Measurement of the ZZ production cross section and \( Z \rightarrow \ell^+\ell^-\ell'^+\ell'^- \) branching fraction in pp collisions at \( \sqrt{s} = 13 \text{ TeV} \)

The CMS Collaboration

Abstract

Four-lepton production in proton-proton collisions, \( pp \rightarrow (Z/\gamma^*) (Z/\gamma^*) \rightarrow \ell^+\ell^-\ell'^+\ell'^- \), where \( \ell, \ell' = e \) or \( \mu \), is studied at a center-of-mass energy of 13 TeV with the CMS detector at the LHC. The data sample corresponds to an integrated luminosity of 2.6 \( \text{fb}^{-1} \). The ZZ production cross section, \( \sigma(pp \rightarrow ZZ) = 14.6^{+1.9}_{-1.8} \text{(stat)}^{+0.5}_{-0.3} \text{(syst)} \pm 0.2 \text{(theo)} \pm 0.4 \text{(lumi)} \text{pb} \), is measured for events with two opposite-sign, same-flavor lepton pairs produced in the mass region 60 < \( m_{\ell^+\ell^-} \), \( m_{\ell'^+\ell'^-} \) < 120 GeV. The Z boson branching fraction to four leptons is measured to be \( B(Z \rightarrow \ell^+\ell^-\ell'^+\ell'^-) = 4.9^{+0.8}_{-0.7} \text{(stat)}^{+0.3}_{-0.2} \text{(syst)}^{+0.2}_{-0.1} \text{(theo)} \pm 0.1 \text{(lumi)} \times 10^{-6} \) for the four-lepton invariant mass in the range 80 < \( m_{\ell^+\ell^-\ell'^+\ell'^-} \) < 100 GeV and dilepton mass \( m_{\ell^+\ell^-} > 4 \text{ GeV} \) for all opposite-sign, same-flavor lepton pairs. The results are in agreement with standard model predictions.

1 Introduction

Measurements of diboson production at the CERN LHC allow precision studies of the standard model (SM). These measurements are important for testing predictions that were recently made available at next-to-next-to-leading-order (NNLO) in quantum chromodynamics (QCD) \[1\]. Comparing these predictions to data at a range of center-of-mass energies gives insight into the structure of the electroweak gauge sector of the SM, and new proton-proton collision data at $\sqrt{s} = 13$ TeV allow diboson measurements at the highest energies to date. Any deviations from expected values could be an indication of physics beyond the SM.

Previous measurements of the ZZ production cross section from CMS were performed in the $ZZ \rightarrow \ell^+\ell^-\ell'^+\ell'^-$ and $ZZ \rightarrow \ell^+\ell^-\nu\nu$ decay channels, where $\ell = e, \mu$ and $\ell' = e, \mu, \tau$ for both Z bosons produced on-shell, in the dilepton mass range 60–120 GeV \[2–4\]. These measurements were made with data sets corresponding to integrated luminosities of $5.1 \, \text{fb}^{-1}$ at $\sqrt{s} = 7$ TeV and $19.6 \, \text{fb}^{-1}$ at $\sqrt{s} = 8$ TeV, and agree with SM predictions. The ATLAS Collaboration produced similar results at $\sqrt{s} = 7, 8$, and $13$ TeV \[5–7\], which also agree with the SM.

Extending the mass window for the dilepton candidates to lower values allows measurements of $(Z/\gamma^*)$ $(Z/\gamma^*)$ production, where “Z” may indicate an on-shell Z boson or an off-shell $Z^*$ boson. The resulting sample includes Higgs boson events in the “golden channel” $H \rightarrow ZZ^* \rightarrow \ell^+\ell^-\ell'^+\ell'^-$, where $\ell'$ = $e, \mu$, and rare Z boson decays to four leptons. The $Z \rightarrow \ell^+\ell^-\gamma^* \rightarrow \ell^+\ell^-\ell'^+\ell'^-$ decay was studied in detail at LEP \[8\] and was observed in pp collisions by CMS \[9\] and by ATLAS \[10\]. Though the branching fraction for this decay is orders of magnitude smaller than that for the $Z \rightarrow \ell^+\ell^-$ decay, the precisely known mass of the Z boson makes the four-lepton mode useful for calibrating mass measurements of the nearby Higgs resonance.

This letter reports a study of four-lepton production (pp $\rightarrow \ell^+\ell^-\ell'^+\ell'^-$, where $\ell$ and $\ell'$ indicate electrons or muons) at $\sqrt{s} = 13$ TeV with a data set corresponding to an integrated luminosity of $2.62 \pm 0.07 \, \text{fb}^{-1}$ recorded in 2015. From this study, cross sections are inferred for nonresonant production of pairs of Z bosons, pp $\rightarrow ZZ$, where both Z bosons are produced on-shell, defined as the mass range 60–120 GeV, and resonant pp $\rightarrow Z \rightarrow \ell^+\ell^-\ell'^+\ell'^-$ production. Discussion of resonant Higgs boson production is beyond the scope of this letter.

2 The CMS detector

A detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in Ref. \[11\].

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass and scintillator hadron calorimeter (HCAL), which provide coverage in pseudorapidity $|\eta| < 1.479$ in a barrel and $1.479 < |\eta| < 3.0$ in two endcap regions. Forward calorimeters extend the coverage provided by the barrel and endcap detectors to $|\eta| < 5.0$. Muons are measured in gas-ionization detectors embedded in the steel flux-return yoke outside the solenoid in the range $|\eta| < 2.4$, with detection planes made using three technologies: drift tubes, cathode strip chambers, and resistive plate chambers.

Electron momenta are estimated by combining energy measurements in the ECAL with momentum measurements in the tracker. The momentum resolution for electrons with transverse momentum $p_T \approx 45$ GeV from $Z \rightarrow e^+e^-$ decays ranges from 1.7% for nonshowering
electrons in the barrel region to 4.5% for showering electrons in the endcaps [12]. Matching muons to tracks measured in the silicon tracker results in a $p_T$ resolution for muons with $20 < p_T < 100$ GeV of 1.3–2.0% in the barrel and better than 6% in the endcaps. The $p_T$ resolution in the barrel is better than 10% for muons with $p_T$ up to 1 TeV [13].

3 Signal and background simulation

Signal events are generated with POWHEG 2.0 [14–16] at next-to-leading-order (NLO) in QCD for quark-antiquark processes and leading-order (LO) for quark-gluon processes. This includes $ZZ, Z\gamma^*, Z,$ and $\gamma^*\gamma^*$ production with a constraint of $m_{\ell^+\ell^-} > 4$ GeV applied between all pairs of oppositely charged leptons at the generator level to avoid infrared divergences. The $gg \to ZZ$ process is simulated at LO with MCFM v7.0 [17]. These samples are scaled to correspond to cross sections calculated at NNLO for $q\bar{q} \to ZZ$ [1] (scaling $K$ factor 1.1) and at NLO for $gg \to ZZ$ [18] ($K$ factor 1.7). The $gg \to ZZ$ process is calculated to $\mathcal{O}(\alpha_s^3)$, where $\alpha_s$ is the strong coupling constant, while the other contributing processes are calculated to $\mathcal{O}(\alpha_s^2)$; this higher-order correction is included because the effect is known to be large [18].

A sample of Higgs boson events is produced in the gluon-gluon fusion process with POWHEG 2.0 in the NLO QCD approximation. The Higgs boson decay is modeled with JHUGEN 3.1.8 [19–21]. The $q\bar{q} \to WZ$ process is generated with POWHEG 2.0.

The PYTHIA v8.175 [22–24] package is used for parton showering, hadronization, and the underlying event simulation, with parameters set by the CUETP8M1 tune [25]. The NNPDF3.0 [26] set is used as the default set of parton distribution functions (PDFs). For all simulated event samples, the PDFs are calculated to the same order in QCD as the process in the sample.

The detector response is simulated using a detailed description of the CMS detector implemented with the GEANT4 package [27]. The event reconstruction is performed with the same algorithms used for data. The simulated samples include additional interactions per bunch crossing, referred to as “pileup.” The simulated events are weighted so that the pileup distribution matches the data, with an average of about 11 interactions per bunch crossing.

4 Event reconstruction

All long-lived particles in each collision event — electrons, muons, photons, and charged and neutral hadrons — are identified and reconstructed with the CMS particle-flow (PF) algorithm [28,29] from a combination of the signals from all subdetectors. Reconstructed electrons [12] and muons [13] are candidates for inclusion in four-lepton final states if they have $p_T^e > 7$ GeV and $|\eta^e| < 2.5$ or $p_T^\mu > 5$ GeV and $|\eta^\mu| < 2.4$. These are designated “signal leptons.”

Signal leptons are also required to originate from the event vertex, defined as the proton-proton interaction vertex whose associated charged particles have the highest sum of $p_T^2$. The distance of closest approach between each lepton track and the event vertex is required to be less than 0.5 cm in the plane transverse to the beam axis, and less than 1 cm in the direction along the beam axis. Furthermore, the significance of the three-dimensional impact parameter relative to the event vertex, $\text{SIP}_{3D}$, is required to satisfy $\text{SIP}_{3D} \equiv |\text{IP} / \sigma_{\text{IP}}| < 4$ for each lepton, where IP is the distance of closest approach of each lepton track to the event vertex and $\sigma_{\text{IP}}$ is its associated uncertainty.

Signal leptons are required to be isolated from other particles in the event. The relative isolation
is defined as

\[
R_{\text{iso}} = \left[ \sum_{\text{charged hadrons}} p_T + \max \left( 0, \sum_{\text{neutral hadrons}} p_T + \sum_{\text{photons}} p_T - p_{\text{PU}}^T \right) \right] / p_T^\ell, \tag{1}
\]

where the sums run over the charged and neutral hadrons, and photons, in a cone defined by \( \Delta R \equiv \sqrt{(\Delta \eta)^2 + (\Delta \phi)^2} < 0.3 \) around the lepton trajectory, where \( \phi \) is the azimuthal angle in radians. To minimize the contribution of charged particles from pileup to the isolation calculation, charged hadrons are included only if they originate from the event vertex. The contribution of neutral particles from pileup is \( p_{\text{PU}}^T \). For electrons, \( p_{\text{PU}}^T \) is evaluated with the “jet area” method described in Ref. [30]; for muons, it is taken to be half the sum of the \( p_T \) of all charged particles in the cone originating from pileup vertices. The factor one-half accounts for the expected ratio of charged to neutral particle energy in hadronic interactions. A lepton is considered isolated if \( R_{\text{iso}} < 0.35 \).

Emission of final-state radiation (FSR) photons by the signal leptons may degrade the performance of the isolation requirements and Z boson mass reconstruction. These photons are omitted from the isolation determination for signal leptons and are implicitly included in dilepton kinematic calculations. Photons are FSR candidates if \( p_\gamma^T > 2 \text{ GeV}, |\eta_\gamma| < 2.4, \) their relative isolation (defined as in Eq. (1) with \( p_{\text{PU}}^T = 0 \)) is less than 1.8, and \( \Delta R (\ell, \gamma) < 0.5 \) with respect to the nearest signal lepton. To avoid double counting of bremsstrahlung photons that are already included in electron reconstruction, photons are not FSR candidates if there is any signal electron within \( \Delta R (\gamma, e) < 0.15 \) or within \( |\Delta \phi (\gamma, e)| < 2 \) and \( |\Delta \eta (\gamma, e)| < 0.05 \).

Because FSR photons have a higher average energy than photons from pileup and are expected to be mostly collinear with the emitting lepton, a photon candidate is accepted as FSR if \( \Delta R (\ell, \gamma) / (p_\gamma^T)^2 < 0.012 \text{ GeV}^{-2} \).

In simulated \( ZZ \to \ell^+ \ell^- \ell^+ \ell^- \) events, the efficiency to select generated FSR photons is around 55%, and roughly 85% of selected photons are matched to FSR photons. At least one FSR photon is identified in approximately 2%, 5%, and 8% of simulated events in the 4e, 2e2\( \mu \), and 4\( \mu \) channels, respectively. In data events with two on-shell Z bosons, no FSR photons are selected in the 4e decay channel, while at least one FSR photon is selected in three and five events in the 2e2\( \mu \) and 4\( \mu \) decay channels, respectively.

The lepton reconstruction, identification, and isolation efficiencies are measured with a tag-and-probe technique [31] applied to a sample of \( Z \to \ell^+ \ell^- \) data events. The measurements are performed in several bins of \( p_T^\ell \) and \( |\eta^\ell| \). The electron reconstruction and selection efficiency in the ECAL barrel (endcaps) varies from about 85% (77%) at \( p_T^e \approx 10 \text{ GeV} \) to about 95% (89%) for \( p_T^e \geq 20 \text{ GeV} \), while in the barrel-endcap transition region this efficiency is about 85% averaged over all electrons with \( p_T^e > 7 \text{ GeV} \). The muons are reconstructed and identified with efficiencies above \( \sim 98% \) within \( |\eta^\mu| < 2.4 \).

## 5 Event selection

The primary triggers for this analysis require the presence of a pair of loosely isolated leptons of the same or different flavors. The highest \( p_T \) lepton must have \( p_T^\ell > 17 \text{ GeV} \), and the subleading lepton must have \( p_T^\ell > 12 \text{ GeV} \) if it is an electron or \( p_T^\ell > 8 \text{ GeV} \) if it is a muon. The dielectron and dimuon triggers require that the tracks corresponding to the leptons originate from within 2 mm of each other in the plane transverse to the beam axis. Triggers requiring a triplet of lower-\( p_T \) leptons with no isolation criterion, or a single high-\( p_T \) electron without an isolation
requirement, are also used. An event is used if it passes any trigger regardless of the decay channel. The total trigger efficiency for events within the acceptance of this analysis is greater than 98%.

A signal event must contain at least two $Z/\gamma^*$ candidates, each formed from an oppositely charged pair of isolated signal electrons or muons. Among the four leptons, the highest $p_T$ lepton must have $p_T > 20\text{GeV}$, and the second-highest $p_T$ lepton must have $p_T^\ell > 12\text{GeV}$ if it is an electron or $p_T^\mu > 10\text{GeV}$ if it is a muon. All leptons are required to be separated by $\Delta R(\ell_1, \ell_2) > 0.02$, and electrons are required to be separated from muons by $\Delta R(e, \mu) > 0.05$.

Within each event, all permutations of leptons giving a valid pair of $Z/\gamma^*$ candidates are considered separately. Within each $\ell^+\ell^-\ell'^+\ell'^-$ candidate, the dilepton candidate with an invariant mass closest to $91.2\text{GeV}$, taken as the nominal Z boson mass, is denoted $Z_1$ and is required to have a mass greater than $40\text{GeV}$. The other dilepton candidate is denoted $Z_2$. Both $m_{Z_1}$ and $m_{Z_2}$ are required to be less than $120\text{GeV}$. All pairs of oppositely charged leptons in the candidate are required to have $m_{\ell\ell'} > 4\text{GeV}$ regardless of flavor.

If multiple $\ell^+\ell^-\ell'^+\ell'^-$ candidates within an event pass all selections, the passing candidate with $m_{Z_1}$ closest to the nominal Z boson mass is chosen. In the rare case of further ambiguity, which may arise in events with five or more signal leptons, the $Z_2$ candidate that maximizes the scalar $p_T$ sum of the four leptons is chosen.

Additional requirements are applied to select events for measurements of specific processes. The $pp \rightarrow ZZ$ cross section is measured using events where both $m_{Z_1}$ and $m_{Z_2}$ are greater than $60\text{GeV}$. The $Z \rightarrow \ell^+\ell^-\ell'^+\ell'^-$ branching fraction is measured using events with $80 < m_{\ell\ell'} < 100\text{GeV}$, a range chosen to retain most of the decays in the resonance while removing most other processes with four-lepton final states.

## 6 Background estimate

The major background contributions arise from Z boson and WZ diboson production in association with jets and from $t\bar{t}$ production. In all these cases, particles from jet fragmentation satisfy both lepton identification and isolation criteria, and are thus misidentified as signal leptons.

The probability for such objects to be selected is measured from a sample of $Z + \ell_{\text{candidate}}$ events, where $Z$ is a pair of oppositely charged, same-flavor leptons that pass all analysis requirements and satisfy $|m_{\ell\ell'} - m_Z| < 10\text{GeV}$, where $m_Z$ is the nominal Z boson mass. Each event in this sample must have exactly one additional object $\ell_{\text{candidate}}$ that passes relaxed identification requirements with no isolation requirements applied. The misidentification probability for each lepton flavor is defined as a ratio of the number of candidates that pass the final isolation and identification requirements to the total number in the sample, measured in bins of lepton candidate $p_T$ and $\eta$. The number of $Z + \ell_{\text{candidate}}$ events is corrected for contamination from WZ production, or ZZ production in which one lepton is not reconstructed. These events have a third genuine, isolated lepton that must be excluded from the misidentification probability calculation. The WZ contamination is suppressed by requiring the missing transverse energy $E_T^{\text{miss}}$ to be below $25\text{GeV}$. The $E_T^{\text{miss}}$ is defined as the magnitude of the missing transverse momentum vector $\vec{p}_T^{\text{miss}}$, the projection onto the plane transverse to the beams of the negative vector sum of the momenta of all reconstructed particles in the event. Additionally, the transverse mass $m_T \equiv \sqrt{(E_T^{\text{miss}})^2 - (\vec{p}_T + \vec{p}_T^{\text{miss}})^2}$ of $\ell_{\text{candidate}}$ and the missing transverse momentum vector is required to be less than $30\text{GeV}$. The residual contribution of WZ and ZZ events, which may be up to a few percent of the events with $\ell_{\text{candidate}}$ passing all selection criteria, is estimated
from simulation and subtracted.

To account for all sources of background events, two control samples are used to estimate the number of background events in the signal regions. Both are defined to contain events with a dilepton candidate satisfying all requirements (Z\text{\(1\))} and two additional lepton candidates \(\ell^+\ell^-\). In one control sample, enriched in WZ events, one \(\ell^\prime\) candidate is required to satisfy the full identification and isolation criteria and the other must fail the full criteria and instead satisfy only relaxed ones; in the other, enriched in Z+jets events, both \(\ell^\prime\) candidates must satisfy the relaxed criteria, but fail the full criteria. The additional leptons must have opposite charge and the same flavor (e\text{\(\pm\)}e\text{\(\mp\)}, \mu\text{\(\pm\)}\mu\text{\(\mp\)}). From this set of events, the expected number of background events in the signal region is obtained by scaling the number of observed Z\text{\(1\)+\ell^+\ell^-\}) events by the misidentification probability for each lepton failing the selection. Low-mass dileptons may be sufficiently collinear that their isolation cones overlap, and their misidentification probabilities are therefore correlated. To mitigate the effect of these correlations, only the control sample in which both additional leptons fail the full selection is used if \(\Delta R(\ell^\prime+, \ell^\prime-) < 0.6\). The background contributions to the signal regions of Z\(\rightarrow\ell^+\ell^-\ell^\prime+\ell^\prime-\) and ZZ\(\rightarrow\ell^+\ell^-\ell^\prime+\ell^\prime-\) are summarized in Section 8.

7 Systematic uncertainties

Systematic uncertainties are summarized in Table 1. In both data and simulated event samples, trigger efficiencies are evaluated with a tag-and-probe technique. The ratio between data and simulation is applied to simulated events, and the size of the resulting change in expected yield is taken as the uncertainty for the determination of the trigger efficiency. This uncertainty is around 2% of the final estimated yield. For Z\(\rightarrow e^+e^-e^+e^-\) events, the uncertainty increases to 4%.

Table 1: The contributions of each source of signal systematic uncertainty in the cross section measurements. The integrated luminosity uncertainty and the PDF and scale uncertainties are considered separately. All other uncertainties are added in quadrature into a single systematic uncertainty. Uncertainties that vary by decay channel are listed as a range.

| Uncertainty          | Z \(\rightarrow\) 4\(\ell\) | ZZ \(\rightarrow\) 4\(\ell\) |
|----------------------|------------------------------|------------------------------|
| ID efficiency        | 2–6%                         | 0.4–0.9%                     |
| Isolation efficiency | 1–6%                         | 0.3–1.1%                     |
| Trigger efficiency   | 2–4%                         | 2%                           |
| MC statistics        | 1–2%                         | 1%                           |
| Background           | 0.7–1.4%                     | 0.7–2%                       |
| Pileup               | 0.4–0.8%                     | 0.2%                         |
| PDF                  | 1%                           | 1%                           |
| QCD Scales           | 1%                           | 1%                           |
| Integrated luminosity| 2.7%                         | 2.7%                         |

The lepton identification and isolation efficiencies in simulation are corrected with scaling factors derived with a tag-and-probe method and applied as a function of lepton p\text{\(T\)} and \(\eta\). To estimate the uncertainties associated with the tag-and-probe technique, the total yield is recomputed with the scaling factors varied up and down by the tag-and-probe fit uncertainties. The uncertainties associated with the identification efficiency in the ZZ \(\rightarrow\ell^+\ell^-\ell^\prime+\ell^\prime-\) (Z \(\rightarrow\ell^+\ell^-\ell^\prime+\ell^\prime-\)) signal regions are found to be 0.9% (6%) in the 4e final state, 0.7% (4%) in the 2e2\(\mu\) final state, and 0.4% (2%) in the 4\(\mu\) final state. The corresponding uncertainties associated with the isolation efficiency are 1.1% (6%) in the 4e final state, 0.7% (3%) in the 2e2\(\mu\) final
state, and 0.3% (1%) in the 4µ final state. These uncertainties are higher for \( Z \to \ell^+\ell^-\ell^+\ell^- \) events because the leptons generally have lower \( p_T \), and the samples used in the tag-and-probe method have fewer events and more contamination from nonprompt leptons in this low-\( p_T \) region.

Uncertainties due to the effect of factorization (\( \mu_F \)) and renormalization (\( \mu_R \)) scale choice on the \( ZZ \to \ell^+\ell^-\ell^+\ell^- \) acceptance are evaluated with Powheg and MCfM by varying the scales up and down by a factor of two with respect to the default values \( \mu_F = \mu_R = m_{ZZ} \). These variations are much smaller than 1% and are neglected. Parametric uncertainties (PDF+\( \alpha_s \)) are evaluated using the CT10 [32] and NNPDF3.0 sets and are found to be less than 1%. The largest difference between predictions from Powheg and MCfM with different scales and PDF sets, 1.5%, is considered to be the theoretical uncertainty in the acceptance calculation. An additional theoretical uncertainty arises from scaling the Powheg q\( g \) \( \to \) ZZ simulated sample from its NLO cross section to the NNLO prediction, and the MCfM \( gg \) \( \to \) ZZ samples from their LO cross sections to the NLO predictions. The change in the acceptance corresponding to this scaling procedure is found to be 1.1%. All theoretical uncertainties are added in quadrature.

The largest uncertainty in the estimated background yield arises from differences in sample composition between the \( Z + \ell \) control sample used to calculate the lepton misidentification probability and the \( Z + \ell^+\ell^- \) control sample. A further uncertainty arises from the limited number of events in the \( Z + \ell \) sample. A systematic uncertainty of 40% of the estimated background yield is applied to cover both effects. The size of this uncertainty varies by channel, but is less than 1% of the total expected yield.

The uncertainty in the integrated luminosity of the data sample is 2.7% [33].

## 8 Cross section measurements

The distributions of the four-lepton mass and the masses of the \( Z_1 \) and \( Z_2 \) candidates are shown in Fig.1. The SM predictions include nonresonant ZZ predictions normalized using the NNLO cross section, production of the SM Higgs boson with mass 125 GeV [34], and resonant \( Z \to \ell^+\ell^-\ell^+\ell^- \) production. The background estimated from data is also shown. The reconstructed invariant mass of the \( Z_1 \) candidates, and a scatter plot showing the correlation between \( m_{Z_2} \) and \( m_{Z_3} \) in data events, are shown in Fig.2. In the scatter plot, clusters of events corresponding to \( ZZ \to \ell^+\ell^-\ell^+\ell^- \), \( Z_2 \gamma \to \ell^+\ell^-\ell^+\ell^- \), and \( Z \to \ell^+\ell^-\ell^+\ell^- \) production can be seen.

The four-lepton invariant mass distribution below 110 GeV is shown in Fig.3 (left). Figure 3 (right) shows \( m_{Z_2} \) plotted against \( m_{Z_3} \) for events with \( m_{\ell^+\ell^-\gamma\gamma} \) between 80 and 100 GeV, and the observed and expected event yields in this mass region are given in Table 2.

Table 2: The observed and expected yields of four-lepton events in the mass region 80 < \( m_{\ell^+\ell^-\gamma\gamma} \) < 100 GeV and estimated yields of background events evaluated from data, shown for each final state and summed in the total expected yield. The first uncertainty is statistical, the second one is systematic.

| Final state | Expected \( N_{\ell^+\ell^-\gamma\gamma} \) | Background | Total expected | Observed |
|-------------|---------------------------------|------------|----------------|---------|
| 4\( \mu \)     | 16.88 ± 0.14 ± 0.62           | 0.31 ± 0.30 ± 0.12 | 17.19 ± 0.33 ± 0.63 | 17      |
| 2e2\( \mu \)  | 15.88 ± 0.14 ± 0.87           | 0.37 ± 0.27 ± 0.15 | 16.25 ± 0.31 ± 0.88 | 16      |
| 4e            | 5.58 ± 0.08 ± 0.53            | 0.21 ± 0.10 ± 0.08 | 5.78 ± 0.13 ± 0.53 | 6       |
| Total         | 38.33 ± 0.21 ± 1.19           | 0.89 ± 0.42 ± 0.22 | 39.22 ± 0.47 ± 1.21 | 39      |

The reconstructed four-lepton invariant mass is shown in Fig.4 (left) for events with two on-
Figure 1: Distributions of (left) the four-lepton invariant mass $m_\ell^+\ell^-\ell^+\ell^-$ and (right) the invariant mass of the dilepton candidates in all selected four-lepton events, including both $Z_1$ and $Z_2$ in each event. Points represent the data, while shaded histograms represent the SM prediction and background estimate. Hatched regions around the predicted yield represent combined statistical, systematic, theoretical, and integrated luminosity uncertainties.

Figure 3: (left) The distribution of the reconstructed four-lepton mass $m_{\ell^+\ell^-\ell'^+\ell'^-}$ for events selected with $m_{\ell^+\ell^-\ell'^+\ell'^-} < 110$ GeV. Points represent the data, while shaded histograms represent the SM prediction and background estimate. Hatched regions around the predicted yield represent combined statistical, systematic, theoretical, and integrated luminosity uncertainties. (right) The reconstructed $m_{Z_1}$ plotted against the reconstructed $m_{Z_2}$ in data events selected with $m_{\ell^+\ell^-\ell'^+\ell'^-}$ between 80 and 100 GeV, with distinctive markers for each final state.

shell Z bosons. Figure 4 (right) shows the invariant mass distribution for all Z candidates in these events. The corresponding observed and expected yields are given in Table 3.

Table 3: The observed and expected yields of ZZ events, and estimated yields of background events evaluated from data, shown for each final state and summed in the total expected yield. The first uncertainty is statistical, the second one is systematic.

| Final state | Expected | Background | Total observed | Observed |
|-------------|----------|------------|----------------|----------|
| $4\mu$      | $21.80 \pm 0.15 \pm 0.46$ | $0.00_{-0.00}^{+0.10}$ | $21.80_{-0.15}^{+0.28} \pm 0.47$ | $26$ |
| $2e2\mu$    | $36.15 \pm 0.20 \pm 0.81$ | $0.60 \pm 0.34 \pm 0.24$ | $36.75 \pm 0.34 \pm 0.85$ | $30$ |
| $4e$        | $14.87 \pm 0.12 \pm 0.36$ | $0.81 \pm 0.26 \pm 0.33$ | $15.68 \pm 0.26 \pm 0.48$ | $8$ |
| Total       | $72.82 \pm 0.27 \pm 1.00$ | $1.42_{-0.43}^{+0.49} \pm 0.42$ | $74.23_{-0.45}^{+0.56} \pm 1.08$ | $64$ |

The observed yields are used to evaluate the $pp \rightarrow Z \rightarrow \ell^+\ell^-\ell'^+\ell'^-$ and $pp \rightarrow ZZ \rightarrow \ell^+\ell^-\ell'^+\ell'^-$ production cross sections from a combined fit to the number of observed events in all the final states. The likelihood is a combination of individual channel likelihoods for the signal and background hypotheses with the statistical and systematic uncertainties in the form of scaling nuisance parameters. The ratio of the measured cross section to the SM cross section given by this fit including all channels is scaled by the cross section used in the simulation to find the measured fiducial cross section.

The definitions for the fiducial phase spaces for the $Z \rightarrow \ell^+\ell^-\ell'^+\ell'^-$ and $ZZ \rightarrow \ell^+\ell^-\ell'^+\ell'^-$ cross section measurements are given in Table 4.
Table 4: Fiducial definitions for the reported cross sections. The common requirements are applied for both measurements.

| Cross section measurement | Fiducial requirements |
|----------------------------|-----------------------|
| Common requirements        | $p_T^1 > 20 \text{ GeV}$, $p_T^2 > 10 \text{ GeV}$, $p_T^{\ell'1} > 5 \text{ GeV}$, $|\eta^\ell| < 2.5$, $m_{\ell^+\ell^-} > 4 \text{ GeV}$ (any opposite-sign same-flavor pair) |
| $Z \rightarrow \ell^+\ell^-\ell'^+\ell'^-$ | $m_{Z_1} > 40 \text{ GeV}$ |
|                             | $80 < m_{\ell^+\ell^-\ell'^+\ell'^-} < 100 \text{ GeV}$ |
| $ZZ \rightarrow \ell^+\ell^-\ell'^+\ell'^-$ | $60 < m_{Z_1}, m_{Z_2} < 120 \text{ GeV}$ |

Figure 4: Distributions of (left) the four-lepton invariant mass $m_{\ell^+\ell^-\ell'^+\ell'^-}$ and (right) dilepton candidate mass for four-lepton events selected with both Z bosons on-shell. Points represent the data, while shaded histograms represent the SM prediction and background estimate. Hatched regions around the predicted yield represent combined statistical, systematic, theoretical, and integrated luminosity uncertainties.
The measured cross sections are

\[ \sigma_{\text{fid}}(pp \rightarrow Z \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-) = 30.5^{+5.2}_{-4.5} \text{ pb} \]

\[ \sigma_{\text{fid}}(pp \rightarrow ZZ \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-) = 34.8^{+4.6}_{-4.2} \text{ pb} \]

The \( pp \rightarrow Z \rightarrow \ell^+ \ell^- \ell'^+ \ell'^- \) fiducial cross section for the Z section is the contribution of nonresonant four-lepton production to the signal region. The measured cross section, and is computed as

\[ \sigma(pp \rightarrow Z)B(Z \rightarrow 4\ell) = 250^{+43}_{-39} \text{ pb} \]

The branching fraction for the \( Z \rightarrow \ell^+ \ell^- \ell'^+ \ell'^- \) decay, \( B(Z \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-) \), is measured by comparing the cross section given by Eq. (2) with the \( Z \rightarrow \ell^+ \ell^- \) cross section, and is computed as

\[ B(Z \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-) = \frac{\sigma(pp \rightarrow Z \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-)}{C_{60-120}^{\text{fit}}} \]

where \( \sigma(pp \rightarrow Z \rightarrow \ell^+ \ell^-) = 1870^{+50}_{-40} \text{ pb} \) is the Z \( \rightarrow \ell^+ \ell^- \) cross section times branching fraction calculated at NNLO with FEWZ v2.0. Its uncertainty includes PDF uncertainties and uncertainties in \( \alpha_s \), the charm and bottom quark masses, and the effect of neglected higher-order corrections to the calculation. The factor \( C_{60-120}^{\text{fit}} = 0.926 \pm 0.001 \) corrects for the difference in Z mass windows and is estimated using POWHEG. Its uncertainty includes scale and PDF variations. The nominal Z to dilepton branching fraction \( B(Z \rightarrow \ell^+ \ell^-) \) is 0.03366. The measured value is

\[ B(Z \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-) = 4.9^{+0.8}_{-0.7} \text{ (stat)}^{+0.3}_{-0.2} \text{ (syst)}^{+0.2}_{-0.1} \text{ (theo)} \times 10^{-6} \]

where the theoretical uncertainty includes the uncertainties in \( \mathcal{A} \), \( C_{60-120}^{\text{fit}} \), and \( \sigma(pp \rightarrow Z)B(Z \rightarrow \ell^+ \ell^-) \). This can be compared with \( 4.6 \times 10^{-6} \), computed with MADGRAPH5_AMC@NLO [37], and is consistent with the CMS and ATLAS measurements at \( \sqrt{s} = 7 \) and 8 TeV [9, 10].

The total ZZ production cross section for both dileptons produced in the mass range 60–120 GeV and \( m_{\ell^+ \ell^-} > 4 \text{ GeV} \) is found to be

\[ \sigma(pp \rightarrow ZZ) = 14.6^{+1.9}_{-1.8} \text{ (stat)}^{+0.5}_{-0.3} \text{ (syst)}^{+0.2}_{-0.1} \text{ (theo)} \times 0.4 \text{ pb} \]

The measured total cross section can be compared to the theoretical value of 14.5 ± 0.5 ± 0.2 pb calculated with a combination of POWHEG and MCFM with the same settings as described for \( \sigma_{\text{fid}}(pp \rightarrow ZZ \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-) \). It can also be compared to 16.2 ± 0.6 pb, calculated at NNLO in QCD via MATRIX [1] or 15.0 ± 0.6 ± 0.2 pb, calculated with MCFM at NLO in QCD with additional contributions from LO \( gg \rightarrow ZZ \) diagrams. Both values are calculated with the NNPDF3.0 PDF sets, at NNLO and NLO respectively, and fixed scales set to \( m_F = m_R = m_Z \).
The total ZZ cross section is shown in Fig. 5 as a function of the proton-proton center-of-mass energy. Results from the CMS [2–4] and ATLAS [5–7] experiments are compared to predictions from MATRIX and MCFM with the NNPDF3.0 PDF sets and fixed scales $\mu_F = \mu_R = m_Z$. The MATRIX prediction uses PDFs calculated at NNLO, while the MCFM prediction uses NLO PDFs. The uncertainties are statistical (inner bars) and statistical and systematic added in quadrature (outer bars). The band around the MATRIX predictions reflects scale uncertainties, while the band around the MCFM predictions reflects both scale and PDF uncertainties. The theoretical predictions and all CMS measurements are performed in the dilepton mass range 60–120 GeV. All ATLAS measurements are in the mass window 66–116 GeV. The smaller mass window is estimated to cause a 1.6% reduction in the measured cross section.

![Graph showing the total ZZ cross section as a function of the proton-proton center-of-mass energy.](image)

Figure 5: The total ZZ cross section as a function of the proton-proton center-of-mass energy. Results from the CMS and ATLAS experiments are compared to predictions from MATRIX and MCFM with NNPDF3.0 PDF sets and fixed scales $\mu_F = \mu_R = m_Z$. Details of the calculations and uncertainties are given in the text. Measurements at the same center-of-mass energy are shifted slightly along the x-axis for clarity.

9 Summary

Results have been presented for a study of four-lepton final states in proton-proton collisions at $\sqrt{s} = 13$ TeV with the CMS detector at the LHC. The $pp \rightarrow ZZ$ cross section has been measured to be $\sigma(pp \rightarrow ZZ) = 14.6^{+1.9}_{-1.8}$ (stat) $^{+0.5}_{-0.3}$ (syst) $\pm 0.2$ (theo) $\pm 0.4$ (lumi) pb for Z boson masses in the range $60 < m_Z < 120$ GeV. The branching fraction for Z boson decays to four leptons has been measured to be $B(Z \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-) = 4.9^{+0.8}_{-0.7}$ (stat) $^{+0.3}_{-0.2}$ (syst) $^{+0.2}_{-0.1}$ (theo) $\pm 0.1$ (lumi) $\times 10^{-6}$ for four-lepton mass in the range $80 < m_{\ell^+\ell^-\ell'^+\ell'^-} < 100$ GeV and dilepton mass $m_{\ell^+\ell^-} >$
4 GeV for all oppositely charged same-flavor lepton pairs. The results are consistent with SM predictions.

Acknowledgments

We thank Massimiliano Grazzini and his collaborators for providing the NNLO cross section calculations. We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMWFW and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES and CSF (Croatia); RPF (Cyprus); SENESCYT (Ecuador); MoER, ERC IUT and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); OTKA and NIH (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); LAS (Lithuania); MOE and UM (Malaysia); BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI (Mexico); MBIE (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Dubna); MON, RosAtom, RAS and RFBR (Russia); MESTD (Serbia); SEIDI and CPAN (Spain); Swiss Funding Agencies (Switzerland); MST (Taipei); ThEPCenter, IPST, STAR and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU and SFFR (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

Individuals have received support from the Marie-Curie program and the European Research Council and EPLANET (European Union); the Leventis Foundation; the A. P. Sloan Foundation; the Alexander von Humboldt Foundation; the Belgian Federal Science Policy Office; the Fonds pour la Formation à la Recherche dans l’Industrie et dans l’Agriculture (FRIA-Belgium); the Agentschap voor Innovatie door Wetenschap en Technologie (IWT-Belgium); the Ministry of Education, Youth and Sports (MEYS) of the Czech Republic; the Council of Science and Industrial Research, India; the HOMING PLUS program of the Foundation for Polish Science, cofinanced from European Union, Regional Development Fund, the Mobility Plus program of the Ministry of Science and Higher Education, the National Science Center (Poland), contracts Harmonia 2014/14/M/ST2/00428, Opus 2013/11/B/ST2/04202, 2014/13/B/ST2/02543 and 2014/15/B/ST2/03998, Sonata-bis 2012/07/E/ST2/01406; the Thalis and Aristeia programs cofinanced by EU-ESF and the Greek NSRF; the National Priorities Research Program by Qatar National Research Fund; the Programa Clarín-COFUND del Principado de Asturias; the Rachadapisek Sompot Fund for Postdoctoral Fellowship, Chulalongkorn University and the Chulalongkorn Academic into Its 2nd Century Project Advancement Project (Thailand); and the Welch Foundation, contract C-1845.

†: Deceased
1: Also at Vienna University of Technology, Vienna, Austria
2: Also at State Key Laboratory of Nuclear Physics and Technology, Peking University, Beijing, China
3: Also at Institut Pluridisciplinaire Hubert Curien, Université de Strasbourg, Université de Haute Alsace Mulhouse, CNRS/IN2P3, Strasbourg, France
4: Also at Universidade Estadual de Campinas, Campinas, Brazil
5: Also at Universidade Federal de Pelotas, Pelotas, Brazil
6: Also at Université Libre de Bruxelles, Bruxelles, Belgium
7: Also at Deutsches Elektronen-Synchrotron, Hamburg, Germany
8: Also at Joint Institute for Nuclear Research, Dubna, Russia
9: Also at Cairo University, Cairo, Egypt
10: Also at Fayoum University, El-Fayoum, Egypt
11: Now at British University in Egypt, Cairo, Egypt
12: Now at Ain Shams University, Cairo, Egypt
13: Also at Université de Haute Alsace, Mulhouse, France
14: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland
15: Also at Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia
16: Also at Tbilisi State University, Tbilisi, Georgia
17: Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany
18: Also at University of Hamburg, Hamburg, Germany
19: Also at Brandenburg University of Technology, Cottbus, Germany
20: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary
21: Also at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary
22: Also at University of Debrecen, Debrecen, Hungary
23: Also at Indian Institute of Science Education and Research, Bhopal, India
24: Also at Institute of Physics, Bhubaneswar, India
25: Also at University of Visva-Bharati, Santiniketan, India
26: Also at University of Ruhuna, Matara, Sri Lanka
27: Also at Isfahan University of Technology, Isfahan, Iran
28: Also at University of Tehran, Department of Engineering Science, Tehran, Iran
29: Also at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran
30: Also at Universitá degli Studi di Siena, Siena, Italy
31: Also at Purdue University, West Lafayette, USA
32: Also at International Islamic University of Malaysia, Kuala Lumpur, Malaysia
33: Also at Malaysian Nuclear Agency, MOSTI, Kajang, Malaysia
34: Also at Consejo Nacional de Ciencia y Tecnología, Mexico city, Mexico
35: Also at Warsaw University of Technology, Institute of Electronic Systems, Warsaw, Poland
36: Also at Institute for Nuclear Research, Moscow, Russia
37: Now at National Research Nuclear University ‘Moscow Engineering Physics Institute’ (MEPhI), Moscow, Russia
38: Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia
39: Also at University of Florida, Gainesville, USA
40: Also at P.N. Lebedev Physical Institute, Moscow, Russia
41: Also at California Institute of Technology, Pasadena, USA
42: Also at Budker Institute of Nuclear Physics, Novosibirsk, Russia
43: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia
44: Also at INFN Sezione di Roma; Università di Roma, Roma, Italy
45: Also at Scuola Normale e Sezione dell’INFN, Pisa, Italy
46: Also at National and Kapodistrian University of Athens, Athens, Greece
47: Also at Riga Technical University, Riga, Latvia
48: Also at Institute for Theoretical and Experimental Physics, Moscow, Russia
49: Also at Albert Einstein Center for Fundamental Physics, Bern, Switzerland
50: Also at Adiyaman University, Adiyaman, Turkey
51: Also at Mersin University, Mersin, Turkey
52: Also at Cag University, Mersin, Turkey
53: Also at Piri Reis University, Istanbul, Turkey
54: Also at Gaziosmanpasa University, Tokat, Turkey
55: Also at Ozyegin University, Istanbul, Turkey
56: Also at Izmır Institute of Technology, Izmır, Turkey
57: Also at Marmara University, Istanbul, Turkey
58: Also at Kafkas University, Kars, Turkey
59: Also at Istanbul Bilgi University, Istanbul, Turkey
60: Also at Yildiz Technical University, Istanbul, Turkey
61: Also at Hacettepe University, Ankara, Turkey
62: Also at Rutherford Appleton Laboratory, Didcot, United Kingdom
63: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
64: Also at Instituto de Astrofísica de Canarias, La Laguna, Spain
65: Also at Utah Valley University, Orem, USA
66: Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia
67: Also at Facoltà Ingegneria, Università di Roma, Roma, Italy
68: Also at Argonne National Laboratory, Argonne, USA
69: Also at Erzincan University, Erzincan, Turkey
70: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey
71: Also at Texas A&M University at Qatar, Doha, Qatar
72: Also at Kyungpook National University, Daegu, Korea
