This work was supported in part by the Hebei Provinical Natural Science Foundation under Grant E2020203027 and Grant E2021203019, in part by the Central Government Guiding Local Science and Technology Development Fund Project of Hebei Province under Grant 206Z7602G, and in part by the Youth Foundation of Science and Technology of Higher Education of Hebei Province under Grant QN2020230.

ABSTRACT A novel 3-degrees of freedom (DOF) $RPU + UPU + SPU$ parallel manipulator (PM) is proposed in this study, and its complete kinematics and stiffness are studied systematically. First, the architecture description is discussed, and the inverse and the forward positional posture analysis are studied based on the constraints in the PM. Second, the Jacobian matrix, the velocity model, the Hessian matrix and the acceleration model are derived in explicit and compact forms. Third, based on the virtual work principle, the static model and the deformation decompose method, the stiffness model is built. Meanwhile, the stiffness matrix and the compliance matrix are obtained. Finally, the correctness of the models built in this study are verified by simulative PMs. This study is expected to provide new ideas for the design of PM machine tools.

INDEX TERMS 3-DOF parallel manipulator, complete kinematic analysis, stiffness modeling.

I. INTRODUCTION As an essential branch of limited-DOF PMs, 3-DOF PMs have attracted much attention due to their excellent merits, such as simplicity in structure, low cost of manufacturing and easy control [1]. According to these characteristics, 3-DOF PMs are widely used in the field of machine tool. In this field, one of the famous inventions is a 3PRS PM [2], which is the primary mechanism of Sprint Z3. In addition, Neumann proposed a 3UPS+UP PM (Tricept) [3], which owns high dynamics, stiffness and ample workspace. Then, the inventor presented the concept of a 2UPR+SPR PM (Exechon) [4], which can be applied to fill in the gap between the traditional machine tools and the industrial robots.

In recent years, the design and analysis of 3-DOF PMs are still a hot topic in academia. By integrating one active $UPU$ leg into a passive one, Huang et al. [5] designed a modified Tricept robot-TriVariant. Li et al. [6] presented an A3 head applied to manufacturing large structural components. Wang et al. [7] proposed a 3PUU PM possessing good motion/force transmissibility and orientation capability, and studied its optimal design [8]. Sun synthesized some 3-DOF PMs [9], and presented a simple and highly visual approach for type synthesis of 3-DOF over-constraint PMs [10]. Lu et al. [11] innovated some 3-DOF PMs with planar sub-chains using the revised digital topological graphs and arrays. Gallardo and Rodriguez [12] proposed a 3-DOF 3RPRRC+RRPRU robot. Jing et al. [13] designed a redundant collaborative manipulator containing a class of 3-DOF PM heads with high rotational capability. Hu et al. [14] studied the kinematic characteristics of a 3-DOF 3UPU+UP PM with coupling parallel platforms. Yang et al. [15] discussed the kinematics of a 3-DOF 3PPS PM. Here and throughout, $R$, $P$, $U$ and $S$ denotes a revolute joint, a prismatic joint, a universal joint and a sphere joint, respectively.

However, existing 3-DOF PMs are not enough to satisfy the continuous innovation demands of the machine tools. Especially in recent years, the demands for irregular shape components in the aerospace field are increased, the stiffness requirements of each direction are inconsistent during processing. Therefore, the demands for innovative design of asymmetric 3-DOF PMs are increased significantly. In addition, existing asymmetric 3-DOF PMs virtually all contain over-constraint wrenches, which have high requirements for manufacture and assembly. Once the manufacture and assembly are slightly careless, it will seriously affect the accuracy of the machine tools. Compared with over-constraint PMs, non-over-constraint PMs have a simple structure and lower...
requirements in manufacture and assembly, which can better adapt to different working requirements and realize specific requirements. However, so far there are few reports for asymmetric non-over-constraint 3-DOF PMs, which provide motivations for this study.

Stiffness refer to the ability to resist elastic deformations, which is one of the PM’s most important performance parameters and a core factor that must be considered in the machine tool design. Many scientists commit to studying the stiffness of PM. Gosselin [16] established the stiffness model of PMs considering the active factors. Huang et al. [17] studied the stiffness of a tripod-based PM containing the rigidity of the machine frame. Liu et al. [18] conducted an optimum design of a 3-DOF spherical PM concerning the conditioning and stiffness indices. Zhang and Gosselin [19] and Zhang [20] built the kinetostatic and stiffness model for some 3, 4 and 5-DOF PMs. Han et al. [21] analyzed the stiffness of a 4-DOF PM basing on the screw theory. Merlet [22], a famous French mechanism scholar, pointed out that: for lack of considering the role of constraints, many mechanism analysis problems may exist faultiness. For example, constrained forces/torques are bound to cause deformations of the leg and then significantly affect the stiffness of PMs. Therefore, they must be considered when stiffness modeling. Unfortunately, the previously mentioned researches have ignored.

In recent years, the influences of constraints on the force and stiffness of limited-DOF PMs is gratifying caused extensive concerns. Wojtyra [23] used the singular value decomposition and QR decomposition methods to solve the joint constraint reaction forces of over-constraint PMs. Utilizing the instantaneous screw theory, Lian et al. [24] formulated the stiffness model of a 5-DOF PM considering the gravitational effects. Sun et al. [25] established the semi-analytic stiffness model of a hybrid manipulator as a friction stir welding robot composed of a 3-DOF PM module and a 2-DOF rotating head. Hu and Huang [26] proposed the constraints and deformations decomposition matching method for solving the force and stiffness problems of limited-DOF PMs. Liu et al. [27] established the static and stiffness models of over-constraint PMs by combining the weighted Moore-Penrose inverse. Li et al. [28] studied the analytic solution of the elastic stiffness model for limited-DOF PMs using the geometric algebra and strain energy methods. Cao and Ding [29] solved the joint reaction forces of an over-constraint PM with flexible joints. Considering both constrained wrenches and active wrenches, Li and Xu [30] presented the stiffness characteristics of a 3-DOF 3-PUU translational PM; Chen et al. [31] systematically studied the stiffness of a 6-DOF 3CPS PM; Shan and Hen [32] investigated the stiffness of a 2(3PUS+S) PM with two moving platforms. Each of the above method has its own merits, which lays solid foundations for this study.

For these reasons, this study proposes a novel asymmetric non-over-constraint 3-DOF RPU+UPU+SPU PM, the complete kinematics and stiffness analysis of this novel PM are carried out, and is expected to provide new ideas for the design of PM machine tools. Since this novel PM has three different types of legs, and each leg contains different constraints, the researches of the complete kinematic analysis and stiffness analysis are still challenging works.

The remainder of this study is organized as below. In section II, the architecture description of the proposed PM is given, then the constraints analysis is performed. In section III, the complete positional posture analysis is discussed, then the velocity and acceleration kinematics analysis are studied. In section IV, the stiffness model is established. In section V, numerical examples are given to verify the correctness of the analytic models established in this study. Finally, conclusions are drawn.

II. DESCRIPTION OF THE RPU+UPU+SPU PM

A. MECHANISM ARCHITECTURE

The proposed PM includes a moving platform m, a base platform B and three legs \( r_1(i = 1, 2, 3) \), as shown in FIGURE 1. The architectures of \( m \) and \( B \) are equilateral triangles. Each \( r_1(i = 1, 2, 3) \) has one active \( P \) joint. Each \( U \) joint is composed of two perpendicularly intersecting \( R \) joints.

In \( r_1 \), the bottom of the \( P \) joint is attached to \( B \) by a \( R \) joint whose axis is in the plane of \( B \) and perpendicular to one side of \( B \). The other end of the \( P \) joint is fixed to \( m \) with a \( U \) joint. In this \( U \) joint, one \( R \) joint is parallel with the \( R \) joint in the plane of \( B \), the remaining one \( R \) joint is perpendicular to \( m \).

In \( r_2 \), the bottom of the \( P \) joint is attached to \( B \) by a \( U \) joint. In this \( U \) joint, one \( R \) joint is perpendicular to \( B \), the remaining one \( R \) joint is vertical to \( r_2 \). The other end of the \( P \) joint is fixed to \( m \) with a \( U \) joint. In this \( U \) joint, one \( R \) joint is parallel with the \( R \) joint that is perpendicular to \( r_2 \), the remaining one \( R \) joint is in the plane of \( m \) and perpendicular to one side of \( m \).

In \( r_3 \), the bottom of the \( P \) joint is attached to \( B \) by a \( S \) joint. The other end of the \( P \) joint is fixed to \( m \) with a \( U \) joint.

![FIGURE 1. A novel RPU+UPU+SPU PM.](image-url)
The mechanism under study is a 3-DOF PM, as can be calculated by the revised Kutzbach-Grübler equation [1]:

\[ M = 6(n - g - 1) + \sum_{i=1}^{g} m_i - m_0 \]  

(1)

where \( M \) is the DOF number of the PM, \( n \) is the number of links in the PM, \( g \) is the number of joints, \( m_i \) is the DOF number of the \( i \)-th joint and \( m_0 \) is the passive DOF. For the proposed PM, there are one 5 joint, four \( U \) joints, one \( R \) joint and three \( P \) joints, \( n = 8 \) and \( g = 9 \). Application of (1), it leads to:

\[ M = 6 \times (8 - 9 - 1) + (3 \times 1 + 2 \times 4 + 1 \times 4) - 0 = 3 \]

(2)

**B. FRAMES OF REFERENCE, CONSTRAINT JUDGMENT AND VECTOR REPRESENTATION**

To simplify expression, \( B_1, B_2 \) and \( B_3 \) are named as the vertices of \( B \). Denote \( O-XYZ \) be the inertial frame. \( O \) is the center of \( B \). \( X \) is parallel with \( B_1 B_3 \). \( Y \) also lies in the plane of \( B \) while \( Z \) is normal to \( B \) and points upward, thereby forming a right-handed orthogonal frame. \( A_1, A_2 \) and \( A_3 \) are named as the vertices of \( m \). Denote \( O' - X'Y'Z' \) be the moving frame. \( O' \) is the center of \( m \). \( X' \) is parallel with \( A_1 A_3 \). \( Y' \) also lies in the plane of \( m \) while \( Z' \) is normal to \( m \) and points upward, thereby forming a right-handed orthogonal frame. As shown in FIGURE 2.

Let \( R_{ij} \) be the \( j \)-th \( R \) joint from \( B \) to \( m \) in \( r_i(i = 1, 2) \). Based on the mechanism architecture, following relationships can be written:

\[ R_{11} \parallel Y, R_{11} \perp r_1, R_{12} \parallel R_{11}, R_{13} \parallel R_{12}, R_{13} \parallel Z' \]

\[ R_{21} \parallel Z, R_{22} \perp R_{21}, R_{22} \perp r_2, R_{23} \parallel R_{22}, R_{24} \perp R_{23}, R_{24} \parallel Y' \]

(3)

where \( \parallel \) and \( \perp \) denotes parallel and perpendicular constraints, respectively.

Because of the above relationships, there are constrained wrenches in the proposed PM, which can be determined by the geometrical rules [33], [34]:

(a) In each leg, the constrained forces should be perpendicular to all \( P \) joints and coplanar with all \( R \) joints.

(b) In each leg, the constrained torques should be perpendicular to all \( R \) joints. Utilizing the rules (a) and (b), the constrained forces/torques in this PM can be determined. In \( r_1 \), there exists one constrained force \( F_{p1} \) which is parallel with \( R_{12} \) and \( R_{11} \), and one constrained torque \( T_i \) which is perpendicular to \( R_{12} \) and \( R_{13} \) as well as passes through \( A_1 \). In \( r_2 \), there exists one constrained force \( F_{p2} \) which is parallel with \( R_{23} \) and \( R_{22} \) as well as passes through a point \( C \). Where \( C \) is an intersection point of \( R_{21} \) and \( R_{24} \). As shown in FIGURE 2.

To simplify expression, denote \( d_1 \) be the unit vector of \( r_i \), \( e_i \) be the vector from \( O' \) to \( A_i, F_{pi} = T_i \) be the value of \( F_{pi} / T_i \), \( f_i / r_1 \) be the unit vector of \( F_{pi} / T_i, d_i \) be the vector from \( O' \) to an arbitrary point on \( F_{pi} \). As shown in FIGURE 2.

**III. KINEMATIC ANALYSIS OF THE RPU+UPU+SPU PM**

**A. COMPLETE POSITIONAL POSTURE MODEL**

In limited-DOF PMs, there exists coupling relationships between the 6-dimensional positional posture of the moving platform, which need to be analyzed first before the kinematic modeling. Denote \( R_{ij}, X, Y, Z, X', Y' \) and \( Z' \) be the unit vector of \( R_{ij}, X, Y, Z, X', Y' \) and \( Z' \) in \{O-XYZ\}, respectively. Based on (3), it leads to:

\[ R_{11} = Y, R_{11} \cdot B_1 A_1 = 0, \]

\[ R_{12} = R_{11} \cdot R_{12} = 0 \]

\[ R_{13} = Z' R_{21} = Z = [0 0 1]^T, R_{22} \cdot R_{21} = 0, \]

\[ R_{23} = R_{22} \cdot R_{24} = 0, R_{24} = Y' \]

(4)

Let \( A_i \) and \( B_i \) (\( i = 1, 2, 3 \) be the vector of \( A_i \) and \( B_i \) in \{O-XYZ\}. And denote \( m A_i (i = 1, 2, 3 \) be the vector of \( A_i \) in \{(O’ X’ Y’ Z’)\}. Based on the mechanism architecture, \( B_i \) and \( m A_i \) can be expressed as below:

\[ B_1 = \frac{1}{2} \begin{bmatrix} \sqrt{3} E \ 0 \ -E \ 0 \ 0 \ 0 \ 0 \ 1 \end{bmatrix}, \]

\[ B_2 = \begin{bmatrix} 0 \ 0 \ 0 \ 0 \ E \ 0 \ 0 \ 0 \end{bmatrix}, \]

\[ B_3 = -\frac{1}{2} \begin{bmatrix} \sqrt{3} E \ 0 \ 0 \ 0 \ 0 \ E \ 0 \ 0 \ 0 \end{bmatrix} \]

(5)

\[ m A_1 = \frac{1}{2} \begin{bmatrix} \sqrt{3} e \ -e \ 0 \ 0 \ e \ 0 \ 0 \ 0 \end{bmatrix}, \]

\[ m A_2 = \begin{bmatrix} 0 \ 0 \ 0 \ 0 \ e \ 0 \ 0 \ 0 \ 0 \end{bmatrix}, \]

\[ m A_3 = -\frac{1}{2} \begin{bmatrix} \sqrt{3} e \ 0 \ 0 \ 0 \ 0 \ e \ 0 \ 0 \ 0 \ 0 \end{bmatrix} \]

where \( E \) is the distance from \( O \) to \( B_1 \) and \( e \) is the distance from \( O' \) to \( A_1 \). Let \( m R \) be the rotational transformation matrix from \{O-XYZ\} to \{(O’ X’ Y’ Z’)\} and \( O' \) be the vectors of \( O' \) in \{O-XYZ\}. Then, \( A_i (i = 1, 2, 3 \) can be expressed as below:

\[ A_i = m B R m A_i + O', \]

\[ m B R = \begin{bmatrix} x_1 & y_1 & z_1 & x_m \ y_m & z_m \ x_n \ y_n \ z_n \end{bmatrix} \]
\[ O' = \begin{bmatrix} X_o \\ Y_o \\ Z_o \end{bmatrix} \tag{6} \]

From (4), (5) and (6), the positional posture coupling relationships of \( m \) for the proposed PM can be obtained.

\[
\begin{align*}
\quad z_m &= 0 \\
Y_o &= \frac{1}{2} \left( -E - \sqrt{3} e_{xm} + e_{ym} \right) \\
X_o &= \frac{y_i}{y_m} (Y_o - E)
\end{align*} \tag{7}
\]

Furthermore, set \( m_B R \) be formed by YXZ-type Euler rotations with \( \alpha \), \( \beta \) and \( \lambda \) as three Euler angles. Combined with (7), \( m_B R \) can be specific expressed as below:

\[
m_B R = \begin{bmatrix}
c_a c_\lambda & -c_a s_\lambda & s_a \\
c_s & c_\lambda & 0 \\
-s_a c_\lambda & s_a s_\lambda & c_\lambda
\end{bmatrix} \tag{8}
\]

where \( s_\theta \) denotes \( \sin(\theta) \) and \( c_\theta \) denotes \( \cos(\theta) \) with \( \theta \) is \( \alpha \) or \( \lambda \), then (7) can be simplified as below:

\[
\begin{align*}
\quad \beta &= 0 \\
Y_o &= \frac{1}{2} \left( -E - \sqrt{3} e_s \right) \\
X_o &= \frac{-c_a s_\lambda}{2c_\lambda} \left( 3E + \sqrt{3} e_s - ec_\lambda \right)
\end{align*} \tag{9}
\]

Equation (9) shows the explicit coupling relationships between the 6-dimensional positional posture of \( m \). According to (9), \( \alpha \), \( \lambda \) and \( Z_o \) can be considered as the independent kinematic parameters of \( m \).

Complete positional posture analysis includes the forward and inverse analysis. When the actuators are set, the positional posture of the moving platform can be determined by the forward model. By contrast, the inverse analysis determines the required actuators variables from a given positional posture of the moving platform.

For the proposed PM, \( r_i \) (\( i = 1, 2, 3 \)) can be derived by the following formulas:

\[
r_1 = |A_1 - B_1| \\
r_2^2 = X_o^2 + Y_o^2 + Z_o^2 + E^2 - e^2 - \sqrt{3} EX_m + EY_o \\
&+ \sqrt{3} e_{(x)X_o} + x_mY_o + x_nZ_o - e_{(y)X_o} + y_mY_o + y_nZ_o \\
&+ \frac{1}{2} E(e_{ym} + Y_o) \\
r_3^2 = X_o^2 + Y_o^2 + Z_o^2 + E^2 + e^2 + 2e_{(y)X_o} + y_mY_o + y_nZ_o \\
&- 2E(e_{ym} + Y_o) \\
r_4^2 = X_o^2 + Y_o^2 + Z_o^2 + E^2 + e^2 + \sqrt{3} EX_m + EY_o \\
&- \sqrt{3} e_{(x)X_o} + x_mY_o + x_nZ_o - e_{(y)X_o} + y_mY_o + y_nZ_o \\
&- \frac{1}{2} E(e_{ym} + Y_o)
\tag{10}
\]

Bring (5), (6), (8) and (9) into (10), it leads to:

\[
r_1^2 = \frac{1}{4c_\lambda^2} \left( 3E c_a s_\lambda - \sqrt{3} E c_\lambda + \sqrt{3} e s_a c_\lambda \right)^2 \\
&+ \frac{1}{4} \left( e s_a s_\lambda - 2Z_0 + \sqrt{3} e s_a c_\lambda \right)^2
\tag{11}
\]

\[
r_2^2 = \left( Z_0 + es_a s_\lambda \right)^2 + \frac{1}{4} \left( 3E - 3e c_\lambda + \sqrt{3} es_a \right)^2 \\
&+ \frac{c_a^2}{4c_\lambda^2} \left( 3E - 3e c_\lambda + \sqrt{3} es_a \right)^2 \\
r_3^2 = \frac{1}{4c_\lambda^2} \left( 3E c_a s_\lambda + \sqrt{3} E c_\lambda + \sqrt{3} es_a - 2\sqrt{3} e c_a s_\lambda \right)^2 \\
&+ \frac{1}{4} \left( 2Z_0 - es_a s_\lambda + \sqrt{3} e s_a c_\lambda \right)^2 + 3e^2 s_\lambda^2
\tag{11}
\]

Equation (11) is the explicit inverse positional posture model of the proposed PM. According to (11), the inverse position solutions can be directly solved by the independent kinematic parameters (\( \alpha \), \( \lambda \) and \( Z_o \)) of \( m \).

Eliminate \( Z_o \) in (10), it leads to:

\[
\begin{align*}
3y_m(r_2^2 - r_1^2 - \sqrt{3} x_m(r_3^2 + r_1^2 - 2r_2^2)) &= 6\sqrt{3} E(y_nX_o - x_nY_o) \\
&- 3\sqrt{3} E(y_1yn + x_myn) - 4\sqrt{3} Eey_{ym} \\
&+ \sqrt{3} Eex_m(3x_l + y_m) \\
&- 6\sqrt{3} Eex_m(x_myn - x_myn) - 6\sqrt{3} Eex_m(x_myn - y_m)n \\
&+ [r_1^2 + r_2^2 + r_3^2 - 3X_o^2 - 3Y_o^2 - 3E^2 - 3e^2 + 2Ee_{ym} \\
&+ E(e_{3x_l} + y_m)]/3 \\
&= [6Ee_{ym} + 4Ee_{ym} - E(e_{3x_l} + y_m) - r_1^2 - 2r_2^2 + 2r_2^2 + 6e_{ym} \\
&- y_1x_o/x_n - y_m y_o/y_m]^2
\end{align*} \tag{12}
\]

Since (12) contains many trigonometric functions, to simplify expression, let \( t_1 = \tan(\alpha/2) \) and \( t_2 = \tan(\gamma/2) \), then \( s_\alpha = 2t_1/(1 + t_1^2) \), \( c_\alpha = (1 - t_1^2)/(1 + t_1^2) \), \( s_\gamma = 2t_2/(1 + t_2^2) \) and \( c_\gamma = (1 - t_2^2)/(1 + t_2^2) \). Combined with (8) and (9), (12) can be simplified as below:

\[
\begin{align*}
&\quad a_1 t_1^2 + a_2 = 0, \tag{13a} \\
&\quad b_1 t_1^6 + b_2 t_1^4 + b_3 t_1^2 + b_4 = 0 \tag{13b}
\end{align*}
\]

where \( a_i(i = 1, 2) \) and \( b_i(i = 1, 2, 3, 4) \) only contain \( t_2 \), which can be easily refined by MATLAB. Multiplying both sides of (13a) by \( t_2^4 \) and \( t_2^4 \), respectively, it leads to:

\[
\begin{align*}
&\quad a_1 t_1^4 + a_2 t_1^2 = 0 \\
&\quad a_1 t_1^6 + a_2 t_1^4 = 0 \tag{14}
\end{align*}
\]

Since (13a), (13b) and (14) form a system of four linearly independent equations with four variables \( t_1 \), \( t_1^2 \), \( t_1^4 \) and \( t_1^6 \), it can be expressed in a matrix form as below:

\[
Q \begin{bmatrix} t_1^6 \\ t_1^4 \\ t_1^2 \\ 1 \end{bmatrix} = 0, \quad Q = \begin{bmatrix} 0 & 0 & a_1 & a_2 \\ 0 & a_1 & a_2 & 0 \\ a_1 & a_2 & 0 & 0 \\ b_1 & b_2 & b_3 & b_4 \end{bmatrix}
\tag{15}
\]

where \( Q \) is a coefficient matrix of the above linear equations about \( t_1 \). Since \( t_1 \) must exist, there must be a nontrivial solution corresponding to (15). Based on the theory of linear algebra, it leads to:

\[
|Q| = 0 \tag{16}
\]

Equation (16) is a nonlinear equation with only regard to \( t_2 \), which can be easily solved by MATLAB. After \( t_2 \) is
solved from (16), \( t_1 \) can be solved from (13a). Then, the independent kinematic parameters \( \alpha \) and \( \gamma \) corresponding to \( t_1 \) and \( t_2 \) can be obtained. Subsequently, the last one independent kinematic parameter \( Z_0 \) can be solved from (11).

Of course, the above forward positional posture model will get multiple solutions. However, combined with the computer-aided design variation geometry method [35], the unique solution can be determined.

**B. INVERSE VELOCITY MODEL**

Denote \( \nu_r \) be the velocity vector of actuators and \( V \) be the velocity vector of \( m \), respectively. For general \( n \)-DOF \((n < 6)\) non-over-constraint PM with linear active leg, \( \nu_r \) can be expressed as below [34]:

\[
\begin{bmatrix}
\nu_r \\
0_{(6-n)\times1}
\end{bmatrix}
= J_{6\times6} V_{6\times1}
\]

\[
J_{6\times6} = \begin{bmatrix}
\varphi \\
\psi
\end{bmatrix},
\]

\[
V_{6\times1} = \begin{bmatrix}
\varphi \\
\psi
\end{bmatrix}.
\]

\[
J_{6\times6} = \begin{bmatrix}
\delta_1^T (e_1 \times \delta_1)^T \\
\delta_2^T (e_2 \times \delta_2)^T \\
\delta_3^T (e_3 \times \delta_3)^T \\
\vdots \\
\delta_n^T (e_n \times \delta_n)^T
\end{bmatrix}_{n\times6}
\]

where \( J \) is the Jacobian matrix which contains two submatrices, one is the traditional \( n \times 6 \) Jacobian matrix of limited-DOF PMs (named \( J_a \)), and the other one is the velocity constraints Jacobian matrix (named \( J_V \)).

For this PM, since \( F_{pl} \) \((i = 1, 2)\) and \( T_1 \) do no work to \( m \), it leads to:

\[
\begin{aligned}
F_{pl} f_1 \cdot \nu + (d_1 \times F_{pl} f_1) \cdot \omega &= 0, d_1 = A_1 - O' \\
F_{pl} f_2 \cdot \nu + (d_2 \times F_{pl} f_2) \cdot \omega &= 0, d_2 = C - O' \\
T_1 \tau_1 \cdot \omega &= 0
\end{aligned}
\]

where \( C \) is the coordinate of \( C \) in \( \{O-XYZ\} \). Since \( C \) is the intersection point of \( R_{21} \) and \( R_{24} \), \( C \) should meet \( R_{21} \) and \( R_{24} \) line equations simultaneously. From (3), the line equation of \( R_{24} \) can be expressed as below:

\[
\frac{x - X_o}{y_l} = \frac{y - y_o}{y_m} = \frac{z - Z_o}{y_n}
\]

Since the point on \( R_{21} \) satisfies: \( x = 0 \) and \( y = E \), substituting \( x = 0 \) and \( y = E \) into (19), \( C \) can be derived.

\[
C = \begin{bmatrix}
0 \\
E \\
Z_o + (E - Y_o) s_\alpha d_\lambda c_\lambda
\end{bmatrix}
\]

Combined (4) with (18), it leads to:

\[
\begin{bmatrix}
\frac{f_1}{f_2} \\
0
\end{bmatrix}
= \begin{bmatrix}
0 \\
1
\end{bmatrix}^T,
\]

\[
\begin{aligned}
\frac{d_1 \times f_1}{d_2 \times f_2} &= \psi \\
\tau_1 &= \frac{R_{12} \times R_{13}}{|R_{12} \times R_{13}|} = R_{12} \times R_{13}
\end{aligned}
\]

Then, combined (17) with (21), the inverse velocity model of the proposed PM is built:

\[
\begin{bmatrix}
\nu_r \\
0_{3\times1}
\end{bmatrix}
= J \begin{bmatrix}
\nu \\
\omega
\end{bmatrix},
\]

\[
J_{6\times6} = \begin{bmatrix}
\delta_1^T (e_1 \times \delta_1)^T & J_1 \\
\delta_2^T (e_2 \times \delta_2)^T & J_2 \\
\delta_3^T (e_3 \times \delta_3)^T & J_3
\end{bmatrix}_{6\times6}
\]

\[
\begin{bmatrix}
v_r \\
v_{r1} \\
v_{r2} \\
v_{r3}
\end{bmatrix}
= \begin{bmatrix}
J_{01} \\
J_{02}
\end{bmatrix}
\]

Since coupling relationships between the 6-dimensional positional posture of the moving platform are existed in limited-DOF PMs, there must exists velocity coupling relationships of the moving platform, which should be added to the inverse velocity model.

The relations between \( V \) and the velocity of independent kinematic parameters \( \theta_{i}(i = 1, \ldots, n) \) for \( n \)-DOF \((n < 6)\) PMs can be expressed as below [34]:

\[
\begin{bmatrix}
\nu_x \\
\nu_y \\
\nu_z \\
\dot{\theta}_1 \\
\dot{\theta}_2 \\
\dot{\theta}_3
\end{bmatrix}
= J_{01} \begin{bmatrix}
\dot{\theta}_1 \\
\dot{\theta}_2 \\
\dot{\theta}_3 \\
\dot{\theta}_n
\end{bmatrix}
\]

\[
J_{01} = \begin{bmatrix}
\frac{\partial X_o}{\partial \theta_1} & \frac{\partial X_o}{\partial \theta_2} & \cdots & \frac{\partial X_o}{\partial \theta_n} \\
\frac{\partial Y_o}{\partial \theta_1} & \frac{\partial Y_o}{\partial \theta_2} & \cdots & \frac{\partial Y_o}{\partial \theta_n} \\
\frac{\partial Z_o}{\partial \theta_1} & \frac{\partial Z_o}{\partial \theta_2} & \cdots & \frac{\partial Z_o}{\partial \theta_n}
\end{bmatrix}
\]

\[
\begin{bmatrix}
\omega_x \\
\omega_y \\
\omega_z
\end{bmatrix}
= J_{02} \begin{bmatrix}
\dot{\theta}_1 \\
\dot{\theta}_2 \\
\dot{\theta}_3 \\
\dot{\theta}_n
\end{bmatrix}
\]

\[
J_{02} = \begin{bmatrix}
\frac{\partial \alpha}{\partial \theta_1} & \frac{\partial \alpha}{\partial \theta_2} & \cdots & \frac{\partial \alpha}{\partial \theta_n} \\
\frac{\partial \beta}{\partial \theta_1} & \frac{\partial \beta}{\partial \theta_2} & \cdots & \frac{\partial \beta}{\partial \theta_n} \\
\frac{\partial \lambda}{\partial \theta_1} & \frac{\partial \lambda}{\partial \theta_2} & \cdots & \frac{\partial \lambda}{\partial \theta_n}
\end{bmatrix}
\]

where \( J_{01} \) and \( J_{02} \) are the linear and angular velocity decoupling Jacobian matrices, respectively.

For this PM, from (8) and (9), it leads to:

\[
\nu = J_{01} \begin{bmatrix}
\dot{\alpha} \\
\dot{\lambda}
\end{bmatrix},
\]

\[
J_{01} = \begin{bmatrix}
\frac{\partial X_o}{\partial \alpha} & \frac{\partial X_o}{\partial \lambda} & \frac{\partial X_o}{\partial \theta_1} \\
\frac{\partial Y_o}{\partial \alpha} & \frac{\partial Y_o}{\partial \lambda} & \frac{\partial Y_o}{\partial \theta_1} \\
\frac{\partial Z_o}{\partial \alpha} & \frac{\partial Z_o}{\partial \lambda} & \frac{\partial Z_o}{\partial \theta_1}
\end{bmatrix}
\]

Likewise, from (8) and (9), it leads to:

\[
\omega = R_o \dot{\alpha} + R_{\beta} \dot{\beta} + R_{\lambda} \dot{\lambda} = \begin{bmatrix}
0 & s_\alpha & 0 \\
1 & 0 & 0 \\
0 & c_\alpha & 0
\end{bmatrix} \begin{bmatrix}
\dot{\alpha} \\
\dot{\lambda}
\end{bmatrix}
\]
where:
\[
R_\alpha = \begin{bmatrix} 0 & s_\alpha & 0 \\ 1 & 0 & 0 \\ 0 & c_\alpha & 0 \end{bmatrix}, \quad R_\beta = \begin{bmatrix} c_\alpha & 0 & s_\alpha \\ 0 & 1 & 0 \\ -s_\alpha & 0 & c_\alpha \end{bmatrix}, \quad R_\lambda = \begin{bmatrix} s_\alpha & 0 & 0 \\ 0 & c_\alpha & 0 \\ 0 & 0 & 1 \end{bmatrix}
\]

Combination of (22), (24) and (25) are the explicit inverse velocity model of the proposed PM. When $\dot{\alpha}$, $\dot{\lambda}$ and $\dot{\theta}_0$ are given, $V$ can be obtained according to (24) and (25). Subsequently, $\tau_r$ can be obtained according to (22).

C. INVERSE ACCELERATION MODEL
Denote $a_r$ be the acceleration vector of actuators and $A$ be the acceleration vector of $m$. Deriving time from both sides of (17), $a_r$ can be expressed as below:
\[
a_r = JA + V^TH_{6\times6}V,
\]
\[
A = \begin{bmatrix} a \\ g \end{bmatrix}, \quad H_{6\times6} = \begin{bmatrix} H_\alpha & H_\nu \\ \end{bmatrix},
\]
\[
a_r = J_a A + V^TH_\alpha V, \quad H_\alpha = \begin{bmatrix} H_H & H_{\alpha 1} \\ H_{\alpha 2} & \vdots \\ \vdots & \vdots \\ H_{\alpha n} \end{bmatrix},
\]
\[
H_{\alpha i} = \begin{bmatrix} \frac{1}{r_i} \left[ 1 - \delta^2_i \right] & \frac{\delta^2_i}{r_i}\delta^2_i & \delta^2_i \\ -\delta^2_i & \delta^2_i & \delta^2_i \\ \delta^2_i & \delta^2_i & \delta^2_i \end{bmatrix}_6, 
\]
\[
\begin{align*}
\sigma &= \begin{bmatrix} \sigma x \\ \sigma y \\ \sigma z \end{bmatrix}, \quad \hat{\sigma} &= \begin{bmatrix} 0 & -\sigma y & \sigma x \\ -\sigma y & 0 & -\sigma z \\ \sigma x & \sigma z & 0 \end{bmatrix}
\end{align*}
\]

where $H$ is the Hessian matrix which contains two sub-matrices, one is the traditional Hessian matrix of limited-DOF PMs (named $H_H$), and the other one is the constraints Hessian matrix (named $H_\alpha$).

In order to solve $H_r$, the derivatives of some vectors in (21) should be derived. For $r_1$:
\[
\dot{\sigma}_1 = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix},
\]
\[
d_1^T = (\dot{\omega} \times d_1)^T = (-\dot{d}_1 \omega)^T = \omega^T d_1^T,
\]
\[
(d_1 \times \dot{f}_1)^T = (d_1 \times f_1 + d_1 \times \dot{f}_1)^T = (\omega \times d_1 \times f_1)^T = (\hat{f}_1 \dot{d}_1 \omega)^T = \omega^T \hat{d}_1^F,
\]
\[
(\hat{r}_1)^T = (R_{12} \times \hat{R}_{13})^T = (\hat{R}_{12} \times R_{13} + R_{12} \times \hat{R}_{13})^T = (R_{12} \times (\omega \times R_{13}))^T = -\omega^T \hat{Z}^T \hat{Y}
\]

Based on the vector algorithm, $H_r$ corresponding to $r_1$ can be expressed as below:
\[
\begin{align*}
\dot{f}_1 = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}, \\
\dot{d}_1 = (\omega \times d_1)^T = (-\dot{d}_1 \omega)^T = \omega^T d_1^\omega. \\
(d_1 \times \dot{f}_1)^T = (d_1 \times f_1 + d_1 \times \dot{f}_1)^T = (\omega \times d_1 \times f_1)^T = (\hat{f}_1 \dot{d}_1 \omega)^T = \omega^T \hat{d}_1^F,
\end{align*}
\]
\[
(\hat{r}_1)^T = (R_{12} \times \hat{R}_{13})^T = (\hat{R}_{12} \times R_{13} + R_{12} \times \hat{R}_{13})^T = (R_{12} \times (\omega \times R_{13}))^T = -\omega^T \hat{Z}^T \hat{Y}
\]

For $r_2$:
\[
\dot{f}_2 = R_{22} = \omega_{22} \times R_{22} = \dot{\theta}_{21} R_{21} \times R_{22} = R_{21} \times R_{22} \dot{\theta}_{21},
\]
\[
(d_2 \times \dot{f}_2)^T = (d_2 \times f_2 + d_2 \times \dot{f}_2)^T = (d_2 \times f_2 + d_2 \times (\dot{\theta}_{21} R_{21} \times R_{22}))^T
\]

In order to get an explicit expression of (29), $\dot{\theta}_{21}$ and $d_2$ need to be solved. Considering $\omega$ is a composite of all $R$ joints in $r_2$, it leads to:
\[
\omega = \dot{\theta}_{21} R_{21} + \dot{\theta}_{22} R_{22} + \dot{\theta}_{23} R_{23} + \dot{\theta}_{24} R_{24}
\]

To eliminate unnecessary parameters, dot multiply both side of (30) by $R_{21}$ and $R_{24}$, respectively, it leads to:
\[
\omega \cdot R_{21} = \dot{\theta}_{21} R_{21} \cdot R_{21} + \dot{\theta}_{22} R_{22} \cdot R_{21} + \dot{\theta}_{23} R_{23} \cdot R_{21} + \dot{\theta}_{24} R_{24} \cdot R_{21}.
\]
\[
\omega \cdot R_{24} = \dot{\theta}_{21} R_{21} \cdot R_{24} + \dot{\theta}_{22} R_{22} \cdot R_{24} + \dot{\theta}_{23} R_{23} \cdot R_{24} + \dot{\theta}_{24} R_{24} \cdot R_{24}
\]

Combined with (3) and (4), (31) can be reduced to the following form. Subsequently, $\dot{\theta}_{21}$ can be obtained:
\[
\omega \cdot Z = \dot{\theta}_{21} + \dot{\theta}_{24} Y' \cdot Z. \quad \omega \cdot Y' = \dot{\theta}_{21} Z \cdot Y' + \dot{\theta}_{24}.
\]
\[
\dot{\theta}_{21} = \frac{[\omega \cdot Z - (Y' \cdot Z) Y']}{\omega \cdot Y'}
\]

In addition, considering $B_2 A_2$, $B_2 C$ and $C A_2$ are a closed-loop, it leads to:
\[
B_2 C + C A_2 = B_2 A_2
\]

Simultaneously derived time from both sides of (33), and let $v_{BZC}$ and $v_{CAZ}$ be the velocity value of $B_2 C$ and $CA_2$, respectively. It leads to:
\[
v_{BZC} R_{21} - v_{CAZ} R_{24} - \omega \cdot C A_2 = v + \omega \times e_2
\]
\[
v_{BZC} R_{21} - v_{CAZ} R_{24} = v + \omega \times (e_2 - C A_2) = v + \omega \times d_2
\]

Meanwhile, $d_2$ can be derived. Combined with (34), it leads to:
\[
\dot{d}_2 = v_{CAZ} R_{24} + \omega \times d_2
\]

Since (35) still contains uncertainties parameters $v_{CAZ}$, dot multiply both sides of (34) by $X$, it leads to:
\[
v_{BZC} R_{21} \cdot X - v_{CAZ} R_{24} \cdot X = v \cdot X + (\omega \times d_2) \cdot X,
\]
\[
v_{BZC} R_{21} \cdot X = v \cdot X + (\omega \times d_2) \cdot X,
\]
\[
\nu_{CA2} = \frac{\nu \cdot X + (\omega \times d_2) \cdot X}{R_{24} \cdot X}
\] (36)

From (32), (35) and (36), (29) can be expressed. Then, based on the vector algorithm, \(H_j\) corresponding to \(r_2\) can be expressed as below (37), as shown at the bottom of the next page.

Combined with (26), (28) and (37), the inverse acceleration model of the proposed PM is established.

It is the same reason that there must exists acceleration coupling relationships of the moving platform, which should be added to the inverse acceleration model. Deriving time from both sides of (23), it leads to:

\[
a = J_{01} \ddot{\theta} + J_{01} \dot{\dot{\theta}} = J_{01} \ddot{\theta} + \dot{\dot{\theta}}^T H_1 \dot{\theta}.
\]

\[
\varepsilon = J_{02} \ddot{\theta} + J_{02} \dot{\dot{\theta}} = J_{02} \ddot{\theta} + \dot{\dot{\theta}}^T H_2 \dot{\theta}.
\]

where:

\[
H_{11} = 
\begin{bmatrix}
\frac{\partial^2 X_o}{\partial \theta_1 \partial \theta_1} & \frac{\partial^2 X_o}{\partial \theta_1 \partial \theta_2} & \cdots & \frac{\partial^2 X_o}{\partial \theta_1 \partial \theta_n} \\
\frac{\partial^2 X_o}{\partial \theta_2 \partial \theta_1} & \frac{\partial^2 X_o}{\partial \theta_2 \partial \theta_2} & \cdots & \frac{\partial^2 X_o}{\partial \theta_2 \partial \theta_n} \\
\vdots & \vdots & \ddots & \vdots \\
\frac{\partial^2 X_o}{\partial \theta_n \partial \theta_1} & \frac{\partial^2 X_o}{\partial \theta_n \partial \theta_2} & \cdots & \frac{\partial^2 X_o}{\partial \theta_n \partial \theta_n}
\end{bmatrix}
\]

\[
H_{12} = 
\begin{bmatrix}
\frac{\partial^2 Y_o}{\partial \theta_1 \partial \theta_1} & \frac{\partial^2 Y_o}{\partial \theta_1 \partial \theta_2} & \cdots & \frac{\partial^2 Y_o}{\partial \theta_1 \partial \theta_n} \\
\frac{\partial^2 Y_o}{\partial \theta_2 \partial \theta_1} & \frac{\partial^2 Y_o}{\partial \theta_2 \partial \theta_2} & \cdots & \frac{\partial^2 Y_o}{\partial \theta_2 \partial \theta_n} \\
\vdots & \vdots & \ddots & \vdots \\
\frac{\partial^2 Y_o}{\partial \theta_n \partial \theta_1} & \frac{\partial^2 Y_o}{\partial \theta_n \partial \theta_2} & \cdots & \frac{\partial^2 Y_o}{\partial \theta_n \partial \theta_n}
\end{bmatrix}
\]

\[
H_{13} = 
\begin{bmatrix}
\frac{\partial^2 Z_o}{\partial \theta_1 \partial \theta_1} & \frac{\partial^2 Z_o}{\partial \theta_1 \partial \theta_2} & \cdots & \frac{\partial^2 Z_o}{\partial \theta_1 \partial \theta_n} \\
\frac{\partial^2 Z_o}{\partial \theta_2 \partial \theta_1} & \frac{\partial^2 Z_o}{\partial \theta_2 \partial \theta_2} & \cdots & \frac{\partial^2 Z_o}{\partial \theta_2 \partial \theta_n} \\
\vdots & \vdots & \ddots & \vdots \\
\frac{\partial^2 Z_o}{\partial \theta_n \partial \theta_1} & \frac{\partial^2 Z_o}{\partial \theta_n \partial \theta_2} & \cdots & \frac{\partial^2 Z_o}{\partial \theta_n \partial \theta_n}
\end{bmatrix}
\]

\[
H_{21} = 
\begin{bmatrix}
\frac{\partial J_{i0}}{\partial \theta_1} & \frac{\partial J_{i0}}{\partial \theta_2} & \cdots & \frac{\partial J_{i0}}{\partial \theta_n} \\
\frac{\partial J_{i0}}{\partial \theta_1} & \frac{\partial J_{i0}}{\partial \theta_2} & \cdots & \frac{\partial J_{i0}}{\partial \theta_n} \\
\vdots & \vdots & \ddots & \vdots \\
\frac{\partial J_{i0}}{\partial \theta_1} & \frac{\partial J_{i0}}{\partial \theta_2} & \cdots & \frac{\partial J_{i0}}{\partial \theta_n}
\end{bmatrix}
\]

\[
H_{22} = 
\begin{bmatrix}
\frac{\partial J_{i2}}{\partial \theta_1} & \frac{\partial J_{i2}}{\partial \theta_2} & \cdots & \frac{\partial J_{i2}}{\partial \theta_n} \\
\frac{\partial J_{i2}}{\partial \theta_1} & \frac{\partial J_{i2}}{\partial \theta_2} & \cdots & \frac{\partial J_{i2}}{\partial \theta_n} \\
\vdots & \vdots & \ddots & \vdots \\
\frac{\partial J_{i2}}{\partial \theta_1} & \frac{\partial J_{i2}}{\partial \theta_2} & \cdots & \frac{\partial J_{i2}}{\partial \theta_n}
\end{bmatrix}
\]

\[
H_{23} = 
\begin{bmatrix}
\frac{\partial J_{i3}}{\partial \theta_1} & \frac{\partial J_{i3}}{\partial \theta_2} & \cdots & \frac{\partial J_{i3}}{\partial \theta_n} \\
\frac{\partial J_{i3}}{\partial \theta_1} & \frac{\partial J_{i3}}{\partial \theta_2} & \cdots & \frac{\partial J_{i3}}{\partial \theta_n} \\
\vdots & \vdots & \ddots & \vdots \\
\frac{\partial J_{i3}}{\partial \theta_1} & \frac{\partial J_{i3}}{\partial \theta_2} & \cdots & \frac{\partial J_{i3}}{\partial \theta_n}
\end{bmatrix}
\]

where, \(H_1\) and \(H_2\) are the linear and angular acceleration decoupling Hessian matrices. \(J_{0i}^{ji}\) denotes the elements in row \(i\) and column \(j\) of \(J_{0i}\).

For this PM, from (9) and (24), it leads to:

\[
a = J_{01i} \ddot{\theta} + J_{01i} \dot{\dot{\theta}} = J_{01i} \ddot{\theta} + \dot{\dot{\theta}}^T H_1 \dot{\theta}.
\]

\[
\varepsilon = J_{02i} \ddot{\theta} + J_{02i} \dot{\dot{\theta}} = J_{02i} \ddot{\theta} + \dot{\dot{\theta}}^T H_2 \dot{\theta}.
\]

Here, \(H_1\) and \(H_2\) can be obtained according to (39) and (40). Subsequently, \(a\) can be obtained according to (26), (28) and (37).

**IV. STIFFNESS ANALYSIS OF THE RPU+UPU+SPU PM**

**A. STATICS ANALYSIS AND CONSTRAINTS DECOMPOSITION**

Utilizing the principle of static equilibrium, the relations between the active forces \((F_a)\) (i = 1, 2, 3), the constrained forces/torque \((F_c/T_c)\) (i = 1, 2) and the loading force/torque \((F/T)\) can be expressed as below:

\[
[F_{a1} \ F_{a2} \ F_{a3} \ F_{p1} \ F_{p2} \ T_1]^T = - \left(J_{i}^{-1}\right)^T [F \ T]^T
\] (41)
FIGURE 3. The constraints decomposition of $r_1$ and $r_2$.

To find the wrenches directly causing deformations, $F_{p2}$ should be decomposed [26]. Based on the principle of force equivalence, $F_{p2}$ can be equivalent to a force $F_1$ which is parallel with $F_{p2}$ as well as passes through $A_2$ and a torque $T_2$ which is perpendicular with $A_2C$ and $F_{p2}$. $F_1$ and $T_2$ can be expressed as below:

\[
F_1 = F_{p2}, \quad T_2 = A_2C \times F_{p2} = (|A_2C| R_{24}) \times (F_{p2} R_{23})
\]

(42)

To find the deformations due to $T_i$, decompose $T_i$ into two elements $(i = 1, 2)$ [26], one is along $r_i$ (named $T_{ip}$), and the other one is perpendicular to $r_i$ (named $T_{iq}$), as shown in FIGURE 3. Let $\tau_2$, $\tau_{ip}$ and $\tau_{iq}$ be the unit vector of $T_2$, $T_{ip}$ and $T_{iq}$, respectively. Based on (4), it leads to:

\[
\begin{align*}
\tau_{1p} &= \delta_1, \quad \tau_{1q} \perp \tau_{1p}, \quad \tau_{1p} \perp R_{12}, \quad \tau_{1q} \perp R_{12}, \\
\tau_{iq} &= \delta_1 \times R_{12} \tau_{2q} \perp R_{23}, \quad \tau_{2q} \perp R_{24}, \\
\tau_{2p} &= \delta_2, \quad \tau_{2q} \perp \tau_{2p}, \quad \tau_{2q} \perp R_{23}, \quad \delta_2 \times R_{23}
\end{align*}
\]

(43)

According to (43), the value of $T_{ip}$ and $T_{iq}$ $(i = 1, 2)$ can be expressed as below:

\[
T_{1p} = s_{1p} T_1, \quad s_{1p} = \tau_1 \cdot \delta_1 \\
T_{1q} = (\tau_1 \cdot \tau_{1q}) T_1 = s_{1q} T_1, \quad s_{1q} = \tau_1 \cdot (\delta_1 \times R_{12}) \\
T_{2p} = T_2 \cdot \tau_{2p} = T_2 \cdot \delta_2 = F_{p2} |A_2C| (R_{24} \times R_{23}) \cdot \delta_2 = s_{2p} F_{p2} \\
T_{2q} = T_2 \cdot \tau_{2q} = T_2 \cdot (\delta_2 \times R_{23}) = s_{2q} F_{p2} \\
s_{1p} = |A_2C| (R_{24} \times R_{23}) \cdot \delta_2 \\
s_{2q} = |A_2C| (R_{24} \times R_{23}) \cdot (\delta_2 \times R_{23})
\]

(44)

where $s_{1p}/s_{1q}$ $(i = 1, 2)$ is a coefficient representing the relationship between the constrained forces/torques and their components.

Though the above analysis, it leads to:

\[
\begin{bmatrix}
F_{a1} \\
F_{a2} \\
F_{a3} \\
F_{p1} \\
F_{p2} \\
F_{p3} \\
T_{1p} \\
T_{1q} \\
T_{2p} \\
T_{2q}
\end{bmatrix} = W_{9 \times 6}
\begin{bmatrix}
F_{a1} \\
F_{a2} \\
F_{a3} \\
F_{p1} \\
F_{p2} \\
F_{p3} \\
T_{1p} \\
T_{1q} \\
T_{2p} \\
T_{2q}
\end{bmatrix}
\]

(45)

where $W$ is a coefficient matrix representing the relationship between the combination of the constrained forces/torques and the active forces and the wrenches directly causing deformations.
B. DEFORMATION ANALYSIS

Suppose that three elastic \( r_i (i = 1, 2, 3) \) elastically suspend \( m \) and all joints are a rigid body. Corresponding to different wrenches, deformations of \( r_i \) can be analyzed based on the material mechanics.

a) The forces directly causing deformations: 
\[ F_{ai} \] produces the longitudinal deformation \( \delta r_i \) along \( r_i \) (i = 1, 2, 3). Let \( k_{ri} \) be a coefficient mapping the relationships of \( \delta r_i \) and \( F_{ai} \), it leads to:
\[ F_{ai} = k_{ri} \delta r_i, k_{ri} = \frac{ES_i}{r_i} \]  

where \( E \) is the modulus of elasticity and \( S_i \) is the area of the cross-section of \( r_i \).

\( F_{pi} \) produces the flexibility deformations \( \delta d_{pi} \) in \( r_i \) and \( F_s \) produces the flexibility deformations \( \delta d_{ps} \) in \( r_s \). Let \( k_{pi} \) be a coefficient mapping the relationship of \( \delta d_{pi} \) and \( F_{pi} \), \( k_{ps} \) be a coefficient mapping the relationship of \( \delta d_{ps} \) and \( F_s \), it leads to:
\[ F_{pi} = k_{pi1} \delta d_{pi}, k_{pi1} = \frac{3EI}{r_i^3}, F_s = k_{ps2} \delta d_{ps}, k_{ps2} = \frac{3EI}{r_s^3} \]  

where \( I \) is the moment inertia.

b) The torques directly causing deformations: 
\( T_{ip} \) produces the torsional deformation \( \delta \theta_{ip} \) in \( r_i \) (i = 1, 2). Let \( k_{ip} \) be a coefficient mapping the relationships of \( \delta \theta_{ip} \) and \( T_{ip} \), it leads to:
\[ T_{ip} = k_{ip} \delta \theta_{ip}, k_{ip} = \frac{GI_p}{r_i} \]  

where \( G \) is the shear modulus and \( I_p \) is the polar moment of inertia.

\( T_{iq} \) produces the bending deformation \( \delta \theta_{iq} \) in \( r_i \) (i = 1, 2). Let \( k_{iq} \) be a coefficient mapping the relationships of \( \delta \theta_{iq} \) and \( T_{iq} \), it leads to:
\[ T_{iq} = k_{iq} \delta \theta_{iq}, k_{iq} = \frac{EI}{r_i} \]  

C. STIFFNESS MODEL

Let \( \delta p = [\delta x \delta y \delta z]^T \), \( \delta \Phi = [\delta \Phi_x \delta \Phi_y \delta \Phi_z]^T \) be the linear and angular deformations of \( m \). According to the principle of virtual work, it leads to:
\[ \begin{bmatrix} F_a^T & F_p^T & T_1^T & T_2^T \end{bmatrix} \begin{bmatrix} \delta r \\ \delta d_p \\ \delta \theta_1 \\ \delta \theta_2 \end{bmatrix} = -[F^T \ T^T] \begin{bmatrix} \delta p \\ \delta \Phi \end{bmatrix} \]  

Substituting (45) into (51), and combining with (41), it leads to:
\[ \begin{bmatrix} W_{9 \times 6} \end{bmatrix}^T \begin{bmatrix} F_{a1} \\ F_{a2} \\ F_{a3} \\ F_{p1} \\ F_{p2} \\ T_{11} \end{bmatrix} \begin{bmatrix} \delta \Phi \\ \delta \theta_1 \\ \delta \theta_2 \end{bmatrix} = -[F^T \ T^T] \begin{bmatrix} \delta p \\ \delta \Phi \end{bmatrix} \]  

According to (52), the deformation relations can be derived as below:
\[ \begin{bmatrix} \delta p \\ \delta \Phi \end{bmatrix} = J_{6 \times 6}^{-1} W_{6 \times 6}^T \begin{bmatrix} \delta r \\ \delta d_p \\ \delta \theta_1 \\ \delta \theta_2 \end{bmatrix} \]  

Furthermore, from (41), (45) and (53), it leads to:
\[ \begin{bmatrix} \delta r \\ \delta d_p \\ \delta \theta_1 \\ \delta \theta_2 \end{bmatrix} = -C_{9 \times 9} W_{9 \times 6} (J_{6 \times 6}^{-1})^T \begin{bmatrix} F \\ T \end{bmatrix}, \quad C_{9 \times 9} = (K'_{9 \times 9})^{-1} \]  

Substituting (54) into (53), it leads to:
\[ \begin{bmatrix} \delta p \\ \delta \Phi \end{bmatrix} = -C_{6 \times 6} \begin{bmatrix} F \\ T \end{bmatrix}, \quad C_{6 \times 6} = -J_{6 \times 6}^{-1} W_{9 \times 6} C_{9 \times 9} W_{9 \times 6} (J_{6 \times 6})^T \]  

(From 55), the stiffness model of the proposed PM is built:
\[ \begin{bmatrix} F \\ T \end{bmatrix} = K_{6 \times 6} \begin{bmatrix} \delta p \\ \delta \Phi \end{bmatrix}, \quad K_{6 \times 6} = -C_{6 \times 6} \]  

where \( K_{6 \times 6} \) and \( C_{6 \times 6} \) is the stiffness matrix and compliance matrix of this PM, respectively.

V. NUMERICAL EXAMPLES

The correctness of the previously established models is verified in this section.
A. FORWARD POSITIONAL POSTURE NUMERICAL EXAMPLE

For this example PM, the dimension parameters and the active parameters of each leg are shown in TABLE 1.

TABLE 1. The dimension parameters and the ACTIVE parameters of each leg for this example PM.

| The dimension parameters | The active parameters of each leg |
|--------------------------|---------------------------------|
| $a$ (cm)                | $r_1$ (cm)        | $r_2$ (cm)        | $r_3$ (cm)        |
| 60                      | 165               | 162               | 163               |
| 40                      |                   |                   |                   |

According to TABLE 1, (15) can be written in a specific expression and $Q$ can be obtained. Then $t_2$ can be solved form (16), the detailed values are listed in TABLE 2. In order to determine the acceptable analytic solution from TABLE 2, the simulative PM is created using the computer-aided design variation geometry method [35], as shown in FIGURE 4.

TABLE 2. The 28 solutions of $t_2$.

| No. | Values          |
|-----|-----------------|
| 1-4 | -2.4730         |
|     | -0.2774         |
|     | -0.2997         |
|     | -0.1389         |
| 5-8 | 0.1612          |
|     | 0.1998          |
|     | 0.2272          |
|     | 1.152           |
| 9-12| -1.236 ± 0.8925 |
|     | -1.236 ± 0.8925 |
|     | -1.0 ± 4.022 × 10⁻³ |
|     | -1.6 ± 4.022 × 10⁻³ |
| 13-16| -0.923 ± 0.8823 |
|     | -0.923 ± 0.8823 |
|     | -0.387 ± 0.6176 |
|     | -0.387 ± 0.6176 |
| 17-20| 1.937 ± 10⁻⁵ |
|     | 1.0 ± 2.251 × 10⁻⁴ |
|     | 1.37 ± 10⁻⁴ |
|     | 1.37 ± 10⁻⁴ |
| 21-24| 0.8374 ± 1.074 |
|     | 0.8374 ± 1.074 |
|     | 1.0 ± 7.696 × 10⁻⁴ |
|     | 1.0 ± 7.696 × 10⁻⁴ |
| 25-28| 4.117 ± 16.66 |
|     | 4.117 ± 16.66 |
|     | 15.57 ± 3.107 × 10⁻⁴ |
|     | 15.57 ± 3.107 × 10⁻⁴ |

In the CAD software when given the identical settings of TABLE 1 to the simulative PM, the value of $\lambda$ can be measured, which is in excellent agreement with the 5th solution in TABLE 2. Subsequently, bring the 5th solution $t_2 = 0.1612$ (corresponding to $\lambda = 18.3146$) into (9), (11) and (13a), other positional posture parameters can be solved. The detailed analytic values are shown in TABLE 3.

Meanwhile, the simulative value of the positional posture parameters can be measured form the simulative PM, the detailed simulative values are shown in TABLE 3. From TABLE 3, it can be seen that the analytic values and the simulative values are in excellent agreement.

TABLE 3. Comparison of the values between analytic and simulative.

| Parameters | Analytic Values | Simulation Values | Parameters | Analytic Values | Simulation Values |
|------------|-----------------|-------------------|------------|-----------------|-------------------|
| $X_0$ (cm) | 26.6848         | 26.68477223      | $\alpha$   | -10.2287        | -10.23400467      |
| $Y_0$ (cm) | -21.9014        | -21.90139099     | $\beta$    | 0               | 0                 |
| $Z_0$ (cm) | 157.5058        | 157.50582064     | $\lambda$  | 18.3146         | 18.31884416       |

TABLE 4. The initial independent motion parameters and their acceleration.

| INITIAL | ACCELERATION |

**FIGURE 6.** The comparison of simulative and analytic results about angular velocity of $m$.

**FIGURE 7.** The comparison of simulative and analytic results about linear acceleration of $m$.

B. KINEMATIC NUMERICAL EXAMPLE

For this example PM, set $E = 0.60m$ and $e = 0.40m$. Meanwhile let the independent motion parameters move according to the items in TABLE 4.

From an analytic point of view, when motions of the independent motion parameters are given, the initial positional posture of $m$ can be calculated based on (9). The velocity $v$ and $\omega$ of $m$ can be calculated based on (24) and (25), FIGURE 5(a) and 6(a) shows the corresponding analytic values curves plotted by MATLAB.

The acceleration $a$ and $\epsilon$ of $m$ can be calculated based on (39) and (40), FIGURE 7(a) and 8(a) shows the corresponding analytic values curves plotted by MATLAB. Furthermore, according to the above expected motions of $m$, the initial length of actuators can be calculated based on (11). $v_{ri}$ ($i = 1, 2, 3$) can be calculated based on (22).
And \( \alpha_{ij} (i = 1, 2, 3) \) can be calculated based on (26), (28) and (37).

From a simulative point of view, a simulative PM by MATLAB/SIMULINK is set, as shown in FIGURE 9. In the simulative PM, three simulation-driven modules are set on \( r_i \) (\( i = 1, 2, 3 \)), a velocity/acceleration sensor is set on \( m \) and the sensor values can display by scope. Applying identical \( \nu_{ij} \), \( \alpha_{ij} \) calculated above to the corresponding simulation-driven module, the scope displays the corresponding simulative values curves, as shown in FIGURE 5, 6, 7, and 8 (b).

The quantitative comparisons between the analytic values and the simulative values at \( t = 0s, t = 1.25s, t = 2.5s \) are shown in TABLE 5.

By comparing the curves in FIGURE 5, 6, 7 and 8 and the values in TABLE 5, it can be seen that the analytic values and the simulative values are in excellent agreement, which verifies the correctness and precision of the kinematic model established in this study.

C. STIFFNESS NUMERICAL EXAMPLE

For this example PM, the dimension parameters, the initial independent motion parameters, the load force/torque and the mechanical parameters of materials are shown in TABLE 6.

| TABLE 6. The dimension parameters, the initial independent motion parameters and the mechanical parameters of materials. |
| --- |
| \( E(m) \) | \( \epsilon(m) \) | \( \alpha(\circ) \) | \( Z_{ai}(m) \) | \( F_{ai}(N) \) | \( T_{ai}(N/k) \) |

This study proposes a novel asymmetric non-over-constraint 3-DOF RPU+UPU+SPU PM.

The complete kinematic models for the RPU+UPU+SPU PM are built. Simulative PMs are set to validate the accuracy of the conducted kinematic models.

A 6 × 6 form Jacobian matrix is derived. And a 6 × 6 × 6 form Hessian matrix is derived. The velocity/acceleration coupling relationships of the moving platform are derived to supplement the inverse kinematic models.

Both considering the active forces and the constraint wrenches, the stiffness model of the RPU+UPU+SPU PM are established.

The stiffness matrix and compliance matrix are derived. A FE simulative PM is built to validate the accuracy of the conducted stiffness model.

APPENDIX

SYMBOL TABLE

| Symbol | Meaning |
|--------|---------|
| R, P, U and S | The revolute joint, the prismatic joint, the universal joint, and the sphere joint, |
| M | The DOF number of the mechanism |
| n | The number of links in the mechanism |
| g | The number of joints |
| mi | The DOF number of the i-th joint |
| m0 | The passive DOF |
| Bi | The vector of vertex Bi in the inertial frame O-XYZ |
| O-XYZ | The coordinate axes of the inertial frame |
| X, Y and Z | The unit vector of axes X, Y, Z |
| E | The distance from origin O to vertex Bi |
| A1, A2 and A3 | The vertex of the moving platform |
| Ai | The vector of vertex Ai in the inertial frame O-XYZ |
| mAi | The vector of vertex Ai in the frame O’ X’ Y’ Z’ |
| O’-X’ Y’ Z’ | The coordinate axes of the moving frame |
| X’, Y’ and Z’ | The unit vector of axes X’, Y’, Z’ |
| e | The distance from origin O’ to vertex Ai |
| mR | The rotational transformation matrix from frame O’-X’ Y’ Z’ to inertial frame O-XYZ |
| Rij, Rji | The j-th R joint from the base platform to the moving platform in the i-th leg, the unit vector of Rij |
| ri, δi | The length of the i-th leg, the unit vector of ri |
| Fp1 and Tp | The constrained force and torque in the 1st leg |
| Fp2 | The constrained force in the 2nd leg |
| fi and τ | The unit vectors of Fpi (i = 1, 2) and Tp |
| C, C | The action point of Fp1, the coordinate of point C in the inertial frame O-XYZ |
| ei | The vector from origin O’ to vertex Ai |
| di | The vector from origin O’ to the action point of Fpi |
| O’ | The vectors of origin O’ in the inertial frame O-XYZ |

VI. CONCLUSION

This study proposes a novel asymmetric non-over-constraint 3-DOF RPU+UPU+SPU PM.
The shear modulus \( G_k \) and the module of elasticity \( k \).

\[
\begin{bmatrix}
-0.3157 & 0.1309 & -0.7097 \\
0.1309 & -0.3138 & 0.8263 \\
-0.7097 & 0.8263 & -4.8755 \\
0.1080 & 0.1799 & 0.0814 \\
-0.0814 & -0.2730 & -0.0143 \\
-0.1874 & 0.0786 & 0.1445 \\
-0.0786 & -0.2585 & -0.0449 \\
-0.1866 & -0.0449 & -0.0251
\end{bmatrix} \times 10^8
\]

\[
\begin{bmatrix}
x, y, z \text{ of origin } O' \\
\alpha, \beta, \text{ and } \lambda
\end{bmatrix}
\]

The position parameters of origin \( O' \) and the orientation parameters of origin \( O' \).

\[
v_r = [v_{r1} v_{r2} v_{r3}]^T
\]

The input velocity/acceleration vector \( / a_r = [a_{r1} a_{r2} a_{r3}]^T \).

\[
J/H
\]

The inverse Jacobian/Hessian matrix.

\[
J_a/H_a
\]

The traditional Jacobian/Hessian matrix of limited-DOF PM.

\[
J_v/H_v
\]

The constraint Jacobian/Hessian matrix.

\[
V = [v \omega]^T
\]

The output velocity/acceleration vector.

\[
A = [a \dot{\omega}]^T
\]

\[
J_{01} \text{ and } J_{02}
\]

The linear and angular velocity decoupling Jacobian matrices.

\[
H_1 \text{ and } H_2
\]

The linear and angular acceleration decoupling Hessian matrix of \( n \)-DOF PM.

\[
F_{ai}
\]

The active force.

\[
F/IT
\]

Loading force/torque.

\[
l_p
\]

The polar moment of inertia.

\[
F_{ip1}, F_s, T_{ip}
\]

The force/torque directly casing deformations.

\[
\tau_{ip} \text{ and } \tau_{iq}
\]

A coefficient that represents the relationship between the constrained force/torque and its component.

\[
\delta_{ri}
\]

The longitudinal deformation along \( r_i \).

\[
k_{ri}
\]

A coefficient for mapping the relationships of \( \delta_{ri} \) and \( F_{ai} \).

\[
E
\]

The modulus of elasticity.

\[
\delta_i
\]

The area of \( r_i \).

\[
\delta_{dpi}
\]

The flexibility deformation in \( r_i \).

\[
k_{pi}
\]

A coefficient for mapping the relationships of \( \delta_{dpi} \) and force.

\[
l
\]

The moment inertia.

\[
\delta_{dpi}
\]

The torsional deformation about \( r_i \).

\[
k_{ip}
\]

A coefficient for mapping the relationships of \( \delta_{dpi} \) and torque.

\[
G
\]

The shear modulus.

\[
k_{iq}
\]

A coefficient for mapping the relationships of \( \delta_{dpi} \) and torque.

\[
\delta_{p} = [\delta x \delta y \delta z]^T
\]

\[
\delta_{\Phi} = [\delta \Phi_f \delta \Phi_y \delta \Phi_z]\]

\[
\Phi_f
\]

The linear and angular deformations of the moving platform.

\[
W
\]

A coefficient matrix that represents the relationship between the constrained force/torque and the force/torque directly casing deformations.

\[
K^r
\]

A coefficient matrix for mapping the relationships of deformation and force/torque.

\[
K_{6\times6} \text{ and } C_{6\times6}
\]

The stiffness matrix and compliance matrix.
