Holomorphic Deformations of Balanced Calabi-Yau $\partial\bar{\partial}$-Manifolds

Dan Popovici

Abstract. Given a compact complex $n$-fold $X$ satisfying the $\partial\bar{\partial}$-lemma and supposed to have a trivial canonical bundle $K_X$ and to admit a balanced (=semi-Kähler) Hermitian metric $\omega$, we introduce the concept of deformations of $X$ that are co-polarised by the balanced class $[\omega^{n-1}] \in H^{n-1,n-1}(X, \mathbb{C}) \subset H^{2n-2}(X, \mathbb{C})$ and show that the resulting theory of balanced co-polarised deformations is a natural extension of the classical theory of Kähler polarised deformations in the context of Calabi-Yau or even holomorphic symplectic compact complex manifolds. The concept of Weil-Petersson metric still makes sense in this strictly more general, possibly non-Kähler context, while the Local Torelli Theorem still holds.

1 Introduction

Let $X$ be a compact complex manifold ($\dim_{\mathbb{C}} X = n$). Recall that a Hermitian metric $\omega$ on $X$ (identified throughout with the corresponding $C^\infty$ positive-definite $(1, 1)$-form $\omega$) is said to be balanced (see [Gau77b] for the actual notion called semi-Kähler there, [Mic82] for the actual term) if

$$d(\omega^{n-1}) = 0,$$

while $X$ is said to be a balanced manifold if it carries such a metric. In dimension $n \geq 3$, the balanced condition on $X$, besides being weaker than the Kähler one, is even weaker than the Fujiki class $\mathcal{C}$ condition thanks to a theorem of Alessandrini and Bassanelli [AB93]. (Recall that a compact complex manifold $X$ is said to be of class $\mathcal{C}$ if it is bimeromorphically equivalent to a compact Kähler manifold, i.e. if there exists a holomorphic bimeromorphic map $\mu : \tilde{X} \to X$, called modification, from a compact Kähler manifold $\tilde{X}$.)

On the other hand, all class $\mathcal{C}$ compact complex manifolds are known to satisfy the $\partial\bar{\partial}$-lemma (cf. [DGMS75]) in the following sense:

for every pure-type $d$-closed form on $X$, the properties of $d$-exactness, $\partial$-exactness, $\bar{\partial}$-exactness and $\partial\bar{\partial}$-exactness are equivalent.

There exist compact complex manifolds satisfying the $\partial\bar{\partial}$-lemma that are not of class $\mathcal{C}$ (see e.g. Observation 1.2), while the $\partial\bar{\partial}$-lemma implies the
Hodge decomposition and the Hodge symmetry on $X$, i.e. it defines canonical isomorphisms (the latter one by conjugation):

$$H^k_{DR}(X, \mathbb{C}) \simeq \bigoplus_{p+q=k} H^{p,q}(X, \mathbb{C})$$ and $$H^p(X, \mathbb{C}) \simeq H^{p,q}(X, \mathbb{C}),$$

relating the De Rham cohomology groups $H^k_{DR}(X, \mathbb{C})$ ($k = 0, 1, \ldots, n$) to the Dolbeault cohomology groups $H^{p,q}(X, \mathbb{C})$ ($p, q = 0, 1, \ldots, n$). These manifolds, sometimes referred to as cohomologically Kähler, will play a key role in this work and thus deserve a name in their own right.

**Definition 1.1** A compact complex manifold $X$ will be said to be a $\partial \bar{\partial}$-manifold if the $\partial \bar{\partial}$-lemma holds on $X$.

If, furthermore, the canonical bundle $K_X$ of $X$ is trivial, $X$ will be called a **Calabi-Yau $\partial \bar{\partial}$-manifold**.

While there are plenty of examples of compact balanced manifolds that do not satisfy the $\partial \bar{\partial}$-lemma (e.g. the Iwasawa manifold), the answer to the question of whether non-balanced $\partial \bar{\partial}$-manifolds exist does not seem to be known and constitutes in our opinion a problem worth investigating. Part of the difficulty stems from the fact that neither twistor spaces (which are always balanced by [Gau91]), nor nilmanifolds (which are never $\partial \bar{\partial}$ unless they are Kähler), nor any other familiar class of compact complex non-Kähler manifolds (e.g. the Calabi-Eckmann manifolds are never either balanced or $\partial \bar{\partial}$) can produce an example. However, such an example is likely to exist.

Our main object of study in this paper will be the class of balanced $\partial \bar{\partial}$-manifolds. The principal reason behind our interest in them stems from their remarkable stability properties under both modifications and small deformations. Indeed, if $\mu : \tilde{X} \to X$ is a modification of compact complex manifolds, the main result of [AB93] states that

$$X \text{ is balanced if and only if } \tilde{X} \text{ is balanced},$$

while the corresponding equivalence for $\partial \bar{\partial}$-manifolds is clear. On the other hand, although the balanced property of $X$ is not open under holomorphic deformations by another result of Alessandrini and Bassanelli (cf. [AB90]), the $\partial \bar{\partial}$-property and the simultaneous occurence of the balanced and $\partial \bar{\partial}$-properties are both deformation open by two results of Wu (cf. [Wu06], a partial survey of which can be found in [Pop11, 4.3]). Specifically, if $(X_t)_{t \in \Delta}$ is a holomorphic family of compact complex manifolds, C.-C. Wu proved in [Wu06] the following two theorems:

(i) if $X_0$ is a $\partial \bar{\partial}$-manifold, then $X_t$ is a $\partial \bar{\partial}$-manifold for all $t \in \Delta$ sufficiently close to $0 \in \Delta$.
(ii) if $X_0$ is a balanced $\partial\bar{\partial}$-manifold, then $X_t$ is a balanced $\partial\bar{\partial}$-manifold for all $t \in \Delta$ sufficiently close to $0 \in \Delta$.

This paper will hopefully provide further evidence to substantiate the view that non-Kähler, balanced Calabi-Yau $\partial\bar{\partial}$-manifolds form a class that is well worth studying. We now pause to point out a few examples in support of the theory that will be developed in the next sections. We have seen that all class $\mathcal{C}$ manifolds are both balanced and $\partial\bar{\partial}$. However, the implications are strict and even the simultaneous occurrence of the balanced and $\partial\bar{\partial}$ conditions does not ensure the class $\mathcal{C}$ property.

**Observation 1.2** There exist compact balanced $\partial\bar{\partial}$-manifolds that are not of class $\mathcal{C}$. In other words, the class of compact balanced $\partial\bar{\partial}$-manifolds strictly contains Fujiki's class $\mathcal{C}$.

**Proof.** To show that the class $\mathcal{C}$ property of compact complex manifolds is not deformation open, [Cam91a] and [LP92] exhibit holomorphic families of twistor spaces $(X_t)_{t \in \Delta}$ in which the central fibre $X_0$ is Moishezon (hence is also a $\partial\bar{\partial}$-manifold), while, for every $t \in \Delta \setminus \{0\}$ sufficiently close to 0, the fibre $X_t$ has vanishing algebraic dimension (hence is non-Moishezon, hence is not of class $\mathcal{C}$ since, by another result of Campana [Cam91b], the Moishezon and class $\mathcal{C}$ properties of twistor spaces are equivalent). However, all the fibres $X_t$ are balanced since, by a result of Gauduchon [Gau91], all twistor spaces are balanced. Moreover, when $t$ is close to 0, $X_t$ is a $\partial\bar{\partial}$-manifold by Wu’s openness theorem for deformations of $\partial\bar{\partial}$-manifolds. Thus any of the fibres $X_t$ with $t \neq 0$ but $t$ close to 0 provides an example as stated. □

Notice that the above examples are not Calabi-Yau manifolds since the restriction of the canonical bundle of any twistor space to any twistor line is isomorphic to $\mathcal{O}_{\mathbb{P}^1}(-4)$, hence it cannot be trivial.

On the other hand, examples of compact, non-Kähler, class $\mathcal{C}$, holomorphic symplectic manifolds have been constructed by Yoshioka in [Yos01, section 4.4]. In particular, Yoshioka's manifolds are compact, non-Kähler, balanced Calabi-Yau $\partial\bar{\partial}$-manifolds. Thus they fall into the category of manifolds that will be investigated in this paper. While Yoshioka's manifolds are of class $\mathcal{C}$, it is natural to wonder whether compact, non-class $\mathcal{C}$, balanced Calabi-Yau $\partial\bar{\partial}$-manifolds (i.e. manifolds as in Observation 1.2 having, in addition, a trivial canonical bundle) exist. It is tempting to expect that such an example could be constructed by starting off with a compact Kähler Calabi-Yau manifold $X$, contracting $X$ under a crepant map to some (possibly non-Kähler, but necessarily class $\mathcal{C}$) manifold $Y$ and then slightly deforming $Y$ to some (possibly non-class $\mathcal{C}$, but necessarily balanced Calabi-Yau $\partial\bar{\partial}$) manifold $Y_t$. The stability properties of balanced $\partial\bar{\partial}$-manifolds under both modifications and small deformations could thus be taken full advantage of if an explicit example obtained in this way (in which $Y$ is smooth) could be written down.
Our first observation (cf. section 3) will be that the Kähler assumption can be weakened to the $\partial \bar{\partial}$ assumption in the Bogomolov-Tian-Todorov theorem. This fact, hinted at in the introduction to [Tia87], is probably known, but we take this opportunity to point out how the $\partial \bar{\partial}$-lemma can be solely relied upon in the proofs given in [Tia87] and [Tod89].

**Theorem 1.3 (Bogomolov-Tian-Todorov for Calabi-Yau $\partial \bar{\partial}$-manifolds)** Let $X$ be a compact complex manifold satisfying the $\partial \bar{\partial}$-lemma and whose canonical bundle $K_X$ is trivial. Then the Kuranishi family of $X$ is unobstructed.

Here, as usual, unobstructedness means that the base space of the Kuranishi family is isomorphic to an open subset of $H^{0,1}(X, T^{1,0}X)$.

Given a compact balanced Calabi-Yau $\partial \bar{\partial}$-manifold $X$ of complex dimension $n$, by a balanced class $[\omega^{n-1}] \in H^{n-1,n-1}(X, \mathbb{C}) \subset H^{2n-2}(X, \mathbb{C})$ we shall mean the Dolbeault cohomology class of type $(n-1, n-1)$ (or the De Rham cohomology class of degree $2n - 2$ that is the image of the former under the above canonical inclusion which holds thanks to the $\partial \bar{\partial}$ assumption – see e.g. Lemma 3.1) of the $(n-1)^{st}$ power of a balanced metric $\omega$ on $X$. 

If $\Delta \subset H^{0,1}(X, T^{1,0}X)$ denotes the open subset that is the base space of the Kuranishi family $(X_t)_{t \in \Delta}$ of $X$ (with $X_0 = X$), we define in section 3 the notion of local deformations $X_t$ of $X$ that are co-polarised by the balanced class $[\omega^{n-1}]$ by requiring that the De Rham cohomology class $\{\omega^{n-1}\} \in H^{2n-2}(X, \mathbb{C})$ be of type $(n-1, n-1)$ for the complex structure $J_t$ of $X_t$. Given a compact balanced Calabi-Yau $\partial \bar{\partial}$-manifold $X$ of complex dimension $n$, by a balanced class $[\omega^{n-1}] \in H^{n-1,n-1}(X, \mathbb{C}) \subset H^{2n-2}(X, \mathbb{C})$ we shall mean the Dolbeault cohomology class of type $(n-1, n-1)$ (or the De Rham cohomology class of degree $2n - 2$ that is the image of the former under the above canonical inclusion which holds thanks to the $\partial \bar{\partial}$ assumption – see e.g. Lemma 3.1) of the $(n-1)^{st}$ power of a balanced metric $\omega$ on $X$. If $\Delta \subset H^{0,1}(X, T^{1,0}X)$ denotes the open subset that is the base space of the Kuranishi family $(X_t)_{t \in \Delta}$ of $X$ (with $X_0 = X$), we define in section 3 the notion of local deformations $X_t$ of $X$ that are co-polarised by the balanced class $[\omega^{n-1}]$ by requiring that the De Rham cohomology class $\{\omega^{n-1}\} \in H^{2n-2}(X, \mathbb{C})$ be of type $(n-1, n-1)$ for the complex structure $J_t$ of $X_t$.

Since all nearby fibres $X_t$ are again $\partial \bar{\partial}$-manifolds by Wu’s first theorem [Wu06], the De Rham cohomology space $H^{2n-2}(X, \mathbb{C})$ (which is independent of the complex structure $J_t$) admits for all $t \in \Delta$ a Hodge decomposition

$$H^{2n-2}(X, \mathbb{C}) = H^{n,n-2}(X_t, \mathbb{C}) \oplus H^{n-1,n-1}(X_t, \mathbb{C}) \oplus H^{n-2,n}(X_t, \mathbb{C})$$  \hspace{1cm} (1)

depending on the complex structure $J_t$ and satisfying the Hodge symmetry $H^{n,n-2}(X_t, \mathbb{C}) \cong H^{n-2,n}(X_t, \mathbb{C})$ (after possibly shrinking $\Delta$ about 0). The original balanced class $[\omega^{n-1}] \in H^{2n-2}(X, \mathbb{R})$ is said to be of type $(n-1, n-1)$ for the complex structure $J_t$ if its components of types $(n, n-2)$ and $(n-2, n)$ in the Hodge decomposition (1) vanish. The balanced class being real, this is equivalent to either of these components vanishing. The condition is still equivalent to the De Rham class $[\omega^{n-1}] \in H^{2n-2}(X, \mathbb{C})$ being representable by a form of $J_t$-pure type $(n-1, n-1)$. We denote by

$$\Delta_{[\omega^{n-1}]} \subset \Delta$$  \text{ and by }  \pi : X_{[\omega^{n-1}]} \to \Delta_{[\omega^{n-1}]}$$

the open subset of local deformations of $X$ co-polarised by the balanced class $[\omega^{n-1}]$, resp. the local universal family of co-polarised deformations of $X$ co-polarised by the balanced class $[\omega^{n-1}]$.

1. Dolbeault cohomology classes will be denoted by $[\ ]$, De Rham cohomology classes will be denoted by $\{\ }$. 

4
X. Since all sufficiently nearby fibres $X_t$ are again balanced $\partial\bar{\partial}$-manifolds by Wu’s second theorem [Wu06], the co-polarising De Rham cohomology class $\{\omega^{n-1}\} \in H^{2n-2}(X, \mathbb{C})$ can still be represented by a form $\omega_t^{n-1}$ with $\omega_t$ a $J_t$-balanced metric for every $t \in \Delta_{[\omega^{n-1}]}$ (after possibly shrinking $\Delta$ about 0).

We go on to show in §4.2 that in the special case where $X$ is Kähler and $\omega$ is a Kähler metric on $X$, the local deformations of $X$ that are co-polarised by the balanced class $[\omega^{n-1}] \in H^{n-1,n-1}(X, \mathbb{C})$ are precisely those that are polarised by the Kähler class $[\omega] \in H^{1,1}(X, \mathbb{C})$. Thus the theory of balanced co-polarisations is a natural extension to the balanced case of the classical theory of Kähler polarisations.

The tangent space to $\Delta_{[\omega^{n-1}]}$ at 0 is isomorphic under the Kodaira-Spencer map to a subspace $H^{0,1}(X, T^{1,0}X)_{[\omega^{n-1}]} \subset H^{0,1}(X, T^{1,0}X)$ which, in turn, is isomorphic under the canonical isomorphism defined by the Calabi-Yau property of $X$ to a subspace $H^{n-1,1}_\text{prim}(X, \mathbb{C}) \subset H^{n-1,1}(X, \mathbb{C})$:

$$T_0\Delta_{[\omega^{n-1}]} \simeq H^{0,1}(X, T^{1,0}X)_{[\omega^{n-1}]} \simeq H^{n-1,1}_\text{prim}(X, \mathbb{C}).$$

It is well known that in the case of deformations polarised by a Kähler class $[\omega]$, $H^{n-1,1}_\text{prim}(X, \mathbb{C})$ is the space of primitive (for the Kähler class $[\omega]$) Dolbeault classes of type $(n - 1, 1)$. In the balanced case, since $\omega$ need not be closed, the standard definition of primitive $(n - 1, 1)$-classes is no longer meaningful, but we use the analogy with the Kähler case to define $H^{n-1,1}_\text{prim}(X, \mathbb{C})$ in an ad hoc way (cf. Definition 4.9).

In section 5 we give two applications of this construction. The Calabi-Yau condition being deformation open, $K_{X_t}$ is still trivial for all $t \in \Delta$ sufficiently close to 0, so when the complex structure $J_t$ of $X$ varies, we get complex lines

$$H^n(X_t, \mathbb{C}) \subset H^n(X, \mathbb{C}), \quad t \in \Delta,$$

varying in a fixed complex vector space in a holomorphic way with $t \in \Delta$. (The above inclusion follows from the $\partial\bar{\partial}$-lemma holding on $X_t$ for all $t$ close to 0 by Wu’s first theorem [Wu06].) There is even a Hermitian subspace $H^n(X, \mathbb{C}) \subset H^n(X, \mathbb{C})$ depending (as well as its metric) only on the differential structure of $X$ such that $H^{n,0}(X_t, \mathbb{C}) \subset H^n(X, \mathbb{C})$ for all $t \in \Delta$. We show (cf. Theorem 5.3) that the resulting (holomorphic) period map

$$\Delta \ni t \mapsto H^{n,0}(X_t, \mathbb{C}) \subset \mathbb{P}H^n(X, \mathbb{C})$$

in which every complex line $H^{n,0}(X_t, \mathbb{C})$ has been identified with a point in the complex projective space $\mathbb{P}H^n(X, \mathbb{C})$ is locally an immersion. This means that the Local Torelli Theorem still holds in this context.

We also propose two variants $\omega^{(1)}_{WP}, \omega^{(2)}_{WP}$ (cf. Definition 5.7) of a notion of Weil-Petersson metric on $\Delta_{[\omega^{n-1}]}$ associated with a $C^\infty$ family of balanced metrics $(\omega_t)_{t \in \Delta_{[\omega^{n-1}].} \text{ on the fibres } X_t$ such that each $\omega_t^{n-1}$ lies in the co-polarising balanced class $\{\omega^{n-1}\} \in H^{2n-2}(X, \mathbb{C})$. The metrics $\omega^{(1)}_{WP}$ and $\omega^{(2)}_{WP}$.
coincide if $\text{Ric}(\omega_t) = 0$ for all $t \in \Delta_{[\omega_{n-1}]}$ (cf. Observation 5.8). Although in the case of Kähler polarised deformations, the Weil-Petersson metric $\omega_{WP}$ coincides with the pullback $\mathcal{P}^*\omega_{FS}$ of the Fubini-Study metric of $\mathbb{P}H^n_{\omega}(X, \mathbb{C})$ under the period map (hence $\omega_{WP}$ is Kähler) by Tian’s Theorem 2 in [Tia87], this need not be the case in our context of balanced co-polarised deformations. However, we can compare these two metrics (cf. Theorem 5.11 and Corollary 5.12), show that

$$\omega_{WP}^{(2)} \geq \mathcal{P}^*\omega_{FS} > 0 \text{ on } \Delta_{[\omega_{n-1}]}$$

and make the difference $\omega_{WP}^{(2)} - \mathcal{P}^*\omega_{FS}$ explicit. The obstruction to the identity $\omega_{WP}^{(2)} = \mathcal{P}^*\omega_{FS}$ holding appears now clearly to be the possible non-existence of a form that is both primitive and $d$-closed in an arbitrary Dolbeault cohomology class of type $(n-1, 1)$ that is assumed to be primitive in the ad hoc balanced sense of section 4 (cf. §4.3).

It is natural to ask whether the Weil-Petersson metric $\omega_{WP}^{(2)}$ is Kähler. We ignore the answer at this stage, although we cannot see why this should be the case for balanced, non-Kähler fibres $X_t$.

Another natural question is whether there is a canonical choice of balanced metrics $\omega_t$ on the fibres $X_t$ such that each $\omega_{n-1}$ lies in the co-polarising balanced class $\{\omega_{n-1}\} \in H^{2n-2}(X, \mathbb{C})$ and such that $\text{Ric}(\omega_t) = 0$ for all $t$. This would induce a canonical (i.e. depending only on the co-polarising balanced class $\{\omega_{n-1}\}$) Weil-Petersson metric $\omega_{WP}$ on $\Delta_{[\omega_{n-1}]}$. The answer would follow from the answer to another tantalising question:

**Question 1.4** *Does there exist a balanced analogue of Yau’s theorem on the Calabi conjecture? In other words, is it true that every balanced class contains the $(n-1)^{st}$ power of a balanced metric for which the volume form has been prescribed?*

In the last section we briefly discuss the case of co-polarised deformations of holomorphic symplectic manifolds.

## 2 Preliminaries

### 2.1 Bochner-Kodaira-Nakano formula on compact balanced manifolds

Let $(X, \omega)$ be a compact complex manifold $(\dim_{\mathbb{C}} X = n)$ equipped with an arbitrary Hermitian metric. Denote, as usual, by $\Lambda = \Lambda_\omega = (\omega \wedge \cdot)^*$ the formal adjoint of $L = L_\omega = \omega \wedge \cdot$ w.r.t. the $L^2$ scalar product defined by $\omega$ on scalar-valued forms. Recall the Hermitian commutation relations (cf. [Dem97, VI-6.2]):
where \( \tau := [\Lambda, \partial \omega \wedge \cdot] \) is the torsion operator associated with \( \omega \). It is clear that \( \tau \) is of order 0 and of type \((1, 0)\) and that it vanishes if \( \omega \) is Kähler. We recall here the following result of Gauduchon for which we give a proof in invariant terms (cf. Gauduchon’s proof in local coordinates). It states that in degree zero (i.e. for functions or sections of Hermitian vector bundles), the Bochner-Kodaira-Nakano formula relating the holomorphic and anti-holomorphic Laplacians defined by \( \omega \):

\[
\Delta' = \partial \bar{\partial}^* + \bar{\partial} \partial^* \quad \text{and} \quad \Delta'' = \bar{\partial} \bar{\partial}^* + \partial \partial^*
\]
is the same in the balanced case as in the Kähler case (i.e. the torsion terms vanish when \( \omega \) is balanced much as they do when \( \omega \) is Kähler).

**Proposition 2.1** ([Gau77, Proposition 1, p.120, Proposition 7, p.128])

(a) Suppose that \( \omega \) is balanced. Then

\[
\Delta'' f = \Delta' f \quad \text{for all functions } f \in C^\infty_{0,0}(X, \mathbb{C}).
\]  

(b) Let \((E, h_E) \to (X, \omega)\) be a complex Hermitian \(C^\infty\) vector bundle of rank \(r \geq 1\) equipped with a Hermitian connection \(D_E = D'_E + D''_E\). If \(\omega\) is balanced, then

\[
\Delta''_E \sigma = \Delta'_E \sigma + [i \Theta(E)^{1,1}, \Lambda](\sigma) \quad \text{for all sections } \sigma \in C^\infty_{0,0}(X, E),
\]

where \(\Delta''_E = D''_E D''_E^* + D''_E^* D''_E\) and \(\Delta'_E = D'_E D'_E^* + D'_E^* D'_E\), while \(i \Theta(E)^{1,1}\) stands for the (multiplication operator by) component of type \((1, 1)\) of the curvature form of \(E\) and \(\Lambda := \Lambda_\omega \otimes \text{Id}_E\).

**Proof.** (a) Fix a \(C^\infty\) function \(f\) on \(X\). Then \(\Delta'' f = \bar{\partial}^* \bar{\partial} f\) and using the first identity in (2) we get

\[
\Delta'' f = -i [\Lambda, \partial] (\bar{\partial} f) - \bar{\tau}*(\bar{\partial} f)
\]

\[
= -i \Lambda (\partial \bar{\partial} f) + i \partial \Lambda (\bar{\partial} f) - (\bar{\partial} \omega \wedge \cdot)^* (\omega \wedge \partial f) + \omega \wedge (\partial \omega \wedge \cdot)^* (\bar{\partial} f)
\]

\[
= -i \Lambda (\partial \bar{\partial} f) - (\bar{\partial} \omega \wedge \cdot)^* (\omega \wedge \partial f),
\]

where in going from the second to the third line we have used the identities \(\Lambda (\bar{\partial} f) = 0\) and \((\partial \omega \wedge \cdot)^* (\bar{\partial} f) = 0\) which hold for bidegree reasons.
On the other hand, \( \Delta' f = \partial^* \partial f \) and using the second identity in (2) we get

\[
\Delta' f = \partial^* \partial f = \partial f = \partial f - \partial (\partial \omega) \cdot (\partial f) - \omega \cdot (\partial f) = \partial f - \omega \cdot (\partial f) = \partial f - \omega \cdot (\partial f),
\]

(6)

where in going from the second to the third line we have used the identities \( \Lambda(\partial f) = 0 \) and \( (\partial \omega) \cdot (\partial f) = 0 \) which hold for bidegree reasons, as well as \( \partial \partial = - \partial \partial \). Putting (5) and (6) together, we get (for any Hermitian, possibly non-balanced, \( \omega \)):

\[
\Delta'' f = \Delta' f + (\partial \omega \cdot \partial^* (\omega \wedge \partial f) - (\partial \omega \cdot \partial^* (\omega \wedge \partial f)).
\]

(7)

Now recall that the balanced assumption on \( \omega \) means that \( \Lambda(\partial \omega) = 0 \) or, equivalently, that \( \Lambda(\partial \omega) = 0 \). (This is because of the equivalences: \( d\omega^{n-1} = 0 \iff \omega^{n-2} \wedge d\omega = 0 \iff d\omega \) is primitive \( \iff \Lambda(d\omega) = 0 \).) Thus, if \( g \) is any \( C^\infty \) function on \( X \), we get

\[
\langle (\partial \omega \cdot \partial^* (\omega \wedge \partial f), g) \rangle = \langle (\omega \wedge \partial f, g \partial \omega) \rangle = \langle (\partial f, g \Lambda(\partial \omega)) \rangle = \langle (\partial f, g \Lambda(\partial \omega)) = \langle (\partial f, 0) \rangle = 0,
\]

where the identity \( \Lambda(g \partial \omega) = g \Lambda(\partial \omega) \) holds since \( \Lambda \) is an operator of order zero, hence it commutes with multiplication by \( C^\infty \) functions (but not by positive-degree forms). Thus \( (\partial \omega \cdot \partial^* (\omega \wedge \partial f) = 0 \) if \( \omega \) is balanced. In the same way one shows that \( (\partial \omega \cdot \partial^* (\omega \wedge \partial f) = 0 \). Thus (7) proves part (a).

Part (b) is proved similarly using the Hermitian commutation relations:

\[
[\Lambda, D^*_E] = i (D^*_E + \tau^*) \quad \text{and} \quad [\Lambda, D''_E] = -i (D^*_E + \tau^*)
\]

(8)

and the fact that \( D^*_ED''_E\sigma + D''_ED^*_E\sigma = \Theta(E)^{1,1} \wedge \sigma \).

We end this subsection by noticing that Proposition 2.1 no longer holds in positive degree even if the forms involved are of type \( (p, 0) \) or \( (0, q) \) with \( p, q \geq 1 \). An immediate example is provided by the Iwasawa manifold which is known to be balanced and to carry a holomorphic 1-form \( \alpha \) that is not \( d \)-closed. Since \( \partial^* \alpha = 0 \) \( \alpha \) being of type \( (1, 0) \) and \( \partial \alpha = 0 \), we have \( \Delta'' \alpha = 0 \) for the \( \partial \)-Laplacian associated with any Hermitian metric. If the \( \partial \) and \( \partial \)-Laplacians \( \Delta' \) and \( \Delta'' \) associated with a balanced metric coincided on \( (1, 0) \)-forms, it would follow that \( \Delta' \alpha = 0 \), hence \( \partial \alpha = 0 \), hence \( d\alpha = 0 \), contradicting the choice of \( \alpha \).
2.2 The balanced Ricci-flat Bochner principle

We collect here essentially known facts that will come in handy later on.

**Proposition 2.2** Let $X$ be a compact complex manifold ($\dim_{\mathbb{C}} X = n$) endowed with an arbitrary Hermitian metric $\omega$. Let $| \cdot |_\omega$ denote the pointwise norm of sections of $K_X$ w.r.t. the metric induced by $\omega$.

(i) For every $u \in C_{n,0}^\infty(X, \mathbb{C}) \simeq C^\infty(X, K_X)$, we have

$$i^n u \wedge \bar{u} = |u|_\omega^2 \omega^n. \quad (9)$$

(ii) Equip $K_X$ with the metric induced by $\omega$ and denote by $D = D' + \partial$ the corresponding Chern connection of $K_X$. If $\omega$ is balanced and $\text{Ric}(\omega) = 0$, then every $u \in C_{n,0}^\infty(X, \mathbb{C}) \simeq C^\infty(X, K_X)$ satisfies

$$||\partial u||^2 = ||D' u||^2,$$

where $|| \cdot ||$ denotes the $L^2$ norm of $K_X$-valued forms w.r.t. the metric induced by $\omega$. In particular, every holomorphic $n$-form $u$ on $X$ (i.e. $u \in H^0(X, K_X)$) is parallel (i.e. $Du = 0$) and satisfies

$$|u|_\omega^2 = C \quad \text{(hence also} \quad i^n u \wedge \bar{u} = C \omega^n \text{)} \quad \text{on} \quad X \quad (10)$$

for some constant $C \geq 0$.

**Proof.** (i) Fix an arbitrary point $x_0 \in X$ and choose local holomorphic coordinates $z_1, \ldots, z_n$ about $x_0$. If we write $u = f dz_1 \wedge \cdots \wedge dz_n$ on some open subset $U \subset X$, where $f$ is a $C^\infty$ function on $U$, we have

$$i^n u \wedge \bar{u} = (-1)^{\frac{n(n-1)}{2}} |f|^2 i dz_1 \wedge d\bar{z}_1 \wedge \cdots \wedge i dz_n \wedge d\bar{z}_n. \quad (11)$$

On the other hand, if we write

$$\omega = i \sum_{\alpha, \beta} \omega_{\alpha\beta} dz_\alpha \wedge d\bar{z}_\beta \quad \text{on} \quad U,$$

we have $\omega^n = \det(\omega_{\alpha\beta}) i dz_1 \wedge d\bar{z}_1 \wedge \cdots \wedge i dz_n \wedge d\bar{z}_n$ on $U$. Thus, if $h = \exp(-\varphi)$ is the fibre metric induced by $\omega$ on $\Lambda^n T^{1,0} X = \det(T^{1,0} X) = -K_X$, we have

$$\det(\omega_{\alpha\beta}) = e^{-\varphi} \quad \text{on} \quad U.$$

If we regard $u$ as a section of $K_X$, we have

$$|u|_\omega^2 = |f|^2 |dz_1 \wedge \cdots \wedge dz_n|_\omega^2 = e^\varphi |f|^2 = \frac{|f|^2}{\det(\omega_{\alpha\beta})} \quad \text{on} \quad U.$$
Since $\omega^n = \det(\omega_{\alpha\beta}) i\, dz_1 \wedge d\bar{z}_1 \wedge \cdots \wedge i\, dz_n \wedge d\bar{z}_n$ on $U$, we get

$$|u|^2 \omega^n = |f|^2 i\, dz_1 \wedge d\bar{z}_1 \wedge \cdots \wedge i\, dz_n \wedge d\bar{z}_n \text{ on } U. \quad (12)$$

Since $(-1)^{(n-1)/2} i^n = i^{2n}$, we see that (11) and (12) add up to (9).

(ii) If $\omega$ is balanced, (b) of Proposition 2.1 applied to $E = K_X$ reads

$$\Delta''_{K_X} u = \Delta'_{K_X} u + [i\Theta_{\omega}(K_X), \Lambda](u).$$

Now, $i\Theta_{\omega}(K_X) = -\text{Ric}(\omega) = 0$, while

$$\langle\langle \Delta''_{K_X} u, u \rangle\rangle = ||\bar{\partial}u||^2 \quad \text{and} \quad \langle\langle \Delta'_{K_X} u, u \rangle\rangle = ||D'u||^2.$$

Thus we get the former part of (ii). To get the latter part of (ii), it suffices to notice that if $u$ is holomorphic, then $\partial u = 0$, hence $D'u = 0$ by the above identity, hence $Du = 0$ at every point of $X$. Meanwhile, for every holomorphic $n$-form $u$, we have

$$d |u|^2_w = d \langle u, u \rangle = \{Du, u\} + \{u, Du\} = 0$$

thanks to $Du = 0$, hence $|u|^2_w$ is constant on $X$. (Here $\{,\}$ stands for the sesquilinear pairing of $K_X$-valued forms combining the exterior product of scalar-valued forms, conjugation in the second factor and the pointwise scalar product $(,)_\omega$ induced by $\omega$ on the fibres of $K_X$.)

It turns out that the balanced assumption is unnecessary in the last statement of Proposition 2.2. Indeed, every holomorphic section of a flat line bundle is parallel. In particular, (10) holds in Proposition 2.2 for any Hermitian metric $\omega$ such that $\text{Ric}(\omega) = 0$.

**Observation 2.3** 

Let $(L, h) \rightarrow X$ be a Hermitian holomorphic line bundle over a compact complex manifold such that the curvature form $i\Theta_h(L)$ vanishes identically on $X$. Then any global holomorphic section $\sigma \in H^0(X, L)$ satisfies $D\sigma = 0$, where $D$ is the Chern connection of $(L, h)$.

**Proof.** Let $n := \dim_{\mathbb{C}} X$. Pick any Gauduchon metric $\omega$ on $X$. Thus $\omega$ is a $C^\infty$ positive definite $(1, 1)$-form such that $\partial\bar{\partial}\omega^{n-1} = 0$ on $X$ (cf. [Gau77a]). If $|\sigma|^2_h$ is the pointwise squared norm of $\sigma$ w.r.t. $h$, Stokes’ theorem implies

$$\int_X i\partial\bar{\partial}|\sigma|^2_h \wedge \omega^{n-1} = 0. \quad (13)$$

2. Both the statement and the proof of this observation have been kindly pointed out to the author by J.-P. Demailly.
On the other hand, computing the real $C^\infty$ $(1, 1)$-form $i\partial\bar{\partial}|\sigma|^2_h$, we get:

\[
i\partial\bar{\partial}|\sigma|^2_h = i\partial\bar{\partial}(\sigma, \sigma)_h = i\partial \{\sigma, D'\sigma\}_h
\]

\[
= i \{D'\sigma, D'\sigma\}_h + i \{\sigma, \bar{\partial}D'\sigma\}_h = i \{D'\sigma, D'\sigma\}_h \geq 0 \quad (14)
\]

at every point in $X$, where $(\ , \ )_h$ stands for the pointwise scalar product defined by $h$ on the fibres of $L$ and $\{ \ , \ \}$ denotes the sesquilinear pairing of $L$-valued forms combining the exterior product of scalar-valued forms, conjugation in the second factor and $(\ , \ )_h$, while $D = D' + \bar{\partial}$ is the splitting of $D$ into components of respective types $(1, 0)$ and $(0, 1)$. Since $\sigma$ is holomorphic, $\bar{\partial}\sigma = 0$, while the flatness assumption $i\Theta_h(L) = 0$ translates to $D'\bar{\partial} + \bar{\partial}D' = 0$. Hence $\bar{\partial}D'\sigma = 0$, accounting for the last identity in (14). To justify the nonnegativity inequality in (14), pick an arbitrary point $x \in X$, a local holomorphic frame $e$ of $L$ and write $D'\sigma = \alpha \otimes e$ for a scalar-valued $(1, 0)$-form $\alpha$ in a neighbourhood of $x$. Then

\[
i \{D'\sigma, D'\sigma\}_h = |e|^2_h \cdot i\alpha \wedge \bar{\alpha} \geq 0, \text{ hence } i\partial\bar{\partial}|\sigma|^2_h \wedge \omega^{n-1} \geq 0, \quad (15)
\]

at every point near $x$ since $i\alpha \wedge \bar{\alpha}$ is a semi-positive $(1, 1)$-form whenever $\alpha$ is a $(1, 0)$-form. Moreover, $i\alpha \wedge \bar{\alpha} \wedge \omega^{n-1}$ vanishes at a given point $x$ if and only if $\alpha$ vanishes at $x$.

By (13), (14) and (15), $|D'\sigma|_h = 0$ at every point in $X$. Thus $D'\sigma = 0$, hence $D\sigma = 0$ on $X$.  

\[\Box\]

3 The Bogomolov-Tian-Todorov theorem for Calabi-Yau $\partial\bar{\partial}$-manifolds

In this section we prove Theorem 1.3 by adapting to the $\partial\bar{\partial}$ context the proofs given in [Tia87] and [Tod89] for the Kähler context. Two preliminary facts are needed. The first is a simple but very useful consequence of the $\partial\bar{\partial}$-lemma that will play a key role in this paper.

Lemma 3.1 Let $X$ be a compact $\partial\bar{\partial}$-manifold. Then any Dolbeault cohomology class of any type $(p, q)$ on $X$ can be represented by a $d$-closed form.

In particular, this lemma defines a canonical injection $H^{p,q}(X, \mathbb{C}) \subset H^{p+q}(X, \mathbb{C})$ (for any $p, q$) by mapping any Dolbeault class $[u] \in H^{p,q}(X, \mathbb{C})$ to the De Rham class $\{u\} \in H^{p+q}(X, \mathbb{C})$ of any of its $d$-closed representatives $u$. Fresh applications of the $\partial\bar{\partial}$-lemma easily show that this map is independent of the choice of the $d$-closed representative of the Dolbeault class and that it is injective.
Proof of Lemma 3.1. Let $\alpha$ be an arbitrary $\bar{\partial}$-closed $(p, q)$-form on $X$. It represents a Dolbeault cohomology class $[\alpha] \in H^{p, q}(X, \mathbb{C})$. We will show that there exists a $d$-closed $(p, q)$-form $\beta$ on $X$ that is Dolbeault cohomologous to $\alpha$. In other words, we are looking for a $(p, q-1)$-form $v$ on $X$ such that

$$\beta := \alpha + \bar{\partial}v$$

is $d$-closed. Since $\alpha$ is $\bar{\partial}$-closed, the condition $d(\alpha + \bar{\partial}v) = 0$ amounts to

$$\partial \bar{\partial}v = -\partial \alpha. \quad (16)$$

Now, $\partial \alpha$ is both $\partial$-closed (even $\partial$-exact) and $\bar{\partial}$-closed (since $\alpha$ is $\bar{\partial}$-closed and $\partial$ anti-commutes with $\bar{\partial}$), hence $\partial \alpha$ is $d$-closed. Being a $\partial$-exact pure-type form that is $d$-closed, $\partial \alpha$ must be $\partial \bar{\partial}$-exact by the $\partial \bar{\partial}$-lemma. Hence a $(p, q-1)$-form $v$ satisfying (16) exists. $\square$

The second preliminary fact is peculiar to manifolds with a trivial canonical bundle. Fix an arbitrary Hermitian metric $\omega$ on a given compact complex manifold $X$ ($n = \dim_{\mathbb{C}} X$). Thus $\omega$ is a Hermitian metric on the holomorphic vector bundle $T^{1,0} X$ of vector fields of type $(1, 0)$ of $X$. Let $D$ denote the corresponding Chern connection of $(T^{1,0} X, \omega)$ and let $D = D' + D''$ be its splitting into components of type $(1, 0)$ and respectively $(0, 1)$, where $D'' = \bar{\partial}$ is the $\bar{\partial}$ operator defining the complex structure of $X$. We denote, as usual, by $D''^* = \bar{\partial}^*$ the formal adjoint of $D'' = \bar{\partial}$ w.r.t. $\omega$ and by

$$\Delta'' = \bar{\partial} \bar{\partial}^* + \bar{\partial}^* \bar{\partial} : C^\infty_{p,q}(X, T^{1,0} X) \to C^\infty_{p,q}(X, T^{1,0} X)$$

the corresponding anti-holomorphic Laplacian on $T^{1,0} X$-valued $(p, q)$-forms. Since $\Delta''$ is elliptic and $\bar{\partial}^2 = 0$, the standard three-space orthogonal decomposition holds:

$$C^\infty_{0,1}(X, T^{1,0} X) = \ker \Delta'' \oplus \text{Im } \bar{\partial} \oplus \text{Im } \bar{\partial}^*. \quad (17)$$

On the other hand, a similar orthogonal decomposition holds for the space of scalar-valued $(n-1, 1)$-forms on $X$ with respect to $\bar{\partial}$ acting on scalar forms, its formal adjoint $\bar{\partial}^*$ and the induced anti-holomorphic Laplacian $\Delta''$.

Suppose now that the canonical bundle $K_X$ of $X$ is trivial. Fix a holomorphic $n$-form $u$ with no zeroes on $X$ (i.e. $u$ is a non-vanishing holomorphic section of the trivial line bundle $K_X$). Thus $u$ can be identified with the class $[u] \in H^{n,0}(X, \mathbb{C}) \simeq \mathbb{C}$, so it is unique up to a nonzero constant factor. It is then clear that, for every $q = 0, \ldots, n$, $u$ defines an isomorphism (that may well be called the Calabi-Yau isomorphism):

$$T_u : C^\infty_{0,q}(X, T^{1,0} X) \xrightarrow{\sim} C^\infty_{n-1,q}(X, \mathbb{C}) \quad (18)$$
mapping any \( \theta \in C_0^\infty(X, T^{1,0}X) \) to \( T_u(\theta) := \theta \cdot u \), where the operation denoted by \( \cdot \) combines the contraction of \( u \) by the \((1, 0)\)-vector field component of \( \theta \) with the exterior multiplication by the \((0, q)\)-form component.

We now record the following well-known fact for future reference.

**Lemma 3.2** Let \( X \) be a compact complex manifold \((\dim_{\mathbb{C}} X = n)\) endowed with a Hermitian metric \( \omega \) such that \( \text{Ric}(\omega) = 0 \). If \( K_X \) is trivial and if \( u \in C_\infty_{n,0}(X, \mathbb{C}) \) such that \( \bar{\partial} u = 0 \), \( u \) has no zeroes and

\[
i^n \int_X u \wedge \bar{u} = \int_X dV_\omega, \quad \text{(where } dV_\omega := \frac{\omega^n}{n!})\]  

(19)

then the Calabi-Yau isomorphism \( T_u : C_0^{\infty}(X, T^{1,0}X) \to C_{n-1,1}^\infty(X, \mathbb{C}) \) (see (18) with \( q = 1 \)) is an isometry w.r.t. the pointwise (hence also the \( L^2 \)) scalar products induced by \( \omega \) on the vector bundles involved.

**Proof.** Fix an arbitrary point \( x_0 \in X \) and choose local holomorphic coordinates \( z_1, \ldots, z_n \) about \( x_0 \) such that

\[\omega(x_0) = i \sum_{j=1}^n \lambda_j \, dz_j \wedge d\bar{z}_j \quad \text{and} \quad u(x_0) = f \, dz_1 \wedge \cdots \wedge dz_n.\]

A simple calculation shows that for any \( \theta, \eta \in C_\infty_{0,1}(X, T^{1,0}X) \), the pointwise scalar products at \( x_0 \) are related by

\[\langle \theta, \eta \rangle = \lambda_1 \cdots \lambda_n \frac{|f|^2}{\lambda_1 \cdots \lambda_n} \langle \theta \cdot u, \eta \cdot u \rangle.\]

Thus having \( \langle \theta, \eta \rangle = \langle \theta \cdot u, \eta \cdot u \rangle \) at \( x_0 \) is equivalent to having \(|f|^2 = \lambda_1 \cdots \lambda_n\).

On the other hand, part (i) of Proposition 2.2 implies that

\[|f|^2 = (n!) |u_\omega|^2 (\lambda_1 \cdots \lambda_n).\]

Thus \( T_u \) is an isometry w.r.t. the pointwise scalar products induced by \( \omega \) if and only if

\[|u_\omega|^2 = \frac{1}{n!} \quad \text{at every point of } X.\]  

(20)

Since we know from (10) of Proposition 2.2 and from Observation 2.3 that \(|u_\omega|^2\) is constant on \( X \), we see from (9) that the normalisation (19) of \( u \) is equivalent to (20), i.e. to \( T_u \) being an isometry w.r.t. the pointwise scalar products induced by \( \omega \) on the vector bundles involved. \( \square \)

We shall now compare in the case \( q = 1 \) the image under the operation \( \cdot u \) of the three-space decomposition (17) of \( C_\infty_{0,1}(X, T^{1,0}X) \) with the analogous three-space decomposition of \( C_{n-1,1}^\infty(X, \mathbb{C}) \).
Lemma 3.3 Let $X$ be a compact complex manifold ($n = \dim_{\mathbb{C}} X$) such that $K_X$ is trivial. Then, for $q = 1$, the isomorphism $T_u$ of (18) satisfies:

$$T_u(\ker \bar{\partial}) = \ker \bar{\partial} \quad \text{and} \quad T_u(\im \bar{\partial}) = \im \bar{\partial}.$$  \hspace{1cm} (21)

Hence $T_u$ induces an isomorphism in cohomology

$$T_u : H^{0,1}(X, T^{1,0}X) \xrightarrow{\cdot u} H^{n-1,1}(X, \mathbb{C})$$  \hspace{1cm} (22)

defined by $T_u([\theta]) = [\theta \cdot u]$ for all $[\theta] \in H^{0,1}(X, T^{1,0}X)$. If $\omega$ is any Hermitian metric on $X$ such that $\text{Ric}(\omega) = 0$, $T_u$ also satisfies:

$$T_u(\im \bar{\partial}^*) = \im \bar{\partial}^* \quad \text{and} \quad T_u(\ker \Delta'') = \ker \Delta''.$$  \hspace{1cm} (23)

Proof. It relies on the easily checked formulae:

$$\bar{\partial}(\theta \cdot u) = (\bar{\partial} \theta) \cdot u + \theta \cdot (\bar{\partial} u), \quad \bar{\partial}(\xi \cdot u) = (\bar{\partial} \xi) \cdot u - \xi \cdot (\bar{\partial} u) = (\bar{\partial} \xi) \cdot u$$  \hspace{1cm} (24)

for all $\theta \in C^\infty_{0,1}(X, T^{1,0}X)$ and all $\xi \in C^\infty(X, T^{1,0}X)$. Note, however, that the analogous identities for $\partial$ fail. These formulae imply the inclusions:

$$T_u(\ker \partial) \subset \ker \bar{\partial} \quad \text{and} \quad T_u(\im \partial) \subset \im \bar{\partial}.$$

To prove the reverse inclusion of the former equality in (21), suppose that $\theta \cdot u \in \ker \bar{\partial}$ for some $\theta \in C^\infty_{0,1}(X, T^{1,0}X)$. By (24), this means that $(\bar{\partial} \theta) \cdot u = 0$, which is equivalent to $\bar{\partial} \theta = 0$ since the map $T_u$ of (18) is an isomorphism. (Here $q = 2$.)

To prove the reverse inclusion of the latter equality in (21), let $\theta \in C^\infty_{0,1}(X, T^{1,0}X)$ such that $\theta \cdot u = \bar{\partial} v$ for some $(n - 1, 0)$-form $v$. With respect to local holomorphic coordinates $z_1, \ldots, z_n$ on some open subset $U \subset X$, let

$$\theta = \sum_{j,k} \theta^j_k d\bar{z}_k \otimes \frac{\partial}{\partial z_j} \quad \text{and} \quad u = f dz_1 \wedge \cdots \wedge dz_n,$$

where $f$ is a holomorphic function with no zeroes on $U$. Then

$$\theta \cdot u = \sum_{j,k} (-1)^{j-1} f \theta^j_k d\bar{z}_k \wedge dz_1 \wedge \cdots \wedge \widehat{dz_j} \wedge \cdots \wedge dz_n.$$

Letting $v = \sum_j v_j dz_1 \wedge \cdots \wedge \widehat{dz_j} \wedge \cdots \wedge dz_n$, the condition $\theta \cdot u = \bar{\partial} v$ reads

$$\sum_{j,k} (-1)^{j-1} f \theta^j_k d\bar{z}_k \wedge dz_1 \wedge \cdots \wedge \widehat{dz_j} \wedge \cdots \wedge dz_n = \sum_{j,k} \frac{\partial v_j}{\partial \bar{z}_k} d\bar{z}_k \wedge dz_1 \wedge \cdots \wedge \widehat{dz_j} \wedge \cdots \wedge dz_n.$$
which is equivalent to \( \theta_k^j = \frac{\partial}{\partial z_k} ((-1)^{j-1} \frac{\bar{\omega}}{T}) \) for all \( j, k \) since \( f \) is holomorphic without zeroes. Setting \( \xi_j := (-1)^{j-1} \frac{\bar{\omega}}{T} \) for all \( j \), we get the local representative of a global vector field \( \xi := \sum_j \xi_j \frac{\partial}{\partial z_j} \in C^\infty(X, T^{1,0}X) \) satisfying \( \theta = \bar{\partial} \xi \) on \( X \). Hence \( \theta \in \text{Im} \bar{\partial} \). We have thus proved that \( \text{Im} \bar{\partial} \subset T_u(\text{Im} \bar{\partial}) \), hence the latter identity in (21).

Thus the identities (21) are proved. Then so is (22), an obvious consequence of (21).

To get (23), recall that we know from (10) of Proposition 2.2 and from Observation 2.3 that \( |u|^2 \) is constant on \( X \) whenever \( \text{Ric}(\omega) = 0 \). Then the proof of Lemma 3.2 shows that \( \langle \theta, \eta \rangle = \text{Const} \cdot \langle \theta \mu, \eta \mu \rangle \) for all \( \theta, \eta \in C^\infty_0(X, T^{1,0}X) \), hence \( \theta \perp \eta \) if and only if \( \theta \mu \perp \eta \mu \). (The notation is the obvious one.) This fact suffices to deduce (23) from the pairwise orthogonality of \( \ker \Delta'' \), \( \text{Im} \bar{\partial} \) and \( \text{Im} \bar{\partial}^* \) in the three-space decompositions of \( C^\infty_0(X, T^{1,0}X) \) and \( C^\infty_{n-1,1}(X, \mathbb{C}) \) and from the identities (21). The proof is complete. \( \square \)

Now recall that the isomorphisms \( T_u \) of (18) and their inverses allow one to define a Lie bracket on \( \oplus_q C^\infty_{n-1,q}(X, \mathbb{C}) \) by setting (cf. [Tia87, p. 631]):

\[
[\zeta_1, \zeta_2] := T_u \left[ T_u^{-1} \zeta_1, T_u^{-1} \zeta_2 \right] \in C^\infty_{n-1,q_1+q_2}(X, T^{1,0}X)
\]  

(25)

for any forms \( \zeta_1 \in C^\infty_{n-1,q_1}(X, \mathbb{C}) \) and \( \zeta_2 \in C^\infty_{n-1,q_2}(X, \mathbb{C}) \), where the operation \( [\cdot, \cdot] \) on the right-hand side of (25) combines the Lie bracket of the \( T^{1,0}X \)-parts of \( T_u^{-1} \zeta_1 \in C^\infty_{0,q_1}(X, T^{1,0}X) \) and \( T_u^{-1} \zeta_2 \in C^\infty_{0,q_2}(X, T^{1,0}X) \) with the wedge product of their \((0, q_1)\)- and respectively \((0, q_2)\)-form parts. The definition (25) can be reformulated as:

\[
[\Phi_1, \Phi_2] \mu = [\Phi_1 \mu, \Phi_2 \mu] \text{ for all } \Phi_1, \Phi_2 \in C^\infty_{0,1}(X, T^{1,0}X).
\]  

(26)

The main technical ingredient in the proofs of [Tia87] and [Tod89] was the following general observation, the so-called Tian-Todorov lemma.

**Lemma 3.4** (cf. Lemma 3.1. in [Tia87], Lemma 1.2.4. in [Tod89]) Let \( X \) be a compact complex manifold \((n = \dim_{\mathbb{C}} X)\) such that \( K_X \) is trivial. Then, for every forms \( \zeta_1, \zeta_2 \in C^\infty_{n-1,1}(X, \mathbb{C}) \) such that \( \partial \zeta_1 = \partial \zeta_2 = 0 \), we have:

\[
[\zeta_1, \zeta_2] \in \text{Im} \partial.
\]

More precisely, the identity \( [\theta_1 \mu, \theta_2 \mu] = \partial(\theta_1 \mu(\theta_2 \mu)) \) holds for \( \theta_1, \theta_2 \in C^\infty_{0,1}(X, T^{1,0}X) \) whenever \( \partial(\theta_1 \mu) = \partial(\theta_2 \mu) = 0 \).
We can now briefly review the main arguments in the proofs of [Tia87] and [Tod89] by pointing out that they are still valid when the Kähler assumption is weakened to the $\partial\bar{\partial}$ assumption.

**Proof of Theorem 1.3.** Let $[\eta] \in H^{0,1}(X, T^{1,0}X)$ be an arbitrary nonzero class. Pick any $d$-closed representative $w_1$ of the class $[\eta] \in H^{n-1,1}(X, \mathbb{C})$. Such a $d$-closed representative exists by Lemma 3.1 thanks to the $\partial\bar{\partial}$ assumption on $X$. This is virtually the only modification of the proof compared to the Kähler case where the $\Delta''$-harmonic representative of the class $[\eta] \in H^{0,1}(X, T^{1,0}X)$ was chosen. Since $\Delta' = \Delta''$ in the Kähler case, $\Delta''$-harmonic forms are also $\partial$-closed, hence $d$-closed, but this no longer holds in the non-Kähler case.

Since $T_u$ is an isomorphism, there is a unique $\Phi_1 \in C^\infty_0(X, T^{1,0}X)$ such that $\Phi_1 \cdot u = w_1$. Now $\bar{\partial}w_1 = 0$, so the former equality in (21) implies that $\bar{\partial}\Phi_1 = 0$. Moreover, since $[\Phi_1 \cdot u] = [w_1]$, (22) implies that $[\Phi_1] = [\eta] \in H^{0,1}(X, T^{1,0}X)$ and this is the original class we started off with. However, $\Phi_1$ need not be the $\Delta''$-harmonic representative of the class $[\eta]$ in the non-Käehler case (in contrast to the Kähler case of [Tia87] and [Tod89]). Meanwhile, by the choice of $w_1$, we have

$$\bar{\partial}(\Phi_1 \cdot u) = 0,$$

so Lemma 3.1 applied to $\zeta_1 = \zeta_2 = \Phi_1 \cdot u$ yields $[\Phi_1 \cdot u, \Phi_1 \cdot u] \in \text{Im } \partial$. On the other hand, $[\Phi_1 \cdot u, \Phi_1 \cdot u] \in \ker \bar{\partial}$ as can be easily checked and is well-known (see e.g. [Tod89, Lemma 1.2.5]). By the $\partial\bar{\partial}$-lemma applied to the $(n-1, 2)$-form $1/2 [\Phi_1 \cdot u, \Phi_1 \cdot u]$, there exists $\psi_2 \in C^\infty_{n-2,1}(X, \mathbb{C})$ such that

$$\bar{\partial}\bar{\partial}\psi_2 = \frac{1}{2} [\Phi_1 \cdot u, \Phi_1 \cdot u].$$

We can choose $\psi_2$ of minimal $L^2$-norm with this property (i.e. $\psi_2 \in \text{Im}(\partial\bar{\partial})^*$, see e.g. the explanation after Definition 5.6 in terms of the Aeppli cohomology). Put $w_2 := \partial\bar{\partial}\psi_2 \in C^\infty_{n-1,1}(X, \mathbb{C})$. Since $T_u$ is an isomorphism, there is a unique $\Phi_2 \in C^\infty_{0,1}(X, T^{1,0}X)$ such that $\Phi_2 \cdot u = w_2$. Implicitly, $\partial(\Phi_2 \cdot u) = \bar{\partial}(\Phi_2 \cdot u) = 0$.

Moreover, using (21), we get

$$(\bar{\partial}\Phi_2) \cdot u = \bar{\partial}(\Phi_2 \cdot u) = \frac{1}{2} [\Phi_2 \cdot u, \Phi_2 \cdot u] = \frac{1}{2} [\Phi_1, \Phi_1] \cdot u,$$

where the last identity follows from (23). Hence

(Eq. 1) \hspace{1cm} \bar{\partial}\Phi_2 = \frac{1}{2} [\Phi_1, \Phi_1].

We can now continue inductively. Suppose we have constructed $\Phi_1, \ldots, \Phi_{N-1} \in C^\infty_{0,1}(X, T^{1,0}X)$ such that

$$\partial(\Phi_k \cdot u) = 0 \text{ and } \bar{\partial}(\Phi_k \cdot u) = \frac{1}{2} \sum_{l=1}^{k-1} [\Phi_l \cdot u, \Phi_{l-1} \cdot u], \quad 1 \leq k \leq N - 1.$$
By formulae (24), (26) and since $T_u$ is an isomorphism, the latter identity above is equivalent to

$$\bar{\partial} \Phi_k = \frac{1}{2} \sum_{l=1}^{k-1} [\Phi_l, \Phi_{k-l}], \quad 1 \leq k \leq N-1.$$ 

Then it is easily seen and well-known (cf. [Tod89, Lemma 1.2.5]) that

$$\frac{1}{2} \sum_{l=1}^{N-1} [\Phi_l, \Phi_{N-l}] \in \ker \bar{\partial}.$$ 

On the other hand, since $\Phi_1, \ldots, \Phi_{N-1} \in \ker \bar{\partial}$, Lemma 3.4 gives

$$[\Phi_l, \Phi_{N-l}] \in \text{Im} \partial \quad \text{for all} \quad l = 1, \ldots, N-1.$$ 

Thanks to the last two relations, the $\partial\bar{\partial}$-lemma implies the existence of a form $\psi_N \in C^\infty_{n-2,1}(X, \mathbb{C})$ such that

$$\bar{\partial} \partial \psi_N = \frac{1}{2} \sum_{l=1}^{N-1} [\Phi_l, \Phi_{N-l}].$$ 

We can choose $\psi_N$ of minimal $L^2$-norm with this property (i.e. $\psi_N \in \text{Im}(\partial\bar{\partial})^\ast$). Letting $w_N := \partial\psi_N \in C^\infty_{n-1,1}$, there exists a unique $\Phi_N \in C^\infty_{0,1}(X, T^{1,0}X)$ such that $\Phi_N = w_N$. Implicitly

$$\partial(\Phi_N) = 0.$$ 

We also have $\bar{\partial}(\Phi_N) = \frac{1}{2} \sum_{l=1}^{N-1} [\Phi_l, \Phi_{N-l}]$ by construction. By formulae (24), (26) and since $T_u$ is an isomorphism, this amounts to

$$\bar{\partial} \Phi_N = \frac{1}{2} \sum_{l=1}^{N-1} [\Phi_l, \Phi_{N-l}].$$ 

We have thus shown inductively that the equation (Eq. $k$) is solvable for every $k \in \mathbb{N}^*$. It is well-known (cf. [Kur62]) that in this case the series $\Phi(t) := \Phi_1 t + \Phi_2 t^2 + \cdots + \Phi_N t^N + \cdots$ converges in a Hölder norm for all $t \in \mathbb{C}$ such that $|t| < \varepsilon \ll 1$. This produces a form $\Phi(t) \in C^\infty_0(X, T^{1,0}X)$ which defines a complex structure $\tilde{\partial}_t$ on $X$ that identifies with $\partial - \Phi(t)$ and is the deformation of the original complex structure $\bar{\partial}$ of $X$ in the direction of the originally given $[\eta] \in H^{0,1}(X, T^{1,0}X)$. The proof is complete. $\square$
4 Co-polarised deformations of balanced Calabi-Yau $\partial\bar{\partial}$-manifolds

4.1 Definitions

Let $(X, \omega)$ be a compact balanced Calabi-Yau $\partial\bar{\partial}$-manifold ($n = \dim_{\mathbb{C}} X$). Denote by $\pi : X \to \Delta$ the Kuranishi family of $X$. Thus $\pi$ is a proper holomorphic submersion from a complex manifold $X$, while the fibres $X_t$ with $t \in \Delta \setminus \{0\}$ can be seen as deformations of the given manifold $X_0 = X$. The base space $\Delta$ is smooth and can be viewed as an open subset of $H^{0,1}(X, T^{1,0}X)$ (or as a ball containing the origin in $\mathbb{C}^N$, where $N = \dim_{\mathbb{C}} H^{0,1}(X, T^{1,0}X)$) by Theorem 1.3. Hence the tangent space at 0 is

$$T_0\Delta \simeq H^{0,1}(X, T^{1,0}X).$$

By Wu’s result [Wu06, Theorem 5.13, p. 56], small deformations of balanced $\partial\bar{\partial}$-manifolds are again balanced $\partial\bar{\partial}$-manifolds. Hence, in our case, $X_t$ is a balanced Calabi-Yau $\partial\bar{\partial}$-manifold for all $t \in \Delta$ sufficiently close to 0.

Recall that in the special case where the class $[\omega] \in H^{1,1}(X, \mathbb{C}) \subset H^2(X, \mathbb{C})$ is Kähler (and is furthermore often required to be integral, but we deal with arbitrary, possibly non-rational classes here), it is standard to define the deformations of $X_0 = X$ polarised by $[\omega]$ as those nearby fibres $X_t$ on which the De Rham class $\{\omega\} \in H^2(X, \mathbb{C})$ is still a Kähler class (hence, in particular, of type $(1, 1)$) for the complex structure $J_t$ of $X_t$. In the more general balanced case treated here, $\omega$ need not define a class, but $\omega^{n-1}$ does. Taking our cue from the standard Kähler case, we propose the following dual notion in the balanced context.

**Definition 4.1** Having fixed a balanced class

$$[\omega^{n-1}] \in H^{n-1, n-1}(X, \mathbb{C}) \subset H^{2n-2}(X, \mathbb{C}),$$

we say that a fibre $X_t$ is co-polarised by $[\omega^{n-1}]$ if the De Rham class

$$\{\omega^{n-1}\} \in H^{2n-2}(X, \mathbb{C})$$

is of type $(n-1, n-1)$ for the complex structure $J_t$ of $X_t$.

The restricted family $\pi : X_{[\omega^{n-1}]} \to \Delta_{[\omega^{n-1}]}$ will be called the universal family of deformations of $X$ that are co-polarised by the balanced class $[\omega^{n-1}]$, where $\Delta_{[\omega^{n-1}]}$ is the set of $t \in \Delta$ such that $X_t$ is co-polarised by $[\omega^{n-1}]$ and $X_{[\omega^{n-1}]} = \pi^{-1}(\Delta_{[\omega^{n-1}]} \subset X$.

After possibly shrinking $\Delta_{[\omega^{n-1}]}$ about 0, we can assume that $[\omega^{n-1}] \in H^{n-1, n-1}(X_t, \mathbb{C})$ is a balanced class for the complex structure $J_t$ of the fibre $X_t$ for every $t \in \Delta_{[\omega^{n-1}]}$. 

18
Note that in the special case where $\omega$ is Kähler on $X_0 = X$, the $(2n-2)$-class $\{\omega^{n-1}\}$ is a balanced class for $J_t$ whenever the 2-class $\{\omega\}$ is a Kähler class for $J_t$. We shall see further down that the converse also holds, meaning that in the special Kähler case the notion of co-polarised deformations of $X$ coincides with that of polarised deformations. Recall that when $\omega$ is Kähler, the deformations of $X$ polarised by $[\omega]$ are parametrised by the following subspace of $H^{0,1}(X, T^{1,0}X)$:

$$H^{0,1}(X, T^{1,0}X)[\omega] := \left\{ [\theta] \in H^{0,1}(X, T^{1,0}X) ; [\theta, \omega] = 0 \in H^{0,2}(X, \mathbb{C}) \right\} \quad (27)$$

which is isomorphic under the restriction of $T[u]$ (cf. (22)) to the space of primitive Dolbeault classes of type $(n-1, 1)$:

$$H^{0,1}(X, T^{1,0}X)[\omega] \xrightarrow{T[u]} H_{prim}^{n-1,1}(X, \mathbb{C}). \quad (28)$$

We shall now see that the co-polarised deformations of $X$ are parametrised by an analogous subspace.

**Lemma 4.2** For a given balanced class $[\omega^{n-1}] \in H^{n-1,n-1}(X, \mathbb{C})$, consider the following vector subspace of $H^{0,1}(X, T^{1,0}X)$:

$$H^{0,1}(X, T^{1,0}X)[\omega^{n-1}] := \left\{ [\theta] \in H^{0,1}(X, T^{1,0}X) ; [\theta, \omega^{n-1}] = 0 \in H^{n-2,n}(X, \mathbb{C}) \right\} \quad (29)$$

Then:

(a) the space $H^{0,1}(X, T^{1,0}X)[\omega^{n-1}]$ is well-defined (i.e. the class $[\theta, \omega^{n-1}] \in H^{n-2,n}(X, \mathbb{C})$ is independent of the choice of representative $\theta$ in the class $[\theta] \in H^{0,1}(X, T^{1,0}X)$ and of the choice of representative $\omega^{n-1}$ in the class $[\omega^{n-1}] \in H^{n-1,n-1}(X, \mathbb{C})$). We can therefore denote

$$[\theta] \cdot [\omega^{n-1}] := [\theta, \omega^{n-1}] \quad (30)$$

(b) the open subset $\Delta \subset H^{0,1}(X, T^{1,0}X)$ satisfies

$$\Delta_{[\omega^{n-1}]} = \Delta \cap H^{0,1}(X, T^{1,0}X)[\omega^{n-1}].$$

Implicitly, $T_0\Delta_{[\omega^{n-1}]} \simeq H^{0,1}(X, T^{1,0}X)[\omega^{n-1}]$.

**Proof.** (a) follows from Lemma 4.3 below. Indeed, if $\theta + \bar{\partial} \xi$ is another representative of the class $[\theta]$ for some vector field $\xi \in \mathcal{C}^\infty(X, T^{1,0}X)$, then

$$(\theta + \bar{\partial} \xi) \cdot \omega^{n-1} = \theta \cdot \omega^{n-1} + \bar{\partial}(\xi \cdot \omega^{n-1})$$
since \(\omega\) is balanced. Hence \([\theta + \bar{\partial} \xi, \omega^{n-1}] = [\theta, \omega^{n-1}]\). Similarly, if \(\omega^{n-1} + \bar{\partial}\lambda\) is another representative of the Dolbeault class \([\omega^{n-1}]\) for some \((n-1, n-2)\)-form \(\lambda\), then

\[\theta, \omega^{n-1} + \bar{\partial}\lambda = \theta, \omega^{n-1} + \bar{\partial}(\theta, \lambda)\]

since \(\bar{\partial}\theta = 0\). Hence \([\theta, \omega^{n-1} + \bar{\partial}\lambda] = [\theta, \omega^{n-1}]\).

(b) Since \(X_t\) is a \(\partial\bar{\partial}\)-manifold for every \(t\) close to 0, it admits a Hodge decomposition which in degree \(2n-2\) spells

\[H^{2n-2}(X, \mathbb{C}) = H^{n-2,n}(X_t, \mathbb{C}) \oplus H^{n-1,n-1}(X_t, \mathbb{C}) \oplus H^{n-2,n}(X_t, \mathbb{C}),\]

with \(H^{n-2,n}(X_t, \mathbb{C}) \cong H^{n-2,n}(X_t, \mathbb{C})\). In our case, the real De Rham class \(\{\omega^{n-1}\} \in H^{2n-2}(X, \mathbb{R})\) splits accordingly as

\[\{\omega^{n-1}\} = \{\omega^{n-1}\} \oplus \{\omega^{n-1}\} \oplus \{\omega^{n-1}\},\]

with \(\{\omega^{n-1}\} = \{\omega^{n-1}\} \oplus \{\omega^{n-1}\} \oplus \{\omega^{n-1}\}\) real. Thus the definition of \(\Delta_{\omega^{n-1}}\) translates to

\[\Delta_{\omega^{n-1}} = \left\{ t \in \Delta ; \{\omega^{n-1}\}_t = 0 \in H^{n-2,n}(X_t, \mathbb{C}) \right\}.\]

Moreover, \(\{\omega^{n-1}\}\) is of type \((n-1, n-1)\) for \(J_0\), so \(\{\omega^{n-1}\}_0 = 0\) and \(\{\omega^{n-1}\}_0 = 0\). Let \(t_1, \ldots, t_N\) be local holomorphic coordinates about 0 in \(\Delta\). So \(t = (t_1, \ldots, t_N) \in \Delta\) identifies with \(\theta\) varying in an open subset of \(H^{0,1}(X, T^{1,0} X)\). Let \(\theta \in H^{0,1}(X, T^{1,0} X)\) be the image of \(\frac{\partial}{\partial t}|_{t=0}\) under the Kodaira-Spencer map \(\rho : T_0 \Delta \rightarrow H^{0,1}(X, T^{1,0} X)\). Then, under the Gauss-Manin connection on the Hodge bundle \(\Delta \ni t \mapsto H^{2n-2}(X_t, \mathbb{C})\), the derivative of the class \(\omega^{n-1}_t = 0 \in H^{n-2,n}(X_t, \mathbb{C})\) in the direction of \(t_i\) at \(t_i = 0\) is the class \(\{\theta, \omega^{n-1}\} \in H^{n-2,n}(X, \mathbb{C})\).

Here is the lemma that has been used in the proof of (a) above.

**Lemma 4.3** Let \(X\) be a compact complex manifold (dim \(\mathbb{C}X = n\)) equipped with an arbitrary Hermitian metric \(\omega\). Then:

(i) \(\bar{\partial}(\xi, \omega^{n-1}) = (\bar{\partial}\xi) \omega^{n-1} - \xi, \bar{\partial} \omega^{n-1}\), for every \(\xi \in C^\infty(X, T^{1,0} X)\).

Hence, if \(\omega\) is balanced, we have \(\bar{\partial}(\xi, \omega^{n-1}) = (\bar{\partial}\xi) \omega^{n-1}\).

(ii) \(\bar{\partial}(\theta, \omega^{n-1}) = (\bar{\partial}\theta) \omega + \theta, \bar{\partial} \omega\), for every \(\theta \in C^\infty_0(X, T^{1,0} X)\).

**Analogous identities hold for forms of any type in place of \(\omega\) or \(\omega^{n-1}\).** However, the analogous identities for \(\partial\) in place of \(\bar{\partial}\) fail (intuitively because
∂ increases the holomorphic degree of forms, while the contraction by a vector field of type (1, 0) decreases the same holomorphic degree.

Proof. See Appendix (section [7]).

4.2 Comparison to polarisations of the Kähler case

We now pause to observe that in the special case of a Kähler class [ω] ∈ H^{1,1}(X, ℂ), co-polarised deformations of X coincide with polarised deformations. Thus, although the space H^{0,1}(X, T^{1,0}X)[ω] of (27) no longer makes sense for a non-Kähler ω, H^{0,1}(X, T^{1,0}X)[ω^{-1}] defined in (29) naturally extends its meaning to the case of a balanced class [ω^{-1}].

Proposition 4.4 Let (X, ω) be a compact Kähler manifold (n = dim_ℂ X) such that K_X is trivial. Then the following identity holds:

\[ H^{0,1}(X, T^{1,0}X)[ω] = H^{0,1}(X, T^{1,0}X)[ω^{-1}]. \]  

Proof. We start by noticing that for any Hermitian metric (no assumption is necessary on ω here) and any θ ∈ C^∞_0(X, T^{1,0}X), we have

\[ \theta \land ω^k = k \land ω^{k-1} \land (\theta \land ω) \quad \text{for any } k. \]  

This follows from the property θ ∧ (ω ∧ ω^{k-1}) = (θ ∧ ω) ∧ ω^{k-1} + ω ∧ (θ ∧ ω^{-1}).

Suppose now that ω is Kähler and let [θ] ∈ H^{0,1}(X, T^{1,0}X)[ω], i.e. θ ∧ ω is ∂-exact. Writing θ ∧ ω = ∂v for some (0, 1)-form v, from (32) we get:

\[ \theta \land ω^{n-1} = (n-1) \land ω^{n-2} \land \partial v = (n-1) \land \partial (\omega^{n-2} \land v) \]

since ∂ω^{n-2} = 0 by the Kähler assumption on ω. Thus θ ∧ ω^{n-1} is ∂-exact, proving that [θ] ∈ H^{0,1}(X, T^{1,0}X)[ω^{-1}]. This proves the inclusion “⊂”.

Proving the reverse inclusion “⊃” in (31) takes more work. Let us consider the Lefschetz operator

\[ L^{n-2}_ω: C^∞_0(X, ℂ) → C^∞_{n-2,n}(X, ℂ), \quad α → ω^{n-2} \land α, \]  

of multiplication by ω^{n-2} which is well known to be an isomorphism for any Hermitian (even non-Kähler or non-balanced) metric ω (see e.g. [Voi02, lemma 6.20, p. 146]). We clearly have θ ∧ ω^{n-1} = (n-1) L^{n-2}_ω(θ ∧ ω) by (32).

The next lemma explains how the three-space decomposition (w.r.t. ω)

\[ C^∞_0(X, ℂ) = \ker Δ'' ⊕ \text{Im } ∂{\bar{}} ⊕ \text{Im } ∂^* \]

transforms under L^{n-2}_ω and compares to the analogous decomposition of C^∞_{n-2,n}(X, ℂ). Note that in C^∞_{n-2,n}(X, ℂ) the subspace Im ∂{\bar{}} is reduced to zero for bidegree reasons.
Lemma 4.5 If $\omega$ is a Kähler metric on a compact complex manifold $X$ with $n = \dim_{\mathbb{C}} X$, then the operator (33) satisfies

\[ L_n^{-2}(\ker \Delta'') = \ker \Delta'' \quad \text{and} \quad L_n^{-2}(\text{Im} \, \bar{\partial} \oplus \text{Im} \, \bar{\partial}^*) = \text{Im} \, \bar{\partial}. \] (34)

This will follow from two formulae that have an interest of their own.

Lemma 4.6 If $\omega$ is Kähler, then for every $\alpha \in C^\infty_0(X, \mathbb{C})$ we have

\[ \bar{\partial}^*(\omega^{n-2} \wedge \alpha) = \omega^{n-2} \wedge \bar{\partial}^* \alpha + (n-2) \omega^{n-3} \wedge i\partial \alpha. \] (35)

Proof. Using the Kähler commutation relation $\bar{\partial}^* = -i [\Lambda, \partial]$, we get

\[ \bar{\partial}^*(\omega^{n-2} \wedge \alpha) = -i \Lambda(\omega^{n-2} \wedge \partial \alpha) + i \partial(\Lambda(\omega^{n-2} \wedge \alpha)). \] (36)

In the first term on the right-hand side of (36), we have

\[ \Lambda(\omega^{n-2} \wedge \partial \alpha) = [\Lambda, L_n^{-2}](\partial \alpha) + \omega^{n-2} \wedge \Lambda(\partial \alpha) = \omega^{n-2} \wedge \Lambda(\partial \alpha). \] (37)

The last identity follows from the well-known formula (cf. [Voi02, p. 148]):

\[ [L^r, \Lambda] = r(k - n + r - 1)L^{r-1} \quad \text{on} \quad k\text{-forms}, \quad \text{for every} \quad r, \] (38)

which, when applied with $r = n - 2$ to the 3-form $\partial \alpha$, gives $[\Lambda, L_n^{-2}](\partial \alpha) = 0$.

In the second term on the right-hand side of (36), we have

\[ \Lambda(\omega^{n-2} \wedge \alpha) = [\Lambda, L_n^{-2}](\alpha) + \omega^{n-2} \wedge \Lambda(\alpha) = (n - 2) \omega^{n-3} \wedge \alpha + \omega^{n-2} \wedge \Lambda(\alpha), \]

where the last identity follows again from (38) applied with $r = n - 2$ to the 2-form $\alpha$. (Note that $\Lambda \alpha = 0$, but we ignore this here.) Taking $\partial$ on either side of the above identity and using the Kähler assumption on $\omega$, we get

\[ \partial(\Lambda(\omega^{n-2} \wedge \alpha)) = (n - 2) \omega^{n-3} \wedge \partial \alpha + \omega^{n-2} \wedge \partial \Lambda(\alpha), \] (39)

Thus, putting (37) and (39) together, we see that (36) transforms to

\[ \bar{\partial}^*(\omega^{n-2} \wedge \alpha) = -i \omega^{n-2} \wedge \Lambda(\partial \alpha) + (n-2) \omega^{n-3} \wedge i\partial \alpha + \omega^{n-2} \wedge i\partial \Lambda(\alpha) \]
\[ = \omega^{n-2} \wedge i [\partial, \Lambda](\alpha) + (n-2) \omega^{n-3} \wedge i\partial \alpha \]
\[ = \omega^{n-2} \wedge \bar{\partial}^* \alpha + (n-2) \omega^{n-3} \wedge i\partial \alpha. \]

This is what we had set out to prove. Note that we have used again the Kähler commutation relation $i [\partial, \Lambda] = -i [\Lambda, \partial] = \bar{\partial}^*$. □

The next formula we need is the following.
Lemma 4.7 If $\omega$ is Kähler, then for every $\alpha \in C^\infty_{0,2}(X, \mathbb{C})$ we have

$$\Delta''_{\omega}(\omega^{n-2} \wedge \alpha) = \omega^{n-2} \wedge \Delta''_{\omega} \alpha.$$  \hfill (40)

Proof. This is an immediate consequence of the commutation property

$$[L_{\omega}, \Delta''_{\omega}] = 0,$$

which in turn follows from the Kähler identities. Alternatively, we can use Lemma 4.6 and the Kähler identities to give a direct proof as follows. Since $\bar{\partial}(\omega^{n-2} \wedge \alpha) = 0$ for bidegree reasons, $\Delta''_{\omega}(\omega^{n-2} \wedge \alpha)$ reduces to its first term, so using (35) we get

$$\Delta''_{\omega}(\omega^{n-2} \wedge \alpha) = \bar{\partial} \bar{\partial}^* \alpha = \frac{1}{2} \bar{\partial} \bar{\partial}^* \alpha + (n-2) \omega^{n-3} \wedge i\partial \bar{\partial} \alpha.$$  \hfill (41)

Now, using the Kähler identity $\bar{\partial}^* = -i [\Lambda, \partial]$, we get

$$\omega^{n-2} \wedge \bar{\partial} \bar{\partial}^* \alpha = -i \omega^{n-2} \wedge [\Lambda, \partial] \bar{\partial} \alpha = -i \omega^{n-2} \wedge \Lambda(\bar{\partial} \bar{\partial} \alpha) = -i \omega^{n-2} \wedge \Lambda(\partial \bar{\partial} \alpha).$$  \hfill (42)

because $\bar{\partial} \alpha$ is of type $(0, 3)$, so $\Lambda(\bar{\partial} \alpha) = 0$ for bidegree reasons. Meanwhile

$$\omega^{n-2} \wedge \Lambda(\bar{\partial} \bar{\partial} \alpha) = [L_{\omega}, \Lambda](\bar{\partial} \bar{\partial} \alpha) + \Lambda(\omega^{n-2} \wedge \partial \bar{\partial} \alpha) = [L_{\omega}, \Lambda](\partial \bar{\partial} \alpha) = (n-2) \omega^{n-3} \wedge \partial \bar{\partial} \alpha.$$  \hfill (43)

The second identity on the top line above follows from $\omega^{n-2} \wedge \partial \bar{\partial} \alpha = 0$ for bidegree reasons (since $\omega^{n-2} \wedge \partial \bar{\partial} \alpha$ is of type $(n-1, n+1)$, hence vanishes), while the last identity follows from formula (35) with $r = n-2$ and $k = 4$. The combined identities (42) and (43) yield

$$\omega^{n-2} \wedge \bar{\partial} \bar{\partial}^* \alpha = -(n-2) \omega^{n-3} \wedge i\partial \bar{\partial} \alpha = (n-2) \omega^{n-3} \wedge i\partial \bar{\partial} \alpha.$$  

This last identity combines with (41) to prove the claim. \hfill \square

We need yet another observation.

Lemma 4.8 For any Hermitian metric $\omega$ on $X$, the normalised Lefschetz operator

$$L_{\omega}^{n-2} : C^\infty_{0,2}(X, \mathbb{C}) \rightarrow C^\infty_{n-2,n}(X, \mathbb{C})$$

is an isometry w.r.t. the $L^2$ scalar product induced by $\omega$ on scalar-valued forms.
Proof. We will show that for every \( l = 3, \ldots, n \), the following formula holds

\[
\langle \langle \omega^{n-2} \land \alpha, \omega^{n-2} \land \beta \rangle \rangle = (n-2)! \frac{(l-2)!}{(n-l)!} \langle \langle \omega^{n-l} \land \alpha, \omega^{n-l} \land \beta \rangle \rangle
\]

(44) for all forms \( \alpha, \beta \in C_{0,2}^\infty(X, \mathbb{C}) \). We have

\[
\langle \langle \omega^{n-2} \land \alpha, \omega^{n-2} \land \beta \rangle \rangle = \langle \langle \Lambda(\omega^{n-2} \land \alpha), \omega^{n-3} \land \beta \rangle \rangle
\]

\[
= \langle \langle [\Lambda, L^{n-2}] \alpha, \omega^{n-3} \land \beta \rangle \rangle
\]

\[
= (n-2) \langle \langle \omega^{n-3} \land \alpha, \omega^{n-3} \land \beta \rangle \rangle,
\]

where in going from the first to the second line, we have used the identities \([\Lambda, L^{n-2}] \alpha = \Lambda(\omega^{n-2} \land \alpha) - \omega^{n-2} \land \Lambda \alpha = \Lambda(\omega^{n-2} \land \alpha)\) since \( \Lambda \alpha = 0 \) for bidegree reasons, while in going from the second to the third line we have used formula (38) with \( r = n-2 \) and the anti-commutation \( [\Lambda, L^{n-2}] = -[L^{n-2}, \Lambda] \). This proves (44) for \( l = 3 \). We can now continue by induction on \( l \). Suppose that (44) has been proved for \( l \). We have

\[
\langle \langle \omega^{n-l} \land \alpha, \omega^{n-l} \land \beta \rangle \rangle = \langle \langle \Lambda(\omega^{n-l} \land \alpha), \omega^{n-l-1} \land \beta \rangle \rangle
\]

\[
= \langle \langle [\Lambda, L^{n-l}] \alpha, \omega^{n-l-1} \land \beta \rangle \rangle
\]

\[
= (n-l)(l-1) \langle \langle \omega^{n-l-1} \land \alpha, \omega^{n-l-1} \land \beta \rangle \rangle
\]

by arguments similar to those above, where formula (38) has been used with \( r = n-l \). We thus obtain (44) with \( l + 1 \) in place of \( l \).

It is now clear that (44) for \( l = n \) proves the contention. \( \square \)

End of proof of Lemma 4.3. Since the map \( L^{n-2}_\omega \) of (33) is an isomorphism, it follows from Lemma 4.7 that \( L^{n-2}_\omega(\ker \Delta''_\omega) = \ker \Delta''_\omega \). Since \( L^{n-2}_\omega \) maps any pair of orthogonal forms in \( C_{0,2}^\infty(X, \mathbb{C}) \) to a pair of orthogonal forms in \( C_{n-2,n}^\infty(X, \mathbb{C}) \) by Lemma 4.8, it follows that the orthogonal complement of \( \ker \Delta''_\omega \) in \( C_{0,2}^\infty(X, \mathbb{C}) \) (i.e. \( \text{Im} \hat{\partial} \oplus \text{Im} \hat{\partial}^* \)) is isomorphic under \( L^{n-2}_\omega \) to the orthogonal complement of \( \ker \Delta''_\omega \) in \( C_{n-2,n}^\infty(X, \mathbb{C}) \) (i.e. \( \text{Im} \hat{\partial} \)). Note that \( \text{Im} \hat{\partial}^* = 0 \) in \( C_{n-2,n}^\infty(X, \mathbb{C}) \) for type reasons. The proof is complete. \( \square \)

End of proof of Proposition 4.4. Recall that we have yet to prove the inclusion "\( \supset \)" in (31). Let \( [\theta] \in H^{0,1}(X, T^{1,0}X)  |_{\omega^{n-1}} \). This means that \( \theta \omega^{n-1} \in \text{Im} \hat{\partial} \subset C_{n-2,n}^\infty(X, \mathbb{C}) \) (cf. (29)). Since \( \theta \omega^{n-1} = (n-1) L^{n-2}_\omega(\theta \omega) \) (cf. (32)) and \( \theta \omega \) is of type \((0, 2)\), we get from Lemma 4.5 that

\[
\theta \omega \in \text{Im} \hat{\partial} \oplus \text{Im} \hat{\partial}^* \subset C_{0,2}^\infty(X, \mathbb{C}).
\]

(45)
On the other hand, \( \bar{\partial} \theta = 0 \) (since \( \theta \) represents a class \([\theta] \in H^{0,1}(X, T^{1,0}X)\) and \( \bar{\partial} \omega = 0 \) (since \( \omega \) is assumed Kähler). Hence (ii) of Lemma 4.3 gives

\[
\bar{\partial}(\theta \omega) = 0, \quad \text{i.e.} \quad \theta \omega \in \ker \bar{\partial} = \ker \Delta'' \oplus \Im \bar{\partial} \subset C^\infty_{0,2}(X, \mathbb{C}). \tag{46}
\]

Since the three subspaces in the decomposition \( C^\infty_{0,2}(X, \mathbb{C}) = \ker \Delta'' \oplus \Im \bar{\partial} \oplus \Im \bar{\partial}^* \) are mutually orthogonal, (45) and (46) imply that \( \theta \omega \in \Im \bar{\partial} \), i.e. \([\theta] \in H^{0,1}(X, T^{1,0}X)_{[\omega]} \) (cf. (27)). \( \square \)

### 4.3 Primitive \((n-1, 1)\)-classes on balanced manifolds

In the case of a Kähler class \([\omega] \), primitive Dolbeault cohomology classes of type \((n-1, 1)\) (for \([\omega]\)) play a pivotal role in the theory of deformations of \( X \) that are polarised by \([\omega]\) thanks to the isomorphism (28) induced by the Calabi-Yau isomorphism. However, if \([\omega]\) is replaced by a balanced class \([\omega^n-1]\), primitive classes can no longer be defined in the standard way except in the case of \((1, 1)\)-classes or, more generally, in that of De Rham 2-classes (since the definition uses then the \((n-1)^{st}\) power of \( \omega \) that is closed by the balanced assumption). In particular, defining an \((n-1, 1)\)-class \([\alpha]\) as primitive by requiring that \( \omega \wedge \alpha \) be \( \bar{\partial}\)-exact would be meaningless if \( \omega \) is not closed since this definition would depend on the choice of representative \( \alpha \) of the class \([\alpha]\). However, since the space \( H^{0,1}(X, T^{1,0}X)_{[\omega^n-1]} \) carries over the meaning of \( H^{0,1}(X, T^{1,0}X)_{[\omega]} \) to the balanced case, it is natural to make the following ad hoc definition in the balanced case.

**Definition 4.9** Let \( X \) be a compact balanced Calabi-Yau \( \bar{\partial} \bar{\partial} \)-manifold (\( n := \dim_{\mathbb{C}} X \)). Fix a non-vanishing holomorphic \((n, 0)\)-form \( u \) and a balanced class \([\omega^n-1]\) on \( X \). The space of **primitive** classes of type \((n-1, 1)\) (for \([\omega^n-1]\)) is defined as the image under the Calabi-Yau isomorphism

\[
T_u : H^{0,1}(X, T^{1,0}X) \overset{\cup [u]}{\rightarrow} H^{n-1,1}(X, \mathbb{C})
\]

in (22) of the subspace \( H^{0,1}(X, T^{1,0}X)_{[\omega^n-1]} \subset H^{0,1}(X, T^{1,0}X) \), i.e.

\[
H^{n-1,1}_{\text{prim}}(X, \mathbb{C}) := T_u \left( H^{0,1}(X, T^{1,0}X)_{[\omega^n-1]} \right) \subset H^{n-1,1}(X, \mathbb{C}).
\]

Explicitly, given the definition (27) of \( H^{0,1}(X, T^{1,0}X)_{[\omega^n-1]} \), this means:

\[
[\theta \cdot u] \in H^{n-1,1}_{\text{prim}}(X, \mathbb{C}) \quad \text{iff} \quad [\theta \cdot \omega^{n-1}] = 0 \in H^{n-2, n}(X, \mathbb{C}) \tag{47}
\]

for any class \([\theta] \in H^{0,1}(X, T^{1,0}X) \).
It is clear that \( H^{n-1,1}_{prim}(X, \mathbb{C}) \) does not depend on the choice of \( u \) (which is unique up to a constant factor), but depends on the choice of balanced class \([\omega^{n-1}]\). When \( \omega \) is Kähler, the ad hoc definition of \( H^{n-1,1}_{prim}(X, \mathbb{C}) \) coincides with the standard definition thanks to the isomorphism (28) and to Proposition 4.4.

Recall that unlike cohomology classes, primitive forms can be defined in the standard way for any Hermitian metric \( \omega \): for any \( k \leq n \), a \( k \)-form \( \alpha \) on \( X \) is primitive for \( \omega \) if \( \omega^{n-k+1} \wedge \alpha = 0 \). This condition is well known to be equivalent to \( \Lambda \omega \alpha = 0 \). No closedness assumption on \( \omega \) is needed.

In the rest of this subsection we shall investigate the extent to which the ad hoc primitive \((n-1, 1)\)-classes defined by a balanced class retain the properties of primitive classes standardly defined by a Kähler class. We start with the form analogue of (47). By the Calabi-Yau isomorphism (18), all \((n-1, 1)\)-forms are of the shape \( \theta \curlyeqwedge u \) for some \( \theta \in C^\infty_{0,1}(X, T^{1,0}X) \).

**Lemma 4.10** Let \((X, \omega)\) be an arbitrary Hermitian compact complex manifold \((n := \dim \mathbb{C}X)\) with \( K_X \) trivial. Fix a non-vanishing holomorphic \((n, 0)\)-form \( u \). Then for any \( \theta \in C^\infty_{0,1}(X, T^{1,0}X) \), the following equivalences hold:

\[
\theta \curlyeqwedge u \text{ is primitive for } \omega \iff \theta \curlyeqwedge \omega = 0 \iff \theta \curlyeqwedge \omega^{n-1} = 0. \tag{48}
\]

**Proof.** By the definition of primitiveness, the \((n-1, 1)\)-form \( \theta \curlyeqwedge u \) is primitive for \( \omega \) if and only if \( \omega \wedge (\theta \curlyeqwedge u) = 0 \). Meanwhile

\[
0 = \theta \curlyeqwedge (\omega \wedge u) = (\theta \curlyeqwedge \omega) \wedge u + \omega \wedge (\theta \curlyeqwedge u),
\]

where the first identity holds for type reasons since the form \( \omega \wedge u \) is of type \((n + 1, 1)\), hence vanishes. Thus the vanishing of \( \omega \wedge (\theta \curlyeqwedge u) \) is equivalent to the vanishing of \( (\theta \curlyeqwedge \omega) \wedge u \) which, in turn, is equivalent to the vanishing of \( \theta \curlyeqwedge \omega \) as can be easily checked using the property \( u \neq 0 \) at every point of \( X \). This proves the first equivalence in (48). The second equivalence follows from

\[
\theta \curlyeqwedge \omega^{n-1} = (n - 1) \omega^{n-2} \wedge (\theta \curlyeqwedge \omega)
\]

(cf. (32)) and from the map (33) being an isomorphism. \( \square \)

We have seen in Lemma 3.1 that every Dolbeault cohomology class on a \( \partial \bar{\partial} \)-manifold can be represented by a \( d \)-closed form (which is, of course, not unique). The question we will now address is the following.

**Question 4.11** Is it true that on a balanced Calabi-Yau \( \partial \bar{\partial} \)-manifold, every primitive \((n - 1, 1)\)-class (in the sense of the ad hoc Definition 4.9) can be represented by a form that is both primitive and \( d \)-closed?
Should the answer to this question be affirmative, it would bear significantly on the discussion of Weil-Petersson metrics in §5.2. It is clear that in the Kähler case the answer is affirmative: the $\Delta''$-harmonic representative of any primitive (in the standard sense defined by the Kähler class = the ad hoc sense in the case of $(n-1,1)$-classes) $(p,q)$-class is both primitive and $d$-closed. We shall now see that the balanced case is far more complicated.

**Lemma 4.12** Let $(X, \omega)$ be a compact Hermitian manifold ($n := \text{dim}_\mathbb{C} X$) and let $v$ be an arbitrary primitive form of type $(n-1,1)$ on $X$. Then the following equivalences hold:

$$\bar{\partial}^* v = 0 \iff \partial v = 0 \quad \text{and} \quad \partial^* v = 0 \iff \bar{\partial} v = 0.$$  \hfill (49)

*Proof.* It is well-known (cf. e.g. [Dem97, VI, §5.1]) that $\bar{\partial}^* = -\ast \partial \ast$ and $\partial^* = -\ast \bar{\partial} \ast$, where $\ast : \Lambda^{p,q} T^*X \to \Lambda^{n-q,n-p} T^*X$ is the Hodge star operator associated with $\omega$. On the other hand, the following formula for primitive forms is also known:

$$\ast v = i^{n^2-2} v \quad \text{for all } v \in C^\infty_{n-1,1}(X, \mathbb{C})_{\text{prim}}.$$  \hfill (50)

(Recall that for primitive forms $v$ of arbitrary type $(p,q)$, the formula reads

$$\ast v = (-1)^{k(k-1)/2} p^{-q} \omega^{n-p-q} \wedge v \quad \text{where } k := p + q,$$  \hfill (51)

see e.g. [Voi02, Proposition 6.29, p. 150].) Since $\ast$ is an isomorphism, we see that the identity $\bar{\partial}^* v = 0$ is equivalent to $\partial(\ast v) = 0$, hence to $\partial v = 0$ by (50). The equivalence for $\partial^* v = 0$ is inferred similarly. \hfill \square

**Corollary 4.13** Under the assumptions of Lemma 4.12, we have:

(i) if $v \in C^\infty_{n-1,1}(X, \mathbb{C})_{\text{prim}}$ and $\bar{\partial} v = 0$, then

$$dv = 0 \iff \Delta'' v = 0.$$

(ii) if $v \in C^\infty_{n-1,1}(X, \mathbb{C})_{\text{prim}}$ and $\partial v = 0$, then

$$dv = 0 \iff \Delta' v = 0.$$

(iii) if $v \in C^\infty_{n-1,1}(X, \mathbb{C})_{\text{prim}}$ and $dv = 0$, then

$$\Delta' v = 0, \quad \Delta'' v = 0 \quad \text{and} \quad \Delta v = 0.$$
Proof. Since $X$ is compact, we have $\ker \Delta'' = \ker \bar{\partial} \cap \ker \partial^*$ and $\ker \Delta' = \ker \partial \cap \ker \partial^*$. Since for any pure-type form $v$, the equivalence

$$dv = 0 \iff \partial v = 0 \quad \text{and} \quad \bar{\partial} v = 0$$

holds, (i) and (ii) follow immediately from the two equivalences in (49). Now (i) and (ii) obviously give $\Delta' v = 0$ and $\Delta'' v = 0$ under the assumptions of (iii). To infer that $\Delta v = 0$, it suffices to notice that for any pure-type form $v$ on a compact Hermitian manifold $(X, \omega)$, we have

$$\langle \langle \Delta v, v \rangle \rangle = \langle \langle \Delta' v, v \rangle \rangle + \langle \langle \Delta'' v, v \rangle \rangle \quad (52)$$

since $\langle \langle \Delta v, v \rangle \rangle = \|dv\|^2 + \|d^* v\|^2$, $\langle \langle \Delta' v, v \rangle \rangle = \|\partial v\|^2 + \|\partial^* v\|^2$, and $\langle \langle \Delta'' v, v \rangle \rangle = \|\bar{\partial} v\|^2 + \|\bar{\partial}^* v\|^2$. Since $\Delta' v = 0$ and $\Delta'' v = 0$, from (52) we get $\langle \langle \Delta v, v \rangle \rangle = 0$ which amounts to $dv = 0$ and $d^* v = 0$, hence to $\Delta v = 0$.

The conclusion (iii) of the above Corollary 4.13 is that if an $(n - 1, 1)$-form is both primitive and $d$-closed, it must be harmonic for each of the Laplacians $\Delta'$, $\Delta''$ and $\Delta$. Thus, if a representative that is both primitive and $d$-closed of a primitive $(n - 1, 1)$-class exists, it can only be the $\Delta''$-harmonic representative. Fortunately we have

**Lemma 4.14** Let $(X, \omega)$ be a compact Hermitian manifold $(n := \dim \mathbb{C} X)$. Suppose $v$ is a primitive $(n - 1, 1)$-form such that $\Delta'' v = 0$. Then $\Delta v = 0$ and $\Delta' v = 0$. In particular, $dv = 0$.

Proof. The assumption $\Delta'' v = 0$ means that $\bar{\partial} v = 0$ and $\partial^* v = 0$. Then (i) of Corollary 4.13 implies that $dv = 0$, i.e. $\partial v = 0$. Then (ii) of Corollary 4.13 ensures that $\Delta' v = 0$. Then (52) ensures that $\Delta v = 0$.}

Thus Question 4.11 reduces to whether on a balanced Calabi-Yau $\overline{\partial} \partial$-manifold $(X, \omega)$, the $\Delta''$-harmonic representative of any primitive $(n - 1, 1)$-class (in the sense of the ad hoc Definition 4.9) is a primitive form. It will then also be $d$-closed by Lemma 4.14. Fix therefore a primitive $(n - 1, 1)$-class $[\theta \omega]$ on $X$, where $[\theta]$ $\in$ $\mathcal{H}^{0,1}(X, T^{1,0} X)$. By (17), this means that

$$\theta \omega^{n-1} \in \operatorname{Im} \bar{\partial} \quad (53)$$

Suppose furthermore that $\Delta''(\theta \omega) = 0$. The question is whether $\theta \omega$ is primitive, or equivalently (cf. (48)) whether $\theta \omega^{n-1} = 0$. Since $\ker \Delta''$ and $\operatorname{Im} \bar{\partial}$ are orthogonal subspaces of $C^\infty_{n-2,n}(X, \mathbb{C})$, (53) reduces the question to determining whether
\[ \Delta''(\theta \omega^{n-1}) = 0 \] or equivalently whether \[ \overline{\partial}^*(\theta \omega^{n-1}) = 0, \] (54)
since \( \overline{\partial}(\theta \omega^{n-1}) = 0 \) (trivially since \( \theta \omega^{n-1} \) is of type \( (n-2, n) \)).

The next lemma transforms identity (54) whose validity we are trying to determine.

**Lemma 4.15** Let \( X \) be a compact complex manifold \( \text{dim}_\mathbb{C} X = n \) equipped with an arbitrary Hermitian metric \( \omega \). Fix any \( \theta \in C^\infty_{0,1}(X, T^{1,0}X) \).

The following equivalence holds:

\[ \overline{\partial}^*(\theta \omega^{n-1}) = 0 \iff \partial(\theta \omega) = 0. \]

**Proof.** Formula (51) applied to the (primitive) \( (0, 2) \)-form \( v := \theta \omega \) reads:

\[ \ast(\theta \omega) = \frac{\omega^{n-2}}{(n-2)!} \wedge (\theta \omega) = \theta \omega \frac{\omega^{n-1}}{(n-1)!}, \] i.e.

\[ \ast \left( \theta \omega \frac{\omega^{n-1}}{(n-1)!} \right) = \theta \omega, \] (55)

having also used the property \( \ast^2 = \text{Id} \) on 2-forms. Now, \( \overline{\partial}^* = - \ast \partial \ast \), hence the condition \( \overline{\partial}^*(\theta \omega^{n-1}) = 0 \) is equivalent to \( \partial(\ast(\theta \omega^{n-1})) = 0 \) which in turn is equivalent to \( \partial(\theta \omega) = 0 \) by (55). This proves the contention. \( \square \)

However, we can see no reason why the desired condition \( \partial(\theta \omega) = 0 \) should hold even if we exploit the assumption \( \Delta''(\theta u) = 0 \). Note that if \( \text{Ric}(\omega) = 0 \), by (23) this assumption means that \( \Delta''(\theta) = 0 \), i.e. \( \overline{\partial}^* \theta = 0 \) since we always have \( \partial \theta = 0 \). The most we can make of the property \( \overline{\partial}^* \theta = 0 \) is expressed in part (ii) of the following lemma. Parts (i) and (iii) show that more can be said about scalar-valued \( (0, 1) \)-forms \( v \), although even if that information applied to the \( T^{1,0}X \)-valued \( (0, 1) \)-form \( \theta \), it would not suffice to deduce that \( \partial(\theta \omega) = 0 \).

**Lemma 4.16** Let \( X \) be a compact complex manifold \( \text{dim}_\mathbb{C} X = n \) supposed to carry a balanced metric \( \omega \).

(i) For every \( v \in C^\infty_{0,1}(X, \mathbb{C}) \), the following equivalence holds:

\[ \overline{\partial}^* v = 0 \iff \partial v \text{ is primitive}. \]

(ii) For every \( \theta \in C^\infty_{0,1}(X, T^{1,0}X) \), the following equivalence holds:

\[ \overline{\partial}^* \theta = 0 \iff (D' \theta) \wedge \omega^{n-1} = 0 \in C^\infty_{n,n}(X, T^{1,0}X). \]

(iii) Suppose, furthermore, that \( X \) is a \( \partial \bar{\partial} \)-manifold. Then, for every \( v \in C^\infty_{0,1}(X, \mathbb{C}) \cap \ker \overline{\partial} \), the following equivalence holds:

\[ \Delta'' v = 0 \iff \partial v = 0 \ (\iff \Delta' v = 0). \]
Proof. Since any $(0, 1)$-form is primitive, for $*: C_{0,1}^\infty(X, \mathbb{C}) \to C_{n-1,n}^\infty(X, \mathbb{C})$ formula (51) reads

$$
\star v = -i v \wedge \frac{\omega^{n-1}}{(n-1)!}, \quad v \in C_{0,1}^\infty(X, \mathbb{C}).
$$

(56)

Since $\bar{\partial} \star = -\star \partial \star$, we see that the condition $\bar{\partial} \star v = 0$ is equivalent to $\partial(v \wedge \omega^{n-1}) = 0$. Since $\partial \omega^{n-1} = 0$ (by the balanced assumption), the last identity is equivalent to $(\partial v) \wedge \omega^{n-1} = 0$, which is precisely the condition that the $(1, 1)$-form $\partial v$ be primitive. This proves (i).

The proof of (ii) runs along the same lines as that of (i) using the formula $\bar{\partial} \star = -\star D' \star$ when $\bar{\partial} \star$ acts on $T^{1,0}X$-valued forms and $D'$ is the $(1, 0)$-component of the Chern connection $D$ of $(T^{1,0}X, \omega)$. Indeed, formula (56) still holds for $T^{1,0}X$-valued $(0, 1)$-forms $\theta$ in place of $v$ and

$$
D'(\theta \wedge \omega^{n-1}) = (D'\theta) \wedge \omega^{n-1} - \theta \wedge \partial \omega^{n-1} = (D'\theta) \wedge \omega^{n-1},
$$

where the last identity follows from $\omega$ being balanced.

To prove (iii), fix an arbitrary form $v \in C_{0,1}^\infty(X, \mathbb{C}) \cap \ker \bar{\partial}$. Since $\ker \Delta'' = \ker \bar{\partial} \cap \ker \bar{\partial}^*$, the condition $\Delta''v = 0$ is equivalent for this $v$ to $\bar{\partial}^*v = 0$, which is equivalent to $\partial v$ being primitive by (i). We are thus reduced to proving for this $v$ the equivalence: $\partial v$ is primitive $\iff \partial v = 0$.

Notice that $\bar{\partial}(\partial v) = 0$ thanks to the assumption $\bar{\partial} v = 0$. Hence the pure-type form $\partial v$ is $d$-closed and $\partial$-exact, so by the $\partial \bar{\partial}$-lemma it must be $\partial \bar{\partial}$-exact:

$$
\partial v = i\partial \bar{\partial} \varphi \quad \text{for some} \ C^\infty \text{ function } \varphi : X \to \mathbb{C}.
$$

Then we have the equivalences:

$$
\partial v \text{ is primitive } \iff \Lambda_\omega(i\partial \bar{\partial} \varphi) = 0 \iff \Delta_\omega \varphi = 0 \iff \varphi \text{ is constant },
$$

where the last equivalence follows by the maximum principle from $X$ being compact. Meanwhile, $\varphi$ being constant is equivalent to the vanishing of $i\partial \bar{\partial} \varphi$, hence to the vanishing of $\partial v$.

The conclusion of these considerations is that Question 4.11 may have a negative answer in general in the balanced case. Let us now notice that even the answer to the following weaker question may be negative in the balanced case.

**Question 4.17** Is it true that on a balanced Calabi-Yau $\partial \bar{\partial}$-manifold, every primitive $(n - 1, 1)$-class (in the sense of the ad hoc Definition 4.9) can be represented by a primitive form?
Let \([\theta.,u]\) \(\in H^{n-1,1}_{\text{prim}}(X, \mathbb{C})\) be a \textit{primitive} class in the ad hoc sense. This means that \(\theta.,\omega^{n-1}\) is \(\bar{\partial}\)-exact (for any representative \(\theta\) of the class \([\theta] \in H^{0,1}(X, T^{1,0}X)_{|\omega_{n-1}}\)). Pick any representative \(\theta\) and any \(\bar{\partial}\)-potential \(w \in C^{\infty}_{-2,n-1}(X, \mathbb{C})\) of \(\theta.,\omega^{n-1}\), i.e. \(\bar{\partial}w = \theta.,\omega^{n-1}\). Since

\[
L_{\omega}^{n-3} : C^{\infty}_{1,2}(X, \mathbb{C}) \rightarrow C^{\infty}_{n-2,n-1}(X, \mathbb{C}), \quad \alpha \mapsto \omega^{n-3} \wedge \alpha,
\]

is an isomorphism (see e.g. [Voi02, lemma 6.20, p. 146]), since there is a Lefschetz decomposition (cf. [Voi02, proposition 6.22, p. 147])

\[
\Lambda^{1,2} = \Lambda^{1,2}_{\text{prim}} \oplus (\omega \wedge \Lambda^{0,1})
\]

and since every \(C^{\infty}(0,1)\)-form can be written as \((n-1)\xi.,\omega\) for a unique vector field \(\xi \in C^{\infty}(X, T^{1,0}X)\) (because \(\omega\) is non-degenerate), we see that there is a unique \textit{primitive} \(C^{\infty}\) form \(\alpha_{0}\) of type \((1,2)\) and a unique \(C^{\infty}\) vector field \(\xi\) of type \((1,0)\) such that

\[
w = \omega^{n-3} \wedge \left(\alpha_{0} + (n-1)\omega \wedge (\xi.,\omega)\right) = \omega^{n-3} \wedge \alpha_{0} + \xi.,\omega^{n-1}.
\]

Consequently, \(\theta.,\omega^{n-1} = \bar{\partial}w = \bar{\partial}(\omega^{n-3} \wedge \alpha_{0}) + (\bar{\partial}\xi).,\omega^{n-1}\) since \(\bar{\partial}(\xi.,\omega^{n-1}) = (\bar{\partial}\xi) . \omega^{n-1} - \xi.,(\bar{\partial}\omega^{n-1})\) (cf. (i) of Lemma 4.3) and here \(\bar{\partial}\omega^{n-1} = 0\) by the balanced assumption on \(\omega\). Thus we get

\[
(\theta - \bar{\partial}\xi.) ,\omega^{n-1} = \bar{\partial}(\omega^{n-3} \wedge \alpha_{0}).
\]

We see that \(\theta - \bar{\partial}\xi\) represents the class \([\theta] \in H^{0,1}(X, T^{1,0}X)_{|\omega_{n-1}}\), so \((\theta - \bar{\partial}\xi.) ,u\) represents the class \([\theta.,u]\) \(\in H^{n-1,1}_{\text{prim}}(X, \mathbb{C})\). We know from Lemma 4.10 that the primitivity condition on the form \((\theta - \bar{\partial}\xi.) ,u\) is equivalent to \((\theta - \bar{\partial}\xi.) ,\omega^{n-1} = 0\), i.e. to \(\bar{\partial}(\omega^{n-3} \wedge \alpha_{0}) = 0\) in this case. However, we can see no reason why this vanishing should occur, part of the obstruction being the primitive \((1,2)\)-form \(\alpha_{0}\).

Thus in the balanced, non-Kähler case, the answer to Question 4.17 may be negative in general.

5 Period map and Weil-Petersson metrics

We now fix an arbitrary balanced Calabi-Yau \(\partial\bar{\partial}\) manifold \(X, \dim_{\mathbb{C}}X = n\). All the fibres \((X_{t})_{t \in \Delta}\) in the Kuranishi family of \(X = X_{0}\) are again balanced Calabi-Yau \(\partial\bar{\partial}\)-manifolds if \(t\) is sufficiently close to \(0 \in \Delta\) by Wu’s theorem and the deformation openness of the triviality of the canonical bundle \(K_{X}\). Thus \(H^{n,0}(X_{t}, \mathbb{C})\) is a complex line varying holomorphically with \(t\) inside the fixed complex vector space \(H^{n}(X, \mathbb{C})\). The canonical injection \(H^{0,0}(X_{t}, \mathbb{C}) \subset H^{n}(X, \mathbb{C})\) is induced by the \(\partial\bar{\partial}\)-lemma property of
The associated period map $\Delta \ni t \mapsto H^{n,0}(X_t, \mathbb{C})$ takes values in the complex projective space $\mathbb{P}^{b_n-1}$ after identifying each complex line $H^{n,0}(X_t, \mathbb{C})$ with the point it defines therein, where $b_n := \dim_{\mathbb{C}} H^n(X, \mathbb{C})$ is the $n^{th}$ Betti number of $X$ (hence of every $X_t$).

### 5.1 Period domain and the local Torelli theorem

Most of the material in this subsection before Theorem 5.5 is essentially known, but we take this opportunity to stress that only minimal assumptions are needed and to fix the notation for the rest of the paper.

Let $\omega$ be a Hermitian metric on $X$. All the formal adjoint operators and Laplacians will be calculated w.r.t. $\omega$. The Hodge $\ast$-operator defined by $\omega$ on $n$-forms $\ast : C^\infty_n(X, \mathbb{C}) \rightarrow C^\infty_n(X, \mathbb{C})$ satisfies $\ast^2 = (-1)^n$, so it induces a decomposition

$$C^\infty_n(X, \mathbb{C}) = \Lambda^n_+ \oplus \Lambda^n_-,$$

where $\Lambda^n_+$ stand for the eigenspaces of $\ast$ corresponding to the eigenvalues $\pm 1$ (if $n$ is even), $\pm i$ (if $n$ is odd). This decomposition is easily seen to be orthogonal for the $L^2$ scalar product induced by $\omega$: for any $u \in \Lambda^n_+$ and any $v \in \Lambda^n_-$, one easily checks that $\langle \langle u, v \rangle \rangle = -\langle \langle u, v \rangle \rangle$ by writing $u = \ast u$ (if $n$ is even) and $u = -i(\ast u)$ (if $n$ is odd) and using the easy-to-check identity $\langle \langle \ast u, v \rangle \rangle = (-1)^n \langle \langle u, \ast v \rangle \rangle$ for any $n$-forms $u, v$.

When $\ast$ is restricted to $\Delta$-harmonic forms, it assumes $\Delta$-harmonic values:

$$\ast : \mathcal{H}^n_\Delta(X, \mathbb{C}) \rightarrow \mathcal{H}^n_\Delta(X, \mathbb{C})$$

since $\Delta := dd^* + d^*d$ commutes with $\ast$ as is well known to follow from the standard formula $d^* = -\ast d \ast$. Thus the Hodge isomorphism $H^n(X, \mathbb{C}) \simeq \mathcal{H}_\Delta^n(X, \mathbb{C})$ mapping any De Rham class to its $\Delta$-harmonic representative extends the definition of $\ast$ to the De Rham cohomology of degree $n$:

$$\ast : H^n(X, \mathbb{C}) \rightarrow H^n(X, \mathbb{C})$$

and we get a decomposition in cohomology analogous to the decomposition (58) on forms:

$$H^n(X, \mathbb{C}) = H^n_+(X, \mathbb{C}) \oplus H^n_-(X, \mathbb{C}),$$
where \( H^n_\pm(X, \mathbb{C}) \) are the eigenspaces of \( \ast \) corresponding to the eigenvalues \( \pm 1 \) (if \( n \) is even), \( \pm i \) (if \( n \) is odd). Thus \( H^n_+ (X, \mathbb{C}) \) (resp. \( H^n_- (X, \mathbb{C}) \)) consists of the De Rham classes \( \{\alpha\} \) of degree \( n \) whose \( \Delta \)-harmonic representative \( \alpha \) lies in \( \Lambda^n_+ \) (resp. \( \Lambda^n_- \)). Note that no assumption whatsoever (either Kähler or balanced) is needed on the Hermitian metric \( \omega \).

On the other hand, the Hodge-Riemann bilinear form can always be defined on the De Rham cohomology of degree \( n \):

\[
Q : H^n(X, \mathbb{C}) \times H^n(X, \mathbb{C}) \rightarrow \mathbb{C},
\]

\[
(\{\alpha\}, \{\beta\}) \mapsto (-1)^{\frac{n(n-1)}{2}} \int_X \alpha \wedge \beta := Q(\{\alpha\}, \{\beta\}),
\]

(61)

It is clear that \( Q(\cdot, \cdot) \) is independent of the choice of representatives \( \alpha \) and \( \beta \) of the respective De Rham classes of degree \( n \) since no power of \( \omega \) is involved in the definition of \( Q \), so no Kähler or balanced or any other assumption is needed on \( \omega \) unlike the case of the De Rham cohomology in degree \( k < n \). Thus \( Q \) is independent of \( \omega \) and of the complex structure of \( X \), depending only on the differential structure of \( X \). It is also clear that \( Q \) is non-degenerate since for any \( \Delta \)-harmonic \( n \)-form \( \alpha \), \( \ast \bar{\alpha} \) is again \( \Delta \)-harmonic and

\[
Q(\{\alpha\}, \{\ast \bar{\alpha}\}) = (-1)^{\frac{n(n-1)}{2}} \int_X \alpha \wedge \ast \bar{\alpha} = (-1)^{\frac{n(n-1)}{2}} \int_X \langle \alpha, \alpha \rangle_\omega dV_\omega
\]

\[
= (-1)^{\frac{n(n-1)}{2}} ||\alpha||^2_\omega \neq 0 \quad \text{if} \ \alpha \neq 0.
\]

Hence the associated sesquilinear form

\[
H : H^n(X, \mathbb{C}) \times H^n(X, \mathbb{C}) \rightarrow \mathbb{C},
\]

\[
(\{\alpha\}, \{\beta\}) \mapsto (-1)^{\frac{n(n+1)}{2}} i^n \int_X \alpha \wedge \bar{\beta} = (-i)^n Q(\{\alpha\}, \{\bar{\beta}\})
\]

(62)

is non-degenerate.

**Lemma 5.1** \text{(a)} \( H(\{\alpha\}, \{\alpha\}) > 0 \) for every class \( \{\alpha\} \in H^n_+(X, \mathbb{C}) \setminus \{0\} \). Hence \( H \) defines a positive definite sesquilinear form (i.e. a Hermitian metric) on \( H^n_+(X, \mathbb{C}) \).

\text{(b)} \( H(\{\alpha\}, \{\alpha\}) < 0 \) for every class \( \{\alpha\} \in H^n_-(X, \mathbb{C}) \setminus \{0\} \).

\text{(c)} \( H(\{\alpha\}, \{\beta\}) = 0 \) for every class \( \{\alpha\} \in H^n_+(X, \mathbb{C}) \) and every class \( \{\beta\} \in H^n_-(X, \mathbb{C}) \). Hence the decomposition (60) is orthogonal for \( H \).
Proof. (a) Let $\alpha$ be a $\Delta$-harmonic $n$-form such that the class $\{\alpha\} \in H^n_+(X, \mathbb{C})$. If $n$ is even, $\star \alpha = \alpha$, hence taking conjugates we get $\star \bar{\alpha} = \bar{\alpha}$. Thus

$$H(\{\alpha\}, \{\alpha\}) = (-1)^{\frac{n(n+1)}{2}} i^n \int_X \alpha \wedge \star \bar{\alpha} = \int_X |\alpha|_{\omega}^2 dV_{\omega} = ||\alpha||^2_{\omega} > 0$$

if $\alpha \neq 0$, since $(-1)^{\frac{n(n+1)}{2}} i^n = i^{n^2+2n} = 1$ when $n$ is even. (Indeed, $n^2 + 2n \in 4\mathbb{Z}$ when $n$ is even.)

If $n$ is odd, $\star \alpha = i \alpha$, hence taking conjugates we get $\star \bar{\alpha} = -i \bar{\alpha}$. Equivalently, $\bar{\alpha} = i \star \alpha$. On the other hand, $(-1)^{\frac{n(n+1)}{2}} i^n = i^{n^2+2n} = -i$ when $n$ is odd since $n^2 + 2n \in 4\mathbb{Z} + 3$ in this case. We then get as above that again $H(\{\alpha\}, \{\alpha\}) = ||\alpha||^2_{\omega} > 0$ if $\alpha \neq 0$. This proves (a). The proof of (b) is very similar and is left to the reader.

(c) Let $\alpha$ and $\beta$ be $\Delta$-harmonic $n$-forms such that $\{\alpha\} \in H^n_+(X, \mathbb{C})$ and $\{\beta\} \in H^n_+(X, \mathbb{C})$. If $n$ is even, this means that $\star \alpha = \alpha$ and $\star \beta = -\beta$. Using the property $\star \beta = -\beta$, we get

$$H(\{\alpha\}, \{\beta\}) = -(-1)^{\frac{n(n+1)}{2}} i^n \int_X \alpha \wedge \star \bar{\beta} = -(-1)^{\frac{n(n+1)}{2}} i^n \langle \alpha, \beta \rangle_{\omega}, \quad (63)$$

while using the property $\star \alpha = \alpha$, we get

$$H(\{\alpha\}, \{\beta\}) = -(-1)^{\frac{n(n+1)}{2}} i^n \int_X \alpha \wedge \bar{\beta} = -(-1)^{n^2} (-1)^{\frac{n(n+1)}{2}} i^n \int_X \bar{\beta} \wedge \alpha$$

$$= (-1)^{\frac{n(n+1)}{2}} i^n \int_X \langle \beta, \alpha \rangle_{\omega} dV_{\omega} = (-1)^{\frac{n(n+1)}{2}} i^n \langle \alpha, \beta \rangle_{\omega}. \quad (64)$$

having used the fact $(-1)^{n^2} = 1$ since $n$ is even and the identity $\langle \bar{\beta}, \alpha \rangle_{\omega} = \langle \alpha, \beta \rangle_{\omega}$. The expressions (63) and (64) for $H(\{\alpha\}, \{\beta\})$ are now seen to differ only by a sign, hence $H(\{\alpha\}, \{\beta\}) = 0$.

When $n$ is odd, we have $\star \alpha = i \alpha$ (hence $\alpha = -i \star \alpha$) and $\star \beta = -i \beta$ (hence $\bar{\beta} = -i \star \bar{\beta}$). Using the former and then the latter of these two pieces of information, we get as above two expressions for $H(\{\alpha\}, \{\beta\})$ that differ only by a sign. Hence $H(\{\alpha\}, \{\beta\}) = 0$. □

Notice that $Q$ and $H$ depend only on the differential structure of $X$, while $\star$ depends also on the (arbitrary) metric $\omega$. However, Lemma 5.1 implies the following

**Corollary 5.2** The decomposition (60) is independent of the Hermitian metric $\omega$ chosen on $X$ (i.e. $H^n_+(X, \mathbb{C})$, $H^n_+(X, \mathbb{C})$ and the Hermitian metric induced by $H$ on $H^n_+(X, \mathbb{C})$ depend only on the differential structure of $X$).
We now bring in the complex structure of $X$ (that is supposed to have the $\partial\bar{\partial}$ property which induces the inclusion $H^{n,0}(X, \mathbb{C}) \subset H^n(X, \mathbb{C})$).

**Lemma 5.3** Let $X$ be a compact complex $\partial\bar{\partial}$-manifold ($\dim_{\mathbb{C}}X = n$). Then the following inclusion holds:

$$H^{n,0}(X, \mathbb{C}) \subset H^n(X, \mathbb{C}).$$

In particular, the restriction $H : H^{n,0}(X, \mathbb{C}) \times H^{n,0}(X, \mathbb{C}) \to \mathbb{C}$ of $H$ to $H^{n,0}(X, \mathbb{C})$ is **positive definite** thanks to (a) of Lemma 5.1 (hence the induced scalar product defines a Hermitian metric on $H^{n,0}(X, \mathbb{C})$).

Before proving this statement, we make a trivial but useful observation.

**Lemma 5.4** Let $(X, \omega)$ be any compact complex Hermitian manifold ($\dim_{\mathbb{C}}X = n$). For every $(n, 0)$-form $\alpha$, the following equivalence and implication hold:

$$\Delta''\alpha = 0 \iff \Delta'\alpha = 0 \iff \Delta\alpha = 0.$$ 

**Proof.** Since $X$ is compact, $\ker \Delta'' = \ker \partial \cap \ker \bar{\partial}$ and $\ker \Delta' = \ker \partial \cap \ker \bar{\partial}$. However, $\partial\alpha = 0$ and $\bar{\partial}\alpha = 0$ for any $(n, 0)$-form $\alpha$ for trivial bidegree reasons. Hence, for any $\alpha \in C^\infty_{n,0}(X, \mathbb{C})$, the following equivalences hold:

$$\Delta'\alpha = 0 \iff \bar{\partial}\alpha = 0 \quad \text{and} \quad \Delta''\alpha = 0 \iff \partial\alpha = 0.$$ 

Consequently, from the identity $\partial^* = -\ast \bar{\partial}\ast$ (cf. e.g. [Dem97, VI, §5.1]) and from the fact that $\ast$ is an isomorphism, we get the equivalence: $\Delta'\alpha = 0 \iff \bar{\partial}(\ast\alpha) = 0$. Since $\alpha$ is of type $(n, 0)$, it is primitive (w.r.t. any metric, hence also w.r.t. $\omega$), so formula (51) applied to $\alpha$ reads:

$$\ast\alpha = (-1)^{n(n-1)/2}i^n\alpha.$$ 

Thus the previous equivalence implies the following equivalence:

$$\Delta'\alpha = 0 \iff \bar{\partial}\alpha = 0,$$

while the equivalence $\partial\alpha = 0 \iff \Delta''\alpha = 0$ has already been observed. We have thus proved the equivalence claimed in the statement. The implication claimed in the statement now follows from identity (52) applied to the pure-type form $\alpha$ and the fact that $\langle \langle \Delta\alpha, \alpha \rangle \rangle \geq 0$ with equality if and only if $\Delta\alpha = 0$. 

**Proof of Lemma 5.3.** Let $[\alpha] \in H^{n,0}(X, \mathbb{C})$ be an arbitrary Dolbeault cohomology class of type $(n, 0)$. Since the only $\bar{\partial}$-exact form of type $(n, 0)$ is the zero form, the class $[\alpha]$ contains a unique representative $\alpha$. Clearly, $\alpha$ is of type $(n, 0)$ and $\Delta''$-harmonic, so from Lemma 5.4 we get $\Delta\alpha = 0$. On the other hand, formula (51) applied to $\alpha$ (which is primitive since it is of type $(n, 0)$) reads:

$$\ast\alpha = (-1)^{n(n-1)/2}i^n\alpha = i^n\alpha,$$

hence $\alpha \in \Lambda^n_{\mathbb{C}}$ since $i^n = 1$ if $n$ is even and $i^n = i$ if $n$ is odd. Therefore the De Rham cohomology
class \(\{\alpha\} \in H^n(X, \mathbb{C})\) represented by the \(\Delta\)-harmonic form \(\alpha\) must belong to \(H^n_+(X, \mathbb{C})\).

It is clear that for any \(\partial\bar{\partial}\) complex structure \(J_t\) on \(X\) and any class \(\varphi_t = [\alpha_t] \in H^{n,0}(X_t, \mathbb{C}) \subset H^n_+(X, \mathbb{C})\), \(Q(\varphi_t, \varphi_t) = 0\) since \(\alpha_t \wedge \alpha_t = 0\) for any class of \(J_t\)-type \((n, 0)\). Thus the period domain, containing the complex lines \(H^{n,0}(X_t, \mathbb{C})\) varying inside \(H^n_+(X, \mathbb{C})\) when \(J_t\) varies, can be defined as in the standard (i.e. Kähler) case as

\[
D = \{\mathbb{C}\text{-line } l \subset H^n_+(X, \mathbb{C}) ; \forall \varphi \in l \setminus \{0\}, \; Q(\varphi, \varphi) = 0 \text{ and } H(\varphi, \varphi) > 0\}.
\]

Given the natural holomorphic embedding \(D \subset \mathbb{P}H^n_+(X, \mathbb{C})\), the complex manifold \(D\) is projective and is a quadric (defined by \(Q\)) in \(\mathbb{P}H^n_+(X, \mathbb{C})\).

We can now show that the local Torelli theorem holds in this context.

**Theorem 5.5** Let \(X\) be a compact Calabi-Yau \(\partial\bar{\partial}\)-manifold, \(\dim_{\mathbb{C}}X = n\), and let \(\pi : X \to \Delta\) be its Kuranishi family. Then the associated period map

\[
\mathcal{P} : \Delta \to D \subset \mathbb{P}H^n_+(X, \mathbb{C}), \quad \Delta \ni t \mapsto H^{n,0}(X_t, \mathbb{C}),
\]

is a local holomorphic immersion.

**Proof.** As usual, we denote by \((X_t)_{t \in \Delta}\) the fibres of the Kuranishi family of \(X = X_0\). They are all \(C^\infty\)-diffeomorphic to \(X\) and the holomorphic family \((X_t)_{t \in \Delta}\) can be seen as a fixed \(C^\infty\) manifold \(X\) equipped with a holomorphic family of complex structures \((J_t)_{t \in \Delta}\). Let \((u_t)_{t \in \Delta}\) be a holomorphic family of nowhere vanishing \(n\)-forms on \(X\) such that for every \(t \in \Delta\), \(u_t\) is of type \((n, 0)\) for the complex structure \(J_t\) and \(\bar{\partial}_t u_t = 0\). The form \(u_t\) identifies with the class \([u_t]\) it defines in \(H^{n,0}(X_t, \mathbb{C})\), hence with the whole space \(H^{n,0}(X_t, \mathbb{C}) = \mathbb{C} u_t\). Thus the period map identifies with the map

\[
\Delta \ni t \mapsto u_t.
\]

It suffices to prove that \(\mathcal{P}\) is a local immersion at \(t = 0\). Recall that in the present situation the Kodaira-Spencer map \(\rho : T_0\Delta \to H^{1,0}(X, T^{1,0}X)\) is an isomorphism (thanks to Theorem [1],[3]) and that for any tangent vector \(\partial/\partial t \in T_0\Delta\), the choice of a representative \(\theta\) in the class \(\rho(\partial/\partial t) = [\theta] \in H^{1,0}(X, T^{1,0}X)\) determines a \(C^\infty\) trivialisation \(\Phi : X \to \Delta \times X_0\) (after possibly shrinking \(\Delta\) about \(0\)), which in turn determines about any pre-given point \(x \in X\) a choice of local \(J_t\)-holomorphic coordinates \(z_1(t), \ldots, z_n(t)\) for every \(t \in \Delta\).

Denote \(u = u_0\). Fix an arbitrary tangent vector \(\partial/\partial t \in T_0\Delta \setminus \{0\}\) and choose a representative \(\theta\) of the class \(\rho(\partial/\partial t) \in H^{1,0}(X, T^{1,0}X)\) such that the representative \(\theta_{\partial/\partial t} u\) of the class \([\theta_{\partial/\partial t} u] \in H^{n-1,1}(X, \mathbb{C})\) is \(d\)-closed. This is
possible by the $\partial\bar{\partial}$ assumption on $X$ and by Lemmas 3.1 and 3.3. The associated local $C^\infty$ trivialisation $\Phi : X \to \Delta \times X_0$ induces $C^\infty$ diffeomorphisms $\Phi^{-1}_t : X_0 \to X_t$, $t \in \Delta$, so the differential of the period map at $t = 0$ in the $\partial/\partial t$-direction identifies with

$$\frac{\partial(\Phi^{-1}_t)^*u_t}{\partial t} \big|_{t=0} = \theta_J u + v \quad \text{on } X,$$

(66)

where $v$ is some $(n, 0)$-form on $X = X_0$. The identity in (66) can be proved in the usual way (see e.g. [Tia87, proof of Lemma 7.2]): having fixed an arbitrary point $x \in X$, one writes

$$u_t = f_t \, dz_1(t) \wedge \cdots \wedge dz_n(t)$$

(67)

where $f_t$ is a holomorphic function in a neighbourhood of $x$ in $X_t$ and $z_1(t), \ldots, z_n(t)$ are the local $J_t$-holomorphic coordinates about $x$ determined by the choice of $\theta$ in the class $\rho(\partial/\partial t)$. Taking $\partial/\partial t$ at $t = 0$ in (67), one finds on the right-hand side the sum of the form $v = (\partial f_t/\partial t)_{t=0} \, dz_1(0) \wedge \cdots \wedge dz_n(0)$ of $J_0$-type $(n, 0)$ with the form $\theta_J u$ of $J_0$-type $(n-1, 1)$. The latter form is easily seen to be the sum of the terms obtained by deriving one of the $dz_j(t)$ in (67) since, with the above choices of $\theta$ and $z_1(t), \ldots, z_n(t)$, we have

$$\frac{\partial}{\partial t}(dz_j(t))_{t=0} = \theta_J dz_j(0), \quad j = 1, \ldots, n.$$

Now, $du_t = 0$ for all $t$, hence the left-hand term in (66) is a $d$-closed $n$-form on $X$. Thus $d(\theta_J u + v) = 0$. By our choice of $\theta$ (based on a key application of the $\partial\bar{\partial}$ lemma), $d(\theta_J u) = 0$, hence $dv = 0$. In particular, $v$ is a $\partial_0$-closed form of $J_0$-type $(n, 0)$, so $v = cu$ for some constant $c \in \mathbb{C}$.

It is now clear that if $(dP_0)(\partial/\partial t) = 0$, then $\theta_J u = 0$ and $v = cu = 0$, so $\theta = 0$ (since $T_u(\theta) = \theta_J u$ and $T_u$ is an isomorphism – see (18)), hence $\partial/\partial t = 0$ (since the Kodaira-Spencer map is an isomorphism here). This last vanishing contradicts the choice of $\partial/\partial t \neq 0$. We have thus shown that $P$ is a local immersion at $t = 0$.

5.2 Weil-Petersson metrics on $\Delta$

We start with a refinement of Lemma 3.1 singling out a particular $d$-closed representative of a given Dolbeault cohomology class on a $\partial\bar{\partial}$-manifold.

**Definition 5.6** Let $X$ be a compact $\partial\bar{\partial}$-manifold equipped with an arbitrary Hermitian metric $\omega$. Given any Dolbeault cohomology class $[\alpha] \in H^{p,q}(X, \mathbb{C})$, let $\alpha$ be its $\Delta''_0$-harmonic representative and let $v_{\min} \in \text{Im}(\partial\bar{\partial})^* \subset C^\infty_{p,q-1}(X, \mathbb{C})$ be the solution of minimal $L^2$ norm (w.r.t. $\omega$) of equation (16).
The $d$-closed $(p, q)$-form $\alpha_{min} := \alpha + \bar{\partial}v_{min}$ will be called the $\omega$-minimal $d$-closed representative of the class $[\alpha]$. (It coincides with the $\Delta''_{\omega}$-harmonic representative if $\omega$ is Kähler.)

A word of explanation is in order. Recall that the Aeppli cohomology group of type $(p, q)$ is standardly defined as

$$H^p_{\Delta}(X, \mathbb{C}) = \frac{\ker(\partial \bar{\partial} : C^\infty_{p, q}(X) \to C^\infty_{p+1, q+1}(X))}{\text{Im}(\partial : C^\infty_{p-1, q}(X) \to C^\infty_{p, q}(X)) + \text{Im}(\bar{\partial} : C^\infty_{p, q-1}(X) \to C^\infty_{p, q}(X))}$$

and that the fourth-order Aeppli Laplacian $\tilde{\Delta}^{p, q}_A : C^\infty_{p, q}(X, \mathbb{C}) \to C^\infty_{p, q}(X, \mathbb{C})$ (cf. [KS60], also [Sch07, 2.c., p. 9-10]) defined by

$$\tilde{\Delta}^{p, q}_A := \partial \bar{\partial}^* + \bar{\partial} \partial^* + (\partial \bar{\partial})(\partial \bar{\partial})^* + (\bar{\partial} \partial)(\bar{\partial} \partial)^* + (\partial \partial)(\partial \partial)^* + (\bar{\partial} \bar{\partial})(\bar{\partial} \bar{\partial})^*$$

is elliptic and thus induces a three-space decomposition

$$C^\infty_{p, q}(X, \mathbb{C}) = \ker \tilde{\Delta}^{p, q}_A \oplus (\text{Im} \partial + \text{Im} \bar{\partial}) \oplus \text{Im}(\partial \bar{\partial})^*$$

that is orthogonal w.r.t. the $L^2$ scalar product defined by $\omega$ and in which

$$\ker(\partial \bar{\partial}) = \ker \tilde{\Delta}^{p, q}_A \oplus (\text{Im} \partial + \text{Im} \bar{\partial}), \quad (68)$$

yielding the Hodge isomorphism $H^p_{\Delta}(X, \mathbb{C}) \simeq \ker \tilde{\Delta}^{p, q}_A$. Since the solution $\nu$ of equation (16) is unique only modulo $\ker(\partial \bar{\partial})$, the solution of minimal $L^2$ norm is the unique solution lying in $\ker(\partial \bar{\partial})^\perp = \text{Im}(\partial \bar{\partial})^*$. Note that if the $\Delta''$-harmonic representative $\alpha$ of the class $[\alpha]$ happens to be $d$-closed (for example, this is the case if the metric $\omega$ is Kähler), then $\partial \alpha = 0$ and $v_{min} = 0$, so $\alpha_{min} = \alpha$. Thus $\alpha_{min}$ can be seen as the minimal $d$-closed correction in a given Dolbeault class of the $\Delta''$-harmonic representative of that class.

Recall that if we fix a compact balanced Calabi-Yau $\partial \bar{\partial}$-manifold $(X, \omega)$ (dim$_C X = n$), the base space $\Delta_{[\omega^{-1}]}$ of the local universal family $(X_t)_{t \in \Delta_{[\omega^{-1}]}^n}$ of deformations of $X$ that are co-polarised by the balanced class $[\omega^{-1}] \in H^{n-1, n-1}(X, \mathbb{C})$ identifies to an open subset of $H^{0, 1}(X, T^{1, 0}X)_{[\omega^{-1}]}$ and

$$T_t \Delta_{[\omega^{-1}]} \simeq H^{0, 1}(X_t, T^{1, 0}X_t)_{[\omega^{-1}]} \simeq H^{n-1, 1}_{\text{prim}}(X_t, \mathbb{C}), \quad t \in \Delta_{[\omega^{-1}]}.$$  

We shall now define two Weil-Petersson metrics on $\Delta_{[\omega^{-1}]}$ induced by pre-given balanced metrics on the fibres $X_t$ whose $(n - 1)^{st}$ powers lie in the co-polarising balanced class.
Definition 5.7 Fix any holomorphic family of nonvanishing holomorphic \( n \)-forms \((u_t)_{t \in \Delta}\) on the fibres \((X_t)_{t \in \Delta}\). Let \((\omega_t)_{t \in \Delta}\) be a \( C^\infty \) family of balanced metrics on the fibres \((X_t)_{t \in \Delta}\) such that \( \omega_t^{-1} \in \{ \omega^{-1} \} \) for all \( t \) and \( \omega_0 = \omega \). The associated Weil-Petersson metrics \( G_{WP}^{(1)} \) and \( G_{WP}^{(2)} \) on \( \Delta_{[\omega^{-1}]} \) are defined as follows. For any \( t \in \Delta_{[\omega^{-1}]} \) and any \( [\theta_t], [\eta_t] \in H^{0,1}(X_t, T^{1,0}X_t)[\omega^{-1}] \), let

\[
G_{WP}^{(1)}([\theta_t], [\eta_t]) := \frac{\langle \langle \theta_t, \eta_t \rangle \rangle}{\int_X dV_{\omega_t}}, \quad \text{(where } dV_\omega := \frac{\omega^n}{n!} \text{)} \tag{69}
\]

and

\[
G_{WP}^{(2)}([\theta_t], [\eta_t]) := \frac{\langle \langle \theta_t \eta_t, \eta_t \cdot u_t \rangle \rangle}{i^n \int_X u_t \wedge \bar{u}_t}, \tag{70}
\]

where \( \theta_t \) (resp. \( \eta_t \)) is chosen in its class \( [\theta_t] \) (resp. \( [\eta_t] \)) such that \( \theta_t \cdot u_t \) (resp. \( \eta_t \cdot u_t \)) is the \( \omega_t \)-minimal \( d \)-closed representative of the class \( [\theta_t \cdot u_t] \in H^{n-1,1}(X_t, \mathbb{C}) \) (resp. \( [\eta_t \cdot u_t] \in H^{n-1,1}(X_t, \mathbb{C}) \)), while \( \langle \langle \cdot, \cdot \rangle \rangle \) stands for the \( L^2 \) scalar product induced by \( \omega_t \) on the spaces involved.

The \( C^\infty \) positive definite \((1, 1)\)-forms on \( \Delta_{[\omega^{-1}]} \) associated with \( G_{WP}^{(1)} \) and \( G_{WP}^{(2)} \) are denoted by

\[
\omega_{WP}^{(1)} > 0 \text{ and } \omega_{WP}^{(2)} > 0 \text{ on } \Delta_{[\omega^{-1}]}.
\]

Since every \( u_t \) is unique up to a constant factor, the definition of \( G_{WP}^{(2)} \) is independent of the choice of the family \((u_t)_{t \in \Delta}\). From Lemma 3.2 we infer

Observation 5.8 If the balanced metrics can be chosen such that \( \text{Ric}(\omega_t) = 0 \) for all \( t \in \Delta_{[\omega^{-1}]} \), then

\[
\omega_{WP}^{(1)} = \omega_{WP}^{(2)} \text{ on } \Delta_{[\omega^{-1}]}.
\]

5.3 Metric on \( \Delta \) induced by the period map

Let \( L = \Omega_{\mathbb{P}H^*_+(X, \mathbb{C})}(-1) \) be the tautological line bundle on \( \mathbb{P}H^*_+(X, \mathbb{C}) \). The Hermitian metric defined by \( H \) on \( H^*_+(X, \mathbb{C}) \) (cf. (a) of Lemma 5.1) induces a natural \( C^\infty \) fibre metric \( h_L \) on \( L \) whose (negative) curvature form \( i \Theta_{h_L}(L) \) defines the associated Fubini-Study metric on \( \mathbb{P}H^*_+(X, \mathbb{C}) \) by

\[
\omega_{FS} = -i \Theta_{h_L}(L) > 0.
\]

It follows from Corollary 5.2 that \( \omega_{FS} \) depends only on the differential structure of \( X \) but not on the metric \( \omega \). Composing the period map with the
holomorphic embedding \( D \hookrightarrow \mathbb{P}H^*_{\pi}(X, \mathbb{C}) \), we obtain a local holomorphic immersion \( \mathcal{P} : \Delta \to \mathbb{P}H^*_{\pi}(X, \mathbb{C}) \) (cf. Theorem 5.5) still denoted by \( \mathcal{P} \). Thus the inverse image of \( \omega_{FS} \) defines a Hermitian metric (i.e. a positive definite \( C^\infty \) \((1, 1)\)-form) on \( \Delta \) which is actually Kähler:

\[
\gamma := \mathcal{P}^*(\omega_{FS}) > 0 \quad \text{on } \Delta.
\] (71)

We can compute \( \gamma \) at an arbitrary point \( t \in \Delta \) (e.g. at \( t = 0 \)) in the same way as in [Tia87, §7]. We spell out the details for the reader’s convenience. Let \( (u_t)_{t \in \Delta} \) be a holomorphic family of nonvanishing holomorphic \( n \)-forms on the fibres \( (X_t)_{t \in \Delta} \). Recall that a tangent vector \( (\partial/\partial t)_{|t=0} \) to \( \Delta \) at 0 identifies via the Kodaira-Spencer map with a class \( [\theta] \in H^{0,1}(X, T^{1,0}X) \). Fix an arbitrary such class \([\theta]\). We will compute \( \gamma_0([\theta], [\theta]) \).

We have: \( L_{u_t} = \mathbb{C} \cdot u_t = H^{n,0}(X_t, \mathbb{C}) \subset H^*_+ (X, \mathbb{C}) \) and \( (-i)^n Q(u_t, \bar{u}_t) = H(u_t, u_t) = |u_t|_\theta^2 = e^{-\rho(t)} \), where \( \rho \) denotes the local weight function of the fibre metric \( h_L \) of \( L \). Thus \( \rho(t) = -\log((-i)^n Q(u_t, \bar{u}_t)) \), hence the curvature form of \((L, h_L)\) on a \( \mathbb{C} \)-line \( \mathbb{C} \cdot t \) in a small neighbourhood of 0 equals

\[
i\Theta_{h_L}(L)|_{\mathbb{C} \cdot t} = i\partial_t \bar{\partial}_t \rho(t) = -i\partial_t \bar{\partial}_t \log Q(u_t, \bar{u}_t) = -i \frac{\partial^2 \log Q(u_t, \bar{u}_t)}{\partial t \partial \bar{t}} \, dt \wedge d\bar{t}.
\]

This means that for \([\theta] = \rho(\partial/\partial t|_{t=0}) \), using the fact that \( \frac{\partial u}{\partial t} = 0 \) (since \( u_t \) varies holomorphically with \( t \)), we get:

\[
\gamma_0([\theta], [\theta]) = \frac{\partial^2 \log Q(u_t, \bar{u}_t)}{\partial t \partial \bar{t}} \bigg|_{t=0} = -\frac{\partial}{\partial t} \left( (-i)^n \frac{Q(u_t, \frac{\partial u}{\partial t})}{Q(u_t, \bar{u}_t)} \right) \bigg|_{t=0} \\
= (-1)^n \left[ \frac{Q\left(\frac{\partial u}{\partial t} \big|_{t=0}, \frac{\partial u}{\partial t} \big|_{t=0}\right)}{Q(u_0, \bar{u}_0)} - \frac{Q\left(\frac{\partial u}{\partial t} \big|_{t=0}, \bar{u}_0\right) \cdot Q\left(u_0, \frac{\partial u}{\partial t} \big|_{t=0}\right)}{Q(u_0, \bar{u}_0)^2} \right].
\]

Now recall that in the proof of Theorem 5.5 a key application of the \( \partial \bar{\partial} \) lemma enabled us to choose the representative \( \theta \) of the class \([\theta]\) such that \( d(\theta, u) = 0 \). With this choice, if \( w := u_0 \), in formula (66) we had \( v = c \cdot u \) and

\[
\frac{\partial u_t}{\partial t} \bigg|_{t=0} = \theta, u + c \cdot u_0,
\]

where \( c \in \mathbb{C} \) is a constant, if we identify \( u_t \) with \((\Phi_t^{-1})^* u_t \) when \( \Phi_t : X_t \to X_0 \) \((t \in \Delta)\) denote the \( C^\infty \) isomorphisms induced by the choice of \( \theta \) in \([\theta]\). Using (72), the above formula for \( \gamma_0([\theta], [\theta]) \) translates to

\[
\gamma_0([\theta], [\theta]) = (-1)^n \frac{Q(u, \bar{u}) \cdot Q(\theta, u, \bar{u}) + |c|^2 Q(u, \bar{u})^2}{Q(u, \bar{u})^2} - \frac{|c|^2 Q(u, \bar{u})^2}{Q(u, \bar{u})^2} \\
= (-1)^n \frac{Q(\theta, u, \bar{u})}{Q(u, \bar{u})}.
\]

40
The conclusion of these calculations is summed up in the following

**Lemma 5.9** The Kähler metric $\gamma := \mathcal{P}^*(\omega_{FS}) > 0$ on $\Delta$ is independent of the choice of any metrics on $(X_t)_{t \in \Delta}$ and is explicitly given by the formula:

$$
\gamma_t([\theta_t], [\theta_t]) = \frac{(-1)^{n+1} i^n \int_X (\theta_{\nu(t)} \wedge \overline{\theta_{\nu(t)}})}{i^n \int_X u_t \wedge \overline{u_t}}, \quad t \in \Delta, \quad [\theta_t] \in H^{0,1}(X_t, T^{1,0}X_t).
$$

In particular, we see that $\gamma_t([\theta_t], [\theta_t])$ is independent of the choice of representative $\theta_t$ in the class $[\theta_t] \in H^{0,1}(X_t, T^{1,0}X_t)$ such that $\theta_{\nu(t)}$ is $d$-closed. Since for every $t \in \Delta$, $u_t$ is unique up to a constant factor, $\gamma$ is independent of the choice of holomorphic family $(u_t)_{t \in \Delta}$ of $J_t$-holomorphic $n$-forms.

Notice that $i^n u_t \wedge \overline{u_t} > 0$ at every point of $X_t$ for any non-vanishing $(n, 0)$-form $u_t$ and that the above formula can also be written as

$$
\gamma_t([\theta_t], [\theta_t]) = \frac{-H(\{\theta_{\nu(t)}\}, \{\theta_{\nu(t)}\})}{i^n \int_X u_t \wedge \overline{u_t}}.
$$

(73)

It can be checked (cf. §5.4 below) that $H(\{\theta_{\nu(t)}\}, \{\theta_{\nu(t)}\}) < 0$ if a $d$-closed representative $\theta_{\nu(t)}$ of the class $[\theta_{\nu(t)}] \in H^{n-1,1}(X_t, \mathbb{C}) \subset H^n(X, \mathbb{C})$ can be chosen to be primitive, reproving that $\gamma_t([\theta_t], [\theta_t]) > 0$ in this special case.

### 5.4 Comparison of metrics on $\Delta$

We shall now compare the Weil-Petersson metric $\omega^{(2)}_{WP}$ with the period-map metric $\gamma$ on $\Delta_{[\omega^{n-1}]}$. We need a general fact first.

Let $X$ be a compact complex manifold $(\dim X = n)$ equipped with a Hermitian metric $\omega$ and let $\star : \Lambda^{n-1,1} \to \Lambda^{n-1,1}$ be the Hodge $\star$ operator defined by $\omega$ on $(n-1, 1)$-forms. Since $\star^2 = (-1)^n \star$ induces a decomposition that is orthogonal for the $L^2$ scalar product defined by $\omega$ on $X$ (cf. §5.1):

$$
\Lambda^{n-1,1} = \Lambda^{n-1,1}_+ \oplus \Lambda^{n-1,1}_- \quad \text{(the duality decomposition)}.
$$

(74)

where $\Lambda^{n-1,1}_\pm$ stand for the eigenspaces of $\star$ corresponding to the eigenvalues $\pm 1$ (if $n$ is even), $\pm i$ (if $n$ is odd). On the other hand, the Hermitian metric $\omega$ induces the Lefschetz decomposition (cf. [Voi02, proposition 6.22, p. 147])

$$
\Lambda^{n-1,1} = \Lambda^{n-1,1}_{\text{prim}} \oplus \left(\omega \wedge \Lambda^{n-2,0}\right),
$$

(75)

41
which is again orthogonal for the $L^2$ scalar product defined by $\omega$ on $X$, where $\Lambda_{\text{prim}}^{n-1,1}$ denotes the space of primitive $(n-1, 1)$-forms $u$ (i.e. those $u \in \Lambda^{n-1,1}$ for which $\omega \wedge u = 0$ or, equivalently, $\Lambda u = 0$), while $\omega \wedge \Lambda^{n-2,0}$ denotes the space of forms $\omega \wedge v$ with $v$ an arbitrary form of bidegree $(n-2, 0)$.

**Lemma 5.10** The decompositions (74) and (75) coincide, i.e.

$$\Lambda_{-}^{n-1,1} = \Lambda_{\text{prim}}^{n-1,1} \quad \text{and} \quad \Lambda_{+}^{n-1,1} = \omega \wedge \Lambda^{n-2,0}.$$  

**Proof.** It suffices to prove the inclusions

$$\text{(A)} \quad \Lambda_{\text{prim}}^{n-1,1} \subset \Lambda_{-}^{n-1,1} \quad \text{and} \quad \text{(B)} \quad \omega \wedge \Lambda^{n-2,0} \subset \Lambda_{+}^{n-1,1}.  

Let $u \in \Lambda_{\text{prim}}^{n-1,1}$. Formula (51) gives $\star u = (-1)^{n(n-1)/2} i^{n-2} u = \iota^{n-2} u$. If $n$ is even, $n^2 - 2 \in 4\mathbb{Z} - 2$, hence $\iota^{n-2} = \iota^{-2} = -1$. If $n$ is odd, $n^2 - 2 \in 4\mathbb{Z} - 1$, hence $\iota^{n-2} = \iota^{-1} = -i$. We see that in both cases $u \in \Lambda_{-}^{n-1,1}$. This proves inclusion (A).

To prove inclusion (B), we first prove the following formula

$$\star (\omega \wedge v) = i^{(n-2)^2} \omega \wedge v \quad \text{for all} \quad v \in \Lambda^{n-2,0}. \quad (76)$$

Pick any $v \in \Lambda^{n-2,0}$. Then $\omega \wedge v \in \Lambda_{-}^{n-1,1}$. For every $u \in \Lambda_{\text{prim}}^{n-1,1}$, we have

$$\int_X u \wedge \star (\omega \wedge v) = \int_X \langle u, \omega \wedge v \rangle \, dV_\omega = \langle \langle u, \omega \wedge v \rangle \rangle = \langle \langle \Lambda u, v \rangle \rangle. \quad (77)$$

On the other hand, the following formula holds

$$\omega \wedge u = \frac{\omega^2}{2!} \wedge \Lambda u \quad \text{for all} \quad u \in \Lambda_{\text{prim}}^{n-1,1}. \quad (78)$$

Indeed, $\omega^2 \wedge \Lambda u = [L^2, \Lambda] \, u = 2(n-n+2-1) \, Lu = 2 \omega \wedge u$, where for the first identity we have used the fact that $L^2 u = 0$ since $L^2 u$ is of type $(n+1, 3)$, while for the second identity we have used the standard formula (38) with $r = 2$ and $k = n$.

Applying (78) on the top line below, for every $u \in \Lambda_{\text{prim}}^{n-1,1}$ we get

$$\int_X u \wedge (\omega \wedge v) = \int_X (\omega \wedge u) \wedge \bar{v} = \int_X \left( \frac{\omega^2}{2!} \wedge \Lambda u \right) \wedge \bar{v}$$

$$= \int_X (\Lambda u) \wedge \left( \frac{\omega^2}{2!} \wedge v \right) = i^{(n-2)^2} \int_X (\Lambda u) \wedge \star \bar{v}$$

$$= i^{(n-2)^2} \int_X \langle \Lambda u, v \rangle \, dV_\omega = i^{(n-2)^2} \langle \langle \Lambda u, v \rangle \rangle. \quad (79)$$
where the last identity on the second line above has followed from the formula

\[ *v = i^{(n-2)} \frac{\omega^2}{2!} \wedge v, \quad v \in \Lambda^{n-2,0} \quad (\text{cf. (51)} \text{ with } (p, q) = (n - 2, 0)). \]

It is clear that the combination of (77) and (79) proves formula (76).

With (76) in place, inclusion (B) follows immediately. Indeed, if \( n \) is even, \( (n - 2)^2 \in 4\mathbb{Z} \), hence \( i^{(n-2)^2} = 1 \). If \( n \) is odd, \( (n - 2)^2 \in 4\mathbb{Z} + 1 \), hence \( i^{(n-2)^2} = i \). In both cases we get \( \omega \wedge v \in \Lambda^{n-1,1} \) for all \( v \in \Lambda^{n-2,0} \). \( \square \)

For any \( \theta \in C_{0,1}^\infty(X, T^1,0X) \), denote by

\[ \theta \wedge u = \theta' \wedge u + \omega \wedge \zeta \]  

the decomposition of \( \theta \wedge u \in \Lambda^{n-1,1} \) induced by the Lefschetz decomposition (75). Thus \( \theta' \wedge u \in \Lambda^{n-1,1}_{\text{prim}} \) and \( \zeta \in \Lambda^{n-2,0} \). By orthogonality we have \( ||\theta \wedge u||^2 = ||\theta' \wedge u||^2 + ||\omega \wedge \zeta||^2 \). Now

\[ ||\omega \wedge \zeta||^2 = \langle \Lambda(\omega \wedge \zeta), \zeta \rangle = \langle \langle [\Lambda, L], \zeta \rangle, \zeta \rangle = 2||\zeta||^2, \]

since \( \Lambda \zeta = 0 \) for bidgree reasons (hence \([\Lambda, L] \zeta = \Lambda(\omega \wedge \zeta) - \omega \wedge \Lambda \zeta = \Lambda(\omega \wedge \zeta)\) and \([\Lambda, L] \zeta = 2\zeta \) (by formula (58) with \( r = 1 \) and \( k = n - 2 \)).

**Theorem 5.11** Let \( X \) be a compact balanced Calabi-Yau \( \partial \bar{\partial} \)-manifold of complex dimension \( n \). Then the metrics \( G^{(2)}_{WP} \) and \( \gamma \) on the base space \( \Delta_{\omega^{n-1}} \) of the local universal family of deformations of \( X \) that are co-polarised by a given balanced class \([\omega^{n-1}] \in H^{n-1,n-1}(X, \mathbb{C}) \subset H^{2n-2}(X, \mathbb{C})\) are given at every point \( t \in \Delta_{\omega^{n-1}} \) by the formulae (see notation (54)):

\[ G^{(2)}_{WP,t}([\theta], [\theta]) := \frac{||\theta' \wedge u_t||^2 + 2||\zeta_t||^2}{i^{n^2} \int_X u_t \wedge \bar{u}_t}, \quad [\theta_t] \in H^{0,1}(X_t, T^{1,0}X_t)[\omega^{n-1}], \quad (81) \]

and

\[ \gamma_t([\theta], [\theta]) := \frac{||\theta' \wedge u_t||^2 - 2||\zeta_t||^2}{i^{n^2} \int_X u_t \wedge \bar{u}_t}, \quad [\theta_t] \in H^{0,1}(X_t, T^{1,0}X_t)[\omega^{n-1}], \quad (82) \]

Here \( \theta_t \) is chosen in its class \([\theta] \) such that \( \theta_t \wedge u_t \) is the \( \omega_t \)-minimal \( d \)-closed representative of the class \([\theta_t \wedge u_t] \in H^{n-1,1}(X_t, \mathbb{C}) \) (where the \( \omega_t \in \{\omega^{n-1}\} \) are balanced metrics in the co-polarising balanced class given beforehand).

**Proof.** We may assume that \( t = 0 \). Formula (81) follows immediately from (70) and from the above considerations. To get (82), notice that Lemma 5.10 shows that if \( n \) is even, then \( \theta \wedge u = *(-\theta' \wedge u + \omega \wedge \zeta) \), from which we get
\[\int_X (\theta \wedge \overline{\theta}) = \int_X \left( \theta' + \omega \wedge \zeta \right) \wedge \left( -\star(\theta' + \omega \wedge \zeta) \right) = -||\theta'||^2 + 2||\zeta||^2,\]

while if \( n \) is odd, then \( \theta = \star(i\theta' - i\omega \wedge \zeta) \), from which we get

\[\int_X (\theta \wedge \overline{\theta}) = \int_X \left( \theta' + \omega \wedge \zeta \right) \wedge \left( -i\star(\theta' + \omega \wedge \zeta) \right) = -i||\theta'||^2 + 2i||\zeta||^2.\]

Now (82) follows from these expressions and from Lemma 5.9. □

**Corollary 5.12** For all \([\theta] \in H^{0,1}(X_t, T^{1,0}X_t)|_{\omega_n-1} \setminus \{0\}\), we have

\[G_W^P(\theta) = \frac{4||\zeta||^2}{in^2 \int_{X_t} u \wedge \overline{u}} \geq 0, \quad t \in \Delta|_{\omega_n-1},\]

hence the Hermitian metric \(\omega_W^P\) on \(\Delta|_{\omega_n-1}\) defined by \(G_W^P\) is bounded below by the Kähler metric \(\gamma\).

It is now clear that the obstruction to the metrics \(\omega_W^P\) and \(\gamma\) coinciding on \(\Delta|_{\omega_n-1}\) is the possible negative answer to Question 4.11 in the case of balanced, non-Kähler fibres. Indeed, if every class in \(H^{n-1,1}(X_t, \mathbb{C})\) could be represented by a form \(\eta \wedge u\) that is both primitive and \(d\)-closed, in the obvious formula

\[G_W^P([\theta], [\eta]) = \frac{\int_{X_t} (\theta \wedge \overline{\eta}) \wedge \star(\eta \wedge u)}{in^2 \int_{X_t} u \wedge \overline{u}} \quad (83)\]

we would have, thanks to Lemma 5.10, that \(\star(\eta \wedge u) = c(\eta \wedge u)\) with \(c = -1\) (if \( n \) is even), \(c = i\) (if \( n \) is odd), hence we would get \(\omega_W^P = \gamma\) (cf. 83) and Lemma 5.9 as in the case of Kähler polarised deformations of [Tia87].

### 6 Balanced holomorphic symplectic \(\partial\bar{\partial}\)-manifolds

#### 6.1 Primitive (1, 1)-classes on balanced manifolds

Let \((X, \omega)\) be a compact, balanced manifold \((\dim_{\mathbb{C}} X = n)\). The balanced class \([\omega_n-1] \in H^{n-1,n-1}(X, \mathbb{C})\) enables one to define the notion of primitive 2-classes on \(X\) in the same way as in the standard Kähler case. Indeed, at the level of Dolbeault cohomology, the linear operator
$$L_{\omega}^{n-1}: H^{1,1}(X, \mathbb{C}) \to H^{n,n}(X, \mathbb{C}) \simeq \mathbb{C}, \quad [\alpha] \mapsto [\omega^{n-1} \wedge \alpha],$$

is well defined because, thanks to the balanced assumption on $\omega$, $\bar{\partial}(\omega^{n-1} \wedge \alpha) = 0$ whenever $\bar{\partial} \alpha = 0$ and $\omega^{n-1} \wedge \alpha = \bar{\partial}(\omega^{n-1} \wedge \beta)$ whenever $\alpha = \bar{\partial} \beta$ is $\bar{\partial}$-exact.

We can then call primitive those classes that are in the kernel of $L_{\omega}^{n-1}$, i.e.

$$H_{prim}^{1,1}(X, \mathbb{C}) := \{ [\alpha] \in H^{1,1}(X, \mathbb{C}) ; \omega^{n-1} \wedge \alpha \text{ is } \bar{\partial} \text{-exact} \}. \quad (85)$$

Analogous definitions can be made for De Rham $(2, 0)$ and $(0, 2)$-classes, but all $(2, 0)$ and $(0, 2)$-classes are primitive for trivial bidegree reasons. Thus, if the $\bar{\partial}\bar{\partial}$-lemma is supposed to hold on $X$, the Hodge decomposition $H^2(X, \mathbb{C}) = H^{2,0}(X, \mathbb{C}) \oplus H^{1,1}(X, \mathbb{C}) \oplus H^{0,2}(X, \mathbb{C})$ shows that only the $H^{1,1}(X, \mathbb{C})$ component supports a nontrivial notion of primitivity. Notice that for $k > 2$, there is no corresponding notion of primitive $k$-classes if $\omega$ is only balanced since $\omega^{n-k+1}$ is not closed unless $\omega$ is Kähler. It had to be replaced in bidegree $(n - 1, 1)$ by the ad-hoc definition 4.9 using the Calabi-Yau isomorphism when $K_X$ was assumed to be trivial.

**Lemma 6.1** Let $(X, \omega)$ be a compact, balanced manifold ($\dim \mathbb{C} X = n$). Then a class $[\alpha] \in H^{1,1}(X, \mathbb{C})$ is primitive if and only if it can be represented by a primitive form.

*Proof.* By the standard definition (applicable to any Hermitian metric $\omega$), a $(1, 1)$-form $\alpha$ is primitive if $\omega^{n-1} \wedge \alpha = 0$. It is thus obvious that any class representable by a primitive form is primitive. To see the converse, pick any class $[\alpha] \in H_{prim}^{1,1}(X, \mathbb{C})$ and any representative $\alpha$. We have to prove the existence of a $(1, 0)$-form $u$ such that the representative $\alpha + \bar{\partial} u$ of $[\alpha]$ is primitive. This amounts to $\omega^{n-1} \wedge (\alpha + \bar{\partial} u) = 0$, which is equivalent to $\bar{\partial}(\omega^{n-1} \wedge u) = -\omega^{n-1} \wedge \alpha$ thanks to the balanced assumption $\bar{\partial} \omega^{n-1} = 0$. Now, $\omega^{n-1} \wedge \alpha$ is $\bar{\partial}$-exact by the primitivity assumption on the class $[\alpha]$. Pick any $w \in C^\infty_{n,n-1}(X, \mathbb{C})$ such that $\bar{\partial} w = -\omega^{n-1} \wedge \alpha$. It thus suffices to prove the existence of a $(1, 0)$-form $u$ such that $\omega^{n-1} \wedge u = w$. The linear operator

$$L_{\omega}^{n-1}: C^\infty_{1,0}(X, \mathbb{C}) \to C^\infty_{n,n-1}(X, \mathbb{C}), \quad u \mapsto \omega^{n-1} \wedge u, \quad (86)$$

is an isomorphism (for any Hermitian metric $\omega$), so there is a unique $(1, 0)$-form $u$ such that $\omega^{n-1} \wedge u = w$. 

The primitive representative of a primitive class $[\alpha] \in H^{1,1}(X, \mathbb{C})$ need not be unique, but we can single out a particular one that is uniquely determined by the metric $\omega$ in the given primitive class in the following way.
Choice of a primitive representative: given a primitive \((1, 1)\)-class, let \(\alpha\) be its \(\Delta''\)-harmonic representative. Then choose \(w \in C_{\Omega n, 1}(X, \mathbb{C})\) to be the solution of minimal \(L^2\)-norm (w.r.t. \(\omega\)) of the equation \(\partial w = -\omega^{n-1} \wedge \alpha\). Since the map \(\mathcal{S}_0\) is an isomorphism, the \((1, 0)\)-form \(u\) such that \(\omega^{n-1} \wedge u = w\) is uniquely determined by \(w\). Since the above choices of \(\alpha\) and \(w\) make them unique, the primitive representative \(\alpha + \bar{\partial} u\) of the primitive class \([\alpha]\) is uniquely determined in this way by \(\omega\) and \([\alpha]\) \(\in H^{1,1}_{\text{prim}}(X, \mathbb{C})\). (*)

When \(\omega\) is Kähler, the \(\Delta''\)-harmonic representative \(\alpha\) of a primitive class is a primitive form, a standard fact that follows from \(\Delta''\) and \(L\) commuting (as can be easily seen from the Kähler identities). Thus \(\omega^{n-1} \wedge \alpha = 0\), hence \(w = 0\) is the minimal \(L^2\)-norm solution of equation \(\bar{\partial} w = -\omega^{n-1} \wedge \alpha\). Consequently, \(u = 0\) and \(\alpha + \bar{\partial} u = \alpha\), showing that our choice (*) of primitive representative coincides with the standard \(\Delta''\)-harmonic choice when \(\omega\) is Kähler. However, when \(\omega\) is only balanced, it is not clear whether the \(\Delta''\)-harmonic representative of a primitive class is a primitive form. This accounts for the need of introducing the choice (*).

### 6.2 Co-polarised deformations of holomorphic symplectic manifolds

Let \((X, \omega)\) be a compact, balanced \(\partial\bar{\partial}\)-manifold \((\dim_{\mathbb{C}} X = n)\). Suppose there exists a \(C^\infty\) \(\bar{\partial}\)-closed \((2, 0)\)-form \(\sigma\) that is non-degenerate at every point of \(X\) and that such a \(\sigma\) is unique up to a nonzero constant factor. Thus \(H^{2,0}(X, \mathbb{C}) \simeq \mathbb{C}\) and \(\sigma\) defines a holomorphic symplectic structure on \(X\). The form \(\sigma\) naturally identifies with the class \([\sigma] \in H^{2,0}(X, \mathbb{C})\).

It follows from the \(\partial\bar{\partial}\)-assumption on \(X\) that \(\sigma\) is actually \(d\)-closed by the following observation which is standard when \(X\) is Kähler (and probably also under the weaker \(\partial\bar{\partial}\)-assumption). The standard Kähler-case proof, using the Laplacian equality \(\Delta' = \Delta''\), no longer holds in the \(\partial\bar{\partial}\)-case for which we spell out the argument below for the sake of completeness.

**Lemma 6.2** Every holomorphic \(p\)-form is \(d\)-closed on any compact complex \(\partial\bar{\partial}\)-manifold \(X\) for any \(0 \leq p \leq n = \dim_{\mathbb{C}} X\).

**Proof.** Fix any \(p\) and let \(\alpha \in C_{p,0}^\infty(X, \mathbb{C})\) be \(\bar{\partial}\)-closed. To show that \(d\alpha = 0\), it suffices to show that \(\partial\alpha = 0\). Now, \(\partial\alpha\) is \(\bar{\partial}\)-closed since \(\alpha\) is, while \(\partial\) and \(\bar{\partial}\) anti-commute. Thus \(\partial\alpha\) is a \(d\)-closed, \(\partial\bar{\partial}\)-exact form of pure type \((p+1, 0)\). By the \(\partial\bar{\partial}\)-lemma, \(\partial\alpha\) must be \(\partial\bar{\partial}\)-exact, i.e. \(\partial\alpha = \partial\beta\) for some \((p, -1)\)-form \(\beta\). Since \(\beta\) must vanish for type reasons, \(\partial\alpha\) vanishes. \(\square\)

We are now ready to connect the primitive \((1, 1)\)-cohomology to the parameter space of co-polarised deformations defined by a balanced class via the natural isomorphism associated with the holomorphic symplectic structure.
Lemma 6.3 Let $X$ be a compact complex manifold $(\dim \mathbb{C}X = n)$ admitting a holomorphic symplectic structure $\sigma$ that is unique up to a constant factor.

(i) The linear map defined by $\sigma$ as

$$T_\sigma : C^\infty_{0,1}(X, T^{1,0}X) \xrightarrow{\cdot \sigma} C^\infty_{1,1}(X, \mathbb{C}), \quad \theta \mapsto T_\sigma(\theta) := \theta \cdot \sigma,$$  

(87)
is an isomorphism satisfying the following properties:

$$T_\sigma(\ker \bar{\partial}) = \ker \bar{\partial} \quad \text{and} \quad T_\sigma(\text{Im } \bar{\partial}) = \text{Im } \bar{\partial}.$$  

(88)

Consequently, $T_\sigma$ induces an isomorphism in cohomology

$$T_{[\sigma]} : H^{0,1}(X, T^{1,0}X) \xrightarrow{\cdot \sigma} H^{1,1}(X, \mathbb{C})$$  

(89)
defined by $T_{[\sigma]}([\theta]) = [\theta \cdot \sigma]$ for all $[\theta] \in H^{0,1}(X, T^{1,0}X)$.

(ii) If $\omega$ is a balanced metric on $X$, then the image under $T_{[\sigma]}$ of the subspace $H^{0,1}_{\text{prim}}(X, T^{1,0}X)_{[\omega]} \subset H^{0,1}(X, T^{1,0}X)$ defined in (29) is the subspace $H^{1,1}_{\text{prim}}(X, \mathbb{C}) \subset H^{1,1}(X, \mathbb{C})$ of primitive $(1, 1)$-classes defined in (87), i.e.

$$T_{[\sigma]} : H^{0,1}(X, T^{1,0}X)_{[\omega]} \xrightarrow{\sim} H^{1,1}_{\text{prim}}(X, \mathbb{C}).$$  

(90)

Proof. It is clear that $T_\sigma$ is an isomorphism. As in the proof of Lemma 3.3, the rest of (i) follows from the easy-to-check formulae

$$\bar{\partial}(\theta \cdot \sigma) = (\bar{\partial} \theta) \cdot \sigma + \theta \cdot (\bar{\partial} \sigma) = (\bar{\partial} \theta) \cdot \sigma, \quad \bar{\partial}(\xi \cdot \sigma) = (\bar{\partial} \xi) \cdot \sigma - \xi \cdot (\bar{\partial} \sigma) = (\bar{\partial} \xi) \cdot \sigma$$  

(91)

for all $\theta \in C^\infty_0(X, T^{1,0}X)$ and all $\xi \in C^\infty(X, T^{1,0}X)$ which readily imply the inclusions $T_\sigma(\ker \bar{\partial}) \subset \ker \bar{\partial}$ and $T_\sigma(\text{Im } \bar{\partial}) \subset \text{Im } \bar{\partial}$.

Let us prove, for example, the identity $\text{Im } \bar{\partial} = T_\sigma(\text{Im } \bar{\partial})$. This amounts to proving that $\theta$ is $\bar{\partial}$-exact if and only if $\theta \cdot \sigma$ is $\bar{\partial}$-exact. Having fixed local holomorphic coordinates $z_1, \ldots, z_n$ on some open subset $U \subset X$, let

$$\theta = \sum_{\alpha, \beta} \theta_{\alpha, \beta} \frac{\partial}{\partial z^\alpha} d\bar{z}^\beta \quad \text{and} \quad \sigma = \sum_{\alpha, \delta} \sigma_{\alpha, \delta} (dz^\alpha \wedge d\bar{z}^\delta),$$

where the coefficients $\sigma_{\alpha, \delta}$ are holomorphic functions (since $\sigma$ is holomorphic) and the matrix $(\sigma_{\alpha, \delta})_{\alpha, \delta}$ is invertible at every point since $\sigma$ is non-degenerate at every point. Then $\theta \cdot \sigma = \sum_{\alpha, \beta, \delta} \theta_{\alpha, \beta} (\sigma_{\alpha, \delta} - \sigma_{\delta, \alpha}) (dz^\delta \wedge d\bar{z}^\alpha).$ Thus $\theta \cdot \sigma$ is $\bar{\partial}$-exact if and only if there exists a $(1, 0)$-form $v = \sum_{\delta} v_{\delta} dz^\delta$ such that $\theta \cdot \sigma = \bar{\partial}v$, which amounts to
\[ \sum_{\alpha, \beta, \delta} \theta_\beta^n (\sigma_{\alpha, \delta} - \sigma_{\delta, \alpha}) \, d\bar{z}^\beta \wedge dz^\delta = \sum_{\delta, \beta} \frac{\partial v_\delta}{\partial \bar{z}^\beta} \, d\bar{z}^\beta \wedge dz^\delta \iff \sum_{\alpha} \theta_\beta^n (\sigma_{\alpha, \delta} - \sigma_{\delta, \alpha}) = \frac{\partial v_\delta}{\partial \bar{z}^\beta} \]

for all \( \beta, \delta \). The last identity is equivalent to \( \theta_\beta^n = \frac{\partial}{\partial \bar{z}^\beta} \left( \sum_{\delta} (\sigma_{\delta, \alpha} - \sigma_{\alpha, \delta}) \right) \)

\[ = \frac{\partial}{\partial \bar{z}^\beta} \left( \sum_{\delta} (\sigma_{\delta, \alpha} - \sigma_{\alpha, \delta}) v_\delta \right) \]

for all \( \alpha, \beta \), where the matrix \( (\sigma_{\delta, \alpha})_{\alpha, \delta} \) is the inverse of \( (\sigma_{\alpha, \delta})_{\alpha, \delta} \). (We have used the fact that the \( \sigma_{\alpha, \delta}'s \) are holomorphic functions since the \( \sigma_{\alpha, \delta}'s \) are.) This, in turn, is equivalent to \( \theta \) being \( \bar{\partial} \)-exact. We have thus proved that \( \theta \bullet \sigma \) is \( \bar{\partial} \)-exact if and only if \( \theta \) is \( \bar{\partial} \)-exact, i.e. the latter identity in (88).

The remaining inclusion in the former identity of (88) is proved in a similar way.

The proof of (ii) will run in two steps. First we prove the inclusion

\[ T[\sigma] \left( H^{0,1}(X, T^{1,0}X)_{[\omega^{n-1}]} \right) \subset H^{1,1}_{prim}(X, \mathbb{C}), \] (92)

which amounts to proving that for every class \( [\theta] \in H^{0,1}(X, T^{1,0}X) \) for which \( \theta \bullet \omega^{n-1} \) is \( \bar{\partial} \)-exact, \( \omega^{n-1} \wedge (\theta \bullet \sigma) \) is also \( \bar{\partial} \)-exact. Now, we always have

\[ 0 = \theta \bullet (\omega^{n-1} \wedge \sigma) = (\theta \bullet \omega^{n-1}) \wedge \sigma + \omega^{n-1} \wedge (\theta \bullet \sigma), \]

where the first identity follows from the fact that \( \omega^{n-1} \wedge \sigma \) is of type \( (n + 1, n - 1) \), hence vanishes. Thus

\[ (\theta \bullet \omega^{n-1}) \wedge \sigma = -\omega^{n-1} \wedge (\theta \bullet \sigma) \quad \text{for all} \quad \theta \in \mathcal{C}_0^{\infty}(X, T^{1,0}X). \]

Now, if \( \theta \bullet \omega^{n-1} \) is supposed to be \( \bar{\partial} \)-exact, then \( (\theta \bullet \omega^{n-1}) \wedge \sigma \) is \( \bar{\partial} \)-exact, too, since \( \sigma \) is \( \bar{\partial} \)-closed. Hence \( \omega^{n-1} \wedge (\theta \bullet \sigma) \) is \( \bar{\partial} \)-exact whenever \( \theta \bullet \omega^{n-1} \) is, proving the inclusion (92).

Since \( T[\sigma] \) is injective by (i), it suffices to prove the dimension equality

\[ \dim H^{0,1}(X, T^{1,0}X)_{[\omega^{n-1}]} = \dim H^{1,1}_{prim}(X, \mathbb{C}) \]

(93)

to be able to conclude that the inclusion (92) is actually an identity.

By definition (85), we have

\[ H^{1,1}_{prim}(X, \mathbb{C}) = \ker \left( L^1_\omega : H^{1,1}(X, \mathbb{C}) \to H^{0,n}(X, \mathbb{C}) \simeq \mathbb{C} \right). \]

The linear map (84) cannot vanish identically, so it is surjective. Hence
\[ \dim H_{\text{prim}}^{1,1}(X, \mathbb{C}) = h^{1,1} - 1, \]  

(94)

where \( h^{1,1} = \dim H^{1,1}(X, \mathbb{C}) \). Meanwhile, definition (29) translates to

\[ H^{0,1}(X, T^{1,0}X)_{[\omega - 1]} = \ker \left( H^{0,1}(X, T^{1,0}X) \ni [\theta] \mapsto [\theta \omega - 1] \in H^{n-2,n}(X, \mathbb{C}) \right), \]

while \( H^{n-2,n}(X, \mathbb{C}) \cong H^{2,0}(X, \mathbb{C}) \cong \mathbb{C} \) by Serre duality and the uniqueness (up to a constant factor) assumption on the holomorphic symplectic structure \([\sigma] \in H^{2,0}(X, \mathbb{C})\). It is clear that the linear map \( T_{[\omega - 1]} \) does not vanish identically, so it must be surjective. Thus we get

\[ \dim H^{0,1}(X, T^{1,0}X)_{[\omega - 1]} = \dim H^{0,1}(X, T^{1,0}X) - 1 = h^{1,1} - 1, \]  

(95)

where the last identity follows from the isomorphism (89) dealt with under (i). It is now clear that the dimension equality (93) is a consequence of the combined identities (94) and (95). The proof is complete. \( \square \)

The use of the isomorphism \( T_{[\sigma]} \) in (89) in the holomorphic symplectic case may be an alternative to the use of the isomorphism \( T_{[\theta]} \) in (22) of the more general Calabi-Yau case while running the construction of the Weil-Petersson metrics of section 5.

## 7 Appendix

Proof of Lemma 4.3. Fix an arbitrary point \( x_0 \in X \) and let \( z_1, \ldots, z_n \) be local holomorphic coordinates about \( x_0 \). If we denote

\[ \omega^{n-1} = i^{n-1} \sum_{\alpha, \beta} \gamma_{\alpha \beta} \overline{dz_\alpha} \wedge \overline{d\bar{z}_\beta} \]  

and \( \xi = \sum_j \xi_j \frac{\partial}{\partial z_j} \),

as \( \overline{dz_\alpha} \wedge \overline{d\bar{z}_\beta} := dz_1 \wedge \cdots \wedge \overline{dz_\alpha} \wedge \cdots \wedge d\bar{z}_1 \wedge \cdots \wedge d\bar{z}\beta \wedge \cdots \wedge d\bar{z}_n \), we get

\[ \xi \omega^{n-1} = i^{n-1} \sum_{\beta} (-1)^j \xi_j \gamma_{\alpha \beta} (dz_j \wedge \overline{dz_\alpha} \wedge \overline{d\bar{z}_\beta}) + i^{n-1} \sum_{\beta} (-1)^j \xi_j \gamma_{\alpha \beta} (dz_\alpha \wedge \overline{dz_j} \wedge \overline{d\bar{z}_\beta}) \]

\[ = i^{n-1} \sum_{\beta} (-1)^j \xi_j \gamma_{\alpha \beta} + (-1)^n \xi_\alpha \gamma_{\alpha \beta} \]

(\( \alpha, j < \alpha \))

(49)
\[(dz_j \wedge dz_\alpha \wedge d\bar{z}_\beta) := dz_1 \wedge \cdots \wedge dz_j \wedge \cdots \wedge dz_\alpha \wedge \cdots \wedge d\bar{z}_\beta \wedge \cdots \wedge d\bar{z}_n.\]

Hence, by applying $\bar{\partial}$, we get
\[
\bar{\partial}(\xi \omega^{n-1}) = i^{n-1} \sum_{j<\alpha} (-1)^{n+\beta-1} \left[ (-1)^{j-1} \xi_j \frac{\partial \gamma_{\alpha\beta}}{\partial \bar{z}_\beta} + (-1)^{j-1} \frac{\partial \xi_j}{\partial \bar{z}_\beta} \gamma_{\alpha\beta} + (-1)^{\alpha} \xi_\alpha \frac{\partial \gamma_{j\beta}}{\partial \bar{z}_\beta} \right] dz_j \wedge dz_\alpha. \tag{96}
\]

Similar calculations yield
\[
(\bar{\partial} \xi) \omega^{n-1} = (-1)^{n} i^{n-1} \sum_{j<\alpha} (-1)^{\beta} \left[ (-1)^{j} \xi_j \frac{\partial \gamma_{\alpha\beta}}{\partial \bar{z}_\beta} - (-1)^{\alpha} \frac{\partial \xi_\alpha}{\partial \bar{z}_\beta} \gamma_{j\beta} \right] dz_j \wedge d\bar{z}_\alpha. \tag{97}
\]

showing that $(\bar{\partial} \xi) \omega^{n-1}$ equals the sum of the second and fourth groups of terms in the expression (96) for $\bar{\partial}(\xi \omega^{n-1})$. On the other hand, we get

\[
\bar{\partial} \omega^{n-1} = (-1)^{n} i^{n-1} \sum_{\alpha, \beta} (-1)^{\beta} \frac{\partial \gamma_{\alpha\beta}}{\partial \bar{z}_\beta} d\bar{z}_\alpha,
\]

leading to

\[
\xi_j \bar{\partial} \omega^{n-1} = (-1)^{n} i^{n-1} \sum_{j<\alpha} (-1)^{j+\beta-1} \xi_j \frac{\partial \gamma_{\alpha\beta}}{\partial \bar{z}_\beta} dz_j \wedge d\bar{z}_\alpha
\]
\[
+ (-1)^{n} i^{n-1} \sum_{j>\alpha} (-1)^{j+\beta} \xi_j \frac{\partial \gamma_{\alpha\beta}}{\partial \bar{z}_\beta} d\bar{z}_\alpha \wedge dz_j
\]
\[
= (-1)^{n} i^{n-1} \sum_{j<\alpha} (-1)^{\beta} \left[ (-1)^{j-1} \xi_j \frac{\partial \gamma_{\alpha\beta}}{\partial \bar{z}_\beta} + (-1)^{\alpha} \xi_\alpha \frac{\partial \gamma_{j\beta}}{\partial \bar{z}_\beta} \right] dz_j \wedge d\bar{z}_\alpha.
\]

Thus $\xi_j \bar{\partial} \omega^{n-1}$ equals the sum multiplied by $(-1)$ of the first and third groups of terms in the expression (96) for $\bar{\partial}(\xi \omega^{n-1})$. Combining with (96) and (97), we get the identity claimed in (i). Similar calculations prove (ii). \square
