Summary The acquisition of the multidrug resistance phenotype in human tumours is associated with an overexpression of the 170 kDa P-glycoprotein encoded by the multidrug resistance 1 (MDR1) gene, and also with a 190 kDa membrane ATP-binding protein encoded by a multidrug resistance-associated protein (MRP) gene. Human bladder cancer is a highly malignant neoplasm which is refractory to anti-cancer chemotherapy. In order to understand the mechanism underlying multidrug resistance in bladder cancer, we established three doxorubicin-resistant cell lines, T24/ADM-1, T24/ADM-2 and KK47/ADM, and one vincristine-resistant cell line, T24/VCR, from human bladder cancer T24 and KK47 cells respectively. Both T24/ADM-1 and T24/ADM-2 cells which had elevated MRP mRNA levels showed both a cross-resistance to etoposide and a decreased intracellular accumulation of etoposide. T24/VCR cells which had elevated levels of MDR1 mRNA and P-glycoprotein but not of MRP mRNA, showed cross-resistance to doxorubicin. On the other hand, KK47/ADM cells, which had elevated levels of both MRP and MDR1 mRNA and a decreased level of topoisomerase II mRNA, were found to be cross-resistant to etoposide, vincristine and a camptothecin derivative, CPT-11. Our present study demonstrates a concomitant induction of increased levels of MRP mRNA, decreased levels of topoisomerase II mRNA and decreased drug accumulation during development of multidrug resistance in human bladder cancer cells. The enhanced expression of the MRP gene is herein discussed in a possible correlation with the decreased expression of the topoisomerase II gene.

Key words: multidrug resistance; MRP; MDR1; DNA topoisomerase II; bladder cancer

The overexpression of membrane P-glycoprotein (P-gp) with Mr of 170 kDa, encoded by the human multidrug resistance 1 (MDR1) gene, is often associated with the acquisition of the multidrug resistance phenotype (Bradley et al., 1988; Gottesman and Pastan, 1988). The reduced drug retention in P-gp-overexpressing cells is due to an enhanced active efflux of anti-cancer agents. The MDR1 gene is often expressed in various tumours from cancer patients (Goldstein et al., 1989), but the expression of the MDR1-encoded P-gp is not always coupled with the acquisition of multidrug-resistant phenotypes in human tumours. One other form of multidrug resistance, in which altered topoisomerase II activity is involved (Takano et al., 1992), has been referred to as atypical multidrug resistance (Beck et al., 1987). Another form of multidrug resistance is non-P-gp-mediated multidrug resistance. This type of multidrug resistance has been reported in doxorubicin-selected lung carcinoma cell lines (Mirsld et al., 1987; Scheper et al., 1993; Barrand et al., 1994) and a leukaemia cell line (Marsh et al., 1987) among others. Expression of a 190 kDa vesicular glycoprotein (Krishnachary et al., 1993) and a 110 kDa membrane glycoprotein (Scheper et al., 1993) appears to be associated with the non-P-gp-mediated multidrug resistance in some of these cell lines. Cole et al. (1992) have isolated a gene named multidrug resistance-associated protein (MRP) from a doxorubicin-selected small-cell lung carcinoma cell line (H69AR): H69AR cells have a MDR phenotype, but do not overexpress P-gp (Mirsld et al., 1987). This MRP gene is amplified in H69AR cells as well as in several other cell lines that overexpress this mRNA (Slovak et al., 1993; Zaman et al., 1993). MDR1 and MRP are both members of the ATP-binding cassette (ABC) superfamily transport system described by Hyde et al. (1990), but have very little sequence homology with each other outside the nucleotide-binding domains (Cole et al., 1992).

Anti-cancer agents such as etoposide, cisplatin, vincristine, vinblastine, doxorubicin and others have been employed in the therapy of human bladder cancer, but their therapeutic effects are not satisfactory (Harry et al., 1987; Sternberg et al., 1988). Resistance to anti-cancer agents in bladder cancer cells in culture and bladder tumour in vivo is sometimes associated with an enhanced expression of P-gp or MDR1 gene (Naito et al., 1992; Shinohara et al., 1993; Kimiya et al., 1992). However, we have also isolated multidrug-resistant cell lines from bladder cancer cells without overexpression of P-gp. It is thus important to know whether other multidrug resistance-related genes play a role in multidrug resistance in human bladder cancer. In the present study, we examined whether overexpression of MRP is associated with acquired multidrug resistance in human bladder cancer cells. Several multidrug-resistant cell lines selected from human bladder T24 or KK47 cells were found to express increased level of MRP mRNA and protein. They also expressed decreased levels of DNA topoisomerase II mRNA, which indicated that resistance in these bladder cell lines results from multiple mechanisms.

Materials and methods

Bladder tumour cells and their MDR cell lines

Both KK47 (Taya et al., 1977) and T24 (Bubenik et al., 1973) were established from transitional cell carcinoma of the bladder and were used as parental cell lines from which multidrug-resistant cells were developed. A doxorubicin-resistant cell line (KK47/ADM) from KK47 cells was established as described previously (Kimiya et al., 1992). Doxorubicin-resistant T24 cell lines, T24/ADM-1 and T24/ADM-2, were independently established by exposure of the T24 cell line for 3 months to the IC50 of doxorubicin followed by a further exposure for 3 months to a 10-fold higher dose of doxorubicin. A vincristine-resistant cell line (T24/VCR) was established according to the same procedure. These drug-resistant cell lines, KK47/ADM, T24/VCR, T24/
ADM-1 and T24/ADM-2, were cloned in the presence of their selecting agents. All cell lines were cultured in minimal essential medium (MEM) supplemented with 10% fetal bovine serum (FBS), 10 units/ml penicillin and 60 mg/ml kanamycin as described previously (Abe et al., 1994; Kotoh et al., 1994).

Doubling times of KK47 and KK47/ADM cells were 27.0 h and 30.0 h in the presence of 10% FBS at 37°C. Doubling times of T24/ADM-1, T24/ADM-2 and T24/VCR were 28.0–35.0 h; the doubling time of the parental T24 cells was 25.0 h. This finding indicated that the growth rate of each resistant cell line did not differ greatly from that of each parental counterpart.

Drugs and chemicals

Doxorubicin was a gift from Kyowa Pharmaceuticals, Tokyo, Japan, vincristine was from Shionogi Pharmaceuticals, Tokyo, Japan and etoposide and cis-diaminedichloroplatinum(II) (cisplatin) were from Nihon Kayaku, Tokyo, Japan. (4S)-4, 11-Diethyl-4-hydroxy-9-[4-piperidino-piperidino] carbonoxy) dione hydrochloride trihydrate (CPT-11) was from Yakult, Tokyo, Japan. [3H]Etoposide (388 Ci mmol-1) was obtained from Moravek Biochemicals (Brea, CA, USA), and [3H]Vincristine (4.8 Ci mmol-1) was obtained from New England Nuclear.

Cell survival by colony formation

Cell survival was determined by plating approximately 104 cells in 35 mm dishes in the absence of any drug (Matsuo et al., 1990; Takano et al., 1991; Abe et al., 1994). Various drugs were added 24 h later. After incubation for 7 days at 37°C, the number of colonies was counted after Giemsa staining. All drugs were freshly prepared in physiological saline or dimethylsulphoxide. The same amount of saline or dimethylsulphoxide was added. The 50% inhibition of cell growth (IC50) for each cell line was determined from dose–response curves of human bladder cancer cell lines.

Drug accumulation

The cells (1–2×105 per 24-well plate) were plated and incubated for 48 h at 37°C. After reaching subconfluence, the plates were incubated on ice in water at 4°C for 15 min and the cells were washed twice with ice-cold phosphate-buffered saline (PBS). Medium was then replaced with 200 µl of buffer (serum-free MEM and 20 mM Hepes, pH 7.5) containing [3H]Etoposide (1 µM, 1 µCi ml-1) and [3H]Vincristine (22 µM, 0.13 Ci ml-1), and the cells were incubated at 37°C as described previously (Matsuo et al., 1990; Takano et al., 1991; Abe et al., 1994). The cells were then washed with ice-cold PBS three times, 400 µl of 0.25 N sodium hydroxide added, and then they were kept at 37°C for at least 30 min. The cell lysates were mixed thoroughly with 4 ml of Scintisol EX-H (Wako Chemicals, Osaka, Japan) and the radioactivity was determined.

Fluorescence microscopy

Human bladder cancer cells in an exponential growth state were centrifuged and suspended in MEM-10% FBS at 1×106 ml-1. The cells were seeded on a glass slide and incubated at 37°C for 24 h. The cells were then incubated with 1 µg ml-1 or greater concentrations of doxorubicin for 40 min at 37°C, followed by washing with ice-cold PBS twice, and mounted in 50% glycerol in PBS. Fluorescence of doxorubicin in the cells was examined by Nikon fluorescence microscopy with a Bio-Rad laser scanning confocal imaging system (MRC-600) (Abe et al., 1994).

Northern blot analysis and Southern blot analysis

A human MRP complementary DNA (cDNA) probe (1 kb EcoRI fragment) (Cole et al., 1992) was used. Human MDR1 cDNA was from MM Gottesman (NIC, NIH, Bethesda, MD, USA), human topoisomerase I cDNA probe from O Koizumi and T Andoh (Aichi Cancer Center, Nagoya, Japan) and human topoisomerase II cDNA probe (pBS-hTOP2) from JC Wang (Harvard University, USA). A Northern blot analysis was performed as described previously (Abe et al., 1994; Kotoh et al., 1994). Treatment of human bladder cancer cells were incubated in MEM containing 10% FBS, and the harvested cells were suspended in 4 ml guanidinium isothiocyanate, 25 mM sodium citrate (pH 7.0), 0.5% sarcosyl and 0.1 M β-mercaptoethanol. Sodium acetate (2 M) (pH 4.0), water-saturated phenol and chloroform were added successively to samples. After mixing vigorously, the samples were left on ice for 20 min and then were centrifuged at 10 000 g for 15 min. The aqueous phase was removed, mixed together with isopropanol and kept at −20°C for 60 min. The samples were then centrifuged at 10 000 g for 20 min and the RNA pellet was washed with 75% ethanol and dissolved in sterile, RNAse-free water. The RNA was fractionated through a 1% agarose gel containing 2.2 M formaldehyde and transferred onto a Hybond N+ filter (Amersham, Bucks, UK). Genomic DNA was isolated from human bladder cancer cells and Southern blotting was performed as previously described (Kohno et al., 1994). DNA was digested to completion with EcoRI. Ten micrograms of DNA was loaded in each lane on 0.8% agarose gel, and the DNA then transferred onto a Hybond N+ filter. The RNA and DNA blots were hybridised with 32P-labelled cDNA probes in Hybrisol for 24 h at 40°C, and then washed at room temperature in 2× SSC and 0.1% SDS, followed by further washing in 0.2× SSC and 0.1% SDS. The mRNA and DNA levels were quantified by a densitometric analysis with a Fujix BAS 2000 bioimaging analyser (Fuji Photo Film, Tokyo, Japan).

Western blot analysis

Western blot analysis was performed as described previously (Ono et al., 1992; Kotoh et al., 1994). Vesicles were prepared from drug-sensitive and drug-resistant cell lines by nitrogen cavitation as described previously (Kiae et al., 1990). The cells were grown to confluence in 10 cm dishes. Cellular monolayers (109–1010 cells) were washed once and scraped into PBS. The cells were washed by centrifugation (4000 g, 10 min) in PBS and then in vesicle buffer (0.01 M Tris–HCl, pH 7.5, 0.25 M sucrose, 0.2 mM calcium chloride). The cells were then resuspended in vesicle buffer and equilibrated at 4°C under nitrogen pressure at 4000 p.s.i. for 15 min. Under these conditions, more than 95% of the cells were lysed. EDTA was added to the cell homogenate to a final concentration of 1 mM. The homogenate was then centrifuged at 0.01 M Tris–HCl, pH 7.5–0.25 M sucrose and 1000 g for 10 min. To remove nuclei and unlysed cells. The supernatant was layered onto a 35% sucrose cushion (0.01 M Tris–HCl, ph 7.5, 35% sucrose, 1 mM EDTA) and centrifuged for 30 min at 16 000 g. The interface was collected and diluted 1:1 in 0.01 M Tris–HCl, pH 7.5, 0.25 M sucrose, and then was centrifuged for 45 min at 100 000 g. The vesicle pellets were resuspended in 0.1 M Tris–HCl, pH 7.5–0.25 M sucrose using a 25 gauge needle and the vesicle suspensions were stored at −80°C. Twenty micrograms of vesicle protein was mixed with 4× sample buffer (250 mM Tris–HCl pH 6.8, containing 20% β-mercaptoethanol and 9% SDS), and then subjected to SDS–PAGE in 7.5% gel. Proteins were then electrophoretically transferred to a nitrocellulose filter. The filter was blocked with 5% skimmed milk in Tris-buffered saline (TBS) containing 0.1% Tween-20, non-specific binding of TBS was blocked with 1% skimmed milk in TBS containing 0.1% Tween-20. For the detection of P-gp, MAB4C6 was used. The filter was incubated with 30 µg ml-1 anti-P-gp antibody for 1 h at room temperature. The secondary antibody, 1:100 diluted anti-mouse IgG, was added and the filter was incubated for 45 min at room temperature. For the detection of MRFP, MAB2C11L (hybridoma supernatant) was used. The filters were washed twice with 1% skimmed milk in TBS containing 0.1% Tween-20 and once with TBS containing 0.1% Tween-
20. Antibody binding was detected by enhanced chemoluminescence (ECL) Western blotting method using ECL Western blotting detection reagents (Amersham, UK) by fluorography on Hyper-Blot ECL western (Amersham, UK) for 1 min at room temperature as described previously (Ono et al., 1992).

Results

Drug resistance to multiple anti-cancer agents in bladder cancer cell lines

We compared the drugs sensitivities to doxorubicin, etoposide, vincristine, cisplatin and CPT-11 of the drug-resistant bladder cancer cell lines, KK47/ADM, T24/ADM-1, T24/ADM-2 and T24/VCR, with those of their parental counterparts. The dose–response curves of the six cell lines to these anti-cancer agents were determined by colony formation assay, and from these survival curves the doses required to inhibit cell growth by 50% (IC50) were calculated for each cell line. The relative drug resistances of KK47/ADM, T24/ADM-1, T24/ADM-2 and T24/VCR cells were determined by comparison with the IC50 of each parental counterpart (Table I). As shown in Table I, KK47/ADM cells were an 18.7-fold resistant to doxorubicin and 3.5- to 4.6-fold resistant to etoposide, vincristine and CPT-11 compared with KK47 cells. In contrast, T24/ADM-1 and T24/ADM-2 showed 4.8- to 10.5-fold higher resistance to doxorubicin and etoposide than T24, but only showed 1.2- to 1.9-fold higher resistance to vincristine. T24/VCR cells showed 6.8-fold and 15.1-fold higher resistance to doxorubicin and vincristine, respectively, but only 1.8- to 3.1-fold higher resistance to etoposide and CPT-11. The KK47/ADM, T24/ADM-1 and T24/ADM-2 cell lines were not cross-resistant to cisplatin, while T24/VCR showed 2-fold higher resistance to cisplatin than T24 (Table I). Thus the four cell lines, KK47/ADM, T24/ADM-1, T24/ADM-2 and T24/VCR, all had acquired a multidrug resistance phenotype, but each cell line appeared to show a unique cross-resistance pattern.

Cellular accumulation of vincristine, etoposide and doxorubicin

The cellular accumulation of vincristine, etoposide and doxorubicin is often reduced in multidrug-resistant cell lines (Kohno et al., 1988; Matsuo et al., 1990). A reduced accumulation of these agents may be responsible for the relatively higher drug resistance in KK47/ADM, T24/ADM or T24/VCR cells. The accumulation of [3H]etoposide in these cell lines reached steady-state levels within 20–40 min at 37°C (data not shown). Cellular etoposide accumulation in KK47/ADM and T24/ADM-1 or T24/ADM-2 cells was half or less of that in each parental cell line (Figure 1). Etoposide accumulation in T24/VCR cells was only slightly reduced, if at all, in comparison with that in the T24 cells. The cellular accumulation of [3H]vincristine in these cell lines reached a plateau within 150 min at 37°C (data not shown), and accumulation of vincristine was measured at 20, 40, 60 and 120 min (Figure 2). The cellular vincristine accumulation in KK47/ADM was 30% or less than that in KK47. In T24/ADM-1 and T24/ADM-2 cells, vincristine accumulation was only slightly reduced if at all in comparison with T24 cells.

By contrast, vincristine accumulation in T24/VCR cells was greatly reduced in comparison with the parental T24 cells.

Doxorubicin accumulation in T24, T24/ADM-2 and T24/VCR cells was compared using fluorescence microscopy. As seen in Figure 3a, doxorubicin accumulated in the nuclei of T24 cells when incubated for 40 min with the drug. This was followed by a gradual decrease in intranuclear doxorubicin concentration during further incubation for 120 min in the absence of the drug. T24, T24/ADM-2 and T24/VCR cells were first incubated with doxorubicin at 1 μg ml⁻¹, 2 μg ml⁻¹ and 4 μg ml⁻¹, respectively, for 40 min. The level of doxorubicin accumulation in the nuclei of T24/ADM-2 and T24/VCR cells was similar to that of T24 cells when incubated with drug for 40 min at 37°C (Figure 3). However, doxorubicin in nuclei was almost completely removed from T24/ADM-2 and T24/VCR cells after further incubation for 120 min in the absence of drug (Figure 3d and f), while doxorubicin still remained in nuclei of the parental T24 cells (Figure 3b).

The expression of DNA topoisomerase I and II, MDR1 and MRP genes

Northern blot analysis was performed to determine if the expression of drug resistance relevant genes such as MRP, MDR1 and DNA topoisomerase I and II was altered in these drug-resistant bladder cancer cell lines. The expression of topoisomerase I was similar in all these bladder cell lines (Figure 4a). In comparison with parental KK47 and T24 cells, the cellular levels of topoisomerase II mRNA expression were much lower in doxorubicin-resistant KK47/ADM, T24/ADM-1 and T24/ADM-2 cells. The expression of the MDR1 gene was found to be much higher in KK47/ADM

Table I Comparison of drug resistance to anti-cancer agents in KK47/ADM, T24/ADM-1, T24/ADM-2 and T24/VCR cells

| Anticancer agents | KK47/ADM IC50 (nM) | Relative resistance | KK47/ADM IC50 (nM) | T24/ADM-1 IC50 (nM) | Relative resistance | T24/VCR IC50 (nM) | Relative resistance |
|------------------|------------------|-------------------|------------------|-------------------|-------------------|------------------|-------------------|
| Doxorubicin       | 14.7 ± 2.1       | 18.7              | 16.8 ± 1.6       | 4.8               | 9.3               | 6.8              |
| Etoposide         | 80.3 ± 5.4       | 3.5               | 47.6 ± 9.9       | 5.1               | 10.5              | 1.8              |
| Vincristine       | 1.8 ± 0.1        | 4.6               | 3.3 ± 1.2        | 1.2               | 1.9               | 15.1             |
| Cisplatin         | 213.3 ± 52.3     | 0.6               | 200.0 ± 30.0     | 0.8               | 1.1               | 2.2              |
| CPT-11            | 433.8 ± 91.2     | 3.5               | 378.5 ± 123.8    | 0.5               | 0.9               | 3.1              |

*Relative resistance was obtained by dividing the IC50 of resistant cell lines by the IC50 of parental cell lines. The values represent the average of triplicate trials.
Figure 2 Vincristine accumulation in the bladder cancer cell lines. Human bladder cells were seeded and then incubated with 22 µM [3H]vincristine for 20, 40, 60 or 120 min. Cell-associated radioactivity was determined, and radioactivity per mg of protein was calculated for each cell line. Each value represents the average of triplicate dishes. Cellular accumulation of both drugs in these cell lines is normalised by comparison with accumulation in parental cells. Bars = s.d.

Figure 3 The analysis of doxorubicin accumulation in T24, T24/ADM-2 and T24/VCR cells using fluorescence microscopy. These cells were incubated for 40 min with doxorubicin (1.0 µg ml⁻¹), followed by incubation in drug-free medium for 120 min. (a), (e) and (f) show the fluorescence of T24, T24/ADM-2 and T24/VCR cells during the initial 40 min incubation. (b), (d) and (f) show the fluorescence of T24, T24/ADM-2 and T24/VCR after further incubation in drug-free medium for 120 min. We repeated two independent assays, and obtained almost the same data as in this analysis.

Figure 4 Northern blot analysis for DNA topoisomerase I and II mRNA (a) and MDR1 and MRP mRNA (b) in human bladder cancer cell lines. Twenty micrograms of RNA from each bladder cancer cell line was loaded in each lane.

The enhanced expression of MRP mRNA in doxorubicin-resistant small-cell lung cancer cell lines which were selected in vitro is due to an amplification of the MRP gene (Cole et al., 1992; Zaman et al., 1993). To determine whether the amplified levels of MRP mRNA in KK47/ADM, T24/ADM-2 cells were due to an amplification of this gene, Southern blot analysis of EcoRI-digested genomic DNA from these cells was performed. As shown in Figure 5 and Table II, an approximately 17-fold amplification of the MDR1 gene was observed in KK47/ADM cells compared with KK47 cells, but no amplification of the MDR1 gene was apparent in the T24/ADM-1, T24/ADM-2 and T24/VCR cells. We could observe 2- and 4-fold amplification of the MRP gene in T24/ADM-1 and T24/ADM-2, respectively, whereas no amplification was observed in KK47/ADM cells.
appreciably confirm cines was more crease MDR1 (Figure 5). P-gp resistance-associated protein, KK47/ADM had about 3-fold 6. Although the 170 D, (Cole et al., 1993; Kohno et al., 1989). On the other hand, non-P-gp-mediated multidrug-resistant cell lines are often selected by exposure to doxorubicin or etoposide, and some of these non-P-gp-mediated resistant cell lines show increased MRP gene expression (Cole et al., 1992; Krishnamachary et al., 1993; Slovak et al., 1993; Zaman et al., 1993; Schenider et al., 1994). We have established several doxorubicin-resistant sublines of human bladder cancer KK47 and T24 cells in vitro by continuous exposure to doxorubicin. KK47/ADM cells overexpressed both MDR1 and MRP genes when assayed by both Northern blot and Western blot analyses: KK47/ADM cells were cross-resistant (about 4-fold) to etoposide, vincristine and CPT-11. In contrast, both T24/ADM-1 and T24/ADM-2 cells overexpressed only the MRP gene. They were cross-resistant to etoposide, but displayed only low levels of vincristine resistance (less than 2-fold). A typical P-gp-mediated drug-resistant T24/VCR cell line which overexpressed the MDR1 gene was cross-resistant to doxorubicin or CPT-11, but was only weakly resistant to etoposide or cisplatin. The acquisition of vincristine resistance in KK47/ADM cells might be specifically correlated with P-gp overexpression rather than with MRP expression, as seen in T24/VCR cells. By contrast, drug resistance to etoposide in KK47/ADM and T24/ADM-1

Table II Summary of expression and amplification of drug resistance related genes in KK47 and T24 cells and their resistant cell lines

| Cell line | Topo I mRNA level | Topo II mRNA level | MDR 1 extra | MRP | DNA level y | MDR 1 | MRP |
|-----------|------------------|-------------------|-------------|-----|------------|-------|-----|
| KK47      | 1.0              | 1.00              | -           | 1.0 | 1.0        | 1.0   | 1.0 |
| KK47/ADM  | 1.0              | 0.70              | +           | 3.0 | 17.0       | 1.0   | 1.0 |
| T24       | 1.0              | 1.00              | -           | 1.0 | 1.0        | 1.0   | 1.0 |
| T24/ADM-1 | 1.0              | 0.40              | -           | 4.0 | 1.0        | 2.0   | 1.0 |
| T24/ADM-2 | 1.0              | 0.25              | -           | 8.0 | 1.0        | 4.0   | 1.0 |
| T24/VCR   | 1.0              | 0.65              | +           | 1.0 | 1.0        | 1.0   | 1.0 |

*yRelative levels of mRNA and DNA of resistant cell lines are presented normalised to the levels of their parental counterparts (see Figures 4 and 5).

Figure 5 Southern blot analysis of the MRP and MDR1 gene. Genomic DNA was digested with EcoRI and hybridised with MRP and MDR1 probe. Molecular weight markers as indicated by the arrows are in kilobasepairs.

(Figure 5). In T24/VCR cells, the MDR1 mRNA level was appreciably increased, but no apparent amplification of the MDR1 gene was observed (Figure 5, Table II).

KK47/ADM cells appeared to overexpress both MRP and MDR1 mRNA. Western blot analysis was performed to confirm whether both the 190 kDa MRP gene product and the 170 kDa P-gp in KK47/ADM cells also increased (Figure 6). Although the parental KK47 cells expressed multidrug resistance-associated protein, KK47/ADM had about 3-fold more MRP gene product than KK47 cells. Furthermore, P-gp was also overexpressed in KK47/ADM cells, but since it was not detectable in parental KK47 cells the relative increase in P-gp expression could not be calculated (Figure 6).

Discussion

P-gp-mediated drug-resistant cells exhibit elevated levels of drug resistance to vinca alkaloids (vincristine) and anthracyclines (daunomycin, doxorubicin), colchicine and actinomycin D, as well as resistance to topoisomerase II-targeting agents such as etoposide and teniposide (Bradley et al., 1988; Kohno et al., 1989). On the other hand, non-P-gp-mediated multidrug-resistant cell lines are often selected by exposure to doxorubicin or etoposide, and some of these non-P-gp-mediated resistant cell lines show increased MRP gene expression (Cole et al., 1992; Krishnamachary et al., 1993; Slovak et al., 1993; Zaman et al., 1993; Schenider et al., 1994). We have established several doxorubicin-resistant sublines of human bladder cancer KK47 and T24 cells in vitro by continuous exposure to doxorubicin. KK47/ADM cells overexpressed both MDR1 and MRP genes when assayed by both Northern blot and Western blot analyses: KK47/ADM cells were cross-resistant (about 4-fold) to etoposide, vincristine and CPT-11. In contrast, both T24/ADM-1 and T24/ADM-2 cells overexpressed only the MRP gene. They were cross-resistant to etoposide, but displayed only low levels of vincristine resistance (less than 2-fold). A typical P-gp-mediated drug-resistant T24/VCR cell line which overexpressed the MDR1 gene was cross-resistant to doxorubicin or CPT-11, but was only weakly resistant to etoposide or cisplatin. The acquisition of vincristine resistance in KK47/ADM cells might be specifically correlated with P-gp overexpression rather than with MRP expression, as seen in T24/VCR cells. By contrast, drug resistance to etoposide in KK47/ADM and T24/ADM-1

Figure 6 Western blot analysis for MRP (a) and P-gp protein (b). The membrane vesicles were prepared as described in Materials and methods. Twenty micrograms of the membrane vesicles was loaded in each lane. Molecular weight markers as indicated by the arrows are in kilodaltons.
or T24 ADM-2 cells might be more closely related to \textit{MRP} overexpression. The cross-resistance to vincristine at low levels (1.2- to 1.9-fold higher) might be also correlated with the \textit{MRP} gene in T24 ADM-1 and T24 ADM-2 cells which overproduced only multidrug resistance-associated protein. Grant et al. (1993) have demonstrated that the transfectants of a full-length \textit{MRP} cDNA plasmid displayed increased resistance to doxorubicin, vincristine and etoposide and increased expression of the 190 kDa MRP. Furthermore, Kruh et al. (1994) have reported the application of a novel approach involving expression complementary DNA library transfer to the identification of drug resistance genes. Using this approach, they establish that \textit{MRP} is capable of conferring a multidrug-resistant phenotype. Although the precise function of this new ABC family protein, \textit{MRP}, is not yet known (Cole et al., 1992; Grant et al., 1994), \textit{MRP} might play some role in intranuclear accumulation of doxorubicin or of etoposide.

Cancer cell lines resistant to DNA topoisomerase I or II targetng agents such as etoposide or CPT-11 often have decreased topoisomerase I or II levels (Takano et al., 1992). Furthermore, in non-P-gp-mediated multidrug-resistant cell lines from various human tumours, a decreased expression of the topoisomerase II gene has been observed with a concomitant enhancement of \textit{MRP} gene expression (Cole et al., 1992; Slovak et al., 1993; Zaman et al., 1993; Schneider et al., 1994). \textit{MRP} gene amplification and decreased topoisomerase II gene expression are also concomitantly observed in non-P-gp-mediated multidrug-resistant cell lines selected in human prostatic cancer cells (M Nakagawa, Y Tasaki, H Tanimura, K Kohno and M Kuwano, unpublished data). Consistent with these findings, our non-P-gp-mediated multidrug-resistant bladder cancer cell lines, KK47/ADM, T24/ADM-1 and T24 ADM-2, also had a higher expression of the \textit{MRP} gene and reduced expression of the topoisomerase II gene. In most non-P-gp-mediated multidrug-resistant cell lines associated with \textit{MRP} gene overexpression, decreased DNA topoisomerase II gene expression might be a prerequisite for the enhancement of \textit{MRP} gene expression. However, \textit{MRP} transfectants have unchanged levels of topoisomerase IIs and topoisomerase II mRNA (Grant et al., 1994).

The enhanced expression of \textit{MRP} mRNA in most resistant cell lines which are selected in vitro is often due to amplification of the\textit{MRP} gene (Cole et al., 1992; Slovak et al., 1993; Zaman et al., 1993). On the other hand, Abe et al. (1994) recently reported that expression of the \textit{MRP} gene is enhanced in some human gloma cells which show spontaneous multidrug resistance to vincristine, doxorubicin and etoposide, and also that the higher \textit{MRP} mRNA levels are due not to gene amplification, but to transcriptional or post-transcriptional events. Consistent with these glioma cell lines, the increased \textit{MRP} mRNA levels in KK47/ADM bladder cell lines appear also to be due to transcriptional or post-transcriptional activation, rather than to gene amplification. By contrast, amplification of the \textit{MRP} gene is probably the main mechanism underlying increased \textit{MRP} mRNA levels in both T24 ADM-1 and T24 ADM-2 cells.

The accumulation of vincristine is often decreased in cancer cell lines overexpressing P-gp or the \textit{MDR1} gene, and is consistent with the findings of our previous study (Nakagawa et al., 1986; Shiraiishi et al., 1987; Kohno et al., 1988). A decreased accumulation of etoposide was observed in bladder cancer cell lines overexpressing the \textit{MRP} gene or its product. Doxorubicin in the nuclei of T24 ADM-2 cells was almost completely removed after incubation for 120 min in the absence of drug, but this was not the case in the parental T24 cells. For the most part, decreased accumulation of etoposide or doxorubicin is observed in non-P-gp-mediated drug-resistant cell lines which overexpress \textit{MRP} (Zaman et al., 1973; Krishnamachary et al., 1993; Schneider et al., 1994). Consistent with previous reports (Cole et al., 1991; Schneider et al., 1994), \textit{MRP} might be somehow involved in translocation of the anti-cancer drug from nuclei into the cytoplasm rather than outward transport from cytoplasm. Marquardt and Center (1992) have demonstrated that doxorubicin is localised at perinuclear regions when the drug is removed from culture medium for non-P-gp-mediated multidrug-resistant leukaemia cells overexpressing \textit{MRP}. Further study is required to determine how \textit{MRP} modulates the intracellular localisation of doxorubicin or etoposide.

In our present study, the enhanced expression of the \textit{MRP} gene, the reduced expression of the topoisomerase II and the decreased drug accumulation were all concomitantly observed in non-P-gp-mediated drug-resistant human bladder cells. Further study will determine whether \textit{MRP} gene overexpression is obligatorily coupled to low topoisomerase II mRNA levels, as well as to decreased drug accumulation in human bladder cancer cells.
