Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Major Article

Prolonged persistence of PCR-detectable virus during an outbreak of SARS-CoV-2 in an inpatient geriatric psychiatry unit in King County, Washington

Background: We describe key characteristics, interventions, and outcomes of a severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) outbreak within an inpatient geriatric psychiatry unit at the University of Washington Medical Center – Northwest.

Methods: After identifying 2 patients with SARS-CoV-2 infection on March 11, 2020, we conducted an outbreak investigation and employed targeted interventions including: screening of patients and staff; isolation and cohorting of confirmed cases; serial testing; and enhanced infection prevention measures.

Results: We identified 10 patients and 7 staff members with SARS-CoV-2 infection. Thirty percent of patients (n = 3) remained asymptomatic over the course of infection. Among SARS-CoV-2 positive patients, fever (n = 5, 50%) and cough (n = 4, 40%) were the most common symptoms. Median duration of reverse transcription polymerase chain reaction (RT-PCR) positivity was 25.5 days (interquartile range [IQR] 22.8-41.8) among symptomatic patients and 22.0 days (IQR 19.5-25.5) among asymptomatic patients. Median initial (19.0, IQR 18.7-25.7 vs 21.7, IQR 20.7-25.6) and nadir (18.9, IQR 18.2-20.3 vs 19.8, IQR 17.0-20.7) cycle threshold values were similar across symptomatic and asymptomatic patients, respectively.

Conclusions: Asymptomatic infection was common in this cohort of hospitalized, elderly individuals despite similar duration of SARS-CoV-2 RT-PCR positivity and cycle threshold values among symptomatic and asymptomatic patients.

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), a novel coronavirus causing coronavirus disease 2019 (COVID-19), was initially described in Wuhan, China in late 2019.1 Infection with SARS-CoV-2 typically causes fever, cough, and shortness of breath, although the clinical spectrum can vary from asymptomatic carriage to critical illness.2,10 Older individuals have been disproportionately affected by COVID-19, with most deaths occurring in persons over the age of 60.6-10

SARS-CoV-2 has now spread to nearly every country in the world.11 and on March 11, 2020, the World Health Organization declared the COVID-19 outbreak to be a global pandemic.12 The first known case of COVID-19 in the United States was diagnosed in Snohomish County, Washington on January 20, 2020,13 and on February 28, 2020 Public Health – Seattle & King County identified an outbreak of COVID-19 within a Seattle-area long-term care (LTC) facility.10 Since that time, there have been over 64,151 cases of SARS-CoV-2 and 1,716 deaths due to COVID-19 in Washington State.14 While persons over the age of 60 represent 19% of diagnosed SARS-CoV-2 cases in Washington State, they account for 89% of COVID-19-related deaths.14 Outbreaks within LTC facilities have been central to the Washington State COVID-19 epidemic6,15; however, there have been no published reports of SARS-CoV-2 outbreaks within hospital-based settings. We describe key characteristics, interventions, and outcomes of a SARS-CoV-2 outbreak within an inpatient geriatric psychiatry unit at the University of Washington Medical Center – Northwest (UWMC – NW).

INDEX CASES

On March 2, 2020, a 74-year-old man with a history of dementia, congestive heart failure, prior stroke, and hypertension was admitted to the UWMC-NW Geropsychiatric Center from a skilled nursing facility (SNF) due to increasing agitation. On March 7, 2020, he developed a fever to 39.2°C; laboratory evaluation revealed a white blood cell count of 5.33 THOU/µL, absolute lymphocyte count of 0.93 THOU/µL, and a negative influenza and respiratory syncytial virus reverse transcription polymerase chain reaction (RT-PCR). He continued to have intermittent fevers, and on March 11, 2020, he tested positive for SARS-CoV-2 by nasopharyngeal RT-PCR. He was transferred to the acute care unit, where he developed bilateral patchy opacities. During his acute care stay, he required intermittent supplemental oxygen but denied respiratory symptoms. On March 15, 2020, he was able to transfer back to the geriatric psychiatry unit in stable condition on droplet and contact isolation precautions.

Concurrently, on March 11, 2020, a 71-year-old man with a history of dementia, psychosis, and hypertension, who had been admitted to the Geropsychiatric Center on February 1, 2020, developed a fever to 38.6°C and new hypoxemia. Chest x-ray revealed a left lung opacity, and he tested positive for SARS-CoV-2 by nasopharyngeal RT-PCR. He was admitted to the acute care unit, where he developed worsening hypoxemia. His family elected to pursue comfort measures only, and he passed away on March 20, 2020.

METHODS

Study design and setting

We conducted a prospective outbreak investigation of the novel SARS-CoV-2 virus within the UWMC – NW Geropsychiatric Center from March 11, 2020 to May 4, 2020. The Geropsychiatric Center, which is split between 2 physically distinct locked units (East and West), provides inpatient psychiatric care for individuals 60 years of age or older, specializing in dementia, depression, anxiety, and psychosis. In general, patients with more advanced dementia and higher care needs are admitted to the East unit, while higher functioning patients are admitted to the West unit. During periods of standard operating procedures, including the time period immediately preceding this outbreak, residents are permitted to ambulate freely and socialize within their locked unit. Residents typically eat together in a shared dining room and often spend considerable time in shared lounge spaces. While staff rotate between units on a daily basis, there is no conmingling of patients between the East and West units.

Outbreak investigation

Following the diagnosis of 2 Geropsychiatric Center patients with SARS-CoV-2 infection on March 11, 2020 (day 0), all patients within these units were screened for SARS-CoV-2 on March 12, 2020 (day 1). All Geropsychiatric Center staff members were similarly offered SARS-CoV-2 screening on March 18 (day 7) and 19 (day 8). Symptomatic staff members had access to additional SARS-CoV-2 testing through the UW Medicine Employee Testing Clinic. Repeat surveillance testing for SARS-CoV-2 positive patients was performed at 3- to 7-day intervals until 2 negative results, separated by at least 24 hours, were obtained. Duration of SARS-CoV-2 RT-PCR positivity was defined as the number of days between a patient’s initial positive RT-PCR test and the first of 2 consecutive negative RT-PCR tests.

All samples were analyzed at the University of Washington (UW) Virology Laboratory using either the UW SARS-CoV-2 real-time RT-PCR assay or the Hologic SARS-CoV-2 real-time RT-PCR assay.7,16 The UW SARS-CoV-2 real-time RT-PCR assay targets 2 distinct regions of the SARS-CoV-2 N gene and produces 2 cycle threshold (Ct) values per test, one for each amplified region of the N gene; whereas the Hologic SARS-CoV-2 real-time RT-PCR assay targets 2 conserved regions of the SARS-CoV-2 ORF1ab gene but produces only one Ct value, as amplification of both targets is recorded in the same channel.16 Both tests use a Ct cut off <40 to indicate viral detection. For this report, Ct values from the UW SARS-CoV-2 assay are reported as a mean of the N1 and N2 cycle thresholds.

Clinical symptoms, medical history, and radiographic findings for patients were obtained by review of the medical record. A symptom screen and review of medical history was performed over the phone for staff members who tested positive for SARS-CoV-2.

Statistical analysis

Descriptive statistics were calculated to summarize clinical characteristics and SARS-CoV-2 PCR cycle thresholds. All statistical analyses were performed using R Studio (© R Foundation for Statistical Computing, 2016).

Ethics

Data presented in this study were obtained through investigation of a hospital-based disease outbreak. As such, approval by an institutional review board was not required, and informed consent was not obtained.

RESULTS

Screening results and baseline characteristics

Following the identification of the 2 index SARS-CoV-2 cases on March 11, 2020 (day 0), the Geropsychiatric Center stopped admitting new patients, and the remaining 22 patients were screened for the virus. An initial round of screening on March 12 (day 1) identified 4 SARS-CoV-2 positive patients, and a second round of screening, performed on day 4, identified 3 additional SARS-CoV-2 positive patients. A third and fourth round of screening on days 5 and 7 resulted in no new SARS-CoV-2 diagnoses. One patient, who discharging from the Geropsychiatric Center on March 11 (day 0),
returned to the emergency department on March 21 (day 10) with respiratory symptoms and tested positive for SARS-CoV-2.

In total, 10 new cases of SARS-CoV-2 infection were detected among 25 patients in the Geropsychiatric Center from March 11 through 18, 2020 (Fig 1). All cases occurred among residents of the East unit, with 6 cases occurring among 3 sets of roommate pairs. The mean age of patients with and without SARS-CoV-2 infection was 77.8 years (standard deviation [SD] 8.5) and 71.7 years (SD 9.0), respectively. Among both groups, 40% of patients were female. Pre-existing medical conditions were common and are outlined in Table 1.

Symptoms

Four (40%) SARS-CoV-2 positive patients were asymptomatic at the time of screening, with 3 (30%) remaining asymptomatic throughout the course of infection. A list of symptoms experienced over the course of SARS-CoV-2 infection is outlined in Table 1, with fever (n = 5, 50%) and cough (n = 4, 40%) being the most common. One death (10%) occurred in the SARS-CoV-2 positive group, with no deaths occurring in the SARS-CoV-2 negative group during the follow-up period.

Table 1

| Characteristics                                      | SARS-CoV-2 positive patients (n = 10) | SARS-CoV-2 negative patients (n = 15) | SARS-CoV-2 positive staff (n = 7) |
|------------------------------------------------------|--------------------------------------|-------------------------------------|---------------------------------|
| Age in years (SD)                                    | 77.8 (8.5)                           | 71.7 (9.0)                          | 47.1 (9.1)                      |
| Female sex (%)                                       | 4 (40)                               | 6 (40)                              | 4 (57)                          |
| Any symptoms (%)                                     | 7 (70)                               | 4 (27)                              | 2 (29)                          |
| Fever ≥38°C                                           | 5 (50)                               | 0 (0)                               | 2 (29)                          |

*One patient died of respiratory failure but was not intubated due to “do not intubate” status.

RT-PCR, reverse transcription polymerase chain reaction; SARS-CoV-2, severe acute respiratory syndrome coronavirus 2; SD, standard deviation.

1Number of chest x-rays performed: SARS-CoV-2 positive patients n = 3; SARS-CoV-2 negative patients n = 1; SARS-CoV-2 positive staff n = 0.
Follow-up viral testing and cycle thresholds

Follow-up SARS-CoV-2 testing was performed at 3- to 7-day intervals for 9 of the 10 SARS-CoV-2 positive patients with the goals of removing isolation precautions, reducing personal protective equipment (PPE) usage, and supporting appropriate discharge planning. The patient who died of COVID-19 did not undergo follow-up testing. Among the 9 patients with follow-up testing data, the median duration of RT-PCR positivity was similar when comparing symptomatic (25.5, interquartile range [IQR] 22.8-41.8) and asymptomatic (22.0, IQR 19.5-29.0) patients (Table 2).

Ct values for the initial positive SARS-CoV-2 RT-PCR among the 10 patients ranged from 17.8 to 35.9 (median 20.2, IQR 18.9-27.5), and were similar when comparing symptomatic (median 19.0, IQR 18.7-25.7) and asymptomatic patients (median 21.7, IQR 20.7-25.6). Nadir Ct values were also similar across symptomatic (median 18.9, IQR 18.2-20.3) and asymptomatic groups (median 19.8, IQR 17.0-20.7; Table 2).

Staff

Between March 11 (day 0) and March 23, 2020 (day 12), 7 UWMC – NW Geropsychiatric Center staff members tested positive for SARS-CoV-2, 6 (86%) of whom were symptomatic at the time of testing (Fig 1). One tested positive through routine screening provided to NW Employee Health policy. The most common findings from the SARS-CoV-2 pandemic thus far, including 1) the vulnerability of elderly persons to COVID-19, 2) the high rate of asymptomatic infection among elderly patients, and 3) the prolonged duration of PCR positivity. The high rate of morbidity and mortality from SARS-CoV-2 infection among elderly individuals, particularly those with comorbidities, has been well described. King County, Washington emerged as the early epicenter of the SARS-CoV-2 epidemic in the United States, driven in large part by a sizeable outbreak among elderly residents of a LTC facility. Since that time, there has been extensive community transmission within the Seattle area, and approximately 200 LTC facilities have reported a case of SARS-CoV-2. We highly suspect that SARS-CoV-2 was introduced into the UWMC – NW Geropsychiatric Center by a patient coming from a local SNF, where cases of SARS-CoV-2 had been identified. Shared patient rooms, dining, and activity space within the East unit of the Geropsychiatric Center, as well as the ability of patients to ambulate and socialized freely before
the identification of the SARS-CoV-2 outbreak likely allowed for rapid dissemination of SARS-CoV-2. Although community transmission was occurring in King County at the time of Geropsychiatric Center outbreak (7.8% of county-wide SARS-CoV-2 tests were positive on day 0 of the outbreak), the fact that no staff were symptomatic at work prior to outbreak identification, no cases of SARS-CoV-2 were observed within the West unit, where SARS-CoV-2 positive staff had rotated, and 6 of the 10 patient cases occurred among roommate pairs, supports the hypothesis that the virus was introduced by a SARS-CoV-2 positive patient and transmitted primarily through co-mingling and shared rooms on the East unit.

Despite the advanced age and medical vulnerability of our cohort, 30% of SARS-CoV-2 patients showed no symptoms of COVID-19 disease. Asymptomatic disease has been well described in the general population, and there is accumulating evidence that asymptomatic infection among elderly persons may be a major contributor to institutional outbreaks. A recent study published by colleagues at the UW described a similarly high proportion of asymptomatic infection among older adults, with 3 of 4 residents who tested positive for SARS-CoV-2 at a senior assisted living facility showing no signs or symptoms of infection. Another study at a Seattle area SNF found that 57% of the 23 residents who tested positive for SARS-CoV-2 were asymptomatic at the time of screening. However, 10 of the 13 SNF residents who were asymptomatic at the time of screening ultimately developed symptoms.

Our findings are unique in that they demonstrate a high proportion of asymptomatic SARS-CoV-2 infection in an elderly population over time, with 40% of patients being asymptomatic at the time of screening and 30% remaining asymptomatic over several weeks of follow-up. Paired with the results of other local studies, our findings suggest that a symptom-based approach to screening in older adults may not be sufficient, particularly in congregate living or hospitalized populations. It is worth noting that only 1 SARS-CoV-2 positive staff members was asymptomatic, despite wide-spread screening of asymptomatic Geropsychiatric Center employees. The lower proportion of staff members with asymptomatic infection may speak toward the difficulty of performing symptom screening in patients with dementia, or perhaps to differences in the immunologic response between younger and older individuals.

Despite a lack of symptoms, it is notable that the median duration of SARS-CoV-2 RT-PCR positivity was 22 days among asymptomatic patients. It is also notable that Ct values were similar across symptomatic and asymptomatic groups. These results indicate that our asymptomatic patients had large quantities of viral RNA in their nasopharynx and may have experienced a prolonged duration of viral shedding. Given the common initial exposure among all geropsychiatric patients, it is unclear if any of the asymptomatic patients transmitted the virus to others; however, asymptomatic transmission has been described, and recent data suggest there is viable virus in specimens collected from asymptomatic patients. Our findings are in keeping with those from a recent study of asymptomatic and pre-symptomatic SARS-CoV-2 infections in a SNF in King County, Washington, where authors found no difference in cycle threshold values between symptomatic, presymptomatic and asymptomatic patients involved in a COVID-19 outbreak. The approximate duration of RT-PCR positivity observed in our investigation is slightly longer than that described in other studies.

Our report has several limitations. First, we performed follow-up surveillance screening on SARS-CoV-2 negative patient within the Geropsychiatric Center for 7 days following identification of the index cases and may have missed asymptomatic infections that arose late in the incubation period. Second, our ability to identify symptoms in our geriatric cohort is limited by their mental status. While signs and symptoms such as cough, fever, and hypoxemia were easily identified by medical staff, more subjective complaints may have been missed. Based on epidemiologic factors, we are highly suspicious that SARS-CoV-2 was introduced to the Geropsychiatric Center from a patient who was symptomatic on the East unit for at least 4 days prior to diagnosis, after arriving from a SNF with known SARS-CoV-2 cases. However, given community wide transmission of SARS-CoV-2 at the time of the outbreak, we cannot say this with complete certainty, and a detailed history of possible community exposures was not obtained from staff. However, no staff members were symptomatic at work prior to the identification of cases and a staff-initiated outbreak is thought to be less likely. Finally, we are unable to determine the exact duration of RT-PCR positivity, as there were variable intervals between follow-up SARS-CoV-2 tests. Further data are needed to better understand the duration of SARS-CoV-2 RT-PCR positivity and how that correlates with viral shedding in older adults.

CONCLUSIONS

Our report highlights SARS-CoV-2 as an important cause of health care-acquired infection, particularly among older adults. In our cohort of hospitalized, elderly individuals, asymptomatic infection was common despite similar SARS-CoV-2 RT-PCR Ct values among symptomatic and asymptomatic patients. Our findings suggest that asymptomatic individuals can remain SARS-CoV-2 RT-PCR positive for a prolonged period of time, and a symptom-based approach to screening in older adults may not be sufficient, particularly in an outbreak setting. Our data support the widespread use of testing to screen all individuals in or entering institutional and hospital settings.

Acknowledgments

We would like to acknowledge the UWMC – NW Geropsychiatric Center patients. We thank all UWMC – NW Geropsychiatric Center staff for their role in addressing this outbreak.
