Abstract
PyOD is an open-source Python toolbox for performing scalable outlier detection on multivariate data. Uniquely, it provides access to a wide range of outlier detection algorithms, including established outlier ensembles and more recent neural network-based approaches, under a single, well-documented API designed for use by both practitioners and researchers. With robustness and scalability in mind, best practices such as unit testing, continuous integration, code coverage, maintainability checks, interactive examples and parallelization are emphasized as core components in the toolbox’s development. PyOD is compatible with both Python 2 and 3 and can be installed through Python Package Index (PyPI) or https://github.com/yzhao062/pyod.

Keywords: Outlier Detection, Anomaly Detection, Outlier Ensembles, Unsupervised Learning, Neural Networks, Python

1. Introduction
Outlier detection, also known as anomaly detection, refers to the identification of rare items, events or observations which differ from the general distribution of a population. Since the ground truth is often absent in such tasks, dedicated outlier detection algorithms are extremely valuable in fields which process large amounts of unlabelled data and require a means to reliably perform pattern recognition. Industry applications include fraud detection in finance (Ahmed et al., 2016), fault diagnosis in mechanics (Shin et al., 2005), intrusion detection in network security (Garcia-Teodoro et al., 2009) and pathology detection in medical imaging (Baur et al., 2018).

To help approach these problems, established outlier detection packages exist in various programming languages such as ELKI Data Mining (Achtert et al., 2010) and RapidMiner (Hofmann and Klinkenberg, 2013) in Java and outliers package (Komsta and Komsta, 2011) in R. However, Python, one of the most important languages in machine learning, still lacks a dedicated toolkit for outlier detection. Existing implementations either stand as single algorithm tools like PyNomaly (Constantinou, 2018) or exist as part of a general-purpose framework like scikit-learn (Pedregosa et al., 2011) which does not cater specifically to anomaly detection. To fill this gap, we propose and implement PyOD—a comprehensive Python toolbox for scalable outlier detection.

Compared to existing libraries, PyOD has six distinct advantages. Firstly, it contains more than 20 algorithms which cover both classical techniques such as local outlier factor and recent neural network architectures such as autoencoders or adversarial models. Secondly, PyOD implements combination methods for merging the results of multiple detectors and outlier ensembles which are an emerging set of models. Thirdly, PyOD includes a unified API, detailed documentation and interactive examples across all algorithms for clarity and ease of use. Fourthly, all models are covered by unit testing with cross platform continuous integration, code coverage and code maintainability checks. Fifthly, optimization instruments are employed when possible: just-in-time (JIT) compilation and parallelization are enabled in select models for scalable outlier detection. Lastly, PyOD is compatible with both Python 2 and 3 across major operating systems (Windows, Linux and MacOS). Popular detection algorithms implemented in PyOD (version 0.6.7) are summarized in Table 1.

2. Project Focus

**Build robustness.** Continuous integration tools (*Travis CI, AppVeyor* and *CircleCI*) are leveraged to conduct automated testing under various versions of Python and operating systems. Tests are executed daily, when commits are made to the development and master branches, or when a pull requested is opened.
Quality assurance. The project follows the PEP8 standard; maintainability is ensured by CodeClimate, an automated code review and quality assurance tool. Additionally, code blocks with high cognitive complexity are actively refactored and a standard set of unit tests exist to ensure 95% overall code coverage. These design choices enhance collaboration and this standard is enforced on all pull requests for consistency.

Community-based development. PyOD’s code repository is hosted on GitHub to facilitate collaboration. At the time of this writing, 6 contributors have helped developed the code base and others have contributed in the form of bug reports and feature requests.

Documentation and examples. Comprehensive documentation is developed using Sphinx and NumPyDoc and rendered using Read the Docs. It includes detailed API references, an installation guide, code examples and algorithm benchmarks. An interactive Jupyter notebook is also hosted on Binder allowing others to experiment prior to installation.

Project relevance. PyOD has been used in various academic and commercial projects (Zhao and Hryniewicki, 2018a,b; Zhao et al., 2019). The GitHub repository receives more than 10,000 monthly views and its PyPI downloads exceed 6,000 per month.

3. Library Design and Implementation

PyOD is compatible with both Python 2 and 3 using six; it relies on numpy, scipy and scikit-learn as well. Neural networks such as autoencoders and SO_GAAL additionally require Keras. To enhance model scalability, select algorithms (Table 1) are optimized with JIT using numba. Parallelization for multi-core execution is also available for a set of algorithms using joblib. Inspired by scikit-learn’s API design, all implemented outlier detection algorithms inherit from a base class with the same interface: (i) fit processes the train data and computes the necessary statistics; (ii) decision_function generates raw outlier scores for unseen data after the model is fitted; (iii) predict returns a binary class label corresponding to each input sample instead of the raw outlier score; (iv) predict_proba offers the result as a probability using either normalization or Unification Kriegel et al., 2011 and (v) fit_predict is equivalent to calling predict after fit. Within this framework, new models are easy to implement by taking advantage of inheritance and polymorphism; base methods can then be overridden as necessary.

Once a detector has been fit on a training set, the corresponding train outlier scores and binary labels are accessible using its decision_scores_ and labels_ attributes. Once fitted, the model’s predict, decision_function and predict_proba methods may be called for use on new data. An example showcasing the ease of use of this API is shown in Code Snippet. 1 with an angle-based outlier detector (ABOD).

In addition to the outlier detection algorithms, a set of helper and utility functions (generate_data, evaluate_print and visualize) are included in the library for quick model exploration and evaluation. The two-dimensional artificial data used in the example is created by generate_data which generates inliers from a Gaussian distribution and outliers from a uniform distribution. An example of using visualize is shown in Fig. 1. Other notable utility functions include: precision at rank n and score order inversion.

4. Conclusion and Future Plans

This paper presents PyOD, a comprehensive toolbox built in Python for scalable outlier detection. It includes more than 20 classical and emerging detection algorithms and is being used in both academic and commercial projects. As avenues for future work, we plan to enhance the toolbox by implementing models that work well with time series and geospatial data, improving computational efficiency through distributed computing and addressing engineering challenges such as handling sparse matrices or memory limitations.
