Abstract:
Background: Despite proven efficacy of intravenous tissue plasminogen activator (tPA) and endovascular thrombectomy (EVT) in acute ischemic stroke, there has been slow administration of these therapies in the real world practice. We examined the ongoing quality improvement in acute stroke care at our comprehensive stroke center.

Methods: Consecutive patients with acute ischemic stroke from 2013 to 2018 were studied. Patients were managed using Code Stroke algorithm per concurrent AHA guidelines and a simple quality improvement protocol implemented in 2015. Demographics and clinical data were collected from Get-With-The-Guideline-Stroke registry and electronic medical records. Patients were divided into 3 groups per admission date of quality improvement initiatives. Quality measures, including rates of intravenous tPA and EVT, door-to-needle (DTN) time, and door-to-puncture (DTP) time, were analyzed with general mean linear regression models and Jonckheere-Terpstra test.

Results: Of the 1,369 eligible patients presenting within 24 hours of symptom onset or wakeup stroke, the rate of intravenous tPA was 20%, 30% and 22%, respectively, in 2013-2014, 2015-2016, and 2017-2018. In contrast, EVT rate was 9%, 14% and 15%, respectively. Based on Jonckheere-Terpstra test, there was significant ongoing improvement in the median DTN time (57, 45, 39 minutes; p < 0.001) and DTP time (172, 130, 114 minutes; p =0.009) during the 3 time periods, with DTN time ≤ 60 and ≤45 minutes in 80% and 63% patients, respectively, in 2017-2018.

Conclusions: Getting with the guidelines and simple quality improvement initiatives are associated with satisfactory rates of acute stroke therapy and ongoing improvement in door to treatment times.

Running Title: Recurrent Hemorrhagic Transformations

Introduction

Stroke is the 5th cause of death and a leading cause of long-term disability in the United States [1,2]. Intravenous thrombolysis with tissue plasminogen activator (tPA) is the only proven medical therapy for acute ischemic stroke (AIS) within 4.5 hours of symptoms onset [3, 4]. The benefit of tPA is time-dependent, with better outcome from earlier treatment [5, 6]. In patients with AIS from large vessel occlusion (LVO), endovascular thrombectomy (EVT) within 6 to 24 hours of last-known-well (LKW) has become the standard of care since 2015 [2,7-13]. EVT is also time sensitive. Every 1-hour delay from LKW to arterial puncture was associated with more severe disability [14].

The American Heart Association (AHA)’s Get With the Guidelines (GWTG)-Stroke programme was established in 2003 to collect data on patient characteristics, hospital adherence to guidelines and inpatient outcomes [15]. For time-sensitive quality measures in stroke care, American Heart Association /American Stroke Association (AHA/ASA) launched the Target: Stroke initiative in January 2010 [16]. Two years later, the Joint Commission started comprehensive stroke center (CSC) certification [17]. Despite these initiatives, only 50% of AIS patients registered in GWTG-Stroke from October 2012 to April 2015 received intravenous tPA within 60 minutes of emergency room arrival [18].
In a study of patients treated at 134 CSCs and 1047 primary stroke centers (PSCs) in the United States from 2013 to 2015, the median door-to-needle (DNT) times were 52 and 61 minutes, respectively [19]. The rate of intravenous tPA was 14.3% at CSCs and 10.3% at PSCs, while the EVT rate was only 4.1% at CSCs and 1.0% at PSCs, respectively [19]. In a most recent study, Menon et al. analyzed data from 195 CSCs and identified 2929 patients treated with EVT from October 2014 to September 2016. The median annual EVT volume per center was 16 and the median door to first pass time was 130 minutes [20].

Benchmarking is critical for quality improvement in stroke care. Our stroke center received CSC certification in 2013 and implemented a simple quality improvement protocol in January 2015 [21]. The aim of this study was to investigate the evolution of stroke care and ongoing improvement in quality indicators since CSC certification.

**Materials and Methods**

Consecutive patients with AIS admitted at a 417-bed comprehensive stroke center in California, USA, from January 1, 2013 to December 31, 2018 were included in the study. The patient list was generated from the prospectively maintained AHA/ASA GWTG-Stroke Registry at our hospital. The registry uses a web-based patient management tool to collect clinical data on consecutively admitted patients, to provide decision support, and to enable real-time online reporting [22]. Patients with TIA, stroke mimics, subacute stroke, inpatient stroke and brain hemorrhage were excluded. Patients who were transferred from outside facilities were also excluded. The screening flow chart for eligible patients is shown in Figure 1.

---

**From January 1, 2013 to December 31, 2018, 1759 patients were admitted to the medical center for acute ischemic stroke AIS. After excluding ineligible patients (n=390), 1369 patients were included in final analysis.**

**Figure 1: Screening of eligible patients for the study**

All patients were managed by the emergency department (ED) and stroke team using standard ED code stroke algorithm per concurrent AHA guidelines (Figure 2).
Abbreviations: ETA: estimated time of arrival; ED: emergency department; CT: Computerized Tomography; CTA: Computerized Tomography Angiography; IR: interventional radiology; NIR: neuro interventional radiology; ABC: airway, breath and circulation; NIHSS: National Institutes of Health Stroke Scale; IV: intravenous; CBC: complete blood count; CMP: comprehensive metabolic panel; PT: prothrombin time; PTT: partial thromboplastin time; INR: international normalized ratio; ETOH: alcohol; EKG: electrocardiogram; CXR: chest X-ray; tPA: tissue plasminogen activator; LKW: last-known well; HTN: hypertension; NPO: nothing by mouth; LVO: large vessel occlusion; OR: operation room; Non-con CT: non-contrast CT; ICU: intensive care unit.

Figure 2: Emergency Department Code Stroke Algorithm
A simple quality improvement protocol was implemented in January 2015 to minimize delays in DTN time for tPA as previously described [21]. It allowed stroke team to treat hypertension in the emergency room to keep blood pressure (BP) < 185/110 mmHg, to give tPA before getting blood test results unless patients were taking anticoagulants, and to give tPA in the CT scan suite. To continuously improve stroke care, we update our ED Code Stroke Algorithm and order sets annually per guidelines and advances in the field. In addition, we have a weekly stroke quality improvement committee meeting and case conferences to review every stroke admission for ongoing quality improvement.

The following data, including patient demographics, co-morbidities, National Institutes of Health Stroke Scale (NIHSS), BP, LKW-to-door time, door-to-imaging time, DTN time for tPA, door-to-puncture (DTP) time for EVT, symptomatic intracranial hemorrhage (sICH), length-of-stay (LOS) in the Intensive Care Unit (ICU) or hospital, and modified Rankin Scale (mRS) at hospital discharge, were collected from the registry and electronic medical record by experienced neurologists.[21] Laboratory results, including comprehensive metabolic panel, fasting lipid profile, and glycol-hemoglobin A1c (HbA1c), were also collected. sICH was defined as intraparenchymal hematoma, subarachnoid hemorrhage, or intraventricular hemorrhage associated with a worsening of the NIHSS score by ≥ 4 points within 24 h of tPA and/or EVT [5]. A mRS score of 0-3 at discharge was defined as favorable outcome. NIHSS, sICH and mRS were estimated by the stroke team. Uncertain cases or disagreement were adjudicated by experienced neurologists.

To investigate the ongoing quality improvement in acute stroke therapy, patients were categorized into three groups according to admission and implementation date of quality improvement initiatives [16-21]: January 1, 2013 to December 31, 2014; January 1, 2015 to December 31, 2016; and January 1, 2017 to December 31, 2018. Time sensitive-quality indicators, including LKW-to door time, DTI time, DTN time, DTP time, rates of tPA and EVT, sICH rate, LOS in the ICU and hospital, and functional outcome at hospital discharge, were analyzed and compared among the three time periods.

Statistical analysis

Categorical variables were expressed as frequencies and percentages (%), and continuous variables as median and interquartile range (IQR). General linear means regression models and Jonckheere-Terpstra test were used to assess the estimated difference of continuous variables. Univariate logistic regression analysis was performed to test the crude ORs (95% CI) of quality benchmarks between groups. Multivariate logistic regression models were performed to determine the adjusted ORs (95% CI) of favorable outcomes (mRS score 0-3) at hospital discharge, in association with the admission time. In the multivariate models, we adjusted age, initial NIHSS scores, and DTN time to exclude the potential confounding factors. The SAS statistical software (version 9.4; SAS Institute, Cary, NC, USA) was used to perform the data analysis.

Results

From January 1, 2013 to December 31, 2018, 1,759 patients were admitted to the medical center for AIS within 24 hours of symptom onset or wakeup stroke. During the initial screening, 390 patients were excluded from the study for the following reasons (Figure 1): 1). 274 patients were transferred from outside hospitals for higher level of care, including 58 treated with intravenous tPA at outside facilities; 2). 78 patients were inpatient consultations for suspected ischemic stroke; 3). 25 patients presented with subacutec infarction that was confirmed by brain imaging. 4). 12 patients were outliers for LOS (≥ 28 days) and discharge outcome due to insurance issue; and 5). 1 patient left hospital against medical advice.

A total of 1,369 patients were included in the final analysis. Of note, 53 patients had 2 admissions, 3 patients had 3 admissions, and 1 patient had 4 admissions during the study period. The median age and interquartile range (IQR) of the patients was 71 (24). There were 755 men and 614 women. There were 52% White, 23% Asian, 18% Hispanic, 2% American African, and 5% other ethnic patient population. Of the entire cohort, 71% listed English as primary language, 16% spoke Spanish, and 12% spoke other languages. The most common past medical histories were hypertension (71%), diabetes mellitus (36%), and hyperlipidemia (39%). The baseline demographics and clinical data of the 3 groups were shown in Table 1.
Abbreviations: DBP, diastolic blood pressure; Hb A1c, hemoglobin A1c; IQR, interquartile range; LDL-c, low-density lipoprotein cholesterol; LKW, last known well; NIHSS, National Institutes of Health Stroke Scale; SBP, systolic blood pressure.

| DTP time, min, median (IQR)       | 172 (71%)   | 130 (67%)   | 114 (65%)   | -              |
| ICH (%)                           | 0 (0%)      | 1 (1.6%)    | 3 (4.1%)    | 0.175          |
| ICU LOS, median (IQR)             | 4 (6)       | 3 (3)       | 3 (3)       | 0.276          |
| Hospital LOS, median (IQR)        | 6 (8)       | 5 (5)       | 4 (7)       | -              |
| Favorable outcome (%)             | 10 (26%)    | 19 (31%)    | 23 (35%)    | -              |
| In-hospital mortality (%)         | 8 (21%)     | 11 (18%)    | 8 (12%)     | -              |

The tPA rate was 20%, 30% and 22% in 2013-2014, 2015-2016, and 2017-2018, respectively (Table 2). In the crude logistic regression model, tPA rate was significantly higher in 2015-2016 than that in 2013-2014 (OR, 1.77; 95% CI, 1.30-2.40; p = 0.0003). There was no significant difference in tPA rate between 2017-2018 and 2013-2014 (OR: 1.17; 95% CI: 0.85-1.61; p = 0.33). There was no significant difference in DTI time among the 3 time periods. However, there was significant ongoing improvement in median DTN time (57, 45, and 39 minutes, respectively) during the 3 groups per trend analysis, with DTN time ≤ 60, 45 and 30 minutes in 80%, 63% and 30% of patients, respectively, during 2017-2018. There was no significant difference in sICH rate, LOS in the ICU or hospital, and mortality at hospital discharge among the 3 groups. Of note, significantly more patients had favorable outcomes (mRS score 0-3) at hospital discharge in 2015-2016 than in 2013-2014. There was no difference between 2013-2014 and 2017-2018. (Table 2) A total of 167 patients received EVT with or without intravenous tPA. The rate of EVT was 9%, 14% and 15%, respectively, during the 3 time periods. Significantly more patients were treated with EVT in 2015-2016.
(OR, 1.70; 95% CI, 1.11 - 2.59; \( p = 0.01 \)) and 2017-2018 (OR, 1.77; 95% CI, 1.16 - 2.68; \( p = 0.008 \)) than in 2013-2014, due to acceptance of EVT as standard of care for patients with AIS from LVO in 2015.

There was also continual improvement in median DTP time (172, 130, 114 minutes) during the 3 time periods per trend analysis with Jonckheere-Terpstra test. There was no significant difference in sICH rate, LOS in the ICU and Hospital, or favorable outcome among the 3 groups. There appeared to be a trend of decreased mortality rate at hospital discharge during the 3 time periods. The overall rates of sICH and mortality after EVT were 2.4% and 16%, respectively.

**Multivariate logistic regression analysis of favorable outcomes with Wald Model**

To examine the predictor of favorable outcomes after intravenous tPA, we performed a multivariate logistic regression model with Wald Chi-Square test (Table 3). After adjusting for age, NIHSS scores and DTP time, age and initial NIHSS were independently associated with favorable outcomes at hospital discharge.

| Year of admission | OR  | 95% CI     | DF | Wald Chi-Square | \( p \) |
|-------------------|-----|------------|----|----------------|-------|
| Age               | 0.97| 0.96-0.99  | 1  | 9.71           | 0.035 |
| Initial NIHSS scores | 0.87| 0.83-0.91 | 1  | 50.30          | <0.001|
| DTN time          | 0.99| 0.98-1.00  | 1  | 2.55           | 0.330 |

**Abbreviations:** OR, odds ratio; CI, Confidence Interval; NIHSS, National Institutes of Health Stroke Scale.

**Table 3:** Multivariate regression model assessing the predictor of favorable outcomes after intravenous tPA therapy

**Discussion**

We have reduced the median DTP times from 172 minutes in 2013-2014 to 114 minutes in 2017-2018. The results were similar to the reported 130-145 minutes at the CSCs registered in GWTG-Stroke program [19, 20], but very suboptimal compared to the median 47 minutes reported at high-volume center with standardized protocol and conscious sedation for EVT [23]. Of note, DTP times were reduced to 17 - 20.5 minutes when the patients were directly transferred from ED to angiography suite [24, 25]. The median annual EVT volume per CSC in the United States was 16 (IQR, 10–27) [20]. That was only slightly more than one EVT a month. Each 5-case increase in EVT volume per year was found to be associated with a 3% shorter door to first pass time, up to a case volume of 40 per year (\( P<0.001 \)) [20]. Currently, only a minority of CSCs in the United States are providing EVT to > 40 patients per year partly due to very lenient criteria for CSC certification [17]. EVT is a labor-intensive procedure that requires a coordinated effort among numerous healthcare providers and timely access to angiography facilities. In addition to the Code Stroke team 24/7 in house, patients may also need intubation for the procedure, timely transport to the angiography suite, anesthesiologist, angiography suite nurses and technicians [24, 26]. Overnight and weekends pose additional challenges. Due to low EVT volume, it is financially impossible for individual CSC to implement rapid EVT protocol that requires the entire stroke team to be brought in for each possible code stroke [23].

Currently, three strategies, including transporting patients directly from emergency medical services to the CT scanner, conscious sedation, and transferring patients with suspected LVO from ER to angiography suite directly, were reported to have large independent effect on reducing door to treatment times [23-26].

Of note, significantly more patients were treated with iv tPA at our center in 2015-2016 due to the implementation of a simple quality improvement initiative in January of 2015 [20]. However, the release of the PRISMS Trial results at the International Stroke Conference in January of 2018 led to decreased treatment of minor non-disabling stroke with tPA at our center in 2017-2018. PRISMS is a randomized trial of tPA versus aspirin for patients with minor nondisabling stroke (NIHSS 1-5). The primary outcome was minimal or no neurologic deficit (mRS 0–1) at 90 days. The study was stopped early, after enrollment of 313 patients with median NIHSS 2 and median DTN time 2.7 hours. There was no significant difference in functional outcome at 90 days (81.5% in the aspirin group and 78.2% of patients in the tPA group). Thrombolysis showed no benefit even after exclusion of stroke mimics. sICH rate was 3.2% with tPA and 0% with aspirin [28].

Our study has many limitations. First, this is a single center retrospective study. The data were collected from GWTG-Stroke Registry and chart review. There could be data collection bias. Second, there was no long-term follow up information. However, benchmarking is essential for continuous quality improvement in stroke care. To further improve the door to treatment times, we plan to implement new initiatives on transporting patients directly from emergency medical services to the CT scanner, conscious sedation, and transferring patients with suspected LVO from ER to angiography suite. We will also start long-term outpatient follow-up on all patients after hospital discharge.

**Conclusions**

We demonstrated satisfactory rates of acute stroke treatment and ongoing improvement in door to treatment times at our CSC. Our findings suggest that implementation of concurrent AHA guidelines and new quality improvement initiatives are essential for continuous quality improvement in acute stroke care.
Declarations

Ethics approval and consent to participate: The study was approved by the Institutional Review Board (IRB) at University of California Irvine Comprehensive Stroke Center. No identifiable information was indicated in the retrospective database-based study, so informed consent was not applicable.

Consent for publication: Not applicable.

Competing interests: Dr. Yu has received compensation for activities with Stryker and Amgen as a scientific consultant. However, the activities are not related to this research project. Other authors have nothing to disclose.

Funding: None.

Authors' contributions: Concept and design: Liu, Yu. Acquisition, analysis, and interpretation of the data, Liu, Zhu, Stradling, Yu. Drafting of the manuscript: Liu. Critical revision of the manuscript for important intellectual content: Zhu, Shafie, Abcede, Shah, Suzuki, Li, Golsahni, Yu. Statistical analysis: Liu, Zhu, and Yu

Acknowledgements: We appreciate the support from the University of California Irvine Xiaoqi Cheng & Dongmei Liao International Stroke Research Scholarship.

Availability of data and materials: Dr. Yu has full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.
