(February 16, 2006)

We attempt to clarify certain puzzles concerning state collapse and decoherence. In open quantum systems decoherence is shown to be a necessary consequence of the transfer of information to the outside; we prove an upper bound for the amount of coherence which can survive such a transfer. We claim that in large closed systems decoherence has never been observed, but we will show that it is usually harmless to assume its occurrence. An independent postulate of state collapse over and above Schrödinger’s equation and the probability interpretation of quantum states, is shown to be redundant.

I. INTRODUCTION

In its most basic formulation, quantum theory encodes the preparation of a system in a pure quantum state, a unit vector $\psi$ in a Hilbert space $\mathcal{H}$. Observables are modelled by (say, nondegenerate) self-adjoint operators on $\mathcal{H}$. The expectation value of an observable $A$ in a state $\psi$ is given by $\langle \psi, A\psi \rangle$. If $a$ is an eigenvalue of $A$ and $\psi_a$ a unit eigenvector, and information concerning $A$ is somehow extracted from the system, then the probability for the value $a$ to be observed is $|\langle \psi_a, \psi \rangle|^2$. If this observation is indeed made, then the subsequent behaviour of the system is predicted using the pure state $\psi_a$. This is called state collapse. It follows that, if the information extraction has taken place but the information on the value of $A$ is disregarded, then the subsequent behaviour can be described optimally using a mixture of eigenstates. This is called decoherence. In this paper we substantiate the following claim concerning decoherence and state collapse.

Decoherence is only observed in open systems, where it is a necessary consequence of the transfer of information to the outside.

So the observed occurrence of decoherence does not contradict the unitary time evolution postulated by quantum mechanics, since open systems do not evolve unitarily. Decoherence can be explained in quantum theory by embedding the quantum system into a larger, closed whole, which in itself evolves unitarily. This is well-known (see e.g. [Neu]). We add the observation that decoherence is not only a possibility for an open system, but a necessary consequence of the leakage of information out of the system. We prove an inequality relating the decoherence between two pure states to the degree in which a decision between the two is possible by a measurement outside. This is the content of Theorem 3 in section III.

Also, we have claimed that one does not actually observe decoherence in closed macroscopic systems. First of all, most of the systems that are ever observed are actually open, since it is extremely difficult to shield large systems from interaction. But more to the point, the difference between coherence and decoherence can only be seen by measuring some highly exotic ‘stray observables’ which are almost always forbiddingly hard to observe. And indeed, in those rare cases where experimenters have succeeded in measuring them, ordinary unitary evolution was found, not decoherence. (See [Arn], [Fri], [Wal].)

We illustrate the latter point in section IV, where we show that the measurement of two classes of observables can not reveal the difference between coherence and decoherence: a class of microscopic observables and a large class of macroscopic observables. Take as an example a volume of gas. Microscopic observables such as the position of one particular atom in a gas, only relate to a small fraction of the system. Macroscopic observables like the center of mass of the gas, are the average over a large number of microscopic observables. Belonging neither to the macroscopic nor to the microscopic class, the ‘stray observables’ referred to above describe detailed correlations between large numbers of atoms in the gas. This kind of information is experimentally almost inaccessible.

Driving home our point concerning decoherence in closed systems: coherent superpositions of macroscopically distinguishable states are not the strange monsters produced by a quantum theory applied outside its domain. They are, on the contrary, everyday occurrences which, however, can not be distinguished from the more classical incoherent superpositions in practice, and can therefore always be regarded as such.
II. ABSTRACT INFORMATION EXTRACTION

Quantum phenomena are inherently stochastic. This means that, if quantum systems are prepared in identical ways, then nevertheless different events may be observed. A quantum state describes an ensemble of physical systems, e.g. a beam of particles, and is modelled by a normalized trace-class operator $\rho$ on the Hilbert space. The expectation value of an observable $A$ in the state $\rho$ is then $\text{tr} (\rho A)$.

An information extraction or measurement on a quantum state is to be considered as the partition of such an ensemble into subensembles, each subensemble corresponding to a measurement outcome. Let us, in the present section, not wonder how the splitting of ensembles can be described by quantum theory, but let us see what such an information extraction, if it can be done, will entail for the subsequent behaviour of the subensembles. Note that this process may serve as part of the preparation for further experiments on the system, so that it must again lead to a state.

A. Information Extraction

For simplicity let us assume that only two outcomes can occur, labelled 0 and 1, say with probabilities $p_0$ and $p_1$. The ensemble is then split in two parts, described by their respective states $\rho_0$ and $\rho_1$. The map

$$M : \rho \mapsto p_0 \rho_0 \oplus p_1 \rho_1 \tag{2.1}$$

must be normalized, affine and positive. Indeed, normalization is the property that $p_0 + p_1 = 1$, and positivity is the requirement that states must be mapped to states. The affine property entails that for all states $\rho$ and $\theta$ on the original system, and for all $\lambda \in [0,1]$,

$$M(\lambda \rho + (1 - \lambda) \theta) = \lambda M(\rho) + (1 - \lambda) M(\theta).$$

This follows from the physical principle that a system which is prepared in the state $\rho$ with probability $\lambda$ and in the state $\theta$ with probability $1 - \lambda$, say by tossing a coin, can not be distinguished from a physical system in the state $\lambda \rho + (1 - \lambda) \theta$. We emphasize that indeed this is a physical principle, not a matter of definitions. It states, for instance, that a bundle of particles having 50% spin up and 50% spin down can not be distinguished from a bundle having 50% spin left and 50% spin right. This is a falsifiable statement.

B. State Collapse

The above elementary observations are sufficient to prove that information extraction implies state collapse. If $M$ distinguishes perfectly between the pure states $\psi_0$ and $\psi_1$, then of course $p_0 = 1$ in case $\rho = \langle \psi_0 | \psi_0 \rangle$, and $p_1 = 1$ if $\rho = \langle \psi_1 | \psi_1 \rangle$.

**Proposition 1** Let $T(\mathcal{H})$ denote the space of trace class operators on a Hilbert space $\mathcal{H}$, and let the map $M : T(\mathcal{H}) \rightarrow T(\mathcal{H}) \oplus T(\mathcal{H}) : \rho \mapsto M_0(\rho) \oplus M_1(\rho)$ be the linear extension of some normalized, affine and positive map on the states. Suppose that unit vectors $\psi_0$ and $\psi_1$ exist such that

$$M(\langle \psi_0 | \psi_0 \rangle) = M_0(\langle \psi_0 | \psi_0 \rangle) \oplus 0 \quad \text{and} \quad M(\langle \psi_1 | \psi_1 \rangle) = 0 \oplus M_1(\langle \psi_1 | \psi_1 \rangle). \tag{2.2}$$

Then we have $M(\langle \psi_0 | \psi_0 \rangle) = M(\langle \psi_1 | \psi_1 \rangle) = 0$.

**Proof.** The positivity of $M$ yields $M(\langle e^{i\varphi} \psi_0 + \psi_1 | e^{i\varphi} \psi_0 + \psi_1 \rangle) \geq 0$ as an operator inequality. In particular, the 0-th component must be positive. As $M_0(\langle \psi_1 | \psi_1 \rangle) = 0$, it follows that for all $\varepsilon, \phi \in \mathbb{R}$, we have $\varepsilon^2 M_0(\langle \psi_0 | \psi_0 \rangle) + \varepsilon (e^{i\phi} M_0(\langle \psi_1 | \psi_1 \rangle) + e^{-i\phi} M_0(\langle \psi_1 | \psi_1 \rangle)) \geq 0$. Taking the limit $\varepsilon \downarrow 0$ yields $(e^{i\phi} M_0(\langle \psi_0 | \psi_1 \rangle) + e^{-i\phi} M_0(\langle \psi_1 | \psi_0 \rangle)) \geq 0$ for all $\varphi \in \mathbb{R}$. In particular for $\varphi = 0, \frac{\pi}{2}, \pi, \frac{3\pi}{2}$, implying $M_0(\langle \psi_0 | \psi_1 \rangle) = M_0(\langle \psi_1 | \psi_0 \rangle) = 0$.

Exchanging the roles of $\psi_0$ and $\psi_1$ in the argument above results in $M_1(\langle \psi_0 | \psi_1 \rangle) = M_1(\langle \psi_1 | \psi_0 \rangle) = 0$, proving the proposition.

$\square$
We may draw two conclusions from Proposition 1. The first is that, for all \( |\psi\rangle = \alpha_0 |\psi_0\rangle + \alpha_1 |\psi_1\rangle \), we have
\[
(M_0 + M_1)(|\psi\rangle \langle \psi|) = (M_0 + M_1)(|\alpha_0^2 |\psi_0\rangle \langle \psi_0| + |\alpha_1^2 |\psi_1\rangle \langle \psi_1|).
\] (2.3)

In words: for the prediction of events after the splitting of the ensemble in two, it no longer matters whether before the splitting the system was in the pure state \( |\alpha_0 |\psi_0\rangle + \alpha_1 |\psi_1\rangle \) or in the mixed state \( |\alpha_0|^2 |\psi_0\rangle \langle \psi_0| + |\alpha_1|^2 |\psi_1\rangle \langle \psi_1| \). This phenomenon, which is a direct consequence of the structure (2.1) of the measurement process, we will call \textit{decoherence}.

The second conclusion from Proposition 1 is the following. For all \( |\psi\rangle = \alpha_0 |\psi_0\rangle + \alpha_1 |\psi_1\rangle \), we have
\[
M(|\psi\rangle \langle \psi|) = |\alpha_0|^2 M_0(|\psi_0\rangle \langle \psi_0|) + |\alpha_1|^2 M_1(|\psi_1\rangle \langle \psi_1|).
\] (2.4)

In words: if an ensemble is split in two parts, then the ‘0-ensemble’ will further behave as if the system had been in state \( \psi_0 \) instead of \( \psi \) prior to splitting, and the ‘1-ensemble’ as if it had been in state \( \psi_1 \) instead of \( \psi \). This phenomenon will be called \textit{collapse}.

Throughout this article, we will maintain a sharp distinction between the collapse \( M : T(\mathcal{H}) \rightarrow T(\mathcal{H}) \oplus T(\mathcal{H}) \) and the decoherence \( (M_0 + M_1) : T(\mathcal{H}) \rightarrow T(\mathcal{H}) \). The former represents the splitting of an ensemble in two parts by means of measurement, whereas the latter represents the splitting and subsequent recombination of this ensemble.

III. OPEN SYSTEMS

A decoherence-mapping \( (M_0 + M_1) : T(\mathcal{H}) \rightarrow T(\mathcal{H}) \) maps the pure state \( |\alpha_0 |\psi_0\rangle + \alpha_1 |\psi_1\rangle \) and the mixed state \( |\alpha_0|^2 |\psi_0\rangle \langle \psi_0| + |\alpha_1|^2 |\psi_1\rangle \langle \psi_1| \) to the same final state. Since unitary maps preserve purity, there can not exist a unitary map \( U : \mathcal{H} \rightarrow \mathcal{H} \) such that for all \( \rho \in T(\mathcal{H}) \):
\[
(M_0 + M_1)(\rho) = U \rho U^*.
\]

However, according to Schrödinger’s equation the development of a closed quantum system is given by a unitary operator. We conclude that the decoherence (2.3) is impossible in a closed system. On the other hand decoherence is a well known and experimentally confirmed phenomenon.

We will therefore consider open systems, i.e. quantum systems which do not obey the Schrödinger equation, but are part of a larger system which does. It has often been pointed out (e.g. [Neu], [Zur]) that decoherence can well occur in this situation, provided that states are only evaluated on the observables of the smaller system. We are more ambitious here: we shall prove that this form of ‘local’ decoherence is not just a possible, but an an \textit{unavoidable} consequence of information-transfer out of the open system.

A. Unitary Information Transfer and Decoherence

We assume that the open system has Hilbert space \( \mathcal{H} \), and that its algebra of observables is given by \( B(\mathcal{H}) \), the bounded operators on \( \mathcal{H} \). We may then assume that the larger system has Hilbert space \( \mathcal{K} \otimes \mathcal{H} \), since the only way to represent \( B(\mathcal{H}) \) on a Hilbert space is in the form \( A \mapsto \mathbf{1} \otimes A \) [Tak]. We may think\(^1\) of \( B(\mathcal{K}) \) as the observable algebra of some ancillary system in contact with our open quantum system. In this context, \( \mathcal{H} \) will be referred to as the ‘open system’, \( \mathcal{K} \) as the ‘ancilla’ and \( \mathcal{K} \otimes \mathcal{H} \) as the ‘closed system’.

We couple the system to the ancilla during a finite time interval \([0, t]\). Let \( \tau \in T(\mathcal{K}) \) denote the state of the ancilla at time 0, and \( \rho \in T(\mathcal{H}) \) that of the small system. The effect of the interaction is described by a unitary operator \( U : \mathcal{K} \otimes \mathcal{H} \rightarrow \mathcal{K} \otimes \mathcal{H} \), and the state of the pair at time \( t \) is given by \( U(\tau \otimes \rho)U^* \in T(\mathcal{K} \otimes \mathcal{H}) \). For convenience, we will define the information transfer map \( T : T(\mathcal{H}) \rightarrow T(\mathcal{K} \otimes \mathcal{H}) \) by \( T(\rho) := U(\tau \otimes \rho)U^* \).

\(^1\)Sometimes it may happen, as for instance in fermionic systems, that the observables of the ancilla do not all commute with those of the open system. Also the observable algebra on \( \mathcal{K} \) may be smaller than \( B(\mathcal{K}) \), but we will neglect these complications here.
1. Decoherence

In the above setup, we are interested in distinguishing whether the open system $\mathcal{H}$ was in state $|\psi_0\rangle$ or $|\psi_1\rangle$ at time $0$. This can be done if there exists a ‘pointer observable’ $B \otimes 1$ in the ancilla $B(\mathcal{K})$ which takes average value $b_0$ in state $T(|\psi_0\rangle \langle \psi_0|)$ and $b_1$ in state $T(|\psi_1\rangle \langle \psi_1|)$. By looking only at the ancilla $\mathcal{K}$ at time $t$, we are then able to gain information on the state of the open system $\mathcal{H}$ at time $0$. We say that information is transferred from $\mathcal{H}$ to $\mathcal{K}$.

Under these circumstances, we wish to prove that decoherence occurs on the open system. We prepare the ground by proving the following lemma.

**Lemma 2.** Let $\vartheta_0, \vartheta_1$ be unit vectors in a Hilbert space $\mathcal{L}$, and let $A$ and $B$ be bounded self-adjoint operators on $\mathcal{L}$ satisfying $\| [A, B] \| \leq \delta \| A \| \cdot \| B \|$. For $j = 0$ or 1, let $b_j := \langle \vartheta_j, B \vartheta_j \rangle$ denote the expectation and $\sigma_j^2 := \langle \vartheta_j, B^2 \vartheta_j \rangle - \langle \vartheta_j, B \vartheta_j \rangle^2$ the variance of $B$ in the state $\vartheta_j$. Then, if $b_0 \neq b_1$, 

$$\left| \langle \vartheta_0, A \vartheta_1 \rangle \right| \leq \frac{\delta \| B \| + \sigma_0 + \sigma_1}{|b_0 - b_1|} \| A \| .$$

**Proof.** Since $\| (B - b_j) \vartheta_j \|^2 = \langle \vartheta_j, (B - b_j)^2 \vartheta_j \rangle = \sigma_j^2$, we have, by the Cauchy-Schwarz inequality,

$$\left| (b_0 - b_1) \langle \vartheta_0, A \vartheta_1 \rangle \right| = \left| \langle \vartheta_0, (A(B - b_1) - (B - b_0)A + |B, A \rangle \vartheta_1 \rangle \right| \leq \| A \| (\sigma_1 + \sigma_0) + \delta \| A \| \cdot \| B \| .$$

Note that, for $\delta = \sigma_0 = \sigma_1 = 0$, Lemma 2 merely states that commuting operators respect each other’s eigenspaces. We proceed to prove that information transfer causes decoherence on the open system. (See [Jan].)

**Theorem 3** Let $\psi_0$ and $\psi_1$ be mutually orthogonal unit vectors in a Hilbert space $\mathcal{H}$, and let $\tau \in T(\mathcal{K})$ be a state on a Hilbert space $\mathcal{K}$. Let $U : \mathcal{K} \otimes \mathcal{H} \to \mathcal{K} \otimes \mathcal{H}$ be unitary and define $T : T(\mathcal{H}) \to T(\mathcal{K} \otimes \mathcal{H})$ by $T(\rho) = U(\tau \otimes \rho)U^*$. Let $B$ be a bounded self-adjoint operator on $\mathcal{K} \otimes \mathcal{H}$, and denote by $b_j$ and $\sigma_j^2$ its expected value and variance in the state $T(|\psi_j\rangle \langle \psi_j|)$ for $j = 0, 1$. Suppose that $b_0 \neq b_1$. Then for all $\psi = \alpha_0 \psi_0 + \alpha_1 \psi_1$ with $|\alpha_0|^2 + |\alpha_1|^2 = 1$ and for all bounded self-adjoint operators $A$ on $\mathcal{K} \otimes \mathcal{H}$ such that $\| [A, B] \| \leq \delta \| A \| \cdot \| B \|$, we have

$$\left| \text{tr} \left( T(|\psi\rangle \langle \psi|)A \right) - \text{tr} \left( T(|\alpha_0|^2 |\psi_0\rangle \langle \psi_0| + |\alpha_1|^2 |\psi_1\rangle \langle \psi_1|)A \right) \right| \leq \frac{\delta \| B \| + \sigma_0 + \sigma_1}{|b_0 - b_1|} \| A \| .$$

**Proof.** First, we prove 3.1 in the special case that $\tau = |\varphi\rangle \langle \varphi|$ for some vector $\varphi \in \mathcal{K}$. We introduce the notation $\theta_j := U(\varphi \otimes \psi_j)$. Recall that the expectation of $B$ is given by $b_j = \text{tr} \left( T(|\psi_j\rangle \langle \psi_j|)B \right)$, and its variance by $\sigma_j^2 = \text{tr} \left( T(|\psi_j\rangle \langle \psi_j|)B^2 \right) - \text{tr}^2 \left( T(|\psi_j\rangle \langle \psi_j|)B \right)$. In terms of $\theta_j$, this reduces to $b_j = \langle \theta_j, B \theta_j \rangle$ and $\sigma_j^2 = \langle \theta_j, B^2 \theta_j \rangle - \langle \theta_j, B \theta_j \rangle^2$. Similarly, the l.h.s. of 3.1 equals $\text{tr} \left( \alpha_0 \alpha_1 \theta_0 A \theta_1 \right) + \alpha_0 \alpha_1 \sigma_1(T(\theta_0 A \theta_1))$, a quantity bounded by $\| \theta_0 A \theta_1 \|$ since $2|\alpha_0||\alpha_1| \leq 1$. Formula 3.1 is then a direct application of Lemma 2.

To reduce the general case to the case above, note that a non-pure state $\tau$ can always be represented as a vector state. Explicitly, suppose that $\tau$ decomposes as $\tau = \sum_{i \in \mathbb{N}} |\beta_i|^2 |\varphi_i\rangle \langle \varphi_i|$. Then define the Hilbert space $\tilde{\mathcal{K}} := \bigoplus_{i \in \mathbb{N}} \mathcal{K}_i$, where each $\mathcal{K}_i$ is a copy of $\mathcal{K}$. Now since $(\bigoplus_{i \in \mathbb{N}} \mathcal{K}_i) \otimes \mathcal{H} \cong \bigoplus_{i \in \mathbb{N}} (\mathcal{K}_i \otimes \mathcal{H})$, we may define, for each $X \in B(\mathcal{K} \otimes \mathcal{H})$, the operator $\tilde{X}(\bigoplus_{i \in \mathbb{N}} (k_i \otimes h_i)) := \bigoplus_{i \in \mathbb{N}} X(k_i \otimes h_i)$. If we now define the vector $\tilde{\varphi} \in \tilde{\mathcal{K}}$ by $\tilde{\varphi} = \bigoplus_i \beta_i \varphi_i$, then we have for all $X \in \mathcal{K} \otimes \mathcal{H}$ and $\chi \in \mathcal{H}$:

$$\text{tr} \left( \tilde{U}(|\tilde{\varphi}\rangle \langle \tilde{\varphi}| \otimes |\chi\rangle \langle \chi|)\tilde{U}^* \tilde{X} \right) = \left( \bigoplus_{i \in \mathbb{N}} (\beta_i \varphi_i \otimes \chi), \tilde{U}^* \tilde{U} \right) \bigoplus_{j \in \mathbb{N}} (\beta_j \varphi_j \otimes \chi) \mathcal{K} \otimes \mathcal{H}
$$

$$= \left( \bigoplus_{i \in \mathbb{N}} (\beta_i \varphi_i \otimes \chi), \bigoplus_{j \in \mathbb{N}} U^* X \bigoplus_{i \in \mathbb{N}} (\beta_i \varphi_i \otimes \chi) \mathcal{K} \otimes \mathcal{H} \right)
$$

$$= \sum_{i \in \mathbb{N}} |\beta_i|^2 \text{tr} \left( U(|\varphi_i\rangle \langle \varphi_i| \otimes |\chi\rangle \langle \chi|)U^* X \right)
$$

$$= \text{tr} \left( U(\tau \otimes |\chi\rangle \langle \chi|)U^* X \right).$$

The second step is due to the diagonal action of the operators on $\tilde{\mathcal{K}} \otimes \mathcal{H}$. The problem is now reduced to the vector-case by applying the above to $\chi = \psi$, $\chi = \psi_0$ or $\chi = \psi_1$ and on the other hand $X = A$, $X = B$ or $X = B^2$. 

$\square$
The backbone of Theorem 3 is formed by the special case $\sigma_0 = \sigma_1 = 0$, $[A, B] = 0$ and $\tau = |\phi\rangle\langle\phi|$, which allows for a short and transparent proof.

In order to arrive at a physical interpretation of Theorem 3, we focus on the case $B = \tilde{B} \otimes 1$, when information is transferred from $\mathcal{H}$ to $K$. Indeed, examining $K$ at time $t$ yields information about $\mathcal{H}$ at time $0$.

2. Quality of Information Transfer

A small ratio $\frac{\sigma_0 - \sigma_1}{|b_0 - b_1|}$ indicates a good quality of information transfer. The ratio equals 0 in the perfect case, when $\sigma_0 = \sigma_1 = 0$. Thus $\tilde{B} \otimes 1$ takes a definite value of either $b_0$ or $b_1$, depending on whether the initial state of $\mathcal{H}$ was $|\psi_0\rangle$ or $|\psi_1\rangle$. In this case, one can infer the initial state of $\mathcal{H}$ with certainty by inspecting only the ancilla $K$. More generally, it is still possible to reliably determine from the ancilla $K$ whether the open system $\mathcal{H}$ was initially in state $|\psi_0\rangle$ or $|\psi_1\rangle$ as long as the standard deviations are small compared to the difference in mean, $\sigma_0, \sigma_1 \ll |b_0 - b_1|$.

As the ratio increases, the restriction 3.1 gets less severe, reaching triviality at $\sigma_0 + \sigma_1 = 2|b_0 - b_1|$.

3. Decoherence on the Commutant of the Pointer

Assume perfect information transfer, i.e. $\sigma_0 = \sigma_1 = 0$. If $[A, B] = 0$, then Theorem 3 says that coherent and mixed initial states yield identical distributions of $A$ at time $t$. In order to distinguish, at time $t$, whether or not $\mathcal{H}$ was in a pure state at time 0, we will have to use observables $A$ which do not commute with $B$. But then $A$ and $B$ cannot be observed simultaneously. Summarizing:

At time $t$, it is possible to distinguish whether $\mathcal{H}$ was in state $\psi_0$ or $\psi_1$ at time 0. It is also possible to distinguish whether $\mathcal{H}$ was in state $\psi$ or $|\alpha_0|^2|\psi_0\rangle\langle\psi_0| + |\alpha_1|^2|\psi_1\rangle\langle\psi_1|$ at time 0. But it is not possible to do both.

We emphasize that this holds even when one has all observables of the entire closed system $K \otimes \mathcal{H}$ at one’s disposal.

4. Decoherence on the Open System

We consider the final state of the open system $\mathcal{H}$, obtained from the final state of the closed system $K \otimes \mathcal{H}$ by tracing out the degrees of freedom of the ancilla $K$: an initial state $\rho \in S(\mathcal{H})$ yields final state $\text{tr}_K(T(\rho)) \in S(\mathcal{H})$.

Suppose that information is transferred to a pointer $B = \tilde{B} \otimes 1$ in the ancilla $K$ with perfect quality, $\sigma_0 = \sigma_1 = 0$. Since $[1 \otimes \tilde{A}, \tilde{B} \otimes 1] = 0$, we see from Theorem 3 that we have $\text{tr}(T(|\psi\rangle\langle\psi|)(1 \otimes \tilde{A})) = \text{tr}(T(|\alpha_0|^2|\psi_0\rangle\langle\psi_0| + |\alpha_1|^2|\psi_1\rangle\langle\psi_1|)(1 \otimes \tilde{A}))$ for all $\tilde{A} \in B(\mathcal{H})$, or equivalently

$$\text{tr}_K(T(|\psi\rangle\langle\psi|)) = \text{tr}_K(T(|\alpha_0|^2|\psi_0\rangle\langle\psi_0| + |\alpha_1|^2|\psi_1\rangle\langle\psi_1|)). \quad (3.2)$$

In words:

Suppose that at time $t$, by making a hypothetical measurement of $\tilde{B}$ on the ancilla, it would be possible to distinguish perfectly whether the open system had been in state $\psi_0$ or $\psi_1$ at time 0. Then, by looking only at the observables of the open system, it is not possible to distinguish whether $\mathcal{H}$ had been in the pure state $\psi = \alpha_0\psi_0 + \alpha_1\psi_1$ or the collapsed state $|\alpha_0|^2|\psi_0\rangle\langle\psi_0| + |\alpha_1|^2|\psi_1\rangle\langle\psi_1|$ at time 0.
This statement holds true, regardless whether \( \tilde{B} \) is actually measured or not. (So we do not assume here that such a measurement is physically possible.) We have shown that the map \( M_0 + M_1 = \tau_\mathcal{K} \circ T \), with \( T : \mathcal{H} \rightarrow \mathcal{H} \mathcal{K} \) the information-transfer operation defined by \( T(\rho) := U(\tau \otimes \rho)U^* \), constitutes a physical realization of the abstract decoherence mapping \( (M_0 + M_1) \) of section II.

All in all, we have proven that decoherence is an unavoidable consequence of information transfer out of an open system.

5. Example

The simplest possible example of unitary information transfer is the following. Let \( \mathcal{K} \sim \mathcal{H} \sim \mathbb{C}^2 \) be the Hilbert space of a qubit; let \( \psi_0 = (1,0) \) and \( \psi_1 = (0,1) \) be the ‘computational basis’, and let \( U : \mathbb{C}^2 \otimes \mathbb{C}^2 \rightarrow \mathbb{C}^2 \otimes \mathbb{C}^2 \) be the ‘controlled-not gate’. Explicitly, \( U \) is defined by \( U|\psi_0 \otimes \psi_1 \rangle = |\psi_0 \otimes \psi_1 \rangle \), \( U|\psi_0 \otimes \psi_1 \rangle = |\psi_1 \otimes \psi_1 \rangle \), \( U|\psi_1 \otimes \psi_0 \rangle = |\psi_1 \otimes \psi_0 \rangle \), and \( U|\psi_0 \otimes \psi_0 \rangle = |\psi_0 \otimes \psi_0 \rangle \). That is, it flips the first qubit whenever the second qubit is set to 1. Let \( \tau \) be the 0 state of the first qubit.

Since both outgoing beams are of particles with positive spin, the other of particles with negative spin, and that both beams have equal intensity. This statement holds true, regardless whether \( \tilde{\tau} \) measurement is physically possible. We have shown that the map \( \mathcal{K} \sim \mathcal{H} \sim \mathbb{C}^2 \) be the Hilbert space of a qubit: let \( \psi_0 = (1,0) \) and \( \psi_1 = (0,1) \) be the ‘computational basis’, and let \( U : \mathbb{C}^2 \otimes \mathbb{C}^2 \rightarrow \mathbb{C}^2 \otimes \mathbb{C}^2 \) be the ‘controlled-not gate’. Explicitly, \( U \) is defined by \( U|\psi_0 \otimes \psi_1 \rangle = |\psi_0 \otimes \psi_1 \rangle \), \( U|\psi_0 \otimes \psi_1 \rangle = |\psi_1 \otimes \psi_1 \rangle \), \( U|\psi_1 \otimes \psi_0 \rangle = |\psi_1 \otimes \psi_0 \rangle \), and \( U|\psi_0 \otimes \psi_0 \rangle = |\psi_0 \otimes \psi_0 \rangle \). That is, it flips the first qubit whenever the second qubit is set to 1. Let \( \tau \) be the 0 state of the first qubit.

Since the initial state of the second qubit can be read off from the first, this situation satisfies the hypotheses of Theorem 3 with \( B = \sigma_z \otimes 1 \) and \( \sigma_0 = \sigma_1 = 0 \). We verify equation 3.2. For any state \( |\psi\rangle = \alpha_0|\psi_0\rangle + \alpha_1|\psi_1\rangle \):

\[
U|\psi_0 \otimes \psi\rangle = \alpha_0|\psi_0 \otimes \psi_0\rangle + \alpha_1|\psi_1 \otimes \psi_1\rangle = |\psi\rangle; \\
\text{tr}_\mathcal{K}(|\psi\rangle\langle\psi|) = |\alpha_0|^2|\psi_0\rangle\langle\psi_0| + |\alpha_1|^2|\psi_1\rangle\langle\psi_1|.
\]

Thus we have \( \text{tr}_\mathcal{K}(T(|\psi\rangle\langle\psi|)) = |\alpha_0|^2|\psi_0\rangle\langle\psi_0| + |\alpha_1|^2|\psi_1\rangle\langle\psi_1| \). This agrees with equation 3.2, since one can easily check that \( \text{tr}_\mathcal{K}(T(|\alpha_0|^2|\psi_0\rangle\langle\psi_0| + |\alpha_1|^2|\psi_1\rangle\langle\psi_1|)) \) equals \( |\alpha_0|^2|\psi_0\rangle\langle\psi_0| + |\alpha_1|^2|\psi_1\rangle\langle\psi_1| \) as well.

B. Unitary Information Transfer and State Collapse

We have derived that, in the context of information transfer to an ancillary system, the initial states \( |\psi\rangle\langle\psi| \) and \( |\alpha_0|^2|\psi_0\rangle\langle\psi_0| + |\alpha_1|^2|\psi_1\rangle\langle\psi_1| \) lead to the same final state. This is decoherence.

State collapse is a much stronger statement: if outcome ‘0’ is observed, then the system will further behave as if its initial state had been \( \psi_0 \) instead of \( \psi \). Similarly, if outcome ‘1’ is observed, then the system will behave as if its initial state had been \( \psi_1 \). Now suppose that we ignore the outcome. Since ‘0’ happens with probability \( |\alpha_0|^2 \) and ‘1’ with probability \( |\alpha_1|^2 \), the system will behave as if its initial state had been \( |\alpha_0|^2|\psi_0\rangle\langle\psi_0| + |\alpha_1|^2|\psi_1\rangle\langle\psi_1| \). We see that collapse implies decoherence.

The converse does not hold however: imagine a Stern-Gerlach experiment, in which a beam of particles in a \( \sigma_z \)-eigenstate is split in two according to spin in the \( z \)-direction. State collapse is the statement that one beam consists of particles with positive spin, the other of particles with negative spin and that both beams have equal intensity. Decoherence is the statement that both outgoing beams together consist for 50% of positive-spin particles and for 50% of negative-spin particles. The former statement is strictly stronger than the latter, and deserves separate investigation.

We will therefore answer the following question: suppose that we transfer information to an ancilla \( \mathcal{K} \), and then separate \( \mathcal{K} \) from \( \mathcal{H} \), dividing \( \mathcal{H} \) into subensembles according to outcome. What states do we use to describe these subensembles?

1. Joint Probability Distributions

A special case of an observable is an event \( p \), which in quantum mechanics is represented by a projection \( P \). The relative frequency of occurrence of \( p \) is given by \( \mathbb{P}(p = 1) = \text{tr}(\rho P) \).

The projection \( 1 - P \) is interpreted as ‘not \( p \)’. Furthermore, if a projection \( Q \) corresponding to an observable \( q \) commutes with \( P \), then \( PQ \) is again a projection. According to quantum mechanics, \( p \) and \( q \) can then be observed simultaneously, and the projection \( PQ \) is interpreted as the event ‘\( p \) and \( q \) are both observed’.

A state \( \rho \) therefore induces a joint probability distribution on \( p \) and \( q \):

\[
\text{tr}(\rho PQ) = \mathbb{P}(p = 1, q = 1) , \quad \mathbb{P}(p = 0, q = 1) = \text{tr}(\rho(1 - P)Q) \\
\text{tr}(\rho(P(1 - Q))) = \mathbb{P}(p = 1, q = 0) , \quad \mathbb{P}(p = 0, q = 0) = \text{tr}(\rho(1 - P)(1 - Q))
\]

6
Particularly relevant is the case in which \( \rho \) is a state on a combined space \( \mathcal{K} \otimes \mathcal{H} \), and the projections are of the form \( \mathcal{Q} \otimes 1 \) and \( 1 \otimes \mathcal{P} \). (The commuting projections are properties of different systems.) We then have \( \mathbb{P}(p = 1, q = 1) = \text{tr}((1 \otimes P)(\mathcal{Q} \otimes 1)\rho) = \text{tr}(P\text{tr}\,(\mathcal{Q} \otimes 1)\rho) \). This holds for all projections \( P \) on \( \mathcal{H} \), so that the normalized version of \( \text{tr}\,((\mathcal{Q} \otimes 1)\rho) \in \mathcal{T}(\mathcal{H}) \) must be interpreted as the state of \( \mathcal{H} \), given that \( q = 1 \). Similarly, the normalized version of \( \text{tr}\,((\mathcal{1} - \mathcal{Q}) \otimes 1)\rho \in \mathcal{T}(\mathcal{H}) \) is the state of \( \mathcal{H} \), given that \( q = 0 \) is observed.

2. Collapse

Let \( T : \rho \mapsto U(\tau \otimes \rho)U^* \) from \( \mathcal{T}(\mathcal{H}) \) to \( \mathcal{T}(\mathcal{K} \otimes \mathcal{H}) \) be an information transfer from \( \mathcal{H} \) to a pointer-projection \( \mathcal{Q} \in B(\mathcal{K}) \). That is, \( \text{tr}\,((\mathcal{Q} \otimes 1)T(|\psi_0\rangle\langle\psi_0|)) = 0 \) and \( \text{tr}\,((\mathcal{Q} \otimes 1)T(|\psi_1\rangle\langle\psi_1|)) = 1 \), so that at time \( t \), one can see from \( \mathcal{K} \) whether \( \mathcal{H} \) was in state \( \psi_0 \) or \( \psi_1 \) at time 0.

Since \( \mathcal{Q} \otimes 1 \) commutes with all of \( 1 \otimes B(\mathcal{H}) \), it is possible to separate \( \mathcal{H} \) from \( \mathcal{K} \), and divide \( \mathcal{H} \) into subsystems according to the outcome of \( \mathcal{Q} \). This is done as follows: with any measurement on \( \mathcal{H} \), a simultaneous measurement of \( \mathcal{Q} \) on \( \mathcal{K} \) is performed to determine in which ensemble this particular system should fall. It follows from the above that the 1-ensemble should be described by the normalized version of \( M_1(\rho) := \text{tr}\,((\mathcal{Q} \otimes 1)T(\rho)) \), and the 0-ensemble by the normalized version of \( M_0(\rho) := \text{tr}\,((\mathcal{1} - \mathcal{Q}) \otimes 1)T(\rho)) \). Since \( \mathcal{Q} \) commutes with \( B(\mathcal{H}) \), this is just conditioning on a classical probability space at time 0. We have arrived at an interpretation of the map \( M(\rho) := M_0(\rho) \oplus M_1(\rho) \) of section II.

We will now prove that \( M \) takes the form \( M(|\psi\rangle\langle\psi|) = |\alpha|^2\text{tr}\,\mathcal{K}T(|\psi_0\rangle\langle\psi_0|) + |\alpha|^2\text{tr}\,\mathcal{K}T(|\psi_1\rangle\langle\psi_1|) \). This is a strong physical statement. For instance, any spin-system \( |\psi_0\rangle + \alpha|\psi_1\rangle \) that is found to have spin 1 in the \( z \)-direction may subsequently be treated as if it had been in state \( \psi_1 \) at time 0. This is nontrivial: a priori, it is perfectly conceivable that the different initial states \( \psi_0 \) and \( \psi \) result in different final states, even though they yield the same \( \mathcal{Q} \)-output.

One could alternatively, (and more trivially), arrive at the ‘collapse of the wavefunction’ \( M(|\psi\rangle\langle\psi|) = |\alpha|^2\text{tr}\,\mathcal{K}T(|\psi_0\rangle\langle\psi_0|) + |\alpha|^2\text{tr}\,\mathcal{K}T(|\psi_1\rangle\langle\psi_1|) \) by assuming that, at time 0, the quantum system makes either the jump \( |\psi_0\rangle \mapsto |\psi_0\rangle \) or the jump \( |\psi_1\rangle \mapsto |\psi_1\rangle \). Since we arrive at the same conclusion, namely the above ‘collapse of the wavefunction’, using only open systems, unitary transformations and the probabilistic interpretation of quantum mechanics, such an assumption of ‘jumps’ at time 0 is made redundant.

**Proposition 4** Let \( T : \rho \mapsto U(\tau \otimes \rho)U^* \) from \( \mathcal{T}(\mathcal{H}) \) to \( \mathcal{T}(\mathcal{K} \otimes \mathcal{H}) \) satisfy \( \text{tr}\,((\mathcal{Q} \otimes 1)T(|\psi_0\rangle\langle\psi_0|)) = 0 \) and \( \text{tr}\,((\mathcal{Q} \otimes 1)T(|\psi_1\rangle\langle\psi_1|)) = 1 \) for some ‘pointer-projection’ \( \mathcal{Q} \) on \( \mathcal{K} \). Define a map \( M : \mathcal{T}(\mathcal{H}) \mapsto \mathcal{T}(\mathcal{H}) \otimes \mathcal{T}(\mathcal{H}) \) by \( M(\rho) := \text{tr}\,((\mathcal{Q} \otimes 1)T(\rho)) \oplus \text{tr}\,((\mathcal{1} - \mathcal{Q}) \otimes 1)T(\rho)) \). Then for \( \psi = \psi_0\psi_0 + \alpha_1\psi_1 \) we have \( M(|\psi\rangle\langle\psi|) = |\alpha|^2\text{tr}\,\mathcal{K}T(|\psi_0\rangle\langle\psi_0|) + |\alpha|^2\text{tr}\,\mathcal{K}T(|\psi_1\rangle\langle\psi_1|) \).

This can be seen almost directly from Proposition 1:

**Proof.** Since \( M_1(|\psi_0\rangle\langle\psi_0|) \geq 0 \) is a positive operator, we may conclude from \( \text{tr}\,(M_1(|\psi_0\rangle\langle\psi_0|)) = 0 \) that \( M_1(|\psi_0\rangle\langle\psi_0|) = 0 \). Similarly \( M_0(|\psi_1\rangle\langle\psi_1|) = 0 \). Utilizing Proposition 1, we find that \( M(|\psi\rangle\langle\psi|) = |\alpha|^2M_0(|\psi_0\rangle\langle\psi_0|) + |\alpha|^2M_1(|\psi_1\rangle\langle\psi_1|) \). The proof is completed by noting from \( \text{tr}\,((\mathcal{Q} \otimes 1)T(|\psi_0\rangle\langle\psi_0|)) = 0 \) that \( \text{tr}\,((\mathcal{Q} \otimes 1)T(|\psi_1\rangle\langle\psi_1|)) = \text{tr}\,((\mathcal{Q} \otimes 1)T(|\psi_1\rangle\langle\psi_1|)) = M_1(|\psi_1\rangle\langle\psi_1|) \), and similarly that \( \text{tr}\,((\mathcal{1} - \mathcal{Q}) \otimes 1)T(|\psi_0\rangle\langle\psi_0|)) = M_0(|\psi_0\rangle\langle\psi_0|) \).

We summarize:

Consider an ensemble of systems of type \( \mathcal{H} \) in state \( \psi \). Suppose that information is transferred to a pointer-projection \( \mathcal{Q} \) on an ancillary system \( \mathcal{K} \). Subsequently, the ensemble is divided into two subsystems according to outcome. Then all observations on \( \mathcal{H} \) made afterwards, conditioned on the observation that the measurement outcome was 0, will be as if the system had originally been in the collapsed state \( \psi_0 \) instead of \( \psi \). No independent ‘collapse postulate’ is needed to arrive at this conclusion.

3. Example

In the simple model of information transfer introduced in Section IIIA, we will now demonstrate why repeated spin-measurements yield identical outcomes.

The probed system is once again a single spin \( \mathcal{H} = \mathbb{C}^2 \), whereas the ancillary system now consists of two spins, \( \mathcal{K} = \mathbb{C}^2 \otimes \mathbb{C}^2 \) in initial state \( |\psi_0\rangle \otimes |\psi_0\rangle \). Repeated information-transfer, first to pointer \( \sigma_{z,1} \) and then to \( \sigma_{z,2} \), is then represented by the unitary \( U := U_2U_1 \) on \( \mathcal{K} \otimes \mathcal{H} \). In this expression, \( U_1 \) is the controlled not-gate flipping the first qubit of \( \mathcal{K} \) if \( \mathcal{H} \) is set to 1, and \( U_2 \) flips the second qubit of \( \mathcal{K} \) if \( \mathcal{H} \) is set to 1.

Since \( U|\psi\rangle \otimes |\psi\rangle \otimes (|\alpha_0\rangle\langle\psi_0| + \alpha_1|\psi_1\rangle\langle\psi_1|) = |\alpha_0\rangle\langle\psi_0| \otimes |\psi_0\rangle \otimes |\psi_0\rangle + |\alpha_1\psi_1\rangle \otimes |\psi_1\rangle \otimes |\psi_1\rangle \), we can explicitly calculate the joint probability distribution on the two pointers \( \sigma_{z,1} \) and \( \sigma_{z,2} \) in the final state:
\[ \mathbb{P}(s_{z,1} = 1, s_{z,2} = 1) = |\alpha_1|^2 \quad \mathbb{P}(s_{z,1} = 1, s_{z,2} = -1) = 0 \]
\[ \mathbb{P}(s_{z,1} = -1, s_{z,2} = 1) = 0 \quad |\alpha_0|^2 = \mathbb{P}(s_{z,1} = -1, s_{z,2} = -1) \]

In particular, we see that if the first outcome is 1 (which happens with probability $|\alpha_1|^2$), then so is the second. Proposition 4 shows that this is the general situation, independent of the (rather simplistic) details of this particular model.

C. Information Leakage to the Environment

On closed systems decoherence does not occur, because unitary time evolution preserves the purity of states. However, macroscopic systems are almost never closed.

Imagine, for example, that $H = \mathbb{C}^2$ represents a two-level atom, and $K$ some large measuring device. Information about the energy $1 \otimes \sigma_z$ of the atom is transferred to the apparatus, where it is stored as the position $B \otimes 1$ of a pointer. Then as soon as information on the pointer-position $B \otimes 1$ leaves the system, collapse on the combined atom-apparatus system takes place. For example, a ray of light may reflect on the pointer, revealing its position to the outside world. (See [J&Z].) It is of course immaterial whether or not someone is actually looking at the photons. If even the smallest speck of light were to fall on the pointer, the information about the pointer position would already be encoded in the light, causing full collapse on the atom-apparatus system. (See [Zur] for an example.)

The quality of this information transfer will not be perfect. If a macroscopic system is interacting normally with the outside world, (the occasional photon happens to scatter on it, for instance), then a number of macroscopic observables $X$ will leak information continually, with a macroscopic uncertainty $\sigma$. This enables us to apply Theorem 3. It says that all coherences between eigenstates $\psi_{x_1}$ and $\psi_{x_2}$ of macroscopic observables $X$ are continually vanishing on the macroscopic system $L$, provided that their eigenvalues $x_1$ and $x_2$ satisfy $|x_1 - x_2| \gg 2\sigma$. (The pointer, e.g. a beam of light, is outside the system, so that $\delta = 0$.)

Take for example a collection of $N$ spins, $L = \bigotimes_{i=1}^N \mathbb{C}^2$. Suppose that for $\alpha = x, y, z$, the average spin-observables $S_\alpha = \frac{1}{N} \sum_{i=1}^N \sigma_\alpha^i$ are continually being measured with an accuracy $N^{-\frac{4}{7}} \ll \sigma \ll 1$. Then between macroscopically different eigenstates of $S_\alpha$, i.e. states for which the eigenvalues satisfy $|s_\alpha - s_\alpha'| \gg \sigma$, coherences are constantly disappearing. However, the information leakage need not have any effect on states which only differ on a microscopic scale. Take for instance $\rho \otimes |\psi\rangle\langle\psi| + \rho \otimes |\phi\rangle\langle\phi|$, with $\rho$ an arbitrary state on $N-1$ spins. Indeed, $|s_\alpha - s_\alpha'| \leq 2/N \ll \sigma$, so Theorem 3 is vacuous in this case: no decoherence occurs.

We see how the variance $\sigma^2$ produces a smooth boundary between the macroscopic and the microscopic world: macroscopically distinguishable states (involving $S_\alpha$-differences $\gg \sigma$) continually suffer from loss of coherence, while states that only differ microscopically (involving $S_\alpha$-differences $\ll \sigma$) are unaffected.

In case of a system monitored by a macroscopic measurement apparatus, we are interested in coherence between eigenstates of the macroscopic pointer. By definition, these eigenstates are macroscopically distinguishable. We may then give the following answer to the question why it is so hard, in practice, to witness coherence:

*If information leaks from the pointer into the outside world, decoherence takes place on the combination of system and measurement apparatus. In practice, macroscopic pointers constantly leak information.*

IV. CLOSED SYSTEMS

Closed systems evolve according to unitary time evolution, so that coherence which is present initially will still be there at later times. Yet on macroscopic systems, coherent superpositions are almost never observed. Why is this the case?

---

2Since $[S_x, S_y] \neq 0$, they cannot be simultaneously measured with complete accuracy, see e.g. [Wer]. However, this problem disappears if the accuracy satisfies $\sigma^2 \geq \frac{1}{2}||[S_x, S_y]|| = \frac{1}{N}$, see [Jan]. For large $N$, (typically $N \sim 6 \times 10^{23}$), this allows for extremely accurate measurement.
A. Macroscopic Systems

Because of the direct link that it provides between the scale of a system on the one hand, and on the other hand the difficulties in witnessing coherence, we feel that the following line of reasoning, essentially due to Hepp [Hep], is the most important mechanism hiding coherence.

Let us first define what we mean by macroscopic and microscopic observables. We consider a system consisting of \(N\) distinct subsystems, i.e. \(K = \bigotimes_{i=1}^{N} K_i\). If one thinks of \(K_i\) as the atoms out of which a macroscopic system \(K\) is constructed, \(N\) may well be in the order of \(10^{23}\).

We will define the "microscopic" observables to be the ones that refer only to one particular subsystem \(K_i\):

**Definition.** An observable \(X \in B(K)\) is called *microscopic* if it is of the form \(X = 1 \otimes \ldots \otimes 1 \otimes X_i \otimes 1 \otimes \ldots \otimes 1\) for some \(i \in \{1, 2, \ldots, N\}\) and some \(X_i \in B(K_i)\).

In this situation we will identify \(X_i \in B(K_i)\) with \(X \in B(K)\). We take macroscopic observables to be averages of microscopic observables ‘of the same size’:

**Definition.** An observable \(Y \in B(K)\) is called *macroscopic* if it is of the form \(Y = \frac{1}{N} \sum_{i=1}^{N} Y_i\), with \(Y_i \in B(K_i)\) such that \(\|Y_i\| \leq \|Y\|\).

We will only use the term ‘macroscopic’ in this narrow sense from here on, even though there do exist observables which are called ‘macroscopic’ in daily life, but do not fall under the above definition.

Now suppose that we transfer information from a system \(\mathcal{H}\) to a macroscopic system \(K = \bigotimes_{i=1}^{N} K_i\), using a macroscopic pointer \(\hat{B} \in B(K)\). As explained before, we then have a map \(T : T(\mathcal{H}) \to T(K \otimes \mathcal{H})\) such that the pointer \(\hat{B} \otimes 1\) has different expectation values \(b_0\) and \(b_1\) in the states \([\psi_0] = T([\psi_0]\langle \psi_0|)\) and \([\psi_1] = T([\psi_1]\langle \psi_1|)\).

Since \(\hat{B}\) is macroscopic, it is unrealistic to require \(T([\psi_0]\langle \psi_0|) = T([\psi_1]\langle \psi_1|)\) to be eigenstates of \(\hat{B}\). Instead, we will require their standard deviations in \(\hat{B}\) to be negligible compared to their difference in mean, i.e. \(\sigma_0 = |b_0 - b_1|\) and \(\sigma_1 \ll |b_0 - b_1|\).

After this information transfer, we try to distinguish whether the system \(\mathcal{H}\) had initially been in the coherent state \(\alpha_0|\psi_0\rangle + \alpha_1|\psi_1\rangle\) or in the incoherent mixture \(|\alpha_0|^2|\psi_0\rangle + |\alpha_1|^2|\psi_1\rangle\). We have already shown that this cannot be done by measuring observables in \(1 \otimes B(\mathcal{H})\). The following adaptation of Theorem 3 shows that it is also impossible to do this by measuring macroscopic or microscopic observables on the closed system \(K \otimes \mathcal{H}\).

**Corollary 5** Let \(\psi_0\) and \(\psi_1\) be orthogonal unit vectors in a Hilbert space \(\mathcal{H}\) and let \(\tau \in T(K)\) be a state on the Hilbert space \(K = \bigotimes_{i=1}^{N} K_i\). Let \(U : K \otimes \mathcal{H} \to K \otimes \mathcal{H}\) be unitary and define \(T : T(\mathcal{H}) \to T(K \otimes \mathcal{H})\) by \(T(\rho) = U(\tau \otimes \rho)U^*.\) Let \(\hat{B}\) be a macroscopic observable in \(B(K),\) and define \(B := \hat{B} \otimes 1\). Denote by \(b_j\) and \(\sigma_j^2\) its expected value and variance in the state \([\psi_j]\langle \psi_j|)\) for \(j = 0, 1\). Suppose that \(b_0 \neq b_1\). Then for all \(\psi = \alpha_0|\psi_0\rangle + \alpha_1|\psi_1\rangle\) with \(|\alpha_0|^2 + |\alpha_1|^2 = 1\) and for all microscopic and macroscopic observables \(A \in B(K \otimes \mathcal{H})\), we have

\[
\left| \text{tr} \left( T([\psi]\langle \psi|)A \right) - \text{tr} \left( T([\alpha_0|^2|\psi_0\rangle + |\alpha_1|^2|\psi_1\rangle]\langle \psi_1|)A \right) \right| \leq \frac{2\|B\| + \sigma_0 + \sigma_1}{|b_0 - b_1|}\|A\|.
\]

**Proof.** If \(A\) is microscopic, we have \(\|A,B\| = \|[A_i, \frac{1}{N} \sum_{j=1}^{N} B_j]\| = \frac{1}{N}\|[A_i, B]\| \leq \frac{2\|A\|\|B\|}{N}\). If \(A\) is macroscopic, we have \(\|A,B\| = \|[\frac{1}{N+1} \sum_{i=0}^{N} A_i, \frac{1}{N} \sum_{j=1}^{N} B_j]\| = \frac{1}{N(N+1)}\sum_{i=1}^{N}\|[A_i, B]\| \leq \frac{2\|A\|\|B\|}{N}.\) Either way, we can now apply Theorem 3. \(\square\)

B. Examples

In order to illustrate the above, we discuss four examples of information transfer to a macroscopic system.
1. The Finite Spin-Chain

We study a single spin $\mathcal{H} = \mathbb{C}^2$ in interaction with a large but finite spin-chain $\mathcal{K} = \bigotimes_{i=1}^N \mathbb{C}^2$, the latter acting as a measurement apparatus. Once again, let $\psi_0 = (1, 0)$ and $\psi_1 = (0, 1)$ be the ‘computational basis’. Initially, all spins in the spin-chain are down: $\tau = \ket{\psi_0 \otimes \cdots \otimes \psi_0} \bra{\psi_0 \otimes \cdots \otimes \psi_0}$. Let $U_t : \mathcal{K} \otimes \mathcal{H} \to \mathcal{K} \otimes \mathcal{H}$ be the ‘controlled-not gate’, which flips spin number $i$ in the chain whenever the single qubit is set to 1. (We define $U_j = 1$ for $j \notin \{1, 2, \ldots, N\}$.)

$$U_i = 1 \otimes P_- + \sigma_{z,i} \otimes P_+ \quad \text{with} \quad P_- = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad P_+ = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}.$$ 

In discrete time $n \in \mathbb{Z}$, the unitary evolution is given by $n \mapsto U_n U_{n-1} \cdots U_2 U_1$. (See [Hep].) This represents a single spin flying over a spin-chain from 1 to $N$, interacting with spin $n$ at time $n$.

Obviously $U_N \ket{\psi_0 \otimes \cdots \otimes \psi_0} \otimes \ket{\psi_0} = \ket{\psi_0 \otimes \cdots \otimes \psi_0} \otimes \ket{\psi_0}$ and $U_N \ket{\psi_0 \otimes \cdots \otimes \psi_0} \otimes \ket{\psi_1} = \ket{\psi_1 \otimes \cdots \otimes \psi_1} \otimes \ket{\psi_1}$. We consider the average spin of the spin-chain as pointer, $B = \frac{1}{N} \sum_{i=1}^N \sigma_{z,i}$. This makes the map $T : \rho \mapsto U_N \tau \otimes \rho U_N^*$ an information transfer to a macroscopic system. Applying Corollary 5 with $b_0 = -1, b_1 = 1$ and $\sigma_0 = \sigma_1 = 0$ yields the estimate

$$\left| \text{tr} \left( T(\ketbra{\alpha_0\psi_0 + \alpha_1\psi_1}{\alpha_0\psi_0 + \alpha_1\psi_1}) A \right) - \text{tr} \left( T(\ketbra{\alpha_0^2\psi_0}{\alpha_0^2\psi_0} + \ketbra{\alpha_1^2\psi_1}{\alpha_1^2\psi_1}) A \right) \right| \leq \frac{1}{N} \|A\|$$

for all microscopic and macroscopic $A \in B(\mathcal{K} \otimes \mathcal{H})$. Indeed, in this particular model, the estimated quantity is identically zero since $\bra{\psi_0 \otimes \cdots \otimes \psi_0} X_i \ket{\psi_0 \otimes \cdots \otimes \psi_0} = \bra{\psi_0 \otimes \cdots \otimes \psi_0}^N \cdot X_i \psi_1 = 0$ for all microscopic $X_i$.

Of course coherence can be detected on the closed system $\mathcal{K} \otimes \mathcal{H}$, but only using observables that are neither macroscopic nor microscopic, such as $\sigma_x \otimes \cdots \otimes \sigma_x$.

2. Finite Spin-Chain at Nonzero Temperature

A more realistic initial state for the spin-chain is the nonzero-temperature state $\tau_\beta = \frac{e^{-\beta H}}{\tr e^{-\beta H}}$. For the spin-chain Hamiltonian we will take $H = \sum_i \sigma_{z,i} = NB$, so that $\tau_\beta$ becomes the tensor product of $N$ copies of the $\mathbb{C}^2$-state

$$\tau_\beta = \frac{1}{e^\beta + e^{-\beta}} \begin{pmatrix} e^{-\beta} & 0 \\ 0 & e^\beta \end{pmatrix}.$$ 

With the same time-evolution as before, we have $T(\ketbra{\psi_0}{\psi_0}) = \ketbra{\psi_0}{\psi_0} \otimes \rho_\beta$ and $T(\ketbra{\psi_1}{\psi_1}) = \ketbra{\psi_1}{\psi_1} \otimes \rho_{-\beta}$. Again we choose the mean energy $B$ as our pointer. A brief calculation shows that $\text{tr} (B \tau_\beta) = \frac{e^{-\beta} - e^{\beta}}{e^\beta + e^{-\beta}} =: \varepsilon(\beta)$ and that $\text{tr} (B^2 \tau_\beta) - \text{tr} (B \rho_\beta)^2 = \frac{1}{N}(1 - \varepsilon^2(\beta))$. Corollary 5 now gives us, for microscopic and macroscopic $A$,

$$\left| \text{tr} \left( T(\ketbra{\alpha_0\psi_0 + \alpha_1\psi_1}{\alpha_0\psi_0 + \alpha_1\psi_1}) A \right) - \text{tr} \left( T(\ketbra{\alpha_0^2\psi_0}{\alpha_0^2\psi_0} + \ketbra{\alpha_1^2\psi_1}{\alpha_1^2\psi_1}) A \right) \right| \leq \left( \frac{1}{\varepsilon(\beta) N} + \frac{\sqrt{1 - \varepsilon^2(\beta)}}{\varepsilon(\beta) \sqrt{N}} \right) \|A\|.$$

For large $N$, we see that the term $\sim \frac{1}{N}$ due to the fact that $[A, B] \neq 0$ is dominated by the thermodynamical fluctuations, which of course go as $\sim \frac{1}{\sqrt{N}}$. In statistical physics, it is standard practice to neglect even the latter.

3. Energy as a Pointer

Hamiltonians often fail to be macroscopic in our narrow sense of the word, since they are generically unbounded and contain interaction terms. However, this does not imply failure of our scheme to estimate coherence.

For example, consider an $N$-particle system with Hilbert space $\mathcal{K} = \bigotimes_{i=1}^N \mathcal{K}_i$ and Hamiltonian $H = \sum_{i=1}^N \frac{p_i^2}{2m_i} + V(x_1, x_2, \ldots, x_N)$. Information is transferred from $\mathcal{H}$ to $\mathcal{K}$ with $H$ as pointer, that is, the two states $\text{tr}_{\mathcal{H}}(T(\ketbra{\psi_0}{\psi_0}))$ and $\text{tr}_{\mathcal{H}}(T(\ketbra{\psi_1}{\psi_1}))$ have different energies $E$ and $E'$. Without loss of generality, assume that they are vector states: $\text{tr}_{\mathcal{H}}(T(\ketbra{\psi_0}{\psi_0})) = \ketbra{\psi}{\psi}$ and $\text{tr}_{\mathcal{H}}(T(\ketbra{\psi_1}{\psi_1})) = \ketbra{\psi'}{\psi'}$. (Density matrices can always be represented as vectors on a different Hilbert space, cf. the proof of Theorem 3.)

We thus have two vector states $|\psi\rangle$ and $|\psi'\rangle$ with different energies $E := \langle \psi, H \psi \rangle$ and $E' := \langle \psi', H \psi' \rangle$. We estimate the coherence between $|\psi\rangle$ and $|\psi'\rangle$ on $x_n$, the position of particle $n$. 

10
\[ (E - E')(\psi, x_n \psi') = \langle E \psi, x_n \psi' \rangle - \langle x_n \psi, E' \psi' \rangle = \langle H \psi - (H - E)\psi, x_n \psi' \rangle - \langle x_n \psi, H \psi' - (H - E')\psi' \rangle = \langle [H, x_n] \psi, \psi' \rangle - \langle (H - E)\psi, x_n \psi' \rangle + \langle x_n \psi, (H - E')\psi' \rangle \]

Now since \( [H, x_n] = \frac{i\hbar p_n}{m_n} \), we can apply the Cauchy-Schwarz inequality in each term to obtain

\[ |E - E'| \leq \frac{\hbar}{m_n} \sqrt{\langle \psi, \psi \rangle} + \sqrt{\langle \psi, x_n \psi \rangle} \sqrt{\langle \psi', (H - E')^2 \psi' \rangle} + \sqrt{\langle \psi', x_n^2 \psi' \rangle} \sqrt{\langle \psi, (H - E)^2 \psi \rangle}. \]

If we define the characteristic speed \( V_n := \sqrt{\langle \psi, (E_m n)^2 \psi \rangle} \), the characteristic positions \( X_n := \sqrt{\langle \psi, x_n^2 \psi \rangle} \), and the standard deviations \( \sigma := \sqrt{\langle \psi, (H - E)^2 \psi \rangle} \) and \( \sigma' := \sqrt{\langle \psi', (H - E')^2 \psi' \rangle} \), we obtain

\[ |\langle \psi, x_n \psi' \rangle| \leq \frac{\hbar V_n + \sigma X_n + \sigma' X_n}{|E - E'|}. \]

As such, this doesn’t tell us very much. We will have to make some physically plausible assumptions on the state of the system in order to obtain results. First, we assume that the system is encased in an \( L \times L \times L \) box so that \( X_n, X'_n \leq L \). Also, we assume \( V_n < c \). This yields \( \langle \psi, x_n \psi' \rangle \leq \frac{\hbar c + L(\sigma + \sigma')}{|E - E'|} \). Secondly, we assume that scaling the system in any meaningful way will produce \( |E - E'| \sim N \) and \( \sigma + \sigma' \sim \sqrt{N} \), so that the coherence on \( x_n \) approaches zero as \( \frac{1}{\sqrt{N}} \). Notice the almost thermodynamic lack of detail required for this estimate.

4. Schrödinger’s Cat

Let us finally analyze the rather drastic extraction of information from a radioactive particle that has become known\(^3\) as ‘Schrödinger’s cat’. (See [Sch].) The experiment is performed as follows. We are interested in a radioactive particle. Is it in a decayed state \( \psi \) or in a non-decayed state \( \psi' \)?

In order to determine this, we set up the following experiment. A Geiger counter is placed next to the radioactive particle. If the particle decays, then the Geiger counter clicks. A mechanism then releases a hammer, which smashes a vial of hydrocyanic acid, killing a cat. All of this happens in a closed box no higher than \( 1 m \), and completely impenetrable to information. A measurement of the atom is done as follows: first, place it inside the box. Then wait for a period of time that is long compared to the decay time of the atom. Finally, open the box, and inspect whether the cat has dropped dead or is still standing upright.

The atom is described by a Hilbert space \( \mathcal{H} \), the combination of Geiger counter, mechanism, hammer, vial and cat by a Hilbert space \( \mathcal{K} \). Initially, the latter is prepared in a state \( |\theta\rangle \). As a pointer, we take the center of mass of the cat, \( Z := \frac{1}{N} \sum_{i=1}^{N} z_i \). In this expression, \( N \) is the amount of atoms out of which the cat is constructed, and \( z_i \) is the \( z \)-component of particle number \( i \). (It is a harmless assumption that all atoms in the cat have the same mass.) Since the box only measures \( 1 m \) in height, we may take \( ||Z|| = 1 \). The unitary evolution \( U \in B(\mathcal{K} \otimes \mathcal{H}) \) then produces \( U|\psi_0 \otimes \theta\rangle := |\gamma_0\rangle \) and \( U|\psi_1 \otimes \theta\rangle := |\gamma_1\rangle \), which are eigenstates\(^4\) of \( Z \) with different eigenvalues.

Suppose that, initially, the atom is either in the decayed state \( \psi_0 \) with probability \( |\alpha_0|^2 \) or in the non-decayed state \( \psi_1 \) with probability \( |\alpha_1|^2 \). That is, the initial state is the incoherent mixture \( |\alpha_0|^2 |\psi_0\rangle + |\alpha_1|^2 |\psi_1\rangle \). By linearity, the final state is then the incoherent state \( |\alpha_0|^2 |\gamma_0\rangle + |\alpha_1|^2 |\gamma_1\rangle \).

On the other hand, if the atom starts out in the coherent superposition \( \alpha_0|\psi_0\rangle + \alpha_1|\psi_1\rangle \), then the combined system ends up in the coherent state \( U(|\alpha_0|\psi_0 + \alpha_1|\psi_1\rangle \otimes \theta) = |\alpha_0|\gamma_0\rangle + |\alpha_1|\gamma_1\rangle \).

The question is now this: why do we not notice the difference between these two situations if we open the box? First of all, according to Theorem 3 (and the observations following it in section III A 3), it is impossible to detect coherence between \( \gamma_0 \) and \( \gamma_1 \) and ascertain the position of the cat. Upon opening the black box, we must make a choice.

\(^3\)Actually, Schrödinger’s proposal was slightly different. In the original thought experiment, death of the cat was correlated with decay of the atom at time \( t \) instead of 0, which wouldn’t make it an information transfer in our sense of the word.

\(^4\)As discussed before, it would be more realistic to allow for a nonzero variance \( 0 < \sigma_j \ll 1 \) instead of requiring \( \theta_j \) to be eigenstates of \( Z \). We use \( \sigma_j = 0 \) for clarity, leaving the argument essentially unchanged.
Secondly, according to the discussion in section III C, the coherences between the macroscopically different states $\gamma_0$ and $\gamma_1$ are extremely volatile. Any speck of light falling on the cat will reveal its position with reasonable accuracy, causing the coherence to disappear according to Theorem 3.

Yet even if we were able to open the box without any information on the position of the cat leaking out, even then would we be unable to detect coherence between $\gamma_0$ and $\gamma_1$. Apply Corollary 5 to the transfer of information from atom to cat. We have $\sigma_0 = \sigma_1 = 0$, and with pointer $Z$ we have $\|Z\| = 1$ (the height of the box is $1$ m) and $z_1 - z_0 = 0.1$ (the difference between a cat that is standing up and one that has dropped dead is $10$ cm). We then obtain for all macroscopic and microscopic $A$:

$$\left|\langle\alpha_0\gamma_0 + \alpha_1\gamma_1, A\alpha_0\gamma_0 + \alpha_1\gamma_1\rangle - (|\alpha_0|^2\langle\gamma_0, A\gamma_0\rangle + |\alpha_1|^2\langle\gamma_1, A\gamma_1\rangle)\right| \leq \frac{20}{N}\|A\|.$$  

On the subset of observables we are normally able to measure, the distinction between coherent and incoherent mixtures practically vanishes for $N \sim 10^{23}$. For all practical intents and purposes, it is completely harmless to assume that the final state of the cat is $|\alpha_0|^2\langle\gamma_0\rangle + |\alpha_1|^2\langle\gamma_1\rangle$ instead of $\alpha_0\gamma_0 + \alpha_1\gamma_1$. But it would be false to state that the former has actually been observed.

V. CONCLUSION

In open systems, we have proven that decoherence is a necessary consequence of information transfer to the outside. More in detail, we have reached the following conclusions:

- Suppose that an open system $H$ interacts with an ancillary system $K$ in such a way, that it is possible, in principle, to determine from $K$ whether $H$ had been in state $\psi_0$ or $\psi_1$ before the interaction. If $H$ started out in a coherent state $\alpha_0|\psi_0\rangle + \alpha_1|\psi_1\rangle$, then it will behave after the information transfer as if it had started out in the incoherent mixture $|\alpha_0|^2|\psi_0\rangle\langle\psi_0| + |\alpha_1|^2|\psi_1\rangle\langle\psi_1|$ instead. This is called ‘decoherence’.

- Suppose again that the information whether $H$ was in state $\psi_0$ or $\psi_1$ is transported to an ancillary system $K$. This is done with an ensemble of $H$-systems described by the state $\alpha_0|\psi_0\rangle + \alpha_1|\psi_1\rangle$. The ensemble is then split into subensembles, according to outcome. The ‘0-ensemble’ then behaves as if it had been in state $\psi_0$ at the beginning of the procedure, and the ‘1-ensemble’ as if it had started in state $\psi_1$. This is called ‘state collapse’.

- These results were obtained entirely within the framework of traditional quantum mechanics and unitary time evolution on a larger, closed system containing $H$. No ‘reduction-postulate’ is needed. From Proposition 1, we see that any information extraction causes collapse, quite independent of its particular mechanism.

- On the closed system containing the smaller, open one no decoherence occurs in principle. In practice however, closed systems are very hard to achieve. We have argued that information transfer from a macroscopic observable $A$, performed with macroscopic precision $\sigma$, causes decoherence between eigenstates of $A$ if their values satisfy $\sigma \ll |\alpha_1 - \alpha_0|$. Since information on macroscopic observables tends to leak out, coherence between macroscopically different states tends to vanish.

Still, even if the combined system $K \otimes H$ is considered perfectly closed, there are some results to be obtained. Again, we investigated the case that a system $H$ interacts unitarily with a system $K$ in such a way that the information whether $H$ was in state $\psi_0$ or $\psi_1$ can be read off from a pointer in $K$. We have reached the following conclusions concerning the closed system $K \otimes H$:

- Using only observables on the closed system that commute with the pointer, it is impossible to detect whether $H$ had started out in state $\alpha_0|\psi_0\rangle + \alpha_1|\psi_1\rangle$ or $|\alpha_0|^2|\psi_0\rangle\langle\psi_0| + |\alpha_1|^2|\psi_1\rangle\langle\psi_1|$. Physically, this means that it is impossible to distinguish between coherent and incoherent initial states while at the same time distinguishing between $\psi_0$ and $\psi_1$.

- Suppose that the closed system $K \otimes H$ is macroscopic, and that one has access to its macroscopic and microscopic observables only. Then it is almost impossible to distinguish whether $H$ had started out in state $\alpha_0|\psi_0\rangle + \alpha_1|\psi_1\rangle$ or $|\alpha_0|^2|\psi_0\rangle\langle\psi_0| + |\alpha_1|^2|\psi_1\rangle\langle\psi_1|$. We have obtained upper bounds on the coherences $\langle\psi_0, A\psi_1\rangle$, evaluated on microscopic or macroscopic $A$. Assuming perfect information transfer ($\sigma_0 = \sigma_1 = 0$), they approach zero as $\frac{1}{N}$, where $N$ is the size of the system.
In short: no decoherence ever occurs on perfectly closed systems, even if they are macroscopic. It is just very hard to distinguish coherent from incoherent states, creating the false impression that it does.

The link between decoherence and macroscopic systems was brought forward by Klaus Hepp in his fundamental paper [Hep], where he considered infinite closed systems, displaying decoherence in infinite time. In infinite systems, the microscopic observables form a non-commutative $C^*$-algebra $\mathcal{A}$. Its weak closure $\mathcal{A}''$ is considered as the (von Neumann-)algebra of all observables. The macroscopic observables form a commutative algebra $\mathcal{C}$ which is contained in the centre of $\mathcal{A}''$, i.e. $\mathcal{C} \subset \mathcal{Z} = \{ Z \in \mathcal{A}'' | [Z,A] = 0 \ \forall A \in \mathcal{A}'' \}$, yet is almost disjoint from the microscopic observables: $\mathcal{C} \cap \mathcal{A} = 0$. Transfer of information to a macroscopic observable therefore implies perfect decoherence on all microscopic and macroscopic observables (cf. section III A 3).

Unfortunately, this transfer cannot be done by any automorphic time-evolution, since the macroscopic observables are central. Hepp proposed information transfer by a $t \to \infty$ limit of automorphisms. He was able to show that this causes decoherence in the weak-operator sense. That is, on each fixed microscopic observable, the coherence becomes arbitrarily small for sufficiently large $t$.

The paper was criticized by John Bell a few years later [Bel], on the grounds that, for each fixed time $t$, there are observables to be found on which coherence is not small. Since Bell was of the opinion that a ‘wave packet reduction’, even on closed systems, ‘takes over from the Schrödinger equation’, this was not to his satisfaction. He did agree however that these observables would become arbitrarily difficult to observe in practice for large $t$.

By considering large but finite closed systems subject to unitary time evolution, we hope to clarify the role that macroscopic systems play in making us mistake coherent superpositions for classical mixtures. It seems striking that the same, simple mathematics can also be used to understand why open systems do undergo decoherence as soon as they lose information.
