_i) P_l(1 + \frac{2t}{s_i - 4}), \quad i = 1,2,
\]
the positivity of \( \text{Im} f_i(s_i) \) and the inequalities \( P_l(1 + \frac{2t}{s_i - 4}) > 1 \) imply that \( F_s(s_i,t) > 0 \) for \( i = 1,2 \). Hence, the double spectral function \( \rho_{st}(s,t) \) is positive when \( \theta \leq 3\theta_0 \), i.e. for
\[
4 \leq t \leq 16, \quad \text{and} \quad \frac{16t}{t-4} \leq s \leq 4\left(\frac{3t + 4}{t - 4}\right)^2,
\]

i.e. \( 4 + 64/(s - 16) \leq t \leq 4 + 32/(\sqrt{s} - 6) \).

Since \( \rho(s,t) \) is symmetrical in its arguments, it is also positive for,
\[
4 \leq s \leq 16, \quad \frac{16s}{s - 4} \leq t \leq 4\left(\frac{3s + 4}{s - 4}\right)^2.
\]  
(16)

**II. Lower bound on inelasticity**

We shall now obtain a lower bound on \( \rho(s,t) \) in the domain \((15)\) in terms of total cross sections \( \sigma_{st}(s_1), \sigma_{tot}(s_2) \), where \( s_1, s_2 \) are such that Eqn. \((12)\) holds for the corresponding \( z_1, z_2 \). We then deduce a lower bound on inelasticity. It will then follow that if there is no inelasticity at one (and only one) energy in the \( s \)-channel (\( s > 20 \)), the double spectral function must vanish in the range \( t = 4 + 64/(s - 16) \) to \( t = 4 + 32/(\sqrt{s} - 6) \), and hence that there is an interval
of energy given by (12) in which the total cross section vanishes. This is impossible and hence the scattering amplitude is zero. It must be realized that only a small fraction of Mandelstam representation is used.

Now, the question which was asked to one of us (AM) by Miguel F. Paulos, during a conference organized by João Penedones at EPFL, Lausanne was, if the inelastic cross section could be arbitrarily small. We want to show that, with some assumptions much weaker than the Mandelstam representation, but slightly stronger than what has been proved from local field theory, there exists a lower bound to inelasticity.

\begin{equation}
\sigma_{\text{inelastic}} > C \exp(-\sqrt{s/s_0} \log(s/s_0)).
\end{equation}

The strategy we shall use is based on the results of Mahoux and Martin [3] on positivity of double spectral functions, and on the research made by Dragt [3], viz.

that the real and imaginary parts of the partial wave amplitudes are dominated by the contributions of the nearby cuts in the crossed channel:

\begin{align*}
&\text{from } t = 4 \text{ to } t = t_M(s) \text{ for } \text{Re} f_i \\
&\text{from } t = 4 + \frac{64}{s-16} \text{ to } t = t_M(s) \text{ for } \text{Im} f_i,
\end{align*}

where,

\begin{equation}
t_M(s) \equiv 4 + \frac{32}{\sqrt{s} - 6}.
\end{equation}

**Estimates of \( f_i(s) \) and \( \text{Im} f_i(s) \)** We shall use a truncated Froissart-Gribov representation for \( \text{Re} f_i(s) \) and \( \text{Im} f_i(s) \). It follows from analyticity of \( F(s, t) \) in \( t \) within an ellipse with right extremity \( t = t_M(s) \) and foci \( t = 0 \) and \( u = 0 \), except for cuts \( 4 \leq t \leq t_M(s) \) and \( 4 \leq u \leq

FIG. 1: The amplitude \( F(s, t) \) is assumed to be analytic in \( t \) within the ellipse shown except for cuts \( t \geq 4, u \geq 4 \); its absorptive part \( F_s(s, t) \), for \( s \geq 20 \) is assumed to be analytic in \( t \) within the same ellipse except for cuts for \( t \geq 4 + \frac{64}{s-16}, u \geq 4 + \frac{64}{s-16} \). The truncated Froissart-Gribov formulae for \( f_i(s) \), Eq. (20) and \( \text{Im} f_i(s) \), Eq. (21) follow from this. Note that the horizontal and vertical scales in this figure are not the same.
\[ t_M(s) \] For \( l \) even,

\[
 f_i(s) = \frac{1}{\pi k^2} \int_4^{4 + \sqrt{s - 6}} Q_l(1 + \frac{2t}{s - 4}) F_i(s, t) \, dt
 + \frac{1}{4i \pi k^2} \int_{\Gamma} Q_l(1 + \frac{2t}{s - 4}) F(s, t) \, dt. \tag{20}
\]

where \( \Gamma \) is an ellipse with foci at \( t = 0 \) and \( u = 0 \), and right extremity at \( t = 4 + \frac{32}{\sqrt{s - 6}} \) (see figure \ref{fig:ellipse}).

Hence,

\[
 Im f_i(s) = \frac{1}{\pi k^2} \int_4^{4 + \sqrt{s - 6}} Q_l(1 + \frac{2t}{s - 4}) \rho(s, t) \, dt
 + \frac{1}{4i \pi k^2} \int_{\Gamma} Q_l(1 + \frac{2t}{s - 4}) F_s(s, t) \, dt. \tag{21}
\]

where \( \rho(s, t) \) is given by the Mandelstam equation \[\text{(5)}.\]

As noted earlier, if \( s \) is in the Mahoux-Martin domain \[\text{(10)}, \rho(s, t) \) is positive.

Now we postulate that \( F(s, t) \) and \( F_s(s, t) \) are bounded by \( B(s) \) in the ellipse \( \Gamma \). The behaviour of \( B(s) \) for \( s \to \infty \) will be discussed later. Now we need some estimates on the \( Q_l \)'s. We prove that, for \( z \) real and \( \theta \) a non-zero, (see Appendix)

\[
 \frac{1}{\sqrt{2l + 2(1 - 1)} l^{1 + 1}} < Q_l(z) < \frac{1}{(z + 1)} \ln |z + 1|, \tag{22}
\]

and for \( z = \cosh((\theta_1 + i \theta_2)) \), (see Appendix),

\[
 |Q_l(\cosh((\theta_1 + i \theta_2)))| < |Q_l(\cosh((\theta_1)))|. \tag{23}
\]

This means that on an ellipse with \( \cos \theta = \pm 1 \) the modulus of \( Q_l(\cos \theta) \) is maximum at the right extremity.

We can get a bound on \( |f_l| \)

\[
 |f_l| < \frac{1}{4 \pi k^2} Q_l(1 + \frac{8}{s - 4}) B(s) L(s) \tag{24}
\]

where \( L(s) \) is the perimeter of the ellipse with extremities at

\[
 \cos \theta_s = \pm \left(1 + \frac{1}{2k^2}(4 + \frac{32}{\sqrt{s - 6}}) \right) \tag{25}
\]

plus 4 times the length of the cuts \( t = 4 \) to \( t = 4 + \frac{32}{\sqrt{s - 6}} \).

For \( s > 16 \),

\[
 L(s) < 4s. \tag{26}
\]

We need now a lower bound for \( \text{Im} f_i(s) \). \( \text{Im} f_i(s) \) is given by a contour integral including the contribution from the cuts and the ellipse. We use the fact that \( Q_l() \) is a decreasing function for an argument \( > 1 \). We limit arbitrarily the integration on the cuts to

\[
 4 + \frac{64}{s - 16} < t < 4 + \frac{64 + P(s)}{s - 16},
\]

where,

\[
 P(s) < \text{Const}; 4 + \frac{64 + P(s)}{s - 16} < 4 + \frac{32}{\sqrt{s - 6}} \tag{27}
\]

which is certainly valid for sufficiently large \( s \). A lower bound on \( \text{Im} f_i \) is given by

\[
 \text{Im} f_i > \frac{1}{\pi k^2} Q_l(1 + \frac{1}{s - 4}(8 + \frac{128 + 2P(s)}{s - 16}))
 \times \int_4^{4 + \sqrt{s - 6}} \rho(s, t) \, dt
 - \frac{1}{4 \pi k^2} B(s) L(s) Q_l(1 + \frac{1}{s - 4}(8 + \frac{64}{\sqrt{s - 6}})) \tag{28}
\]

Notice that \( \rho(s, t) \) according to \[\text{(7)}, \text{is strictly positive, given by the double integral of Mandelstam in the strip} \]

\( 4 < t < 4 + 32/(\sqrt{s - 6}) \).

Now, given \( B(s), L(s) \) and \( \rho(s, t) \) it is possible to prove that \( |f_l|^2 \) is strictly less than \( \text{Im} f_l \) for \( l \) sufficiently large. We have

\[
 |f_l|^2 < \frac{1}{(4 \pi k^2)^2} Q_l^2(1 + \frac{8}{s - 4}) |B(s)|^2 |L(s)|^2 \tag{29}
\]

and so

\[
 \frac{\text{Im} f_i}{|f_l|^2} > \frac{16 \pi k^2}{|B(s)|^2 |L(s)|^2} \frac{Q_l(x_1)}{Q_l(x_2)} \times \int_4^{4 + \sqrt{s - 6}} \rho(s, t) \, dt
 - \frac{4 \pi k^2}{B(s) L(s)} \frac{Q_l(x_3)}{Q_l^2(x_2)}, \tag{30}
\]

where we define,

\[
 x_1 = 1 + \frac{1}{s - 4}(8 + \frac{128 + 2P(s)}{s - 16}),
 x_2 = \frac{8}{s - 4},
 x_3 = 1 + \frac{1}{s - 4}(8 + \frac{64}{\sqrt{s - 6}}). \tag{31}
\]

It is convenient to denote,

\[
 R_1 = \frac{2x_2^2 - 1 + \sqrt{(2x_2^2 - 1)^2 - 1}}{x_1 + \sqrt{x_1^2 - 1}},
 R_2 = \frac{x_2 + \sqrt{x_2^2 - 1}}{x_1 + \sqrt{x_1^2 - 1}}. \tag{32}
\]
Note that, $x_2 < x_1$, and for $s$ sufficiently large,
\[ x_1 < x_3 , \text{and} \; x_1 < 2x_2^2 - 1, \]
\[ \text{hence,} \; R_1 > 1; \; R_2 > 1. \]  
(33)

We now obtain bounds on the relevant Legendre functions. Using the results (90) and (96) in the Appendix, we have,
\[
\frac{Q_l(x_1)}{Q_l^2(x_2)} \geq \frac{1}{2x_2Q_o(x_2)} \frac{Q_l(2x_2^2 - 1)}{Q_l^2(x_1)} \geq \frac{1}{2x_2Q_o(x_2)} R_l^{l+1}. 
\]  
(34)

Further Equations (98) and (91) in the Appendix yield,
\[
\frac{Q_l(x_3)}{Q_l^2(x_2)} \leq \sqrt{\frac{2(l+1)}{\pi}} \left( \frac{R_1}{R_2} \right)^{l+1},
\]  
(35)

and Eqn (96) gives,
\[
\frac{Q_l(x_3)}{Q_l(x_1)} \leq \left( \frac{1}{R_2} \right)^{l+1}. 
\]  
(36)

We now have,
\[
\frac{\text{Im} f_l}{|f_l|^2} \geq \frac{16\pi k^2}{|B(s)|^2 L(s)^2} \frac{1}{2x_2Q_o(x_2)} R_l^{l+1} \times \int_{4s}^{4s+g(s,t)} \rho(s,t)dt 
- \frac{4\pi k^2}{B(s)L(s)} \sqrt{\frac{2(l+1)}{\pi}} \left( \frac{R_1}{R_2} \right)^{l+1}, 
\]  
(37)

without asymptotic approximations.

For $s \to \infty$,
\[
x_1 + \sqrt{x_1^2 - 1} \sim 1 + \frac{4}{\sqrt{s}} + \frac{8}{s} + ..., \]
\[
x_3 + \sqrt{x_3^2 - 1} \sim 1 + \frac{4}{\sqrt{s}} + \frac{24}{s} + ..., \]
\[
2x_2^2 - 1 + \sqrt{(2x_2^2 - 1)^2 - 1} \sim 1 + \frac{4}{\sqrt{s}} + \frac{32}{s} + ..., \]
\[
R_1 \sim 1 + 4/\sqrt{s}, \; \text{and} \; (1/R_2) \sim 1 - 16/s. \]  
(38)

It is clear that since $R_2 > 1$, for $l$ large enough, i.e. for

\[ l > L_0(s) = \text{Const.s ln s}, \; s \to \infty, \]

the contribution of the first term on the right-hand side of Eqn. (77) involving a positive double spectral function is dominant, and that term implies that
\[
\frac{\text{Im} f_l}{|f_l|^2} \to \infty, \; l > \text{Const.s ln s}. 
\]

Hence the inelastic cross section is dominant and non-zero for $l > L_0(s)$. The fact that $\rho(s, t)$ is different from zero is essential. We now evaluate the lower bound on $\text{Im} f_l$, and hence on the inelastic cross section at high energies.

**III. Lower bound on the double spectral function.**

We must get a lower bound on $\rho(s, t)$. This is relatively easy. We return to the Mandelstam equation (5) for $4 < t < 16$ and restrict ourselves to the Mahoux-Martin domain (15) of positivity of $\rho(s, t)$. To get a lower bound on $\rho(s, t)$ we shall do rather wild majorizations.

1) We reduce the domain of integration in the $\theta_1, \theta_2$ plane (11) to the union of three regions $A, B, C$ (see figure 2).

\[
A : \; \theta_0 \leq \theta_i \leq \theta_M \equiv \theta/2, \; i = 1, 2 \]
\[
i.e. z_0 \leq z_1 \leq z_M \equiv \frac{1 + z}{2} i = 1, 2 \]
\[
B : \; \theta_0 \leq \theta_i \leq \theta_{1M} \equiv (\theta/4 + \theta_0/2) \]
\[
i.e. z_0 \leq z_1 \leq z_{1M} \equiv \cos(\theta/4 + \theta_0/2) \]
\[
\theta/2 \leq \theta_2 \leq \theta_{2M} \equiv (3\theta/4 - \theta_0/2) \]
\[
i.e. z_2 \leq z_1 \leq z_{2M} \equiv \cos(3\theta/4 - \theta_0/2) \]
\[
C : \; \theta_0 \leq \theta_2 \leq \theta_{1M} \]
\[
i.e. z_0 \leq z_2 \leq z_{1M} \]
\[
\theta/2 \leq \theta_1 \leq \theta_{2M} \]
\[
i.e. z_M \leq z_1 \leq z_{2M} \]  
(39)

Notice that under $z_1 \leftrightarrow z_2$, the regions $B \leftrightarrow C$ and $A \leftrightarrow A$.

2) Using Eqs. (7), (8), we shall replace $H(z_1, z_2)$ in the denominator by simple upper bounds on it in the three regions:

\[
A: H(z_1, z_2) \leq (z - 1)^2 \]
\[
B, C : H(z_1, z_2) \leq (z - z_0^2) \leq (z - z_0)^2 ; \]
\[
z_3 \equiv \cos(\theta/4 - \theta_0/2). \]  
(40)

It will be convenient to define,
\[
(z_M, z_{1M}, z_{2M}, z_3) = 1 + \frac{2}{t - 4} (s_M, s_{1M}, s_{2M}, s_3) \]  
(41)

3) Since we are in the Mahoux-Martin domain in which $F_s(s_1, t)$ and $F_s(s_2, t)$ have convergent partial wave expansions with positive partial waves, and $t$ is positive, the absorptive parts obey the bounds,
\[
F_s(s_1, t) \geq F_s(s_1, 0) = \frac{k_i \sqrt{s_1}}{16\pi} \sigma_{\text{tot}}(s_1); \; i = 1, 2. \]  
(42)

They also obey stronger bounds in terms of $\sigma_{\text{tot}}(s_1)$, originally derived by Martin [2] or $0 < t < 4$, but also valid for $4 < t < 4 + \frac{2}{\sqrt{s_1}}$ under the present assumptions. At high energies they have the simple form,
\[
F_s(s_1, t) \geq F_s(s_1, 0) \frac{2 I_1(x_i)}{x_i} (1 + O(1/\sqrt{s_1})); \; x_i = \sqrt{\sigma_{\text{tot}}(s_i)/(4\pi)}; \; i = 1, 2 \]  
(43)
FIG. 2: We show the triangular integration region in the $\theta_1, \theta_2$ plane in Mandelstam’s continued elastic unitarity equation in $t$-channel, defined by $\theta_1 \geq \theta_0$, $\theta_2 \geq \theta_0$, and $\theta_1 + \theta_2 \leq \theta$. The sub-regions $A, B, C$ are used to calculate lower bounds on the double spectral function.

Using the majorizations 1), 2) and the weaker bound 3), we obtain

$$\rho(s, t) \geq \frac{4}{\pi \sqrt{t(t-4)}} \left[ I^2(s_M) + \frac{2}{s-s_3} I(s_{1M}) I(s_{2M}) \right],$$

where the first term in the braces on the right is the contribution of region $A$ and the second term of regions $B$ and $C$.

$$I(s_M) = \int_4^{s_M} ds_1 k_1 \sqrt{s_1 \sigma_{\text{tot}}(s_1)} \frac{1}{16\pi},$$

and $I(s_{1M})$, $I(s_{2M})$ are defined similarly by replacing $s_M$ by $s_{1M}$ and $s_{2M}$ respectively. Note that $s_M$, $s_{1M}$ and $s_{2M}$ depend on $s, t$. E.g.

$$2s_M = \sqrt{(t-4)(t-4+s)} - (t-4).$$

A simple bound is obtained by retaining only the region $A$. In addition to the above results for general $P(s)$, we shall evaluate bounds on $I(s_M), \rho(s, t)$ and the integral over $t$ of $\rho(s, t)$, for two simple choices of $P(s)$.

(i) $P(s)$ independent of $s$. Let $P_1 < p < P_2$ then we can get a lower bound on the integral over $t$ of $\rho(s, t)$ by restricting to the interval

$$\frac{(64 + P_1)/(s - 16)}{s - 16} < t - 4 = \frac{(64 + p)/(s - 16)}{s - 16} < \frac{(64 + P_2)/(s - 16)}{s - 16}.$$

Then,

$$t(t-4) < \frac{(64 + P_2)(4s + P_2)}{(s-16)^2}.$$

For fixed $s$ large enough, $s_M$ is an increasing function of $t$, and hence it’s minimum value is at the lowest value
of \( t \),

\[
s_M \geq (s_M)_{\text{min}} \equiv \sqrt{(64 + P_1)(64 + P_1 + s(s - 16))} - (64 + P_1) \quad \frac{2(s - 16)}{2(s - 16)}
\]  

(48)

and

\[
I(s_M) \geq I((s_M)_{\text{min}}).
\]  

(49)

Finally we have the bound,

\[
\int_{4 + \frac{64 + p_1(s)}{s - 16}}^{4 + \frac{64 + p_2(s)}{s - 16}} \rho(s, t) dt \geq \frac{4(P - P_1)I^2((s_M)_{\text{min}})}{\pi s \sqrt{(64 + P_2)(4s + P_2)}}
\]

(50)

which is positive definite and \( > Const.s^{-3/2} \) unless the total cross section vanishes identically at all energies up to \((s_M)_{\text{min}}\).

(ii) \( P(s) \to 0 \) for \( s \to \infty \). Then, we integrate over the region,

\[
4 + \frac{(64 + p_1(s))}{(s - 16)} < t = 4 + \frac{(64 + p(s))}{(s - 16)} < 4 + \frac{(64 + p_2(s))}{(s - 16)}
\]

(51)

where \( p_1(s) \) and \( p_2(s) \) \( \to 0 \), for \( s \to \infty \), and we get \( s_M - 4 \sim p(s)/32 \to 0 \). In the integral defining \( I(s_M) \) we can therefore replace

\[
\sigma_{\text{tot}} \to 8\pi a^2_0,
\]

(52)

where \( a_0 \) is the \( S^- \) wave scattering length, and obtain

\[
I^2((s_M)_{\text{min}}) \to (p(s)/32)^3a^4_0/9 \geq (p_1(s)/32)^3a^4_0/9.
\]

(53)

Finally we obtain for \( s \to \infty \), \( p_1(s) \) and \( p_2(s) \) \( \to 0 \), as slowly as we like,

\[
\int_{4 + \frac{64 + p_1(s)}{s - 16}}^{4 + \frac{64 + p_2(s)}{s - 16}} \rho(s, t) dt \geq \frac{p_2(s) - p_1(s)}{36\pi s^{3/2}} \frac{(p_1(s))^3a^4_0}{32}.
\]

(54)

This bound is of interest as it shows that the asymptotic inelastic cross section cannot vanish if the \( S^- \) wave scattering length is non-zero. However, the bound \( (50) \) is preferable as it does not need any asymptotic approximation.

**IV. Asymptotic behaviour of the lower bound on inelastic cross section and discussion of the assumptions.**

Now we know that, above a certain energy, the inelastic cross section cannot be zero. A lower bound can be obtained if we know something about \( B(s) \) and if we accept the postulated analyticity. If we believe in the validity of the Mandelstam representation with a finite number of subtractions, \( B(s) = s^N \). In fact we tend to believe that \( B(s) = s^2/s^2_0 \), because we postulate an ellipse (with cuts) which in the limit of high energy coincides with the ellipse with foci \( t = 0, u = 0 \) and extremities \( t = 4, u = 4 \). Inside this ellipse the absorptive part \( F_a(s, t) \) is maximum for \( t \) real, \( 0 < t < 4 \), and the integral

\[
\int \frac{F_a(s, t) ds}{s^4} < \infty
\]

(55)

which means that \( F_a(s, t) \) is almost everywhere less than \( s^2 \). Concerning the dispersive part which is, modulo subtractions, the Hilbert transform of the absorptive part we have a rather tricky argument to show again that it is almost everywhere bounded by \( s^2 + \epsilon \), \( \epsilon \) arbitrarily small, for any \( t \) for which dispersion relations are valid. But we shall not use that result here.

Using the lower bound on the integral of the double spectral function, and \( B(s) = s^N \), we deduce that the ratio of the contributions of the cut term and the elliptical contour \((\Gamma) \) term to \( Imf_1 \) goes to infinity if

\[
l > L_0(s) = \frac{(N + 5/2)}{16}s \ln s.
\]

(56)

The ratio of the contribution of the cut term to \( Imf_1 \) to the upper bound on \(|f_1|^2 \) goes to infinity for a much smaller value, viz. if

\[
l > L_1(s) = \sqrt{s}/4(2N + 5/2) \ln s.
\]

(57)

Hence, summing the contributions of partial waves with \( l > L_0(s) \) we see that for \( s \to \infty \),

\[
\sigma_{\text{inel}}(s) > \frac{\text{Const}}{s^{5/2}} \exp\left[-\frac{\sqrt{s}}{4}(N + 5/2) \ln s\right].
\]

(58)

**V. Real Pions of Isotopic Spin 1.** Let \( F^{(i)}(s, t, u) \) denote the \( \pi\pi \to \pi\pi \) amplitudes with total iso-spin \( I \) in the \( s \)-channel, \( I = 0, 1, 2 \), and \( F^{(i)}(t, s, u) \) the amplitudes with iso-spin \( I \) in the \( t \)-channel. They are related by the crossing matrix \( C_{st} \),

\[
\begin{bmatrix}
F^{(0)}(t, s, u) \\
F^{(1)}(t, s, u) \\
F^{(2)}(t, s, u)
\end{bmatrix}
= C_{st}
\begin{bmatrix}
F^{(0)}(s, t, u) \\
F^{(1)}(s, t, u) \\
F^{(2)}(s, t, u)
\end{bmatrix}.
\]

\[
C_{st} = \begin{bmatrix}
1/3 & 1 & 5/3 \\
1/3 & 1/2 & -5/6 \\
1/3 & -1/2 & 1/6
\end{bmatrix}.
\]

(59)

We do not assume the unsubtracted Mandelstam representation,

\[
F^{(i)}(s, t, u) = \frac{1}{\pi^2} \int \int \frac{\rho^{(i)}_{su}(s', t') ds' dt'}{(s' - s)(t' - t)} + \frac{1}{\pi^2} \int \int \frac{\rho^{(i)}_{u}(t', u') ds' dt'}{(s' - s)(u' - u)}
\]

(60)

However, we use the definitions

\[
F^{(i)}_{su}(s, t, u) = \rho^{(i)}_{su}(s, t), F^{(i)}_{tu}(s, t, u) = \rho^{(i)}_{tu}(s, t, u),
\]

(61)
and Eq. (59) then implies that
\[ F^{(I)}_{st}(t, s, u) = \rho^{(I)}_{st}(t, s) = \sum_{I' = 0, 1, 2} C^{I'}_{st} \rho_{st}^{(I')}(s, t). \] (62)

Note that in \( \rho^{(I)}_{st}(t, s) \) and \( \rho_{st}^{(I')}(s, t) \), the superscripts \( I, I' \) denote iso-spins in the channels specified by the first argument, viz. t-channel and s-channel respectively. The Mandelstam unitarity equations for t-channel Iso-spin \( I \), and \( 4 \leq t \leq 16 \) is given by Mahoux and Martin [8],
\[ \rho^{(I)}(t, s) = \frac{2\rho(t)}{\pi} \int \int \frac{dz_1 dz_2 \theta(z - z_+)}{\sqrt{H(z, z_1, z_2)}} C^{(I)}(t, s, z_2), \]
and
\[ G^{(I)}(t, s, z_2) = (-1)^I F^{(I)}_{st}(t, s_1) F^{(I')}_{s_1 t}(s_2, t), \] (63)

Crossing, Eq. (59) immediately yields
\[ G^{(I)}(t, s_1, s_2) = \sum_{I', I'' = 0, 1, 2} C_{s_1 t}^{I'} F^{(I')}_{s_1 t}(s_1, t) F^{(I'')}_{s_2 t}(s_2, t)^*, \]
\[ \zeta_{I', I''}^I = (-1)^I C_{st}^{I''} C_{st}^{I'}, \] (64)

where,
\[ \zeta^0 = \begin{bmatrix} 1/9 \\ 1/3 \\ 5/9 \end{bmatrix}, \zeta^1 = \begin{bmatrix} -1/9 \\ -1/6 \\ 5/18 \end{bmatrix}, \zeta^2 = \begin{bmatrix} 1/9 \\ -1/6 \\ 1/18 \end{bmatrix}, \zeta^3 = \begin{bmatrix} -1/6 \\ 1/4 \\ -1/12 \end{bmatrix}, \] (65)

which are identical to the values obtained in [8], and quoted again for ready reference. We now have,
\[ \rho^{(I)}(t, s) = \frac{2\rho(t)}{\pi} \int \int \frac{dz_1 dz_2 \theta(z - z_+)}{\sqrt{H(z, z_1, z_2)}} C^{(I)}(t, s, z_2), \]
\[ \times \sum_{I', I'' = 0, 1, 2} \zeta_{I', I''}^I F^{(I')}_{s_1 t}(s_1, t) F^{(I'')}_{s_2 t}(s_2, t)^*. \] (66)

Mahoux and Martin [8] have noted that all the main elements of
\[ \zeta^0, \zeta^0 - \zeta^2, \zeta^0 + \zeta^1, \zeta^0 - 2\zeta^1, \text{ and } \zeta^0 + 2\zeta^2 \] (67)
are positive, and for \( s, t \) in the Mahoux-Martin domain [16] the \( F^{(I)}_{s_1 t}(s_1, t), i = 1, 2 \) are positive for the relevant values of \( s_i \) due to unitarity. From Eqn. (66), it follows that,
\[ \sum_{I} \beta_{I} \zeta_{I', I''}^I > 0, \text{ for all } I', I'' \implies \sum_{I} \beta_{I} \rho^{(I)}(t, s) > 0. \] (68)

Hence,
\[ \rho^{(0)}(t, s), \rho^{(0)}(t, s) - \rho^{(2)}(t, s), \rho^{(0)}(t, s) + \rho^{(1)}(t, s), \]
\[ \rho^{(0)}(t, s) - 2\rho^{(1)}(t, s), \text{ and } \rho^{(0)}(t, s) + 2\rho^{(2)}(t, s) \] (69)
are positive in the Mahoux-Martin domain. We can exploit these results to get bounds on inelastic cross sections for real pions (of iso-spin 1).

**New results.** The truncated Froissart-Gribov formula will enable us to obtain lower bounds on imaginary parts of s-channel partial waves of the following five amplitudes:
\[ \frac{1}{3} F^{(0)} + F^{(1)} + \frac{5}{3} F^{(2)}(s, t) = F^{(0)}(t, s); \]
\[ \frac{3}{2} F^{(1)} + F^{(2)}(s, t) = (F^{(0)} - F^{(2)})(t, s); \]
\[ \frac{5}{6} F^{(0)} + \frac{3}{2} F^{(1)} + \frac{5}{6} F^{(2)}(s, t) = (F^{(0)} + F^{(1)})(t, s); \]
\[ \frac{1}{3} (F^{(0)} + 2F^{(2)})(s, t) = \frac{1}{3} (F^{(0)} + 2F^{(2)})(t, s), \]
\[ F^{(0)} = \frac{1}{3} (F^{(0)} + 2F^{(2)}). \] (70)

where the right-hand sides correspond to the t-channel Iso-spin combinations in Eq. (69) and the left-hand sides are the corresponding linear combinations of s-channel Iso-spin amplitudes. These equations are of the form,
\[ \sum_{I} \alpha_{I} F^{(I)}(t, s) = \sum_{I} \beta_{I} F^{(I)}(t, s), \] (71)

where the coefficients \( \alpha_{I} \) and \( \beta_{I} \) can be read off the Equations (70). E.g. \( \alpha_0 = \beta_0 = 1/3, \alpha_2 = \beta_2 = 2/3, \alpha_1 = \beta_1 = 0 \) for the last equation which is just the \( \pi^0, \pi^0 \rightarrow \pi^0, \pi^0 \) amplitude,
\[ F^{(0)} \equiv \frac{1}{3} (F^{(0)} + 2F^{(2)}). \] (72)

The partial waves given by the truncated Froissart-Gribov formula are then, for even \( l + I \),
\[ \sum_{I} \alpha_{I} F^{(I)}_{lt}(s) = \frac{1}{4\pi k^2} \int_{\Gamma} Q_I(1 + \frac{2t}{s - a}) \sum_{I} \beta_{I} F^{(I)}(t, s) dt + \frac{1}{\pi k^2} \int_{\Gamma} Q_I(1 + \frac{2t}{s - a}) \sum_{I} \beta_{I} F^{(I)}(t, s) dt \] (73)

and
\[ \sum_{I} \alpha_{I} Im F^{(I)}_{lt}(s) = \frac{1}{4\pi k^2} \int_{\Gamma} Q_I(1 + \frac{2t}{s - a}) \sum_{I} \beta_{I} F^{(I)}(t, s) dt + \frac{1}{\pi k^2} \int_{\Gamma} Q_I(1 + \frac{2t}{s - a}) \sum_{I} \beta_{I} F^{(I)}(t, s) dt \] (74)

As before, \( \Gamma \) is an ellipse with foci at \( t = 0 \) and \( u = 0 \), and right extremity at \( t = 4 + \frac{4}{\pi^2 b} \). As for pions without iso-spin, we prove, if we only use the region \( A \) in Fig. 2, that the combinations \( \sum_{I} \beta_{I} F^{(I)}(t, s) \) on the right-hand side are not any positive, but also have a lower bound,
\[ \sum_{I} \beta_{I} F^{(I)}(t, s) \geq \frac{4}{\pi \sqrt{t(t - 4)}} \sum_{I} \beta_{I} \zeta_{I', I''}^I F^{(I)}(s_M) F^{(I'')}^{(s_M)} \] (75)
provided that \( \sum l \beta_l c f_{l, \nu} > 0 \), for all \( \Gamma, \Gamma' \), and
\[
I''(s_M) = \int_{s_M}^{\infty} ds_k k_1 \sqrt{\sigma^{(l)}(s_1)} / 16 \pi.
\]

We can now obtain lower bounds on the cut contributions to linear combinations of imaginary parts of \( s \)-channel partial waves,
\[
\begin{align*}
1/3f_1(0) + f_1(1) + 5/3f_2(2), & \quad 3/2(f_1 + f_1(2)), \\
2/3f_1(0) + 3/2f_1(1) + 5/6f_2(2), & \quad -1/3f_1(0) + 10/3f_3(2), \\
1/3f_1(0) + 2/3f_2(2).
\end{align*}
\]

from lower bounds respectively on the combinations of \( \rho^{(l)}(t, s) \) given in Eqn. (69). The contributions to these imaginary parts from the elliptical contours \( \Gamma \) are negligible for \( l > L_0(s) \); the elastic \( \pi^0 \pi^0 \) cross sections are negligible for \( l > L_1(s) \), and hence also for \( l > L(s) \). On summing the contributions of \( l > L_0(s) \) lower bounds on \( \im \Gamma(3/2f_1(1) + f_1(2)) \) and \( \im \Gamma(1/3f_1(0) + 2/3f_2(2)) \) to inelastic cross sections we obtain the three inequalities,
\[
s^{1/2} \sigma^{(1)}(s), \sigma^{(2)}(s), \sigma^{0,0}(s) > \frac{\text{Const}}{s^{1/2}} \exp[\frac{-\sqrt{5}}{4}(N + 5/2) \ln s].
\]

APPENDIX. Bounds on Associated Legendre Functions.

We derive bounds on \( Q_l(x) \) for real \( l \) and complex \( x \) using the integral representation,
\[
Q_l(x) = \int_{0}^{\infty} \frac{dt}{(x + \sqrt{x^2 - 1} \cosh t)^{l+1}}.
\]

1. Upper Bound. For \( x \) real \( > 1 \),
\[
Q_l(x) \leq (x + \sqrt{x^2 - 1})^{-l} Q_l(0).
\]

This is obvious because, \( x + \sqrt{x^2 - 1} \cosh t \geq (x + \sqrt{x^2 - 1}) \).

2. Lower Bound. For \( x \) real \( > 1 \),
\[
Q_l(x) \geq (x + \sqrt{x^2 - 1})^{-l-1} \frac{\pi}{\sqrt{2(l + 1)}}.
\]

Proof. It is obvious that
\[
Q_l(x) \geq (x + \sqrt{x^2 - 1})^{-l-1} \int_{0}^{\infty} \frac{dt}{(\cosh t)^{l+1}},
\]
because \( (x + \sqrt{x^2 - 1} \cosh t) \leq (x + \sqrt{x^2 - 1}) \cosh t \). The integral on the right-hand side is exactly known [6],
\[
\int_{0}^{\infty} \frac{dt}{(\cosh t)^{l+1}} = \frac{2l-1}{\Gamma(l+1)} \Gamma^2 \left( \frac{l+1}{2} \right),
\]
but we shall need only a lower bound on it. Using \( \cosh t \leq \exp(t^2/2) \) we have,
\[
\int_{0}^{\infty} \frac{dt}{(\cosh t)^{l+1}} \geq \int_{0}^{\infty} dt \exp(-t^2(l + 1)/2) = \sqrt{\pi} / 2(l + 1).
\]

Inserting this in Eq. (82) we obtain the quoted lower bound Eq. (81).

3. Upper bound on an ellipse in complex \( z \)-plane.

We prove that for real values of \( \theta_1, \theta_2 \),
\[
|Q_l(\cosh(\theta_1 + i\theta_2))| \leq Q_l(\cosh \theta_1),
\]
i.e. geometrically, for \( z \) on an ellipse with foci \(-1 \) and 1, and right extremity \( z_0 = \cosh \theta_1 \),
\[
|Q_l(z)| \leq Q_l(z_0) \text{ for } z = \cosh(\theta_1 + i\theta_2).
\]
The denominator in the integral representation of \( Q_l(z) \) is \( |D(z, t)|^{l+1} \), where
\[
D(z, t) = \cosh(\theta_1 + i\theta_2) + \cosh t \sinh(\theta_1 + i\theta_2).
\]

It suffices to prove that
\[
|D(z, t)| > D(z, t)_{\theta_2 = 0}.
\]

Trigonometric identities yield,
\[
|D(z, t)|^2 = D(z, t)D(z, t)^* = \frac{1}{2} \cosh 2\theta_1(1 + \cosh^2 t) + \cosh t \sinh 2\theta_1 - \frac{1}{2} \cos 2\theta_2 \sinh^2 t.
\]

Minimising over \( \theta_2 \) now yields the desired result, Eq. (88).

4. Upper bound on \( Q_l(x) \) in terms of \( Q_0(x) \) and \( Q_l(2x^2 - 1) \) for \( x > 1 \). We prove that,
\[
Q_l^2(x) \leq 2xQ_0(x)Q_l(2x^2 - 1), \text{ for } x > 1.
\]

(i) The integral representation of \( Q_l(x) \) and Schwarz inequality yield,
\[
Q_l^2(x) \leq Q_0(x)Q_{2l}(x).
\]

Hence, to prove (90) it will be sufficient to prove that
\[
Q_{2l}(x) \leq 2xQ_0(2x^2 - 1).
\]

Using,
\[
(x + \sqrt{x^2 - 1} \cosh t)^2 = 2x^2 - 1 + \sqrt{(2x^2 - 1)^2 - 1} \cosh t + (x^2 - 1) \sinh^2 t
\]
\[
\geq 2x^2 - 1 + \sqrt{(2x^2 - 1)^2 - 1} \cosh t,
\]
and
\[
2x^2 - 1 + \sqrt{(2x^2 - 1)^2 - 1} \cosh t = 2x(x + \sqrt{x^2 - 1} \cosh t) - 1, \tag{94}
\]
we have the required result
\[
Q_{2l}(x) \leq \int_0^\infty dt \left( \frac{2x - \frac{1}{x + \sqrt{x^2 - 1} \cosh t}}{2x^2 - 1 + \sqrt{(2x^2 - 1)^2 - 1} \cosh t} \right)^{l+1}
\times \left( \frac{1}{2xQ_l(2x^2 - 1)} \right) \leq 2xQ_l(2x^2 - 1). \tag{95}
\]

5. **Upper bound on** $Q_l(x)/Q_l(z)$ **for** $x > z > 1$.

We prove that for $x > z > 1$
\[
\frac{Q_l(x)}{Q_l(z)} \leq \left( \frac{z + \sqrt{z^2 - 1}}{x + \sqrt{x^2 - 1}} \right)^{l+1} \leq \left( \frac{1 + \sqrt{2(x - 1)}}{1 + \sqrt{2(z - 1)}} \right)^{l+1}. \tag{96}
\]

Using the integral representation we obtain,
\[
\frac{d}{dz} \left( (z + \sqrt{z^2 - 1})^{l+1} Q_l(z) \right) = -\frac{l+1}{\sqrt{z^2 - 1}}
\times (z + \sqrt{z^2 - 1})^l \int_0^\infty dt (\cosh t - 1)
\times (z + \sqrt{z^2 - 1} \cosh t)^{l+2}
\leq 0, \tag{97}
\]

which implies the left-hand side of the inequality (96). The right-hand side now follows if,
\[
\left( \frac{z + \sqrt{z^2 - 1}}{x + \sqrt{x^2 - 1}} \right) \leq \left( \frac{1 + \sqrt{2(x - 1)}}{1 + \sqrt{2(z - 1)}} \right), \tag{98}
\]
or if,
\[
\left( \frac{z + \sqrt{z^2 - 1}}{1 + \sqrt{2(z - 1)}} \right) \leq \left( \frac{x + \sqrt{x^2 - 1}}{1 + \sqrt{2(x - 1)}} \right), \tag{99}
\]

for $x > z > 1$. This holds since the left-hand side of the above inequality is an increasing function of $z$ for $z > 1$.

**Acknowledgements.** One of us (AM) is grateful to Jo˜ão Penedones for inviting him to participate in a workshop on S-matrix bootstrap in Lausanne, and to Miguel F. Paulos for raising the question whether inelasticity could be arbitrarily small ;(SMR) wishes to thank the Indian National Science Academy for the INSA Honorary Scientist position.
