ABSTRACT

Learning functions on point clouds has applications in many fields, including computer vision, computer graphics, physics, and chemistry. Recently, there has been a growing interest in neural architectures that are invariant or equivariant to all three shape-preserving transformations of point clouds: translation, rotation, and permutation. In this paper, we present a first study of the approximation power of these architectures. We first derive two sufficient conditions for an equivariant architecture to have the universal approximation property, based on a novel characterization of the space of equivariant polynomials. We then use these conditions to show that two recently suggested models (Thomas et al., 2018; Fuchs et al., 2020) are universal, and for devising two other novel universal architectures.

1 INTRODUCTION

Designing neural networks that respect data symmetry is a powerful approach for obtaining efficient deep models. Prominent examples being convolutional networks which respect the translational invariance of images, graph neural networks which respect the permutation invariance of graphs (Gilmer et al., 2017; Maron et al., 2019b), networks such as (Zaheer et al., 2017; Qi et al., 2017a) which respect the permutation invariance of sets, and networks which respect 3D rotational symmetries (Cohen et al., 2018; Weiler et al., 2018; Esteves et al., 2018; Worrall & Brostow, 2018; Kondor et al., 2018a).

While the expressive power of equivariant models is reduced by design to include only equivariant functions, a desirable property of equivariant networks is universality: the ability to approximate any continuous equivariant function. This is not always the case: while convolutional networks and networks for sets are universal (Yarotsky, 2018; Segol & Lipman, 2019), popular graph neural networks are not (Xu et al., 2019; Morris et al., 2018).

In this paper, we consider the universality of networks that respect the symmetries of 3D point clouds: translations, rotations, and permutations. Designing such networks is a popular paradigm in recent years (Thomas et al., 2018; Fuchs et al., 2020; Poulenard et al., 2019; Zhao et al., 2019). While there have been many works on the universality of permutation invariant networks (Zaheer et al., 2017; Maron et al., 2019c; Keriven & Peyré, 2019), and a recent work discussing the universality of rotation equivariant networks (Bogatskiy et al., 2020), this is a first paper which discusses the universality of networks which combine rotations, permutations and translations.

We start the paper with a general, architecture-agnostic, discussion, and derive two sufficient conditions for universality. These conditions are a result of a novel characterization of equivariant polynomials for the symmetry group of interest. We use these conditions in order to prove universality of the prominent Tensor Field Networks (TFN) architecture (Thomas et al., 2018; Fuchs et al., 2020). The following is a weakened and simplified statement of Theorem 2 stated later on in the paper:

**Theorem (Simplification of Theorem 2).** Any continuous equivariant function on point clouds can be approximated uniformly on compact sets by a composition of TFN layers.
We use our general discussion to prove the universality of two additional equivariant models: the first is a simple modification of the TFN architecture which allows for universality using only low dimensional filters. The second is a minimal architecture which is based on tensor product representations, rather than the more commonly used irreducible representations of $\text{SO}(3)$. We discuss the advantages and disadvantages of both approaches.

To summarize, the contributions of this paper are: (1) A general approach for proving the universality of rotation equivariant models for point clouds; (2) A proof that two recent equivariant models (Thomas et al., 2018; Fuchs et al., 2020) are universal; (3) Two additional simple and novel universal architectures.

2 PREVIOUS WORK

Deep learning on point clouds. (Qi et al., 2017a; Zaheer et al., 2017) were the first to apply neural networks directly to the raw point cloud data, by using pointwise functions and pooling operations. Many subsequent works used local neighborhood information (Qi et al., 2017b; Wang et al., 2019; Atzmon et al., 2018). We refer the reader to a recent survey for more details (Guo et al., 2020). In contrast with the aforementioned works which focused solely on permutation invariance, more related to this paper are works that additionally incorporated invariance to rigid motions. (Thomas et al., 2018) proposed Tensor Field Networks (TFN) and showed their efficacy on physics and chemistry tasks. (Kondor et al., 2018b) also suggested an equivariant model for continuous rotations. (Li et al., 2019) suggested models that are equivariant to discrete subgroups of $\text{SO}(3)$. (Poulenard et al., 2019) suggested an invariant model based on spherical harmonics. (Fuchs et al., 2020) followed TFN and added an attention mechanism. Recently, (Zhao et al., 2019) proposed a quaternion equivariant point capsule network that also achieves rotation and translation invariance.

Universal approximation for invariant networks. Understanding the approximation power of invariant models is a popular research goal. Most of the current results assume that the symmetry group is a permutation group. (Zaheer et al., 2017; Qi et al., 2017a; Segol & Lipman, 2019; Maron et al., 2020; Serviansky et al., 2020) proved universality for several $S_n$-invariant and equivariant models. (Maron et al., 2019a; Keriven & Peyré, 2019; Machara & NT, 2019) studied the approximation power of high-order graph neural networks. (Maron et al., 2019c; Ravanbakhsh, 2020) targeted universality of networks that use high-order representations for permutation groups (Yarotsky, 2018) provided several theoretical constructions of universal equivariant neural network models based on polynomial invariants, including an $SE(2)$ equivariant model. In a recent work (Bogatskiy et al., 2020) presented a universal approximation theorem for networks that are equivariant to several Lie groups including $SO(3)$. The main difference from our paper is that we prove a universality theorem for a more complex group that besides rotations also includes translations and permutations.

3 A FRAMEWORK FOR PROVING UNIVERSALITY

In this section, we describe a framework for proving the universality of equivariant networks. We begin with some mathematical preliminaries:

3.1 MATHEMATICAL SETUP

An action of a group $G$ on a real vector space $W$ is a collection of maps $\rho(g) : W \to W$ defined for any $g \in G$, such that $\rho(g_1) \circ \rho(g_2) = \rho(g_1g_2)$ for all $g_1, g_2 \in G$, and the identity element of $G$ is mapped to the identity mapping on $W$. We say $\rho$ is a representation of $G$ if $\rho(g)$ is a linear map for every $g \in G$. As is customary, when it does not cause confusion we often say that $W$ itself is a representation of $G$.

In this paper, we are interested in functions on point clouds. Point clouds are sets of vectors in $\mathbb{R}^3$ arranged as matrices:

$$X = (x_1, \ldots, x_n) \in \mathbb{R}^{3 \times n}.$$

Many machine learning tasks on point clouds, such as classification, aim to learn a function which is invariant to rigid motions and relabeling of the points. Put differently, such functions are required
to be invariant to the action of $G = \mathbb{R}^3 \times \text{SO}(3) \times S_n$ on $\mathbb{R}^{3 \times n}$ via
\[
\rho_G(t, R, P)(X) = R(X - t_1^T)P^T,
\]
where $t \in \mathbb{R}^3$ defines a translation, $R$ is a rotation and $P$ is a permutation matrix.

Equivariant functions are generalizations of invariant functions: If $G$ acts on $W_1$ via some action $\rho_1(g)$, and on $W_2$ via some other group action $\rho_2(g)$, we say that a function $f : W_1 \rightarrow W_2$ is equivariant if
\[
f(\rho_1(g)w) = \rho_2(g)f(w), \forall w \in W_1 \text{ and } g \in G.
\]

Invariant functions correspond to the special case where $\rho_2(g)$ is the identity mapping for all $g \in G$.

In some machine learning tasks on point clouds, the functions learned are not invariant but rather equivariant. For example, segmentation tasks assign a discrete label to each point. They are invariant to translations but equivariant to both rotations and permutations. Another example is predicting a normal for each point of a point cloud. This task is invariant to translations but equivariant to both rotations and permutations.

In this paper, we are interested in learning equivariant functions from point clouds into $W_T^n$, where $W_T$ is some representation of SO(3). The equivariance of these functions is with respect to the action $\rho_G$ on point clouds defined in equation [1] and the action of $G$ on $W_T^n$ defined by applying the rotation action from the left and permutation action from the right as in [1] but ‘ignoring’ the translation component. Thus, $G$-equivariant functions will be translation invariant. This formulation of equivariance includes the normals prediction example by taking $W_T = \mathbb{R}^3$, as well as the segmentation case by setting $W_T = \mathbb{R}$ with the trivial identity representation. We focus on the harder case of functions into $W_T^n$ which are equivariant to permutations, since it easily implies the easier case of permutation invariant functions to $W_T$.

**Notation.** We use the notation $\mathbb{N}_+ = \mathbb{N} \cup \{0\}$ and $\mathbb{N}^*_+ = \bigcup_{n \in \mathbb{N}} \mathbb{N}^*_n$. We set $|D| = \{1, \ldots, D\}$ and $|D|_0 = \{0, \ldots, D\}$.

**Proofs.** Proofs appear in the appendices, arranged according to sections.

3.2 Conditions for universality

**The semi-lifted approach** In general, highly expressive equivariant neural networks can be achieved by using a ‘lifted approach’, where intermediate features in the network belong to high dimensional representations of the group. In the context of point clouds where typically $n \gg 3$, many papers, e.g., (Thomas et al., 2018; Kondor, 2018; Bogatskiy et al., 2020) use a ‘semi-lifted’ approach, where hidden layers hold only higher dimensional representations of SO(3), but not high order permutation representations. In this subsection, we propose a strategy for achieving universality with the semi-lifted approach.

We begin by an axiomatic formulation of the semi-lifted approach (see illustration in inset): we assume that our neural networks are composed of two main components: the first component is a family $\mathcal{F}_{\text{feat}}$ of parametric continuous $G$-equivariant functions $f_{\text{feat}}$ which map the original point cloud $\mathbb{R}^{3 \times n}$ to a semi-lifted point cloud $W_{\text{feat}}^n$, where $W_{\text{feat}}$ is a lifted representation of SO(3). The second component is a family of parametric linear SO(3)-equivariant functions $\mathcal{F}_{\text{pool}}$, which map from the high order representation $W_{\text{feat}}$ down to the target representation $W_T$. Each such SO(3)-equivariant function $\Lambda : W_{\text{feat}} \rightarrow W_T$ can be extended to a SO(3) $\times S_n$ equivariant function $\hat{\Lambda} : W_{\text{feat}}^n \rightarrow W_T^n$ by applying $\Lambda$ elementwise. For every positive integer $C$, these two families of functions induce a family of functions $\mathcal{F}_C$ obtained by summing $C$ different compositions of these functions:

\[
\mathcal{F}_C(\mathcal{F}_{\text{feat}}, \mathcal{F}_{\text{pool}}) = \{ f | f(X) = \sum_{c=1}^C \hat{\Lambda}_c(g_c(X)), \ (\Lambda_c, g_c) \in \mathcal{F}_{\text{pool}} \times \mathcal{F}_{\text{feat}} \}.
\]
In the remainder of the paper, we prove the universality of several Corollary 1.

As a result of Theorem 1 and Lemma 1 we obtain our lifted approach. The first step is showing, as in (Yarotsky, 2018), that continuous functions generated by a pair of function spaces (see inset for illustration) (Linear universality).

Definition 1 (D-spanning). For \( D ∈ \mathbb{N}_+ \), let \( \mathcal{F}_{\text{feat}} \) be a subset of \( \mathcal{C}_G(\mathbb{R}^{3\times n}, W_3^n) \). We say that \( \mathcal{F}_{\text{feat}} \) is \( D \)-spanning, if there exist \( f_1, \ldots, f_K ∈ \mathcal{F}_{\text{feat}} \), such that every polynomial \( p : \mathbb{R}^{3\times n} → \mathbb{R}^n \) of degree \( D \) which is invariant to translations and equivariant to permutations, can be written as

\[
p(X) = \sum_{k=1}^K \hat{\Lambda}_k(f_k(X)),
\]

where \( \Lambda_k : W_3^{n,\text{feat}} → \mathbb{R} \) are all linear functionals, and \( \hat{\Lambda}_k : W_3^{n,\text{feat}} → \mathbb{R}^n \) are the functions defined by elementwise applications of \( \Lambda_k \).

In Lemma 4 we provide a concrete condition which implies \( D \)-spanning.

The second sufficient condition is that the set of linear \( \text{SO}(3) \) equivariant functionals \( \mathcal{F}_{\text{pool}} \) contains all possible equivariant linear functionals:

Definition 2 (Linear universality). We say that a collection \( \mathcal{F}_{\text{pool}} \) of equivariant linear functionals between two representations \( W_{\text{feat}} \) and \( W_T \) of \( \text{SO}(3) \) is linearly universal, if it contains all linear \( \text{SO}(3) \)-equivariant mappings between the two representations.

When these two necessary conditions apply, a rather simple symmetrization arguments leads to the following theorem:

Theorem 1. If \( \mathcal{F}_{\text{feat}} \) is \( D \)-spanning and \( \mathcal{F}_{\text{pool}} \) is linearly universal, then there exists some \( C(D) ∈ \mathbb{N} \) such that for all \( C ≥ C(D) \) the function space \( \mathcal{F}_G(\mathcal{F}_{\text{feat}}, \mathcal{F}_{\text{pool}}) \) contains all \( G \)-equivariant polynomials of degree \( ≤ D \).

As a result of Theorem 1 and Lemma 1, we obtain our universality result (see inset for illustration)

Corollary 1. For all \( C, D ∈ \mathbb{N}_+ \), let \( \mathcal{F}_{C,D} \) denote function spaces generated by a pair of functions spaces which are \( D \)-spanning and linearly universal as in equation 2. Then any continuous \( G \)-equivariant function in \( \mathcal{C}_G(\mathbb{R}^{3\times n}, W_3^n) \) can be approximated uniformly on compact sets by equivariant functions in

\[
\mathcal{F} = \bigcup_{D ∈ \mathbb{N}} \mathcal{F}_{C(D), D}.
\]

3.3 SUFFICIENT CONDITIONS IN ACTION

In the remainder of the paper, we prove the universality of several \( G \)-equivariant architectures, based on the framework we discussed in the previous subsection. We discuss two different strategies for achieving universality, which differ mainly in the type of lifted representations of \( \text{SO}(3) \) they use: (i) The first strategy uses (direct sums of) tensor-product representations; (ii) The second uses (direct sums of) irreducible representations. The main advantage of the first strategy from the perspective of our methodology is that achieving the \( D \)-spanning property is more straightforward. The advantage of irreducible representations is that they almost automatically guarantees the linear universality property.

In Section 4, we discuss universality through tensor product representations, and give an example of a minimal tensor representation network architecture that would satisfy universality. In section 5
we discuss universality through irreducible representations, which is currently the more common strategy. We show that the TFN architecture [Thomas et al. 2018; Fuchs et al. 2020] which follows this strategy is universal, and describe a simple tweak that achieves universality using only low order filters, though the representations throughout the network are high dimensional.

4 UNIVERSALITY WITH TENSOR REPRESENTATIONS

In this section, we prove universality for models that are based on tensor product representations, as defined below. The main drawback is that its data representation is somewhat redundant and that characterizing the linear equivariant layers is more laborious.

**Tensor representations** We begin by defining tensor representations. For $k \in \mathbb{N}_+$ denote $T_k = \mathbb{R}^{3^k}$. $SO(3)$ acts on $T_k$ by the tensor product representation, i.e., by applying the matrix Kronecker product $k$ times: $\rho_k(R) := R \otimes^k$. The inset illustrates the vector spaces and action for $k = 1, 2, 3$. With this action, for any $i_1, \ldots, i_k \in [n]$, the map from $\mathbb{R}^{3 \times n}$ to $T_k$ defined by

$$(x_1, \ldots, x_n) \mapsto x_{i_1} \otimes x_{i_2} \ldots \otimes x_{i_k},$$

is $SO(3)$ equivariant.

**A $D$-spanning family** We now show that tensor representations can be used to define a finite set of $D$-spanning functions. The lifted representation $W_{\text{feat}}$ will be given by

$$W_{\text{feat}}^d = \bigoplus_{T=0}^{D} T_T.$$  

The $D$-spanning functions are indexed by vectors $\vec{r} = (r_1, \ldots, r_K)$, where each $r_k$ is a non-negative integer. The functions $Q^{(\vec{r})} = (Q_j^{(\vec{r})})_{j=1}^n$ are defined for fixed $j \in [n]$ by

$$Q_j^{(\vec{r})}(X) = \sum_{i_2, \ldots, i_K = 1}^n x_{i_1}^{\otimes r_1} \otimes x_{i_2}^{\otimes r_2} \otimes x_{i_3}^{\otimes r_3} \otimes \ldots \otimes x_{i_K}^{\otimes r_K}.$$  

The functions $Q_j^{(\vec{r})}$ are $SO(3)$ equivariant as they are a sum of equivariant functions from equation 4. Thus $Q^{(\vec{r})}$ is $SO(3) \times S_n$ equivariant. The motivation behind the definition of these functions is that known characterizations of permutation equivariant polynomials (Segol & Lipman 2019) tell us that the entries of these tensor valued functions span all permutation equivariant polynomials (see the proof of Lemma 2 for more details). To account for translation invariance, we compose the functions $Q^{(\vec{r})}$ with the centralization operation and define the set of functions

$$Q_D = \{ \iota \circ Q_j^{(\vec{r})}(X - \frac{1}{n} X 1_n 1_n^T) \mid \vec{r} \in \mathbb{Z}^n \leq D \},$$

where $\iota$ is the natural embedding that takes each $T_T$ into $W_{\text{feat}}^T = \bigoplus_{T=0}^{D} T_T$. In the following lemma, we prove that this set is $D$-spanning.

**Lemma 2.** For every $D \in \mathbb{N}_+$, the set $Q_D$ is $D$-spanning.

**A minimal universal architecture** Once we have shown that $Q_D$ is $D$-spanning, we can design $D$-spanning architectures, by devising architectures that are able to span all elements of $Q_D$. As we will now show, the compositional nature of neural networks allows us to do this in a very clean manner.

We define a parametric function $f(X, V|\theta_1, \theta_2)$ which maps $\mathbb{R}^{3 \times n} \oplus T_k \nabla$ to $\mathbb{R}^{3 \times n} \oplus T_{k+1} \nabla$ as follows: For all $j \in [n]$, we have $f_j(X, V) = (X_j, \tilde{V}_j(X, V))$, where

$$\tilde{V}_j(X, V|\theta_1, \theta_2) = \theta_1 (x_j \otimes V_j) + \theta_2 \sum_i (x_i \otimes V_i)$$

(7)
We denote the set of functions \((X, V) \mapsto f(X, V|\theta_1, \theta_2)\) obtained by choosing the parameters \(\theta_1, \theta_2 \in \mathbb{R}\) by \(\mathcal{F}_{\text{min}}\). While in the hidden layers of our network the data is represented using both coordinates \((X, V)\), the input to the network only contains an \(X\) coordinate and the output only contains a \(V\) coordinate. To this end, we define the functions

\[
\text{ext}(X) = (X, 1_n) \quad \text{and} \quad \pi_V(X, V) = V.
\]  

We can achieve \(D\)-spanning by composition of functions in \(\mathcal{F}_{\text{min}}\) with these functions and centralizing:

**Lemma 3.** The function set \(\mathcal{Q}_D\) is contained in

\[
\mathcal{F}_{\text{feat}} = \{ \ell \circ \pi_V \circ f^1 \circ f^2 \circ \ldots \circ f^T \circ \text{ext}(X - \frac{1}{n}X1_n1_n^T) | f^j \in \mathcal{F}_{\text{min}}, T \leq D \}.
\]

Thus \(\mathcal{F}_{\text{feat}}\) is \(D\)-spanning.

To complete the construction of a universal network, we now need to characterize all linear equivariant mappings into \(\mathcal{W}_T\). In Appendix [C] we show how this can be done for the trivial representation \(\mathcal{W}_T = \mathbb{R}\). This characterization gives us a set of linear function \(\mathcal{F}_{\text{pool}}\), which combined with \(\mathcal{F}_{\text{feat}}\) defined in equation [9] (corresponds to \(\text{SO}(3)\) invariant functions) gives us a universal architecture as in Theorem [H]. However, the disadvantage of this approach is that implementation of the linear functions in \(\mathcal{F}_{\text{pool}}\) is somewhat cumbersome.

In the next section we discuss irreducible representations, which give us a systematic way to address linear equivariant mappings into \textit{any} \(\mathcal{W}_T\). Proving \(D\)-spanning for these networks is accomplished via the \(D\)-spanning property of tensor representations, through the following lemma

**Lemma 4.** If all functions in \(\mathcal{Q}_D\) can be written as

\[
\ell \circ Q^{(\ell)}(X - \frac{1}{n}X1_n1_n^T) = \sum_{k=1}^{K} \hat{A}_k f_k(X),
\]

where \(f_k \in \mathcal{F}_{\text{feat}}\), \(A_k : \mathcal{W}_{\text{feat}} \rightarrow \mathcal{W}_{\text{feat}}^n\) and \(\hat{A}_k : \mathcal{W}_{\text{feat}}^n \rightarrow (\mathcal{W}_{\text{feat}})^n\) is defined by elementwise application of \(A_k\), then \(\mathcal{F}_{\text{feat}}\) is \(D\)-spanning.

## 5 Universality with Irreducible Representations

In this section, we discuss how to achieve universality when using irreducible representations of \(\text{SO}(3)\). We will begin by defining irreducible representations, and explaining how linear universality is easily achieved by them, while the \(D\)-spanning properties of tensor representations can be preserved. This discussion can be seen as an interpretation of the choices made in the construction of TFN and similar networks in the literature. We then show that these architectures are indeed universal.

### 5.1 Irreducible Representations of \(\text{SO}(3)\)

In general, any finite-dimensional representation \(W\) of a compact group \(H\) can be decomposed into irreducible representations: a subspace \(W_0 \subset W\) is \(H\)-invariant if \(hw \in W_0\) for all \(h \in H, w \in W_0\). A representation \(W\) is irreducible if it has no non-trivial invariant subspaces. In the case of \(\text{SO}(3)\), all irreducible real representations are defined by matrices \(D^{(\ell)}(R)\), called the real Wigner D-matrices, acting on \(W_\ell := \mathbb{R}^{2\ell+1}\) by matrix multiplication. In particular, the representation for \(\ell = 0, 1\) are \(D^{(0)}(R) = 1\) and \(D^{(1)}(R) = R\).

**Linear maps between irreducible representations** As mentioned above, one of the main advantages of using irreducible representations is that there is a very simple characterization of all linear equivariant maps between two direct sums of irreducible representations. We use the notation \(W_l\) for direct sums of irreducible representations, where \(l = (\ell_1, \ldots, \ell_K) \in \mathbb{N}_+^K\) and \(W_l = \bigoplus_{k=1}^K W_{\ell_k}\).

**Lemma 5.** Let \(\ell^{(1)} = (\ell^{(1)}_1, \ldots, \ell^{(1)}_K)\) and \(\ell^{(2)} = (\ell^{(2)}_1, \ldots, \ell^{(2)}_K)\). A function \(\Lambda = (\Lambda_1, \ldots, \Lambda_K)\) is a linear equivariant mapping between \(W_{\ell^{(1)}}\) and \(W_{\ell^{(2)}}\), if and only if there exists a \(K_1 \times K_2\) matrix
M with $M_{ij} = 0$ whenever $\ell_i^{(1)} \neq \ell_j^{(2)}$, such that
\[
\Lambda_j(V) = \sum_{i=1}^{K_j} M_{ij} V_i
\]
where $V = (V_i)_{i=1}^{K_j}$ and $V_i \in W_{\ell_i^{(j)}}$ for all $i = 1, \ldots, K_j$.

We note that this lemma, which is based on Schur’s lemma, was proven in the complex setting in (Kondor [2018]). Here we observe that it holds for real irreducible representations of SO(3) as well since their dimension is always odd.

**Clebsch-Gordan decomposition of tensor products** As any finite-dimensional representation of SO(3) can be decomposed into a direct sum of irreducible representations, this is true for tensor representations as well. In particular, the Clebsch-Gordan coefficients provide an explicit formula for decomposing the tensor product of two irreducible representations $W_{\ell_1}$ and $W_{\ell_2}$ into a direct sum of irreducible representations. This decomposition can be easily extended to decompose the tensor product $W_{\ell_1} \otimes W_{\ell_2}$ into a direct sum of irreducible representations, where $\ell_1, \ell_2$ are now vectors. In matrix notation, this means there is a unitary linear equivariant $U: W_{\ell_1} \otimes W_{\ell_2} \rightarrow W_\ell$, where the explicit values of $\ell = \ell(1, \ell_2)$ and the matrix $U(\ell_1, \ell_2)$ can be inferred directly from the case where $\ell_1$ and $\ell_2$ are scalars.

By repeatedly taking tensor products and applying Clebsch-Gordan decompositions to the result, TFN and similar architectures can achieve the $D$-spanning property in a manner analogous to tensor representations, and also enjoy linear universality since they maintain irreducible representations throughout the network.

### 5.2 Tensor field networks

We now describe the basic layers of the TFN architecture (Thomas et al., 2018), which are based on irreducible representations, and suggest an architecture based on these layers which can approximate the standard CNN, a filter here depends on the input, and is a function $f: X \rightarrow Y$. Convolutional layers involve taking tensor products of a filter and a feature vector to create a new feature vector, and then decomposing into irreducible representations. Unlike in standard CNN, a filter here depends on the input, and is a function $F: \mathbb{R}^D \rightarrow W_{\ell_D}$, where $\ell_D = [0, 1, \ldots, D]^T$. The $\ell$-th component of the filter $F(x) = [F^{(0)}(x), \ldots, F^{(D)}(x)]$ will be given by
\[
F_m^{(\ell)}(x) = R^{(\ell)}(\|x\|)Y_m^\ell(\hat{x}), \quad m = -\ell, \ldots, \ell
\]
where $\hat{x} = x/\|x\|$ if $x \neq 0$ and $\hat{x} = 0$ otherwise, $Y_m^\ell$ are spherical harmonics, and $R^{(\ell)}$ any polynomial of degree $\leq D$. In Appendix F we show that these polynomial functions can be replaced by fully connected networks, since the latter can approximate all polynomials uniformly.

The convolution of an input feature $V \in W_{\ell_D}^n$ and a filter $F$ as defined above, will give an output feature $\hat{V} = (\hat{V}_a)_{a=1}^n \in W_{\ell_D}^n$, where $I_o = I(\ell_f, \ell_i)$, which is given by
\[
\hat{V}_a(X, V) = U(I_f, I_i) \left( \theta_0 V_a + \sum_{b=1}^n F(x_a - x_b) \otimes V_b \right).
\]

More formally we will think of convolutional layer as functions of the form $f(X, V) = (X, \hat{V}(X, V))$. These functions are defined by a choice of $D$, a choice of a scalar polynomial

---

1 Since convolution layers in TFN are not linear, the nonlinearities are formally redundant.
Alternative architecture. Self interaction layers are linear functions from \( \hat{A} : W^n_l \to W^n_{l'} \), which are obtained from elementwise application of equivariant linear functions \( \Lambda : W_l \to W_{l'} \). These linear functions can be specified by a choice of matrix \( M \) with the sparsity pattern described in Lemma 5.

Network architecture. For our universality proof, we suggest a simple architecture which depends on two positive integer parameters \((C,D)\): For given \( D \), we will define \( \mathcal{F}_{\text{feat}}(D) \) as the set of function obtained by 2D recursive convolutions

\[
\mathcal{F}_{\text{feat}}(D) = \{ \pi_V \circ f^{2D} \circ \ldots \circ f^1 \circ \text{ext}(X) \| f^j \in \mathcal{F}_D \},
\]

where \( \text{ext} \) and \( \pi_V \) are defined as in equation 8. The output of a function in \( \mathcal{F}_{\text{feat}}(D) \) is in \( W^n_{l(D)} \), for some \( l(D) \) which depends on \( D \). We then define \( \mathcal{F}_{\text{pool}}(D) \) to be the self-interaction layers which map \( W^n_{l(D)} \) to \( W^n_{l'} \). This choice of \( \mathcal{F}_{\text{feat}}(D) \) and \( \mathcal{F}_{\text{pool}}(D) \), together with a choice of the number of channels \( C \), defines the final network architecture \( \mathcal{F}^{\text{TFN}}_{C,D} = \mathcal{F}_C(\mathcal{F}_{\text{feat}}(D), \mathcal{F}_{\text{pool}}(D)) \) as in equation 12. In the appendix we prove the universality of TFN:

**Theorem 2.** For all \( n \in \mathbb{N} \), \( l_T \in \mathbb{N}^+_T \),

1. For \( D \in \mathbb{N}_+ \), every \( G \)-equivariant polynomial \( p : \mathbb{R}^{3 \times n} \to W^n_l \) of degree \( D \) is in \( \mathcal{F}^{\text{TFN}}_{C,D} \).

2. Every continuous \( G \)-equivariant function can be approximated uniformly on compact sets by functions in \( \bigcup_{D \in \mathbb{N}_+} \mathcal{F}^{\text{TFN}}_{C,D,D} \).

As discussed previously, the linear universality of \( \mathcal{F}_{\text{pool}} \) is guaranteed. Thus proving Theorem 2 amounts to showing that \( \mathcal{F}_{\text{feat}}(D) \) is \( D \)-spanning. This is done using the sufficient condition for \( D \)-spanning defined in Lemma 4.

**Alternative architecture** The complexity of the TFN network used to construct \( G \)-equivariant polynomials of degree \( D \), can be reduced using a simple modifications of the convolutional layer in equation 12. We add two parameters \( \theta_1, \theta_2 \in \mathbb{R} \) to the convolutional layer, which is now defined as:

\[
\tilde{V}_a(X,V) = U(l_f,l_i) \left( \sum_{b=1}^n F(x_a - x_b) \otimes V_b + \theta_2 \sum_{b=1}^n F(x_a - x_b) \otimes V_a \right).
\]

With this simple change, we can show that \( \mathcal{F}_{\text{feat}}(D) \) is \( D \)-spanning even if we only take filters of order 0 and 1 throughout the network. This is shown in Appendix E.

6 Conclusion

In this paper, we have presented a new framework for proving the universality of \( G \)-equivariant point cloud networks. We used this framework for proving the universality of the TFN model (Thomas et al., 2018; Fuchs et al., 2020), and for devising two additional novel simple universal architectures.

We believe that the framework we developed here will be useful for proving the universality of other \( G \)-equivariant models for point cloud networks, and other related equivariant models. We note that while the discussion in the paper was limited to point clouds in \( \mathbb{R}^3 \) and to the action of \( \text{SO}(3) \), large parts of it are relevant to many other setups involving \( d \)-dimensional point clouds with symmetry groups of the form \( G = \mathbb{R}^d \rtimes H \rtimes S_n \) on \( \mathbb{R}^{d \times n} \), where \( H \) can be any compact topological group.

A Notation

We introduce some notation for the proofs in the appendices. We use the shortened notation $\tilde{X} = X - \frac{1}{n} X 1_n 1_n^T$ and denote the columns of $\tilde{X}$ by $(\tilde{x}_1, \ldots, \tilde{x}_n)$. We denote

$$\Sigma_T = \{ \vec{r} \in \mathbb{N}_+^n | ||\vec{r}||_1 = T \}$$

10
B PROOFS FOR SECTION 3

B.1 G-equivariant polynomials are dense

A first step in proving denseness of $G$-equivariance polynomials, and in the proof used in the next subsection is the following simple lemma, which shows that translation invariance can be dealt with simply by centralizing the point cloud.

In the following, $\rho_{W_T}$ is some representation of $\text{SO}(3)$ on a finite dimensional real vector space $W_T$. This induces an action $\rho_{W_T \times S_n}$ of $\text{SO}(3) \times S_n$ on $W_T^n$ by

$$\rho_{W_T \times S_n}(R, P)(Y) = \rho_{W_T}(R)YP$$

This is also the action of $G$ which we consider, $\rho_{G} = \rho_{W_T \times S_n}$, where we have invariance with respect to the translation coordinate. The action of $G$ on $\mathbb{R}^{3 \times n}$ is defined in equation [4].

**Lemma B.1.** A function $f : \mathbb{R}^{3 \times n} \rightarrow W_T^n$ is $G$-equivariant, if and only if there exists a function $h$ which is equivariant with respect to the action of $\text{SO}(3) \times S_n$ on $\mathbb{R}^{3 \times n}$, and

$$f(X) = h(X - \frac{1}{n}X1_n1_n^T) \quad (14)$$

**Proof.** Recall that $G$-equivariance means $\text{SO}(3) \times S_n$ equivariance and translation invariance. Thus if $f$ is $G$-equivariant then equation [4] holds with $h = f$.

On the other hand, if $f$ satisfies equation [4] then we claim it is $G$-equivariant. Indeed, for all $(t, R, P) \in \mathbb{R}^3 \times \text{SO}(3) \times S_n$, since $P^T1_n1_n^T = 1_n1_n^TP^T$,

$$f(\rho_G(t, R, P)(X)) = f(R(X + t1_n)P^T) = h(R(X + t1_n)P^T - \frac{1}{n}R(X + t1_n)P^T1_n1_n^T)$$

$$= h(R(X - \frac{1}{n}X1_n1_n^T)P^T) = h\left(\rho_{\mathbb{R}^{3 \times n}}(R, P)(X - \frac{1}{n}X1_n1_n^T)\right)$$

$$= \rho_{W_T \times S_n}(R, P)h\left(X - \frac{1}{n}X1_n1_n^T\right)$$

$$= \rho_G(t, R, P)f(X).$$

$\Box$

We now prove denseness of $G$-equivariant polynomials in the space of $G$-invariant continuous functions (Lemma 1).

**Lemma 1.** Any continuous $G$-equivariant function in $C_G(\mathbb{R}^{3 \times n}, W_T^n)$ can be approximated uniformly on compact sets by $G$-equivariant polynomials in $P_G(\mathbb{R}^{3 \times n}, W_T^n)$.

**Proof of Lemma 1.** Let $K \subseteq \mathbb{R}^{3 \times n}$ be a compact set. We need to show that continuous $G$-equivariant functions can be approximated uniformly in $K$ by $G$-equivariant polynomials. Let $K_0$ denote the compact set which is the image of $K$ under the centralizing map $X \mapsto X - \frac{1}{n}X1_n1_n^T$. By Lemma B.1 it is sufficient to show that every $\text{SO}(3) \times S_n$ equivariant continuous function $f$ can be approximated uniformly on $K_0$ by a sequence of $\text{SO}(3) \times S_n$ equivariant polynomials $p_k$. The argument is now concluded by the following general lemma:

**Lemma B.2.** Let $G$ be a compact group, Let $\rho_1$ and $\rho_2$ be continuous representations of $G$ on the Euclidean spaces $W_1$ and $W_2$. Let $K \subseteq W_1$ be a compact set. Then every equivariant function $f : W_1 \rightarrow W_2$ can be approximated uniformly on $K$ by a sequence of equivariant polynomials $p_k : W_1 \rightarrow W_2$.

Let $\mu$ be the Haar probability measure associated with the compact group $G$. Let $K_1$ denote the compact set obtained as an image of the compact set $G \times K$ under the continuous mapping

$$(g, X) \mapsto \rho_1(g)X.$$

\footnote{By this we mean that the maps $(g, X) \mapsto \rho_j(g)X, j = 1, 2$ are jointly continuous}
Using the Stone-Weierstrass theorem, let \( p_k \) be a sequence of (not necessarily equivariant) polynomials which approximate \( f \) uniformly on \( K_1 \). Every degree \( D \) polynomial \( p : W_1 \to W_2 \) induces a \( G \)-equivariant function

\[
\langle p \rangle(X) = \int_G p_2(g^{-1})p(\rho_1(g)X)d\mu(g).
\]

This function \( \langle p \rangle \) is a degree \( D \) polynomial as well: This is because \( \langle p \rangle \) can be approximated uniformly on \( K_1 \) by “Riemann Sums” of the form \( \sum_{j=1}^{N} w_j p_2(g_j^{-1})p(\rho_1(g_j)X) \) which are degree \( D \) polynomials, and because degree \( D \) polynomials are closed in \( C(K_1) \).

Now for all \( X \in K_1 \), continuity of the function \( g \mapsto p_2(g^{-1}) \) implies that the operator norm of \( p_2(g^{-1}) \) is bounded uniformly by some constant \( N > 0 \), and so

\[
\| (p_k)(X) - f(X) \| = \left| \int_G p_2(g^{-1}) p_k(\rho_1(g)X) - p_2(g^{-1})f(\rho_1(g)X)d\mu(g) \right|
\]

\[
= \left| \int_G p_2(g^{-1}) [p_k(\rho_1(g)X) - f(\rho_1(g)X)]d\mu(g) \right| \leq N\| f - p_k \|_{C(K_1)} \to 0
\]

We prove Theorem 1.

**Theorem 1.** If \( \mathcal{F}_{\text{feat}} \) is \( D \)-spanning and \( \mathcal{F}_{\text{pool}} \) is linearly universal, then there exists some \( C(D) \in \mathbb{N} \) such that for all \( C \geq C(D) \) the function space \( \mathcal{F}_C(\mathcal{F}_{\text{feat}}, \mathcal{F}_{\text{pool}}) \) contains all \( G \)-equivariant polynomials of degree \( \leq D \).

**Proof.** By the \( D \)-spanning assumption, there exist \( f_1, \ldots, f_K \in \mathcal{F}_{\text{feat}} \) such that any vector valued polynomial \( p : \mathbb{R}^{3 \times n} \to \mathbb{R}^n \) invariant to translations and equivariant to permutations is of the form

\[
p(X) = \sum_{k=1}^{K} \Lambda_k(f_k(X)), \quad (15)
\]

where \( \Lambda_k \) are linear functions to \( \mathbb{R} \). If \( p \) is a matrix value polynomial mapping \( \mathbb{R}^{3 \times n} \) to \( W_T^n = \mathbb{R}^{d \times n} \), which is invariant to translations and equivariant to permutations, then it is of the form \( p = (p_i)_{i \in [1], \in [n]} \), and each \( p_i = (p_{ij})_{j \in [n]} \) is itself invariant to translations and permutation equivariant. It follows that matrix valued \( p \) can also be written in the form equation (15) the only difference being that the image of the linear functions \( \Lambda_k \) is now \( \mathbb{R}^d \).

Now let \( p : \mathbb{R}^{d \times n} \to W_T \) be a \( G \)-equivariant polynomial of degree \( \leq D \). It remains to show that we can choose \( \Lambda_k \) to be \( \text{SO}(3) \) equivariant. We do this by a symmetrization argument: denote the Haar probability measure on \( \text{SO}(3) \) by \( \nu \), and the action of \( \text{SO}(3) \) on \( W_{\text{feat}} \) and \( W_T \) by \( \rho_1 \) and \( \rho_2 \) respectively. Denote \( p = (p_i)_{i=1}^{n} \) and \( f_k = (f_k^i)_{i=1}^{n} \). For every \( j = 1, \ldots, n \), we use the \( \text{SO}(3) \) equivariance of \( p_j \) and \( f_k^j \) to obtain

\[
p_j(X) = \int_{\text{SO}(3)} \rho_2(R^{-1}) \circ p_j(RX) d\nu(R) = \sum_{k=1}^{K} \int_{\text{SO}(3)} \rho_2(R^{-1}) \circ \Lambda_k \circ f_k^j(RX) d\nu(R)
\]

\[
= \sum_{k=1}^{K} \int_{\text{SO}(3)} \rho_2(R^{-1}) \circ \Lambda_k \left( \rho_1(R) \circ f_k^j(X) \right) d\nu(R) = \sum_{k=1}^{K} \Lambda_k \circ f_k^j(X),
\]

where \( \tilde{\Lambda}_k \) stands for the equivariant linear functional from \( W_{\text{feat}} \) to \( W_T \), defined for \( w \in W_{\text{feat}} \) by

\[
\tilde{\Lambda}_k(w) = \int_{\text{SO}(3)} \rho_2(R^{-1}) \circ \Lambda_k \left( \rho_1(R)w \right) d\nu(R).
\]

Thus we have shown that \( p \) is in \( \mathcal{F}_C(\mathcal{F}_{\text{feat}}, \mathcal{F}_{\text{pool}}) \) for \( C = K \), as required.

\[\square\]
C PROOBS FOR SECTION 4

We prove Lemma 2.

Lemma 2. For every \( D \in \mathbb{N}_+ \), the set \( Q_D \) is \( D \)-spanning.

Proof. It is known [Segol & Lipman 2019] (Theorem 2) that polynomials \( p : \mathbb{R}^{3 \times n} \rightarrow \mathbb{R}^n \) which are \( S_n \)-equivariant, are spanned by polynomials of the form \( p_{\vec{a}} = (p_{\vec{a}}^j)_{j=1}^n \), defined as

\[
p_{\vec{a}}^j(X) = \sum_{i_2, \ldots, i_K=1}^n x_{i_j}^{\alpha_{i_2}} x_{i_2}^{\alpha_{i_2}} \ldots x_{i_K}^{\alpha_{i_K}}
\]

where \( \vec{a} = (\alpha_1, \ldots, \alpha_K) \) and each \( \alpha_k \in \mathbb{N}_+^3 \) is a multi-index. It follows that \( S_n \)-equivariant polynomials of degree \( \leq D \) are spanned by polynomials of the form \( p_{\vec{a}}^D \) where \( \sum_{k=1}^K |\alpha_k| \leq D \). Denoting \( r_k = |\alpha_k|, k = 1, \ldots, K \), the sum of all \( r_k \) by \( T \), and \( \vec{r} = (r_k)_{k=1}^K \), we see that that exists a linear functional \( \Lambda_{\vec{a}, \vec{f}} : T_T \rightarrow \mathbb{R} \) such that

\[
p_{\vec{a}}^D(X) = \Lambda_{\vec{a}, \vec{f}} \circ Q_{\vec{r}}^D(X)
\]

where we recall that \( Q_{\vec{r}} = \left( Q_{\vec{r}}^j(X) \right)_{j=1}^n \) is defined in equation 5 as

\[
Q_{\vec{r}}^j(X) = \sum_{i_2, \ldots, i_K=1}^n x_i^{r_{i_2}} x_{i_2}^{r_{i_2}} \ldots x_{i_K}^{r_{i_K}}.
\]

Thus polynomials \( p = (p_j)_{j=1}^n \) which are of degree \( \leq D \), and are \( S_n \) equivariant, can be written as

\[
p_j(X) = \sum_{T \leq D} \sum_{\vec{r} \in \Sigma_T} \sum_{|\alpha_k|=r_k} \Lambda_{\vec{a}, \vec{f}} \left( Q_{\vec{r}}^j(X) \right) = \sum_{T \leq D} \sum_{\vec{r} \in \Sigma_T} \Lambda_\vec{f} \left( \iota \circ Q_{\vec{r}}^j(X) \right), j = 1, \ldots, n,
\]

where \( \Lambda_\vec{f} = \sum_{|\alpha_k|=r_k} \Lambda_{\vec{a}, \vec{f}} \circ \iota^{-1}_{\vec{r}} \), and \( \iota^{-1}_{\vec{r}} \) is the left inverse of the embedding \( \iota \). If \( p \) is also translation invariant, then

\[
p(X) = p(X - \frac{1}{n} X 1_n 1_n^T) = \sum_{T \leq D} \sum_{\vec{r} \in \Sigma_T} \Lambda_\vec{f} \left( \iota \circ Q_{\vec{r}}^j(X - \frac{1}{n} X 1_n 1_n^T) \right)
\]

Thus \( Q_D \) is \( D \)-spanning.

We prove Lemma 3.

Lemma 3. The function set \( Q_D \) is contained in

\[
F_{\text{feat}} = \{ \iota \circ \pi_V \circ f_1 \circ f_2 \circ \ldots \circ f_T \circ \text{ext}(X - \frac{1}{n} X 1_n 1_n^T) | f_j \in F_{\text{min}}, T \leq D \}.
\]

Thus \( F_{\text{feat}} \) is \( D \)-spanning.

Proof. In this proof we make the dependence of \( F_{\text{feat}} \) on \( D \) explicit and denote \( F_{\text{feat}}(D) \).

We prove the claim by induction on \( D \). Assume \( D = 0 \). Then \( Q_0 \) contains only the constant function \( X \mapsto 1_n \in T_0 \), and this is precisely the function \( \pi_V \circ \text{ext} \in F_{\text{feat}}(0) \).

Now assume the claim holds for all \( D' \) with \( D - 1 \geq D' \geq 0 \), and prove the claim for \( D \). Choose \( \vec{r} = (r_1, \ldots, r_K) \in \Sigma_T \) for some \( T \leq D \), we need to show that the function \( Q_{\vec{r}}(X) \) is in \( F_{\text{feat}}(D) \). Since \( F_{\text{feat}}(D - 1) \subseteq F_{\text{feat}}(D) \) we know from the induction hypothesis that this is true if \( T < D \). Now assume \( T = D \). We consider two cases:

1. If \( r_1 > 0 \), we set \( \vec{r} = (r_1 - 1, r_2, \ldots, r_K) \). We know that \( \iota \circ Q_{\vec{r}}(X) \in F_{\text{feat}}(D - 1) \) by the induction hypothesis. So there exist \( f_2, \ldots, f_D \) such that

\[
\iota \circ \pi_V \circ f_2 \circ \ldots \circ f_D \circ \text{ext}(X) = \iota \circ Q_{\vec{r}}(X).
\]
Now choose $f_1 \in \mathcal{F}_{\text{min}}$ to be the function whose $V$ coordinate $\tilde{V} = (\tilde{V}_j)_{j=1}^n$, is given by $\tilde{V}_j(X, V) = x_j \otimes V_j$, obtained by setting $\theta_1 = 1, \theta_2 = 0$ in equation $7$. Then, we have

$$\tilde{V}_j(\tilde{X}, Q^{(f)}(\tilde{X})) = \sum_{i_2, \ldots, i_K = 1}^n \tilde{x}_j \otimes \tilde{x}_j^{(r_1-1)} \otimes \tilde{x}_{i_2}^{r_2} \otimes \ldots \otimes \tilde{x}_{i_K}^{r_K} = Q^{(f)}_j(\tilde{X}).$$

and so

$$\iota \circ f_1 \circ f_2 \circ \ldots \circ f_D \circ \text{ext}(X - \frac{1}{n} X 1_n 1_n^T) = \iota \circ Q^{(f)}(\tilde{X}).$$

and $\iota \circ Q^{(f)}(X - \frac{1}{n} X 1_n 1_n^T) \in \mathcal{F}_{\text{feat}}(D)$.}

2. If $r_1 = 0$. We assume without loss of generality that $r_2 > 0$. Set $\tilde{r} = (r_2 - 1, r_3, \ldots, r_K)$. As before by the induction hypothesis there exist $f_2, \ldots, f_D$ which satisfy equation $17$. This time we choose $f_1 \in \mathcal{F}_{\text{min}}$ to be the function whose $V$ coordinate $\tilde{V} = (\tilde{V}_j)_{j=1}^n$, is given by $\tilde{V}_j(X, V) = \sum_j x_j \otimes V_j$, obtained by setting $\theta_1 = 0, \theta_2 = 1$ in equation $7$. Then we have

$$\tilde{V}_j(\tilde{X}, Q^{(f)}(\tilde{X})) = \sum_{j=1}^n \sum_{i_2, i_3, \ldots, i_K = 1}^n \tilde{x}_j \otimes \tilde{x}_j^{(r_2-1)} \otimes \tilde{x}_{i_2}^{r_2} \otimes \ldots \otimes \tilde{x}_{i_K}^{r_K}
= \sum_{i_2, i_3, \ldots, i_K = 1}^n \tilde{x}_{i_2}^{r_2} \otimes \tilde{x}_{i_3}^{r_3} \otimes \ldots \otimes \tilde{x}_{i_K}^{r_K}
= Q^{(f)}_j(\tilde{X}).$$

Thus equation $18$ holds, and so again we have that $\iota \circ Q^{(f)}(X - \frac{1}{n} X 1_n 1_n^T) \in \mathcal{F}_{\text{feat}}(D)$.

Finally we prove Lemma $4$.

**Lemma 4.** If all functions in $\mathcal{Q}_D$ can be written as

$$\iota \circ Q^{(f)}(X - \frac{1}{n} X 1_n 1_n^T) = \sum_{k=1}^K \hat{A}_k f_k(X),$$

where $f_k \in \mathcal{F}_{\text{feat}}, A_k : W_{\text{feat}} \rightarrow W_{\text{feat}}^T$ and $\hat{A}_k : W_{\text{feat}}^n \rightarrow (W_{\text{feat}}^T)^n$ is defined by elementwise application of $A_k$, then $\mathcal{F}_{\text{feat}}$ is D-spanning.

**Proof.** If the conditions in Lemma $4$ hold, then since $\mathcal{Q}_D$ is $D$-spanning, every translation invariant and permutation equivariant polynomials $p$ of degree $D$ can be written as

$$p(X) = \sum_{\tilde{r} \| \tilde{r} \|_1 \leq D} \hat{A}_{\tilde{r}} \left( \iota \circ Q^{(f)}(X - \frac{1}{n} X 1_n 1_n^T) \right) = \sum_{\tilde{r} \| \tilde{r} \|_1 \leq D} \hat{A}_{\tilde{r}} \left( \sum_{k=1}^{K_{\tilde{r}}} \iota \circ \hat{A}_{k, \tilde{r}} f_k, \tilde{r}(X) \right)
= \sum_{\| \tilde{r} \|_1 \leq D} \sum_{k=1}^{K_{\tilde{r}}} \hat{A}_{k, \tilde{r}} (f_k, \tilde{r}(X))$$

where we denote $\Lambda_{k, \tilde{r}} = \Lambda_{\tilde{r}} \circ \iota \circ A_{k, \tilde{r}}$. Thus we proved $\mathcal{F}_{\text{feat}}$ is $D$-spanning. 

**D  PROOFS FOR SECTION 5**

We prove Lemma $5$. 

---

14
Lemma 5. Let $I^{(1)} = (\ell_1^{(1)}, \ldots, \ell_{K_1}^{(1)})$ and $I^{(2)} = (\ell_1^{(2)}, \ldots, \ell_{K_2}^{(2)})$. A function $\Lambda = (\Lambda_1, \ldots, \Lambda_{K_2})$ is a linear equivariant mapping between $W_{\ell_1^{(1)}}$ and $W_{\ell_2^{(2)}}$, if and only if there exists a $K_1 \times K_2$ matrix $M$ with $M_{ij} = 0$ whenever $\ell_i^{(1)} \neq \ell_j^{(2)}$, such that

$$\Lambda_j(V) = \sum_{i=1}^{K_1} M_{ij} V_i \quad (10)$$

where $V = (V_i)_{i=1}^{K_1}$ and $V_i \in W_{\ell_i^{(1)}}$ for all $i = 1, \ldots, K_1$.

Proof. As mentioned in the main text, this lemma is based on Schur’s lemma. This lemma is typically stated for complex representations, but holds for odd dimensional real representation as well. We recount the lemma and its proof here for completeness (see also [Fulton & Harris 2013]).

Lemma D.1 (Schur’s Lemma for $SO(3)$). Let $\Lambda : W_\ell \rightarrow W_{\ell'}$ be a linear equivariant map. If $\ell \neq \ell'$ then $\Lambda = 0$. Otherwise $\Lambda$ is a scalar multiply of the identity.

Proof. Let $\Lambda : W_\ell \rightarrow W_{\ell'}$ be a linear equivariant map. The image and kernel of $\Lambda$ are invariant subspaces of $W_\ell$ and $W_{\ell'}$, respectively. It follows that if $\Lambda \neq 0$ then $\Lambda$ is a linear isomorphism so necessarily $\ell_1 = \ell_2$. Now assume $\ell_1 = \ell_2$. Since the dimension of $W_\ell$ is odd, $\Lambda$ has a real eigenvalue $\lambda$. The linear function $\Lambda - \lambda I$ is equivariant and has a non-trivial kernel, so $\Lambda - \lambda I = 0$.

We now return to the proof of Lemma 5. Note that each $\Lambda_j : W_{\ell_1^{(1)}} \rightarrow W_{\ell_2^{(2)}}$ is linear and $SO(3)$ equivariant. Next denote the restrictions of each $\Lambda_j$ to $W_{\ell_1^{(1)}}, i = 1, \ldots, K_2$ by $\Lambda_{ij}$, and note that

$$\Lambda_j(V_1, \ldots, V_{K_1}) = \sum_{i=1}^{K_1} \Lambda_{ij}(V_i) \quad (19)$$

By considering vectors in $W_{\ell_1^{(1)}}$ of the form $(0, \ldots, 0, V_i, 0, \ldots, 0)$ we see that each $\Lambda_{ij} : W_{\ell_1^{(1)}} \rightarrow W_{\ell_2^{(2)}}$ is linear and $SO(3)$-equivariant. Thus by Schur’s lemma, if $\ell_i^{(1)} = \ell_j^{(2)}$ then $\Lambda_{ij}(V_i) = M_{ij} V_i$ for some real $M_{ij}$, and otherwise $M_{ij} = 0$. Plugging this into equation 19 we obtain equation 10.

We prove Theorem 2 which shows that the TFN network described in the main text is universal:

Theorem 2. For all $n \in \mathbb{N}, L_T \in \mathbb{N}^+_*$,

1. For $D \in \mathbb{N}_+$, every $G$-equivariant polynomial $p : \mathbb{R}^{3 \times n} \rightarrow W_T^n$ of degree $D$ is in $\mathcal{F}_{C(D),D}^{\text{TFN}}$.

2. Every continuous $G$-equivariant function can be approximated uniformly on compact sets by functions in $\bigcup_{D \in \mathbb{N}_+} \mathcal{F}_{C(D),D}^{\text{TFN}}$.

Proof. As mentioned in the main text, we only need to show that the function space $\mathcal{F}_{\text{feat}}(D)$ is $D$-spanning. Recall that $\mathcal{F}_{\text{feat}}(D)$ is obtained by $2D$ consecutive convolutions with $D$-filters. In general, we denote the space of functions defined by applying $J$ consecutive convolutions by $\mathcal{G}_{J,D}$.

If $\mathcal{Y}$ is a space of functions from $\mathbb{R}^{3 \times n} \rightarrow Y^n$, we denote by $\langle \mathcal{Y}, \mathcal{T}_T \rangle$ the space of all functions $p : \mathbb{R}^{3 \times n} \rightarrow \mathcal{T}_T^n$ of the form

$$p(X) = \sum_{k=1}^{K} \hat{A}_k f_k(X) \quad (20)$$

where $A_k : Y \rightarrow \mathcal{T}_T$ are linear functions, $\hat{A}_k : Y^n \rightarrow \mathcal{T}_T^n$ are induced by elementwise application, and $f_k \in \mathcal{Y}$. This notation is useful because: (i) by Lemma 4 it is sufficient to show that $Q^{(\ell)}(\bar{X})$ is in $\langle \mathcal{G}_{2D,D}, \mathcal{T}_T \rangle$ for all $\ell \in \Sigma_{\mathcal{T}}$ and all $T \leq D$, and because (ii) it enables comparison of the expressive power of function spaces $\mathcal{Y}_1, \mathcal{Y}_2$ whose elements map to different spaces $Y_1^n, Y_2^n$, since
the elements in \( \langle Y_i, T_R \rangle, i = 1, 2 \) both map to the same space. In particular, note that if for every \( f \in Y_2 \) there is a \( g \in Y_1 \) and a linear map \( A : Y_1 \to Y_2 \) such that \( f(X) = A \circ g(X) \), then \( \langle Y_2, T_R \rangle \subseteq \langle Y_1, T_R \rangle \).

We now use this abstract discussion to prove some useful results: the first is that for the purpose of this lemma, we can ‘forget about’ the multiplication by a unitary matrix in equation 12 used for decomposition into irreducible representations: To see this, denote by \( \hat{G}_{J,D} \) the function space obtained by taking \( J \) consecutive convolutions with \( D \)-filters without multiplying by a unitary matrix in equation 12. Since Kronecker products of unitary matrices are unitary matrices, we obtain that the elements in \( \hat{G}_{J,D} \) and \( \hat{G}_{J,D} \) differ only by multiplication by a unitary matrix, and thus \( \langle \hat{G}_{J,D}, T_R \rangle \subseteq \langle G_{J,D}, T_R \rangle \) and \( \langle G_{J,D}, T_R \rangle \), so both sets are equal.

Next, we prove that adding convolutional layers (enlarging \( J \)) or taking higher order filters (enlarging \( D \)) can only increase the expressive power of a network.

**Lemma D.2.** For all \( J, D, T \in \mathbb{N}_+ \),

1. \( \langle G_{J,D}, T_R \rangle \subseteq \langle G_{J+1,D}, T_R \rangle \).
2. \( \langle G_{J,D}, T_R \rangle \subseteq \langle G_{J+1,D+1}, T_R \rangle \).

**Proof.** The first claim follows from the fact that every function \( f \) in \( \langle G_{J,D}, T_R \rangle \) can be identified with a function in \( \langle G_{J+1,D}, T_R \rangle \) by taking the \( J+1 \) convolutional layer in equation 12 with \( \theta_0 = 1, F = 0 \).

The second claim follows from the fact that \( D \)-filters can be identified with \( D+1 \)-filters whose \( D+1 \)-th entry is 0. \( \square \)

The last preliminary lemma we will need is

**Lemma D.3.** For every \( J, D \in \mathbb{N}_+ \), and every \( t, s \in \mathbb{N}_+ \), if \( p \in \langle G_{J,D}, T_t \rangle \), then the function \( q \) defined by

\[
q_a(X) = \sum_{b=1}^{n} (\bar{x}_a - \bar{x}_b)^{\otimes s} \otimes p_b(X)
\]

is in \( \langle G_{J+1,D}, T_{t+s} \rangle \).

**Proof.** This lemma is based on the fact that the space of \( s \) homogeneous polynomial on \( \mathbb{R}^3 \) is spanned by polynomials of the form \( \|x\|^{s-\ell} Y_m(\ell) \) for \( \ell = s, s-2, s-4 \ldots \) [Dai & Xu, 2013]. For each such \( \ell \), and \( \ell \leq D \), these polynomials can be realized by filters \( F^{(s)} \) by setting \( y^{(s)}(\|x\|) = \|x\|^s \). For every \( D \in \mathbb{N} \) and \( s \leq D \), we can construct a \( D \)-filter \( F^{(s,D)} = (F^{(0)}, \ldots, F^{(s)}) \) where \( F^{(s)}, F^{(s-2)}, \ldots \) are as defined above and the other filters are zero. Since both the entries of \( F^{(s,D)}(x) \), and the entries of \( x^{\otimes s} \), span the space of \( s \)-homogeneous polynomials on \( \mathbb{R}^3 \), it follows that there exists a linear mapping \( B_s: W_{s,t} \to T_s \) so that

\[
x^{\otimes s} = B_s(F^{(s,D)}(x)), \forall x \in \mathbb{R}^3.
\]

Thus, since \( p \) can be written as a sum of compositions of linear mappings with functions in \( \hat{G}_{J,D} \) as in equation 20 and similarly \( x^{\otimes s} \) is obtained as a linear image of functions in \( \hat{G}_{1,D} \) as in equation 21, we deduce that

\[
\sum_{b=1}^{n} (\bar{x}_a - \bar{x}_b) \otimes p_b(X) = \sum_{b=1}^{n} (\bar{x}_a - \bar{x}_b) \otimes p_b(X)
\]

is in \( \langle G_{J+1,D}, T_{t+s} \rangle \). \( \square \)
As a final preliminary, we note that $D$-filters can perform an averaging operation by setting $R^{(0)} = 1$ and $\theta_0, R^{(1)}, \ldots, R^{(D)} = 0$ in equations \[11\] and equation \[12\]. We call this $D$-filter an averaging filter.

We are now ready to prove our claim: we need to show that for every $D, T \in \mathbb{N}_+$ where $T \leq D$, for every $\vec{r} \in \Sigma_T$, the function $Q^{(r)}$ is in $\langle \mathcal{G}_{2D,D}, T_T \rangle$. Note that due to the inclusion relations in Lemma \[D.2\] it is sufficient to prove this for the case $T = D$. We prove this by induction on $D$. For $D = 0$, vectors $\vec{r} \in \Sigma_0$ contains only zeros and so

$$Q^{(r)}(X) = 1_n = \pi_V \circ \text{ext}(X) \in \langle \mathcal{G}_{0,0}, T_0 \rangle.$$ 

We now assume the claim is true for all $D'$ with $D > D' \geq 0$ and prove the claim is true for $D$. We need to show that for every $\vec{r} \in \Sigma_D$ the function $Q^{(r)}$ is in $\langle \mathcal{G}_{2D,D}, T_D \rangle$. We prove this yet again by induction, this time on the value of $r_1$: assume that $\vec{r} \in \Sigma_D$ and $r_1 = 0$. Denote by $\vec{r}$ the vector in $\Sigma_{D-1}$ defined by

$$\vec{r} = (r_2 - 1, r_3, \ldots, r_K).$$

By the induction assumption on $D$, we know that $Q^{(r)}(X) \in \mathcal{G}_{2(D-1),D-1,D-1}$ and so

$$q_a(X) = \sum_{b=1}^{n} (\bar{x}_a - \bar{x}_b) \otimes Q^{(r)}_b(X) = \sum_{b=1}^{n} (\bar{x}_a - \bar{x}_b) \otimes \bar{x}_b^{\otimes r_2 - 1} \otimes \sum_{i_3, \ldots, i_K = 1}^{n} \bar{x}_{i_3}^{\otimes r_3} \otimes \ldots \otimes \bar{x}_{i_K}^{\otimes r_K}$$

is in $\langle \mathcal{G}_{2D-1,D-1,T_D} \rangle$ by Lemma \[D.3\] which is contained in $\langle \mathcal{G}_{2D-1,D,T_D} \rangle$ by Lemma \[D.2\]. Since $\bar{x}_a$ has zero mean, while $Q^{(r)}_a(X)$ does not depend on $a$ since $r_1 = 0$, applying an averaging filter to $q_a$ gives us a constant value $\bar{Q}^{(r)}_a(X)$ in each coordinate $a \in [n]$, and so $Q^{(r)}(X)$ is in $\langle \mathcal{G}_{2D,D}, T_D \rangle$.

Now assume the claim is true for all $\vec{r} \in \Sigma_D$ which sum to $D$, and whose first coordinate is smaller than some $r'_1 \geq 1$, we now prove the claim is true when the first coordinate of $\vec{r}$ is equal to $r'_1$. The vector $\vec{r} = (r_2, \ldots, r_K)$ obtained from $\vec{r}$ by removing the first coordinate, sums to $D' = D - r'_1 \leq D$, and so by the induction hypothesis on $D$ we know that $Q^{(r)} \in \langle \mathcal{G}_{2D',D'}, T_{D'} \rangle$. By Lemma \[D.3\] we obtain a function $q_a \in \langle \mathcal{G}_{2D'+1,D', T_{D'}} \rangle \subseteq \langle \mathcal{G}_{2D,D}, T_D \rangle$ defined by

$$q_a(X) = \sum_{b=1}^{n} (\bar{x}_a - \bar{x}_b)^{\otimes r_1} \otimes Q^{(r)}_b(X)$$

$$= \sum_{b=1}^{n} (\bar{x}_a - \bar{x}_b)^{\otimes r_1} \otimes \bar{x}_b^\otimes r_2 \otimes \sum_{i_3, \ldots, i_K = 1}^{n} \bar{x}_{i_3}^\otimes r_3 \otimes \ldots \otimes \bar{x}_{i_K}^\otimes r_K$$

$$= Q^{(r)}_a(X) + \text{additional terms}$$

where the additional terms are linear combinations of functions of the form $P_D Q^{(r')}_a(\bar{X})$ where $r' \in \Sigma_D$ and their first coordinate $r_1$ is smaller than $r'_1$, and $P_D : T_D \rightarrow T_D$ is a permutation. By the induction hypothesis on $r_1$, each such $Q^{(r')}$ is in $\langle \mathcal{G}_{2D,D}, T_D \rangle$. It follows that $P_D Q^{(r')}_a(\bar{X}), a = 1, \ldots, n$, and thus $Q^{(r)}(X)$, are in $\langle \mathcal{G}_{2D,D}, T_D \rangle$ as well. This concludes the proof of Theorem \[2\].

\[\square\]

### E Alternative TFN Architecture

In this appendix we show that replacing the standard TFN convolutional layer with the layer defined in equation \[13\]

$$\tilde{V}_a(X, V) = U(I_f, I_t) \left( \theta_1 \sum_{b=1}^{n} F(x_a - x_b) \otimes V_b + \theta_2 \sum_{b=1}^{n} F(x_a - x_b) \otimes V_a \right),$$

we can obtain $D$-spanning networks using $2D$ consecutive convolutions with 1-filters (that is, filters in $W_{1,1}$, where $I_1 = [0, 1]^F$). Our discussion here is somewhat informal, meant to provide the general
We will only need two fixed filters for our argument here: The first is the completely rigorous proof of Theorem 2. In the end of our discussion we will explain what is necessary to make this argument completely rigorous.

We prove our claim by showing that a pair of convolutions with 1-filters can construct any convolutional layer defined in equation 7 for the $D$-spanning architecture using tensor representations. The claim then follows from the fact that $D$ convolutions of the latter architecture suffice for achieving $D$-spanning, as shown in Lemma 3.

Convolutions for tensor representations, defined in equation 7, are composed of two terms:

$$\tilde{V}_a^{\text{tensor},1}(X,V) = \bar{x}_a \otimes V_a \text{ and } \tilde{V}_a^{\text{tensor},2}(X,V) = \sum_{b=1}^{n} \bar{x}_b \otimes V_b.$$ 

To obtain the first term $\tilde{V}_a^{\text{tensor},1}$, we set $\theta_1 = 0, \theta_2 = 1/n, F = F_{Id}$ in equation 12, we obtain (the decomposition into irreducibles of) $\tilde{V}_a^{\text{tensor},1}(X,V) = \bar{x}_a \otimes V_a.$ Thus this term can in fact be expressed by a single convolution. We can leave this outcome unchanged by a second convolution, defined by setting $\theta_1 = 0, \theta_2 = 1/n, F = F_1$.

To obtain the second term $\tilde{V}_a^{\text{tensor},2}$, we apply a first convolution with $\theta_1 = -1, F = F_{Id}, \theta_2 = 0$, to obtain

$$\sum_{b=1}^{n} (x_b - x_a) \otimes V_b = \sum_{b=1}^{n} (\bar{x}_b - \bar{x}_a) \otimes V_b = \tilde{V}_a^{\text{tensor},2}(V,X) - \bar{x}_a \otimes \sum_{b=1}^{n} V_b.$$ 

By applying an additional averaging filter, defined by setting $\theta_1 = \frac{1}{n}, F = F_1, \theta_2 = 0$, we obtain $\tilde{V}_a^{\text{tensor},2}(V,X)$. This concludes our ‘informal proof’.

Our discussion here has been somewhat inaccurate, since in practice $F_{Id}(x) = (0, x) \in W_0 \oplus W_1$ and $F_1(x) = (1, 0) \in W_0 \oplus W_1$. Moreover, in our proof we have glossed over the multiplication by the unitary matrix used to obtain decomposition into irreducible representations. However the ideas discussed here can be used to show that $2D$ convolutions with 1-filters can satisfy the sufficient condition for $D$-spanning defined in Lemma 3. See our treatment of Theorem 2 for more details.

F COMPARISON WITH ORIGINAL TFN PAPER

In this Appendix we discuss three superficial differences between the presentation of the TFN architecture in [Thomas et al., 2018] and our presentation here:

1. We define convolutional layers between features residing in direct sums of irreducible representations, while [Thomas et al., 2018] focuses on features which inhabit a single irreducible representation. This difference is non-essential, as direct sums of irreducible representations can be represented as multiple channels where each feature inhabits a single irreducible representation.

2. The term $\theta_0 V_{a1}$ in equation 12 is separable in [Fuchs et al., 2020], but does not appear explicitly in [Thomas et al., 2018]. However it can be obtained by concatenation of the input of a self-interaction layer to the output, and then applying a self-interaction layer.

3. We take the scalar functions $R^{(l)}$ to be polynomials, while [Thomas et al., 2018] take them to be fully connected networks composed with radial basis functions. Using polynomial scalar bases is convenient for our presentation here since it enables exact expression of
equivariant polynomials. Replacing polynomial bases with fully connected networks, we obtain approximation of equivariant polynomials instead of exact expression. It can be shown that if \( p \) is a \( G \)-equivariant polynomial which can be expressed by some network \( F_{C,D} \) defined with filters coming from a polynomial basis, then \( p \) can be approximated on a compact set \( K \), up to an arbitrary \( \epsilon \) error, by a similar network with scalar functions coming from a sufficiently large fully connected network.

\section*{G Tensor Universality}

In this section we show how to construct the complete set \( \mathcal{F}_{\text{pool}} \) of linear SO(3) invariant functionals from \( W^{T}_{\text{feat}} = \bigoplus_{T=0}^{D} T_{T} \) to \( \mathbb{R} \). Since each such functional \( \Lambda \) is of the form

\[ \Lambda(w_0, \ldots, w_D) = \sum_{T=0}^{D} \Lambda_T(w_T), \]

where each \( \Lambda_T \) is SO(3)-invariant, it is sufficient to characterize all linear SO(3)-invariant functionals \( \Lambda : T_{D} \to \mathbb{R} \).

It will be convenient to denote

\[ W = \mathbb{R}^3 \text{ and } W^{\otimes D} \cong \mathbb{R}^{3^D} = T_{D}. \]

We achieve our characterization using the bijective correspondence between linear functional \( \Lambda : W^{\otimes D} \to \mathbb{R} \) and multi-linear functions \( \hat{\Lambda} : W^D \to \mathbb{R} \): each such \( \Lambda \) corresponds to a unique \( \hat{\Lambda} \), such that

\[ \hat{\Lambda}(e_{i_1}, \ldots, e_{i_D}) = \Lambda(e_{i_1} \otimes \ldots \otimes e_{i_D}), \quad \forall (i_1, \ldots, i_D) \in [3]^D, \]

(22)

where \( e_1, e_2, e_3 \) denote the standard basis elements of \( \mathbb{R}^3 \). We define a spanning set of equivariant linear functionals on \( W^{\otimes D} \) via a corresponding characterization for multi-linear functionals on \( W^D \).

Specifically, set

\[ K_D = \{ k \in \mathbb{N}_+ | D - 3k \text{ is even and non-negative.} \} \]

For \( k \in K_D \) we define a multi-linear functional:

\[ \hat{\Lambda}_k(w_1, \ldots, w_D) = \det(w_1, w_2, w_3) \times \ldots \times \det(w_{3k-2}, w_{3k-1}, w_{3k}) \times \langle w_{3k+1}, w_{3k+2} \rangle \times \ldots \]

\[ \times \langle w_{D-1}, w_D \rangle, \]

(23)

and for \((k, \sigma) \in K_D \times S_D\) we define

\[ \hat{\Lambda}_{k,\sigma}(w_1, \ldots, w_D) = \hat{\Lambda}_k(w_{\sigma(1)}, \ldots, w_{\sigma(D)}) \]

(24)

\begin{proposition}

The space of linear invariant functions from \( T_D \) to \( \mathbb{R} \) is spanned by the set of linear invariant functionals \( \lambda_D = \{ \lambda_{k,\sigma} | (k, \sigma) \in K_D \times S_D \} \) induced by the multi-linear functional \( \hat{\Lambda}_{k,\sigma} \) described in equation 23 and equation 24.

\end{proposition}

We note that (i) equation 22 provides a (cumbersome) way to compute all linear invariant functionals \( \lambda_{k,\sigma} \) explicitly by evaluating the corresponding \( \hat{\lambda}_{k,\sigma} \) on the \( 3^D \) elements of the standard basis and (ii) the set \( \lambda_D \) is spanning, but is not linearly independent. For example, since \( \langle w_1, w_2 \rangle = \langle w_2, w_1 \rangle \), the space of SO(3) invariant functionals on \( T_2 = W^{\otimes 2} \) is one dimensional while \( |\lambda_2| = 2 \).

\begin{proof}[Proof of Proposition]

We first show that the bijective correspondence between linear functional \( \Lambda : W^{\otimes D} \to \mathbb{R} \) and multi-linear functions \( \hat{\Lambda} : W^D \to \mathbb{R} \), extends to a bijective correspondence between SO(3)-invariant linear/multi-linear functionals. The action of SO(3) on \( W^D \) is defined by

\[ \tilde{\rho}(R)(w_1, \ldots, w_D) = (Rw_1, \ldots, Rw_D). \]

The action \( \rho(R) = R^{\otimes D} \) of SO(3) on \( W^{\otimes D} \) is such that the map

\[ (w_1, \ldots, w_D) \mapsto w_1 \otimes w_2 \ldots w_D \]

is SO(3)-equivariant. It follows that if \( \hat{\Lambda} \) and \( \Lambda \) satisfy equation 22, then for all \( R \in \text{SO}(3) \), the same equation holds for the pair \( \hat{\Lambda} \circ \tilde{\rho}(R) \) and \( \Lambda \circ \rho(R) \). Thus SO(3)-invariance of \( \hat{\Lambda} \) is equivalent to SO(3)-invariance of \( \Lambda \).

\end{proof}
Multi-linear functionals on $W^D$ invariant to $\tilde{\rho}$ are a subset of the set of polynomials on $W^D$ invariant to $\tilde{\rho}$. It is known (see Kraft & Procesi, 2000, page 114), that all such polynomials are algebraically generated by functions of the form

$$\det(w_{i_1}, w_{i_2}, w_{i_3}) \text{ and } \langle w_{j_1}, w_{j_2} \rangle,$$

where $i_1, i_2, i_3, j_1, j_2 \in [D]$.

Equivalently, $\text{SO}(3)$-invariant polynomials are spanned by linear combinations of polynomials of the form

$$\det(w_{i_1}, w_{i_2}, w_{i_3}) \det(w_{i_4}, w_{i_5}, w_{i_6}) \ldots \langle w_{j_1}, w_{j_2} \rangle \langle w_{j_3}, w_{j_4} \rangle \ldots$$

(25)

When considering the subset of multi-linear invariant polynomials, we see that they must be spanned by polynomials as in equation (25) where each $w_1, \ldots, w_D$ appears exactly once in each polynomial in the spanning set. These precisely correspond to the functions in $\lambda_D$.  

\[\square\]
