Delay-induced self-organization dynamics in a prey-predator network with diffusion

Q.Hu · J.W. Shen

Abstract Time delays can induce the loss of stability and degradation of performance. In this paper, the pattern dynamics of a prey-predator network with diffusion and delay are investigated, where the inhomogeneous distribution of species in space can be viewed as a random network, and delay can affect the stability of the network system. Our results show that time delay can induce the emergence of Hopf and Turing bifurcations, which are independent of the network, and the conditions of bifurcation are derived by linear stability analysis. Moreover, we find that the Turing pattern can be related to the network connection probability. The Turing instability region involving delay and network connection probability is obtained. Finally, the numerical simulation verifies our results.

Keywords Hopf bifurcation · Turing instability · prey-predator · delay · network diffusion

1 Introduction

Colorful patterns emerge from reaction-diffusion equations and can explain a wide variety of natural phenomena. Since Turing published his groundbreaking work [1], the Turing pattern has received increasing attention in biology, physics, chemicals, and other fields [2,3,4,5]. At present, it has been applied to more complex interdisciplinary subjects. Recently, many scientists have also found Turing patterns in prey-predator systems [6,7,8]. For the prey-predator
model, there are many variations in this model; for example, Aziz-Alaoui and Daher [9] proposed a modified predator-prey model, and Leslie [10] studied the boundedness and global stability of the model.

For a reaction-diffusion system, Turing [1] first discovered that diffusion could cause the system to be unstable under certain conditions and obtained Turing pattern phenomena. Then, many scholars began to study the pattern formations of the prey-predator model by using the reaction-diffusion equation [11,12,13,14,15]. Camara and Aziz-Alaoui [16] investigated a modified Holling-Tanner model and found Turing and Hopf bifurcations; they also derived the bifurcation conditions. Then, for a diffusive predator-prey model with the Holling-Tanner functional response, Shi et al. [17] investigated the stability and the existence of a positive solution.

By studying diffusion, Othmer and Scriven [18] proposed a general method for analyzing the instability of the reaction-diffusion model in small networks, and they also obtained the effect of network topology changes on the stability and pattern. Then, Jansen and Lloyd [19] extended the method to large random networks and gave the corresponding Turing patterns. Aly and Farkas [20] studied the effect of diffusion in a small network on the Turing pattern of the prey-predator system, where the migration of populations among patches causes diffusion. Subsequently, Turing patterns in complex organized networks were studied in [21,22,23]. For the FitzHugh-Nagumo model in a network-organized system, Zheng and Shen [24] recently studied Turing instability, where the network structure and diffusion lead to Turing instability. Liu et al. [25] placed the prey-predator model into complex networks and found that the network topology and diffusion rate can affect the Turing pattern formation. Considering the inhomogeneous distribution of prey and predators in communities and the fact that communities in real life can be abstracted as a complex network structure, we can investigate a prey-predator diffusive system functional response in the random network.

Time delay is a universal phenomenon in biological systems [26,27,28]. For the prey-predator system, delay generally represents the gestation or maturity period of population reproduction; it can destroy the stability and lead to Hopf bifurcation as well as Turing bifurcation. Ruan and Sen [29,30] provided two methods to investigate the time delay. In [31], Yang and Zhang considered a diffusive prey-predator system with delay, and they obtained Turing instability and Hopf bifurcation caused by the delay. Recently, Chang et al. [32] investigated a predator-prey diffusive model in complex networks and found that delay can induce pattern dynamics. Wang et al. [33] found that the network structure hardly has an impact on the stability of this model with delay and that a large time delay can induce the thick-tailed phenomenon of evolution patterns.

However, there are few studies on reaction-diffusion systems with delays in diffusion networks. In this paper, for a prey-predator diffusion network with Holling type II and modified Leslie-Gower functional response, we will investigate the dynamical behaviors emerging from the time delay caused by predator gestation. For the random migration and inhomogeneous spatial distribution
of prey and predators among different communities, we consider them through a complex network and derive the stability condition of the positive equilibrium by linear stability analysis in Section 2. Then, in Section 3, we use two methods to study Hopf and Turing bifurcations caused by delay and network diffusion. In Section 4, consistent results are obtained by numerical simulation. Finally, the results are summarized in Section 5.

2 Stability analysis of the prey-predator diffusion network without delay

The modified Leslie-Gower prey-predator diffusion network with a Holling type II functional response can be written as follows:

\[
\begin{align*}
\frac{du}{dt} &= u(1 - u) - \frac{uv}{u + a} + d_1 \nabla^2 u = f(u, v) + d_1 \nabla^2 u, \\
\frac{dv}{dt} &= v(\delta - \beta \frac{v}{u + b}) + d_2 \nabla^2 v = g(u, v) + d_2 \nabla^2 v,
\end{align*}
\]

where \(\frac{v}{u + b}\) is the modified Leslie-Gower functional response.

Considering the inhomogeneous distribution of species and the effect of delay \(\tau (\tau > 0)\) caused by predator gestation, model (1) with delay in the random network is

\[
\begin{align*}
\frac{dud_i}{dt} &= u_i(1 - u_i) - \frac{u_i v_i(t-\tau)}{u_i + a} + d_1 \sum_{j=1}^{N} L_{ij} u_j, \\
\frac{dv_i}{dt} &= v_i(\delta - \beta \frac{v_i(t-\tau)}{u_i + b}) + d_2 \sum_{j=1}^{N} L_{ij} v_j,
\end{align*}
\]

where \(i = 1, \ldots, N\), \(L_{ij} = A_{ij} - k_i \delta_{ij}\) is the network Laplacian matrix’s element, where \(k_i\) is the degree of node \(i\) (we assume that \(k_1 \geq k_2 \geq \cdots \geq k_N\) and \(A_{ij}\) is the adjacency matrix’s element. \(N\) nodes make up the random network, and the nodes are connected with the connection probability \(p\) [24].

If \(\tau = 0\), the system (2) becomes:

\[
\begin{align*}
\frac{dud_i}{dt} &= f(u_i, v_i) + d_1 \sum_{j=1}^{N} L_{ij} u_j, \\
\frac{dv_i}{dt} &= g(u_i, v_i) + d_2 \sum_{j=1}^{N} L_{ij} v_j.
\end{align*}
\]

Clearly, the equilibrium points of system (3) are derived by the following equations:

\[
\begin{align*}
f(u_i, v_i) &= u_i(1 - u_i) - \frac{u_i v_i}{u_i + a} = 0, \\
g(u_i, v_i) &= v_i(\delta - \beta \frac{v_i}{u_i + b}) = 0.
\end{align*}
\]

Then, when \(a - \frac{\delta}{\beta} b > 0\), we obtain only one positive equilibrium point \(E(u^*, v^*)\):

\[
\begin{align*}
u^* &= \frac{1}{2}[-(a + \frac{\delta}{\beta} - 1) + \sqrt{(a + \frac{\delta}{\beta} - 1)^2 - 4(\frac{\delta}{\beta} - a)}], \\
v^* &= \frac{\delta}{\beta} (u^* + b).
\end{align*}
\]

We assume that system (3) has only a positive equilibrium point \(E(u^*, v^*)\) in the following, namely, \(a - \frac{\delta}{\beta} b > 0\).
2.1 Stability analysis of the model without delay and diffusion

By linear stability analysis, the Jacobian matrix of (3) without diffusion at \( E(u^*, v^*) \) is
\[
J = \begin{pmatrix}
a_{11} & a_{12} \\
a_{21} & a_{22}
\end{pmatrix} = \begin{pmatrix}
1 - 2u^* + \frac{a(1-u^*)}{u^*+a} - \frac{u^*}{u^*+a} \\
\delta^2
\end{pmatrix}.
\]

Then, the corresponding characteristic equation is
\[
\lambda^2 - trJ\lambda + detJ = 0,
\]
where
\[
trJ = a_{11} + a_{22} = 1 - 2u^* + \frac{a(1-u^*)}{u^*+a} - \delta,
\]
\[
detJ = a_{11}a_{22} - a_{12}a_{21} = \frac{3u^*}{u^*+a}(2u^* + a + \frac{a}{\delta} - 1).
\]

The roots of Eq. (5) are
\[
\lambda_{1,2} = \frac{1}{2}(trJ \pm \sqrt{(trJ)^2 - 4detJ}).
\]

According to the Routh-Hurwitz Criterion, Eq. (5) has roots with negative real parts when \( trJ < 0 \) and \( detJ > 0 \), namely, \( Re\lambda_{1,2} < 0 \) when \( 1 - a - \delta > 0 \), \( (1 - a - \delta)^2 - 8\delta a < 0 \) and \( a + \frac{a}{\delta} - 1 > 0 \). That is, the particular equilibrium point \( E(u^*, v^*) \) is stable if
\[
\begin{cases}
1 - a - \delta > 0, \\
(1 - a - \delta)^2 - 8\delta a < 0, \\
a + \frac{a}{\delta} - 1 > 0.
\end{cases}
\]

\textbf{Lemma 1} Suppose that condition (7) holds, for system (3) without diffusion, \( E(u^*, v^*) \) is asymptotically stable [9].

In the following, we assume that \( trJ < 0 \) and \( detJ > 0 \). Namely, condition (7) is satisfied.

2.2 Stability analysis of the network diffusion model without delay

For system (3), the eigenvalues \( \Lambda_\alpha \) and their corresponding eigenvectors \( \phi^{(\alpha)} = (\phi_1^{(\alpha)}, ..., \phi_N^{(\alpha)})^T \) of network Laplacian matrix \( L \) satisfy \( \sum_{j=1}^N L_{ij}\phi_j^{(\alpha)} = \Lambda_\alpha\phi_i^{(\alpha)} \), where \( \alpha = 1, ..., N \), and \( \Lambda_\alpha \leq 0 \) because \( L \) is a negative semidefinite real matrix. We assume that \( |\Lambda_\alpha| \) is in decreasing order, namely, \( \Lambda_1 \leq \Lambda_2 \leq \cdots \leq \Lambda_N = 0 \).

Suppose Eq. (3) has the general solution of the following form:
\[
\begin{align*}
u_i &= \sum_{\alpha=1}^N C_\alpha^1 e^{\lambda_\alpha t}\phi_i^{(\alpha)}, \\
v_i &= \sum_{\alpha=1}^N C_\alpha^2 e^{\lambda_\alpha t}\phi_i^{(\alpha)}.
\end{align*}
\]
Substituting Eq. (8) into Eq. (3) give the following

$$
\lambda_{\alpha} \begin{pmatrix} C_{\alpha 1}^1 \\ C_{\alpha 2}^2 \end{pmatrix} = \begin{pmatrix} a_{11} + d_1 \Lambda & a_{12} \\ a_{21} & a_{22} + d_2 \Lambda \end{pmatrix} \begin{pmatrix} C_{\alpha 1}^1 \\ C_{\alpha 2}^2 \end{pmatrix}.
$$

(9)

Thus, the characteristic equation of system (3) is

$$
\lambda_{\alpha}^2 - p_1 \lambda_{\alpha} + q_1 = 0,
$$

(10)

where

$$
p_1 = \text{tr} J + (d_1 + d_2) \Lambda, \\
q_1 = d_1 d_2 \Lambda^2 + (d_1 a_{22} + d_2 a_{11}) \Lambda + \text{det} J.
$$

The roots of Eq. (10) are

$$
\lambda_{\alpha} = \frac{p_1 \pm \sqrt{p_1^2 - 4q_1}}{2}.
$$

Then, for Eq. (10), the real part of the roots is negative when $p_1 < 0$ and $q_1 > 0$.

**Theorem 1** Supposing that condition (7) holds, then for system (3), $E(u^*, v^*)$ is asymptotically stable if the diffusion coefficients $d_1$ and $d_2$ satisfy

$$
s_2 d_1 < d_2 < s_1 d_1
$$

(11)

where $s_1 = s_+ = \max\{1, s_-, s_3\}$, $s_\pm = \pm \sqrt{ \frac{1}{2} |J| a_{11} a_{22} \pm 2 \sqrt{ \text{det} J (\text{det} J - a_{11} a_{22})} }$, $s_3 = -a_{22} a_{11}$.

**Proof** Define

$$
q(z) = d_1 d_2 z^2 + (d_1 a_{22} + d_2 a_{11}) z + \text{det} J,
$$

$z < 0$. If $\Delta = (d_1 a_{22} + d_2 a_{11})^2 - 4 d_1 d_2 \text{det} J < 0$ and $d_1 a_{22} + d_2 a_{11} > 0$, namely, if $s_2 d_1 < d_2 < s_1 d_1, q(z) > 0$ always holds, then $q_1 > 0$. In addition, it is evident that $p_1 < 0$ (due to that $\Lambda_{\alpha} \leq 0$ always holds). The proof is completed.

□

**Remark.** According to biological significance, $a_{11} > 0$ must be held [16]. Therefore, $a_{11} > 0$ if $\delta > \frac{2 a}{1 + 2 b - \alpha \beta}$. Therefore, from $a_{11} + a_{22} < 0$ and $d_1 a_{22} + d_2 a_{11} > 0$, we can calculate that the diffusion coefficients satisfy $d_2 > d_1$ for system (3).

3 Stability analysis of the predator-prey diffusion network with delay

For system (2), the equilibrium point is clearly $E(u^*, v^*)$. Here, we use two methods [29,30] to study the bifurcation dynamics property of system (2).
3.1 Method I

In this section, according to the method in [29] and regarding the delay \( \tau \) as the bifurcation parameter, we analyze the local stability of \( E(u^*, v^*) \) and Hopf bifurcation.

By linear stability analysis and substituting Eq. (8) into Eq. (2), we can obtain
\[
\lambda_\alpha \begin{pmatrix} C_1 \alpha \\ C_2 \alpha \end{pmatrix} = \begin{pmatrix} a_{11} + d_1 A_\alpha & a_{12} e^{-\lambda \tau} \\ a_{21} & a_{22} e^{-\lambda \tau} + d_2 A_\alpha \end{pmatrix} \begin{pmatrix} C_1 \alpha \\ C_2 \alpha \end{pmatrix}.
\]

Therefore, the corresponding characteristic equation is
\[
\lambda^2 - A_\alpha \lambda + B_\alpha + (C_\alpha - a_{22} \lambda) e^{-\lambda \tau} = 0,
\]
where
\[
A_\alpha = a_{11} + (d_1 + d_2) A_\alpha,
B_\alpha = d_1 d_2 A_\alpha^2 + d_2 a_{11} A_\alpha,
C_\alpha = \det J + d_1 a_{22} A_\alpha.
\]

When \( \tau = 0 \), Eq. (12) becomes (10).

**Lemma 2** Suppose (7) and (11) hold and regardless of what the network connection probability \( p \) is, then Equation (12) has at least a simple pair of complex roots with zero real part \( \pm i \omega_\alpha \), when \( \tau = \tau^0_\alpha \), where
\[
\omega_\alpha = \sqrt{-\frac{(A_\alpha^2 - a_{22}^2 - 2B_\alpha) \pm \sqrt{(A_\alpha^2 - a_{22}^2 - 2B_\alpha)^2 - 4(B_\alpha^2 - C_\alpha^2)}}{2}}
\]
\[
\tau^0_\alpha = \frac{1}{\omega_\alpha} \arccos\left[\frac{(\omega_\alpha^2 - B_\alpha) C_\alpha - A_\alpha a_{22} \omega_\alpha^2}{\omega_\alpha^2 a_{22}^2 + C_\alpha^2}\right] + \frac{2j\pi}{\omega_\alpha}, \quad j = 0, 1, \ldots.
\]

**Proof** Suppose \( i \omega \) is the root of (12), then
\[
- \omega^2 - i \omega A_\alpha + B_\alpha + (C_\alpha - i \omega a_{22})(\cos \omega \tau - i \sin \omega \tau) = 0.
\]

Separating the imaginary and real parts, we obtain
\[
(\omega^2 a_{22}^2 + C_\alpha^2) \sin \omega \tau = (-\omega^2 + B_\alpha) \omega a_{22} - A_\alpha C_\alpha \omega,
- (\omega^2 a_{22}^2 + C_\alpha^2) \cos \omega \tau = (-\omega^2 + B_\alpha) C_\alpha + A_\alpha \omega^2 a_{22}.
\]

From (14), we obtain
\[
\omega^4 + (A_\alpha^2 - a_{22}^2 - 2B_\alpha) \omega^2 + B_\alpha^2 - C_\alpha^2 = 0.
\]

The two roots of Eq. (15) can be expressed as follows:
\[
\omega^2_{\alpha \pm} = \frac{1}{2} \left[ -(A_\alpha^2 - a_{22}^2 - 2B_\alpha) \pm \sqrt{(A_\alpha^2 - a_{22}^2 - 2B_\alpha)^2 - 4(B_\alpha^2 - C_\alpha^2)} \right].
\]

When conditions (7) and (11) hold, we have
\[
B_\alpha + C_\alpha = d_1 d_2 A_\alpha^2 + (d_1 a_{22} + d_2 a_{11}) A_\alpha + \det J = q_1 > 0
\]
and
\[
B_\alpha - C_\alpha = d_1 d_2 A_\alpha^2 + (-d_1 a_{22} + d_2 a_{11}) A_\alpha - \det J.
\]
According to $\det J > 0$, $B_\alpha - C_\alpha = 0$ has a negative root $\Lambda_\alpha$, where $\Lambda_\alpha = \frac{-(d_2 a_{11} - d_1 a_{22}) - \sqrt{(d_2 a_{11} - d_1 a_{22})^2 + 4 d_1 d_2 \det J}}{2 d_1 d_2}$. That is $B_\alpha - C_\alpha > 0$ when $\alpha \in (-\infty, \Lambda_\alpha)$ and $B_\alpha - C_\alpha < 0$ when $\alpha \in (\Lambda_\alpha, 0]$. Then, $B_\alpha^2 - C_\alpha^2 > 0$ for $\alpha \in (-\infty, \Lambda_\alpha)$ and $B_\alpha^2 - C_\alpha^2 < 0$ for $\alpha \in (\Lambda_\alpha, 0]$. Hence, Eq. (15) has a positive root $\omega^2_{\alpha^+}$ when $\alpha \in (\Lambda_\alpha, 0]$. In addition, from $A_1 \leq A_2 \leq \cdots \leq A_N = 0$, we know that $A_0 \leq 0$ always holds regardless of what $p$ is, so Equation (12) has at least one pair of roots with zero real part $\pm \omega_{\alpha^+}$ when $\tau = \tau_0^\alpha$, and $\tau_0^\alpha$ values are revealed from (14).

We denote $\lambda_\alpha(\tau) = \nu_\alpha(\tau) + i \omega_\alpha(\tau)$ as the root of Equation (12). Obviously, $\nu_\alpha(\tau_0^\alpha) = 0$ and $\omega_\alpha(\tau_0^\alpha) = \omega_{\alpha^+}$. In addition, we define $\tau^* = \min \{\tau_0^\alpha\}$. Then, we have the following theorem:

**Theorem 2** Suppose (7) and (11) hold. For system (2), regardless of what $p$ is,

(i) if $\tau \in [0, \tau^*)$, then Eq. (12) has roots with a negative real part. Thus, the equilibrium $E(u^*, v^*)$ is asymptotically stable.

(ii) if $\tau > \tau^*$, then Eq. (12) has at least one root with a positive real part. Thus, the equilibrium $E(u^*, v^*)$ is unstable.

(iii) if $\tau = \tau^*$, then Eq. (12) has at least a pair of roots with zero real part $\pm i \omega_{\alpha^+}$. In addition, $\frac{d Re \lambda}{d \tau} |_{\tau=\tau^*} > 0$. Thus, system (2) exhibits Hopf bifurcation at the equilibrium $E(u^*, v^*)$.

**Proof** From Eq. (12), we have

$$\frac{d \lambda}{d \tau} |_{\tau=\tau^*} = \frac{(2\lambda - A_\alpha)e^{\lambda\tau} - (C_\alpha - \lambda a_{22})\tau - a_{22}}{\lambda(C_\alpha - \lambda a_{22}).}$$

Therefore, when conditions (7) and (11) hold and existing $A_\alpha \in (\Lambda_\alpha, 0]$,

$$[\frac{d Re \lambda}{d \tau} |_{\tau=\tau^*}] = \Re \left(\frac{-A_\alpha + 2i \omega_\alpha^+ e^{i \omega_\alpha^+ \tau^*} + (C_\alpha - ia_{22} \omega_\alpha^+ \tau^* - a_{22}}{\omega_\alpha^+ (a_{22} \omega_\alpha^+ + i C_\alpha)}\right)$$

$$= \frac{1}{a_{22} \omega_\alpha^2 + C_\alpha^2} \sqrt{(A_\alpha^2 - a_{22}^2 - 2 B_\alpha)^2 - 4 (B_\alpha^2 - C_\alpha^2)} > 0.$$ 

Therefore, from $\nu_\alpha(\tau^*) = 0$, $\frac{d Re \lambda}{d \tau} |_{\tau=\tau^*} > 0$ and Lemma 2, we obtain $\tau^*$ as the bifurcation value. Furthermore, $Re \lambda < 0$ when $\tau < \tau^*$, $Re \lambda < 0$ is violated when $\tau > \tau^*$, and $Re \lambda = 0$ when $\tau = \tau^*$. Therefore, the proof is complete. □

### 3.2 Method II

In this section, according to the method in [30] and assuming the delay $\tau$ to be small, we consider the Turing instability of system (2).

Because $\tau$ is small enough, we replace $v_i(t-\tau) = v_i(t) - \tau \frac{dv_i}{dt}$, and then, system (2) can be written as

$$\begin{align*}
\frac{du_i}{dt} &= f(u_i, v_i) - \tau \frac{dv_i}{dt} + d_i \sum_{j=1}^{N} L_{ij} u_j, \\
\frac{dv_i}{dt} &= \nu_i(h(u_i, v_i) - \tau \frac{dv_i}{dt} + d_i \sum_{j=1}^{N} L_{ij} v_j. \\
\end{align*}$$

(16)
where \( g(u_i, v_i) = v_i h(u_i, v_i) \), and \( g_{v_i} = \delta + 2v_i h_{v_i} \).

Expanding (16) in the Taylor series and neglecting the higher order nonlinearities, we have

\[
\begin{align*}
\frac{du_i}{dt} &= f(u_i, v_i) - \tau f_{v_i} \frac{du_i}{dt} + d_1 \sum_{j=1}^{N} L_{ij} u_j, \\
\frac{dv_i}{dt} &= g(u_i, v_i) - \tau g_{v_i} \frac{dv_i}{dt} + d_2 \sum_{j=1}^{N} L_{ij} v_j.
\end{align*}
\] (17)

According to the research method in Section 2.2, we obtain the corresponding characteristic equation of the system at \( \bar{E}(u^*, v^*) \) as

\[
\lambda^2 - p_2 \lambda + q_2 = 0,
\] (18)

where

\[
p_2 = \frac{1}{1 + \tau a_{22}} (trJ + (d_1 + d_2)A_n + \tau (detJ + d_1 a_{22} A_n)),
\]
\[
q_2 = \frac{1}{1 + \tau a_{22}} (d_1 d_2 A_n^2 + (d_1 a_{22} + d_2 a_{11}) A_n + detJ).
\]

Because \( \tau \) is small, \( \frac{1}{1 + \tau a_{22}} > 0 \), namely, \( \tau < \tau_1 = -\frac{1}{a_{22}} \).

Turing instability means that system (2) without diffusion is stable (namely, when (7) holds), but unstable for diffusion system (2). According to the Routh-Hurwitz criterion, system (2) is stable when \( p_2 < 0 \) and \( q_2 > 0 \) always hold. When at least one of \( p_2 < 0 \) and \( q_2 > 0 \) is violated, Turing instability occurs. Therefore, we have the following theoretical results.

**Theorem 3** Suppose \( \tau < \tau_1 \) and condition (7) hold, for system (2)

(i) If \( \tau \in \{ \tau_1, \tau_2 \} \) \( (\tau_2 = -\frac{trJ}{d_2}) \) and \( s_2 d_1 < d_2 < s_1 d_1 \), then \( p_2 < 0 \) and \( q_2 > 0 \) hold. Thus, the equilibrium point \( \bar{E}(u^*, v^*) \) is asymptotically stable.

(ii) If \( \tau < \min \{ \tau_1, \tau_2 \} \), \( d_2 > s_1 d_1 \) and existing \( A_n \in [A_{1a}, A_{1c}] \) for some \( p, q \), then \( q_2 > 0 \) is violated. Thus, Turing bifurcation occurs at \( \bar{E}(u^*, v^*) \), where

\[
A_{1c} = \frac{-s_1 d_2 A_n^2 + d_2 a_{11} A_n}{2d_1 d_2 ds_2}.
\]

(iii) If \( \tau_2 < \tau < \tau_1, s_2 d_1 < d_2 < s_1 d_1 \) and existing \( A_n > A_{1c} = \frac{-trJ + s_1 d_1 A_n}{s_1 + d_2 + d_1 a_{22} A_n} \), then \( p_2 > 0 \) is violated. Thus, system (2) exhibits Turing bifurcation at \( \bar{E}(u^*, v^*) \).

**Proof**

From \( p_2 = \frac{1}{1 + \tau a_{22}} (trJ + (d_1 + d_2)A_n + \tau (detJ + d_1 a_{22} A_n)) \), we know that \( p_2 < 0 \) when \( \tau < \min \{ \tau_1, \tau_2 \} \). While \( p_2 > 0 \) when \( \tau_2 < \tau < \tau_1 \) and existing \( A_n > A_{1c} \). And from \( q_2 = \frac{1}{1 + \tau a_{22}} q_1 \), we know that \( q_2 > 0 \) if \( \tau < \tau_1 \) and \( q_1 > 0 \) hold. According to the proof of Theorem 1, \( q_1 > 0 \) when \( s_2 d_1 < d_2 < s_1 d_1 \), \( q_2 > 0 \) is violated when \( \tau < \tau_1 \), and some existing \( A_n \) satisfy \( q_1 < 0 \). By \( q_1 = d_1 d_2 A_n^2 + (d_1 a_{22} + d_2 a_{11}) A_n + detJ \), we know that if \( \Delta > 0, d_1 a_{22} + d_2 a_{11} > 0 \) and existing \( A_n \in [A_{1a}, A_{1c}] \), namely when \( d_2 > s_1 d_1 \) and existing \( A_n \in [A_{1a}, A_{1c}] \) \( (A_n \) is related to \( p, q_1 > 0 \) does not always hold. Therefore, we obtain conclusions (i), (ii) and (iii). The proof is complete. \( \Box \)

**4 Numerical results**

In this section, based on the above theoretical results, we present some numerical simulations. Here, we construct a random network with \( N = 100 \) nodes and consider the parameters as:

\[
a = 0.08, b = 0.04, \delta = 0.6, \beta = 0.6, d_1 = 0.02.
\]
For this case, the positive equilibrium point is \( E(0.1640, 0.2040) \), and \( \text{tr}\, J = -0.201, \det J = 0.1645, s_1 = 6.8386, \) and \( s_2 = 1.5078 \). These parameters satisfy condition (7). Therefore, according to Lemma 1, system (3) without diffusion is asymptotically stable [Figure 1]. If we choose \( d_1 = 0.02 \) and \( d_2 = 0.1 \), condition (11) holds. For system (3) and according to Theorem 1, \( E(u^*, v^*) \) is asymptotically stable, which is shown in Figure 2.

![Figure 1](image1.png)

**Fig. 1** When the parameters \( a = 0.08, b = 0.04, \delta = 0.6, \) and \( \beta = 0.6 \), (a) the phase space shows that system (2) without delay and diffusion has only one positive equilibrium point \( E(u^*, v^*) \), (b) the time series diagram shows that \( E(u^*, v^*) \) is stable.

![Figure 2](image2.png)

**Fig. 2** When the parameters \( a = 0.08, b = 0.04, \delta = 0.6, \beta = 0.6, d_1 = 0.02, \) and \( d_2 = 0.1 \), the equilibrium point \( E(u^*, v^*) \) of system (2) without delay is stable, where the initial values are randomly chosen and \( p = 0.1 \).

When \( \tau \) is small, we obtain \( \tau_1 = 1.6667 \) and \( \tau_2 = 1.2285 \). Considering \( d_2 \) and \( \tau \) as the bifurcation parameters and from Theorem 3, \( E(u^*, v^*) \) is asymptotically stable when \( \tau < \min\{\tau_1, \tau_2\} \) and \( s_2d_1 < d_2 < s_1d_1 \), which is shown in Figure 3 when \( \tau = 0.3657 \) and \( d_2 = 0.1 \). In contrast, Turing instability occurs when \( d_2 > s_1d_1 \) for existing \( \Lambda_\alpha \in [\Lambda_{\alpha+}, \Lambda_{\alpha-}] \) or \( \tau_2 < \tau < \tau_1 \) for existing \( \Lambda_\alpha > \Lambda_{\alpha+} \). Therefore, we have two types of Turing instability. Figures 7 and 8 show that Turing bifurcation occurs when \( p \) approximately satisfies \( \frac{1}{N} \leq p \leq s_1 \ln^N \) (due to \( \Lambda_{\alpha-} = -17.7705 \) and \( \Lambda_{\alpha+} = -0.9257 \)), where \( \tau = 0.5 \) and \( d_2 = 0.5 \). Figure 9 shows the distribution of network eigenvalues \( \Lambda_\alpha \) when...
For system (2), the equilibrium point $E(u^*, v^*)$ is asymptotically stable, where $\tau = \tau^* - 0.5$, $d_1 = 0.02$, and $d_2 = 0.1$, and the initial values are randomly chosen. (a)(b)$p = 0.1$, (c)(d)$p = 0.6$.

For system (2), when $p = 0.1$, $d_1 = 0.02$, $d_2 = 0.1$ and the initial values are randomly chosen, (a)(b)the equilibrium point $E(u^*, v^*)$ is unstable and there is a periodic solution when $\tau = \tau^* + 1$, (c)(d)there is a Hopf bifurcation when $\tau = \tau^*$. 
For system (2), when $p = 0.6$, $d_1 = 0.02$, $d_2 = 0.1$ and the initial values are randomly chosen, (a)(b) the equilibrium point $E(u^*, v^*)$ is unstable and there is a periodic solution when $\tau = \tau^* + 1$, (c)(d) there is a Hopf bifurcation when $\tau = \tau^*$.

\[ \begin{array}{cc}
\text{(a)} & \text{(b)} \\
\text{(c)} & \text{(d)}
\end{array} \]

**Fig. 5** For system (2), when $p = 0.6$, $d_1 = 0.02$, $d_2 = 0.1$ and the initial values are randomly chosen, (a)(b) the equilibrium point $E(u^*, v^*)$ is unstable and there is a periodic solution when $\tau = \tau^* + 1$, (c)(d) there is a Hopf bifurcation when $\tau = \tau^*$.

\[ \begin{array}{cc}
\text{(a)} & \text{(b)}
\end{array} \]

**Fig. 6** Bifurcation diagram of system (2) with respect to $\tau$ when $d_2 = 0.1$.

$p = 0.1/0.6$. Then, we give the approximate Turing bifurcation region of system (2) with respect to $d_2$ and $p$ [Figure 10]. Figure 11 shows the Turing bifurcation caused by delay and diffusion, where $\tau = 1.5$, $d_2 = 0.1$, and $\Lambda_{ac} = -0.4379$.

For system (2), taking $d_2 = 0.1$ and $p$ as randomly selected, we obtain that $\Lambda_{0} = -28.7563$ and $\tau^* = 0.8657$. Therefore, considering delay $\tau$ as the bifurcation parameter and from Theorem 2, $E(u^*, v^*)$ is asymptotically stable when $\tau \in [0, \tau^*)$, which is shown in Fig 3. When $\tau$ reaches the critical value $\tau^*$, the system undergoes Hopf bifurcation when $\tau = \tau^*$, and the system becomes unstable when $\tau > \tau^*$, where prey and predator will coexist and periodic oscillations will occur. The numerical simulations of the two cases are shown.
Fig. 7 When $d_2 = 0.5, \tau = 0.5, p = 0.1$ and the initial values are randomly chosen, system (2) is unstable and Turing bifurcation with respect to $d_2$ occurs.

Fig. 8 When $d_2 = 0.5, \tau = 0.5, p = 0.6$ and the initial values are randomly chosen, there is no Turing bifurcation. Namely, system (2) is stable regardless of the $d_2$ value.
Fig. 9 The distribution of network eigenvalues $\lambda_n$. (a) There exist some $\lambda_n$ that satisfy $\lambda_n \in [\lambda_n^{-}, \lambda_n^{+}]$ and $\lambda_n > \lambda_{ac}$ when $p = 0.1$. (b) $\lambda_n \in [\lambda_n^{-}, \lambda_n^{+}]$ is violated when $p = 0.6$.

Fig. 10 Turing instability region of the network delay system (2) with respect to $p$ and $d_2$, where $\tau = 0.5$ and the red region is the Turing instability region.

Fig. 11 When $d_2 = 0.1$ and $p = 0.1$, (a) Turing instability occurs, where $\tau = 1.5$ and the initial values are randomly chosen. (b) The corresponding Turing bifurcation graph with respect to $\tau$.

In Figures 4 and 5. Finally, we obtain the bifurcation diagram of $\tau$, which is shown in Figure 6.
5 Conclusion

In this paper, a prey-predator diffusion network with delay is studied, and the stability of the positive equilibrium point \( E(u^*, v^*) \) is investigated. From the linear stability analysis, we find that delay can change the stability and produce Hopf and Turing bifurcations. Then, the numerical simulations are given.

First, for the network model without delay, we give the conditions of asymptotic stability, and the corresponding figures are shown in Figures 1 and 2. Then, for the network system with delay, we use two methods to analyze the influences of delay and diffusion on the stability (Theorems 2 and 3). Hopf and Turing bifurcations are obtained. When condition (11) holds, the network system always undergoes Hopf bifurcation and Turing bifurcation regardless of the network connection probability \( p \) [Figures 3, 4, 5, 6, and 11]. Namely, regardless of how the network nodes are connected, prey and predators will coexist, and the system will oscillate periodically. If condition (11) is not held, Turing instability occurs when \( p \) approximately satisfies \( \frac{N}{\Lambda^2} \leq p \leq s_1 \ln \frac{N}{\Lambda} \) \( (A^*_a \in [A^*_a-, A^*_a^+]) \). Figures 7-10 show the numerical simulations. For this Turing instability caused by network diffusion, the network structure affects the stability. However, there are some problems that we have not studied, such as the stability and period as well as the direction of the bifurcating periodic solution. Thus, we will study these problems in the future.
