Orofacial clefts are among the most common birth defects in humans worldwide. A large-scale, genome-wide association study (GWAS) in the Chinese population recently identified several genetic risk variants for nonsyndromic cleft lip with or without cleft palate (NSCL/P). We selected 16 significant SNPs from the GWAS I stage (P < 1.00E-5) that had not been replicated to validate their association with NSCL/P in 1931 NSCL/P cases and 2258 controls. Ultimately, we identified a NSCL/P susceptibility locus (rs17095681 at 10q25.3, intron of SHTN1 and 27.2 kb downstream of VAX1, \( P_{\text{meta}} = 3.80\times10^{-9} \), OR = 0.64) in Chinese Han and Hui populations. This locus was not high LD with the reported loci in 10q25.3. It was a newly identified independent locus in 10q25.3 associated with NSCL/P. These results imply that SHTIN1 may involve in the pathogenesis of NSCL/P advance our understanding of the genetic susceptibility to NSCL/P.

Nonsyndromic cleft lip with or without cleft palate (NSCL/P) is one of the most common birth defects with heterogeneous etiologies, including both genetic and environmental factors and their joint effects. Linkage and association analyses have identified a number of candidate genes and chromosomal loci that may be associated with the risk for NSCL/P. However, mutations and/or polymorphisms in these genes can only explain a small fraction of the genetic contribution to the pathogenesis of this structural abnormality due to genetic heterogeneity and gene-environment interactions. The only gene with a confirmed role in CL/P etiology across multiple populations is IRF6. The protein encoded by IRF6 is a key determinant of the keratinocyte proliferation-differentiation...

**Results**

**Validation results.** Sixteen SNPs were selected for validation based on a stepwise series of criteria (see Methods), none of which were in high LD with each other. We then performed the validation of these 16 SNPs in 1668 Chinese Han cases and 1924 Chinese Han controls from multiple hospitals in China. Three SNPs showed evidence of association with NSCL/P ($P_{\text{meta}} < 0.05$, Supplementary Table S1), but the association direction of two of these SNPs was not in concordance with the GWAS stage. One SNPs, rs17095681 at 10q25.3 ($P_{\text{meta}} = 8.50E-5$, OR = 0.70) displayed consistent association with NSCL/P, and the significant direction was in concordance with the GWAS stage (Table S1). We then validated rs17095681 in Chinese Hui population, which is a minority of China, including 263 case and 334 control from General Hospital of Ningxia Medical University. The validation result was close to significance ($P = 6.42E-2$) and the association direction was in concordance with the GWAS stage (OR = 0.64). The Meta analysis P-values of Han and Hui population validations was 1.50E-5 (Table S1). In the combined analysis of GWAS and validation stages, rs17095681 showed strong evidence of association ($P_{\text{meta}} = 3.80E-9$, OR = 0.64), which reached the genome-wide significance level among the Chinese Han and Hui samples ($P_{\text{meta}} < 5.00E-8$, Table S1). Another reported significant locus in 10q25.3, rs7078160, was also validated in these validation samples. To test the independence of these two SNPs, We fix one SNP as conditional factor and analysis the association between the other SNP and NSCL/P. The conditional analysis results indicated that the effect of rs17095681 was not correlated with rs7078160 ($P = 9.85E-6$) in validation stage (Table S2). The LD analysis indicated that rs17095681 was not linkage with rs7078160 in four validation cohort ($r^2 < 0.1$, Supplementary Table S3). These results indicated that rs17095681 may be an independent locus associated with NSCL/P at 10q25.3 in Chinese Han and Hui populations.

**Analysis of different genetic models.** For the significant SNP rs17095681, we used other genetic models, the additive model, allelic model and genotypic model for further analysis. We observed that this locus significant under the dominant model achieved similar results under the additive model ($P_{\text{meta}} = 8.96E-5$), allelic model ($P_{\text{meta}} = 2.56E-5$) and genotypic model ($P_{\text{meta}} = 9.85E-6$) in validation stage (Table 2). In the combined analysis of the two stages, this locus achieved similar results with dominant model under the genotypic (het) model ($P_{\text{meta}} = 3.40E-9$). It also achieved near genome-wide significance in additive ($P_{\text{meta}} = 6.50E-8$) and allelic model ($P_{\text{meta}} = 5.65E-8$). In Summary, the SNP rs17095681 was associated with NSCL/P significantly in additive model, allelic model and genotypic model.
In this validation study of NSCL/P, we identified one SNP at 10q25.3, rs17095681, which were significantly associated with NSCL/P risk in Chinese Han and Hui populations. It reached the genome-wide significance threshold ($P_{\text{meta}} = 3.40 \times 10^{-9}$) in the combined analysis. The SNP rs17095681 is located in the intron of SHTN1 (also known as KIAA15598) and 27.2 kb downstream of VAX1 (ventral anterior homeobox 1, Fig. 1). It has been reported that four SNPs with $P_{\text{GWA}} < E^{-4}$ are located in a 30-kb region that is 50 kb downstream of VAX1. The SNP rs17095681 is not in high LD ($r^2 > 0.8$) with these SNPs. Rs7078160 has been successfully validated in a Chinese population. The SNPs rs17095681 and rs7078160 are 33 kb apart from each other, but the effect of rs17095681 is not correlated with rs7078160, indicating that rs17095681 is in an independent block associated with NSCL/P.

**SHTN1** code a linker molecule shootin 1 that couples F-actin retrograde flow and the cell adhesion molecule (CAM) L1-CAM at neuronal growth cones to promote neuronal polarization and axon outgrowth. The attractive axon guidance molecule netrin-1 induces Pak1-mediated shootin1 phosphorylation in axonal growth cones which in turn enhances the coupling between F-actins and shootin1, thereby promoting the traction.

**Figure 1. Regional plots of the susceptibility locus rs17095681.** Regional plots of newly discovered locus rs17095681 associated with the risk for NSCL/P in a Chinese population in the GWAS discovery stage. The results ($-\log_{10} P$, $P$-value of GWAS) are shown for SNPs in the region 400 kb upstream or downstream of the marker SNP. The marker SNP is shown as a purple diamond in the GWAS stage and as a purple circle in the combined stage. The LD values ($r^2$) between the SNPs and the most strongly associated SNP (diamond), rs17095681 are indicated by the heat scale. The genes within the region of interest are annotated, and the directions of transcripts are shown in arrows.

**Discussion**

In this validation study of NSCL/P, we identified one SNP at 10q25.3, rs17095681, which were significantly associated with NSCL/P risk in Chinese Han and Hui populations. It reached the genome-wide significance threshold ($P_{\text{meta}} = 3.40 \times 10^{-9}$) in the combined analysis. The SNP rs17095681 is located in the intron of SHTN1 (also known as KIAA15598) and 27.2 kb downstream of VAX1 (ventral anterior homeobox 1, Fig. 1). It has been reported that four SNPs with $P_{\text{GWA}} < E^{-4}$ are located in a 30-kb region that is 50 kb downstream of VAX1. The SNP rs17095681 is not in high LD ($r^2 > 0.8$) with these SNPs. Rs7078160 has been successfully validated in a Chinese population. The SNPs rs17095681 and rs7078160 are 33 kb apart from each other, but the effect of rs17095681 is not correlated with rs7078160 (Supplementary Table S2), indicating that rs17095681 is in an independent block associated with NSCL/P.

SHTN1 code a linker molecule shootin 1 that couples F-actin retrograde flow and the cell adhesion molecule (CAM) L1-CAM at neuronal growth cones to promote neuronal polarization and axon outgrowth. The attractive axon guidance molecule netrin-1 induces Pak1-mediated shootin1 phosphorylation in axonal growth cones which in turn enhances the coupling between F-actins and shootin1, thereby promoting the traction.
forces for axon outgrowth. It has been reported that netrin-1 gene NTN1 is associated with NSCL/P\(^{10,11,17}\). NTN1 encodes the protein NETRIN 1, which plays a role in the developing nervous system by promoting both axonal outgrowth and axonal guidance in pathfinding\(^{18–21}\). In addition, NTN1 was up regulated in dental pulp stem cell cultures from NSCL/P patients\(^{11}\). This information suggested that SHTIN1 and NTN1 play important roles in the development of NSCL/P.

The other gene near SNP rs17095681, VAX1 was also been reported associated with NSCL/P. Mice with homozygous Vax1 mutations display craniofacial malformations including cleft palate\(^{22}\). Two individuals with a 10q terminal deletion syndrome with breakpoints in 10q25 have been reported, one with a submucous cleft palate\(^{23}\) and the other with a cleft lip\(^{24}\).

In summary, in this validation of a NSCL/P GWAS in Chinese populations, we identified a susceptibility locus at 10q25.3 that reached genome-wide significance. The rs1709568 SNP at 10q25.3 is located in an independent block and therefore is not related to any previously reported associated loci. Genes near this locus participate in the processes of neuronal axon outgrowth and cell migration. It is known that cell migration are crucial for oral-facial development. Further studies with larger sample sizes are warranted to replicate our findings. Fine mapping around this locus and related functional studies should also be performed to elucidate the molecular mechanisms underlying the observed associations.

**Methods**

**Study populations.** We performed the validation study using samples from four regions in China, including 1931 NSCL/P cases and 2258 controls. A summary of all cases and controls in the study is provided in Table 3. All of the samples were unrelated individuals of Chinese descent, obtained from Guangdong Maternal and Child Health Care Hospital (validation a, 497 Chinese Han cases and 497 Chinese Han controls for validation), Western China Hospital of Stomatology Sichuan University (validation b, 480 Chinese Han cases and 482 Chinese Han controls, independent with GWAS samples), the Institute of Stomatology, Nanjing Medical University (validation c, 446 Chinese Han cases, 522 Chinese Han controls, independent with GWAS samples), and General Hospital of Ningxia Medical University (validation d, 245 Chinese Han cases, 423 Chinese Han controls; validation e, 263 Chinese Hui cases and 334 Chinese Hui control). All cases were recruited in local hospitals and independently confirmed as NSCL/P by two gynecologic pathologists during routine diagnosis. Syndromic cleft lip or palate patients and cleft palate-only patients were excluded. Controls were recruited in local hospitals for individuals receiving routine physical examinations or healthy newborns whose parents volunteered to donate their umbilical cord blood. All controls were clinically assessed to be without cleft lip or palate or family history of cleft lip or cleft palate (including first, second, and third degree relatives). The cases and controls were frequency-matched for age and gender. At recruitment, informed consent was obtained from each subject. This study was approved by the ethics committees of Guangdong Maternal and Child Health Care Hospital, Western China Hospital of Stomatology Sichuan University, the Institute of Stomatology, Nanjing Medical University and General Hospital of Ningxia Medical University and the methods were carried out in accordance with the approved guidelines.

**SNP selection and genotyping.** SNPs for the replication stage were selected using the following criteria: (i) SNPs with \(P < 1.00E-5\) in the first GWAS study but were not significant or imputed successfully in the second GWAS study; (ii) only the SNP with the lowest \(P\)-value was selected when multiple SNPs were observed but in strong linkage disequilibrium (LD) (\(r^2 > 0.8\)); (iii) primers could be successfully designed using Sequenom primer design software; and (iv) SNPs had not previously been validated. A total of 16 SNPs that matched these criteria were included in the replication stage. Genotyping of replicates was conducted by the Sequenom MassARRAY system at Beijing CapitalBio Technology Company, Beijing, China.

**Quality control at the replication stage.** We excluded SNPs with a call rate < 90% or a deviation from Hardy-Weinberg equilibrium \((P < 0.05)\) in the controls. All 16 SNPs exceed quality control and were used for further analysis.

**Association analysis in the replication and combined stage.** For the replication studies, associations between SNP genotypes and disease status were assessed in a dominant model in PLINK v1.07 (http://pngu.mgh.harvard.edu/Bpurcell/plink/) using logistic regression modeling with gender as a covariate. Joint analyses of all combined samples at the validation stage and GWAS stage were conducted by using either the random effects model \((I^2 > 25\%)\) or by using the fixed-effect model \((I^2 < 25\%)\). Another genetic model (the additive, allelic and genotypic model) was also calculated for the associated SNPs. The chromosome regions of significant loci were plotted using an online tool, LocusZoom 1.1 (http://csg.sph.umich.edu/locuszoom/).

**Table 3. Sample characteristics of cases with NSCL/P and controls.**
