Abstract

In this paper, we present and analyze an SEIR Zika epidemic model. Firstly, we investigate the model with constant controls. The steady states of the model is found to be locally and globally asymptotically stable. Thereafter, we incorporate time dependent controls into the model in order to investigate the optimal effects of bednets, treatments of infective and spray of insecticides on the disease spread. Furthermore, we used Pontryagin’s Maximum Principle to determine the necessary conditions for effective control of the disease. Also, the numerical results were presented.

1 Introduction

Zika virus was first discovered in 1947 in Uganda among a certain Rhesus macaque population [1]. The “Aedes” mosquito is the vector responsible for zika virus transmission. It has also been established that there is potential transmission to humans during transplacental transmission or during child delivery from mother to child [1, 2]. There are several characteristics of Zika virus species which are associated with dengue virus and chikungunya virus [3]. Zika virus (ZIKV), a Flavivirus closely related to dengue, is primarily transmitted to humans by the bites of infected female mosquitoes from the Aedes genus [4]. Aedes mosquitoes transmit Zika virus. Mosquitoes become infected by taking a blood meal from an infected person and then they pass the virus as they bite other people. There is also evidence that Zika virus can be transmitted through sex [5, 6].

The signs and symptoms of Zika virus is similar to dengue fever symptoms and the disease clinical symptoms manifest in humans within 3 to 12 days. Symptoms is often not severe and the duration is very short, which is 2-7 days, hence, it is often misdiagnosed as dengue fever. Nearly one in four persons infected by Zika virus is likely to develop the symptoms of the disease [2, 3]. Zika virus is currently spreading to many countries in South and Central Americas and the Caribbean. Precisely, anywhere “Aedes” species of mosquitoes be found, Zika virus infection is highly possible to can occur [7]. The spread of Zika virus across many geographical regions has attracted global attention [8].
There is presently no definite treatment for Zika virus yet, except the control of vectors using insecticide spray and destruction of the larval breeding grounds. Recent studies have revealed a devastating effect of Zika virus infection on pregnant women [7]. D. Gao et al. [4] presented a mathematical model on zika virus with prevention and optimal control.

In recent decades, mathematical modeling has played an important role in the understanding of disease epidemiology and control [9]. Lee and Pietz [10] developed a mathematical model on zika transmission with vector-host structure focusing on logistic growth in human population and dynamic growth in vector population. The authors observed that digital disease surveillance is crucial in minimizing the spread of the disease. Li et al. [11] constructed a multi-group brucellosis model comprised sheep and cattle and found out that the best way to contain the brucellosis is to avoid cross infection. They further suggested that the concept of mix feeding must be avoided. While, Sun and Zhang [12] formulated and developed a sheep brucellosis model incorporating immigration and proportional birth. The authors also took into consideration both direct and indirect transmission through animals who have been infected and the bacteria in the environment. Their study revealed that the best control strategies were the following: elimination, vaccination, reduction of migration and disinfection. In Xing et al., [13], the authors further proposed a mathematical model on H7N9 avian influenza among migrant birds, resident birds, domestic poultry and human in China. They found out that temperature cycling might be the main cause of the disease, however, controlling trading markets would help to control the spread of the disease. While Sun et al., [14] developed a cholera transmission model which focused on the disease dynamics in China. They further observed that in order to reduce the spread of the disease, immunization coverage must be improved and also the environment must be managed very well. Also, Yu and Lin [15] studied a complex dynamical behaviour in biological systems as a result of multiple limit cycles bifurcation using simple predator-prey model. The analysis indicated that bistable phenomenon exist. A modified SIR model was developed by Gui and Zhang [16], which has a nonlinear incidence and recovery rates with the main aim was to comprehend any government intervention and hospital resources influence on diseases spread. In their studies, it was observed that the model exhibited a backward bifurcation phenomenon, which implied that reduction in the reproduction number to less than one is not sufficient enough to stop the spread of the diseases. In Li [17], a dynamical model was constructed to explain the periodic behaviour of HFRS in China. He also found out that the critical issues associated with the spread of this disease is periodic transmission rates and the rodent periodic birth rate of HFRS in China.

These models are characterized with vivid qualitative accounts of the complex nonlinear process involved in the transmission process of diseases and provide insight into the dynamics of the disease. This eventually lead to proper and effective disease control strategies and management by health authorities. However, to the best of our knowledge there are very few mathematical models proposed on Zika virus.

With regard to some vector-borne diseases, such as malaria, dengue fever and Buruli ulcer, there are many mathematical models that have provided insight into the management and control of these diseases [9, 18]. For instance, Nishiura et al. [19] developed a Zika mathematical model which appeared to exhibit the same dynamics as dengue fever. While Khan et al. [20] proposed a mathematical model with saturation function to investigate the dynamic of typhoid fever. In Khan et al. [21], the authors developed a mathematical model on Leptospirosis with saturation function to explore the dynamics of the disease. The authors in Bonyah et al. [18] developed a SIR mathematical model to study the dynamics of Buruli ulcer and suggested that medical resources should be made available for patients in order to control the disease.
Jinhong et al. [22] constructed a SEIR epidemic model with saturated incidence rate and saturated treatment function and their results showed that hospital facilities should be expanded to accommodate more patients for treatment. Wan and Cui [23] constructed mathematical model to examine the impact of resources for hospitalized people and established that sufficient number of sickbeds and medical resources are as important as disease control mechanism. Shi et al. [24] proposed an HIV model with saturated reverse function to study the dynamics of infected cells. Javidi, and Nyamorady, [25] however, developed a mathematical model with a saturated function to explore the dynamics of computer virus.

In this paper, we construct a mathematical model Zika virus. The population of human is divided into four sub-classes, that is, \( S_H(t), E_H(t), I_H(t) \) and \( R_H(t) \) while the mosquitoes population is divided into three sub-classes, namely; \( S_V, E_V \) and \( I_V \). This paper is two fold; initially, we construct a mathematical model and explore their mathematical results, after that an optimal control problem is formulated. Different strategies are developed for the numerical results.

The paper is arranged as follow: Section 2 presents the model description and mathematical assumptions underlying the model. In Section 3, we examine and analyze the model equilibria and stability analysis. Section 4 is constructed to obtain the mathematical results for endemic equilibrium and bifurcation analysis. The global stability for both the disease free and endemic equilibrium is presented in section 5. In section 6 a sensitivity analysis of the model is presented.

Section 7 is devoted to optimal control analysis of the model, while the numerical results are presented in Section 8 and the conclusion is presented in Section 9.

### 2 Mathematical model formulation

In this section, we take into account the human to human infection as well as the vector (mosquito) to human transmission. The model subdivide the total human population, \( N_H(t) \), into susceptible humans \( S_H(t) \), exposed human \( E_H(t) \), infected humans \( I_H(t) \), and recovered humans \( R_H(t) \), so that \( N_H(t) = S_H + E_H + I_H + R_H \). The entire mosquito population, denoted by \( N_V(t) \), is partitioned into susceptible vector \( S_V(t) \), exposed vector \( E_V(t) \) and infected mosquito \( I_V(t) \) and hence \( N_V = S_V + E_V + I_V \). Based on the above discussion we present the following system:

\[
\begin{align*}
\frac{d}{dt} S_H &= \Lambda_H - \beta_H S_H (I_V + \rho I_H) - \mu_H S_H, \\
\frac{d}{dt} E_H &= \beta_H S_H (I_V + \rho I_H) - (\mu_H + \gamma_H) E_H, \\
\frac{d}{dt} I_H &= \gamma_H E_H - (\mu_H + \gamma + \eta) I_H, \\
\frac{d}{dt} R_H &= \gamma I_H - \mu_H R_H, \\
\frac{d}{dt} S_V &= \Lambda_V - \beta_V S_V I_H - \mu_V S_V, \\
\frac{d}{dt} E_V &= \beta_V S_V I_H - (\mu_V + \delta_V) E_V, \\
\frac{d}{dt} I_V &= \delta_V E_V - \mu_V I_V.
\end{align*}
\]

Recruitment of susceptible humans is denoted by \( \Lambda_H \), while susceptible mosquito recruitment
is denoted $\Lambda_V$. The effective contact rate between susceptible humans and infected mosquitoes is denoted by $\beta_H$. Here, $\beta_V$ is the transmission rate from infected humans to susceptible vector.
The effective contact rate between infected humans and susceptible humans that can result into infection is denoted by $\rho$. The disease induced mortality rate is denoted by $\delta$. Natural mortality rates due to each subpopulation of human and vector compartment are denoted $\mu_H$ and $\mu_V$ respectively. $\gamma$ and $\eta$ are the natural and treatment rate.

Let the total dynamics of the human population given as

$$N'_H(t) = \Lambda_H - \mu_H N_H - \eta I_H.$$  \hfill (2)

i. e.,

$$N'_H(t) + \mu_H N_H \leq \Lambda_H.$$  \hfill (3)

Now integrating both sides of the above inequality and using the theory of differential inequality due to Birkhoff and Rota [26], we get

$$0 \leq N_H(S_H, E_H, I_H, R_H) \leq \frac{\Lambda_H}{\mu_H} (1 - e^{-\mu_H t}) + N_H(S_H(0) + E_H(0) + I_H(0) + R_H(0)) e^{-\mu_H t}.$$  

Now, taking, $t \to \infty$, we get $0 < N_H \leq \frac{\Lambda_H}{\mu_H}$.

The total dynamics of vector population is given by

$$N'_V(t) = \Lambda_V - \mu_V N_V.$$  \hfill (4)

The exact solution of Eq (4) when $t \to \infty$ is given by

$$N_V(t) = \frac{\Lambda_V}{\mu_V}.$$

It is obvious that

$$\Pi = \{S_H, E_H, I_H, R_H, S_V, E_V, I_V \} \in R_+^7 | 0 \leq S_H + E_H + I_H + R_H \leq \frac{\Lambda_H}{\mu_H}$$

and $0 \leq S_V + E_V + I_V \leq \frac{\Lambda_V}{\mu_V}$,

which is positively invariant, dissipative and the global attractor is attained in $\Pi$.

### 3 Equilibria and disease free stability

The disease free equilibrium for the model (1) is $E_0 = \left( \frac{\Lambda_H}{\mu_H}, 0, 0, \frac{\Lambda_V}{\mu_V}, 0, 0 \right)$. To obtain the basic reproduction number for the model (1), we follow the method [27], and obtain the following matrices

$$F = \begin{pmatrix}
0 & \frac{\mu_H \Lambda_H}{\rho_H} & 0 & \frac{\mu_H \Lambda_H}{\rho_H} \\
0 & 0 & 0 & 0 \\
0 & \frac{\mu_V \Lambda_V}{\rho_V} & 0 & 0 \\
0 & 0 & 0 & 0
\end{pmatrix}, \quad V = \begin{pmatrix}
k_1 & 0 & 0 & 0 \\
0 & X_H & k_2 & 0 \\
0 & 0 & k_3 & 0 \\
0 & 0 & 0 & -\delta_V \mu_V
\end{pmatrix},$$

where $k_1 = \mu_H + X_H$, $k_2 = (\mu_H + \gamma + \eta)$ and $k_3 = (\mu_V + \delta_V)$. The spectral radius of the matrix
\(\rho(F_{V^{-1}})\) is the basic reproduction number of the Model (1), given by

\[
R_0 = \frac{\rho F_{H} L_{II}}{2\mu_{II}k_{II}k_{II}} + \sqrt{\frac{\rho F_{H} L_{II}^2}{4\mu_{II}^2k_{II}^2k_{II}^2} + \frac{\rho F_{H} L_{II} \beta_{II} \delta_{II} \Lambda_{V}}{\mu_{II}^2k_{II}^3k_{II}^3}} = R_1 + R_2
\]

where

\[
R_1 = \frac{\rho F_{H} L_{II}}{2\mu_{II}k_{II}k_{II}}
\]

and

\[
R_2 = \sqrt{\frac{\rho F_{H} L_{II}^2}{4\mu_{II}^2k_{II}^2k_{II}^2} + \frac{\rho F_{H} L_{II} \beta_{II} \delta_{II} \Lambda_{V}}{\mu_{II}^2k_{II}^3k_{II}^3}}.
\]

### 3.1 Local stability disease free equilibrium

In this subsection we show the local stability of disease free equilibrium \(E_0\). We present the following result:

**Theorem 3.1.** The disease free equilibrium of model (1) is stable locally asymptotically if \(R_0 < 1\), otherwise unstable.

**Proof:** The associated Jacobian matrix of the system (1) at \(E_0 = \left(\frac{\Lambda_{II}}{\mu_{II}}, 0, 0, \frac{\Lambda_{V}}{\mu_{V}}, 0, 0\right)\) is given by

\[
J_0 = \begin{pmatrix}
-\mu_{II} & 0 & -\frac{\rho F_{II} \Lambda_{II}}{\mu_{II}} & 0 & 0 & 0 \\
0 & -k_I & \frac{\rho F_{II} \Lambda_{II}}{\mu_{II}} & 0 & 0 & 0 \\
0 & k & -k_2 & 0 & 0 & 0 \\
0 & 0 & \gamma & -\mu_{II} & 0 & 0 \\
0 & 0 & -\frac{\rho F_{II} \Lambda_{II}}{\mu_{V}} & 0 & -\mu_{V} & 0 \\
0 & 0 & \frac{\rho F_{II} \Lambda_{II}}{\mu_{V}} & 0 & 0 & -k_3 \\
0 & 0 & 0 & 0 & \delta_{II} & -\mu_{V}
\end{pmatrix}
\]

The three eigenvalues of the above jacobian matrix are clearly negative, that is \(-\mu_{II}, -\mu_{II}\) and \(-\mu_{V}\). The remaining four roots can then be determined through the following equation:

\[
\lambda^4 + a_1\lambda^3 + a_2\lambda^2 + a_3\lambda + a_4 = 0,
\]

where

\[
\begin{align*}
a_1 &= k_1 + k_2 + k_3 + \mu_{II} \\
2 &= (k_1 + k_2 + k_3)\mu_{II} + (k_1 + k_2)k_3 + \left(k_1k_2 - \frac{\rho F_{II} \Lambda_{II} \mu_{II}}{\mu_{II}}\right) \\
3 &= (k_1 + \mu_{II})\left(k_1k_2 - \frac{\rho F_{II} \Lambda_{II} \mu_{II}}{\mu_{II}}\right) + k_1k_2\mu_{II} + k_1k_3\mu_{II} \\
4 &= k_1k_2k_3\mu_{II}（1 - R_0^*)
\end{align*}
\]

The above characteristics equation will give four negative eigenvalues if \(R_0 < 1\) and the Routh Hurtwiz criteria, \(a_i > 0\), for \(i = 1, 2, 3, 4\), and \(a_ia_2a_3 > a_1^2a_4 + a_2^4\) satisfy. It is obvious that the coefficients \(a_i\) for \(i = 1, \ldots, 4\) are clearly positive, if \(R_0 < 1\) and \(\left(k_1k_2 - \frac{\rho F_{II} \Lambda_{II} \mu_{II}}{\mu_{II}}\right) > 0\). Thus, it
follows, that the system (1) at the disease free equilibrium $E_0$ is locally asymptotically stable if $R_0 < 1$.

### 4 Endemic equilibria and bifurcation analysis

The endemic equilibria of the System (1) at $E_i = (S_i, E_{H}, I_{H}, R_{H}, S_{V}, E_{V}, I_{V})$ is given by

$$
\begin{align*}
S_{H} &= \frac{k_{i}\Lambda_{H}\mu_{v}(I_{H}\beta_{v} + \mu_{v})}{k_{i}\mu_{v}(\rho\beta_{H}I_{V} + \mu_{H}) + \mu_{H}I_{H}\delta_{v}\Lambda_{v}}, \\
E_{H} &= \frac{\beta_{H}I_{H}\Lambda_{H}(k_{i}\rho\mu_{v}(I_{H}\beta_{v} + \mu_{v}) + \beta_{v}\delta_{v}\Lambda_{v})}{k_{i}(k_{i}\mu_{v}(\rho\beta_{H}I_{V} + \mu_{H}) + \mu_{H}I_{H}\delta_{v}\Lambda_{v})}, \\
R_{H} &= \frac{\gamma I_{H}}{\mu_{H}}, \\
S_{V} &= \frac{\Lambda_{V}}{\mu_{v} + I_{H}\beta_{v}}, \\
E_{V} &= \frac{I_{H}\beta_{v}\Lambda_{v}}{k_{i}(\mu_{v} + I_{H}\beta_{v})}, \\
I_{V} &= \frac{I_{H}\beta_{v}\delta_{v}\Lambda_{v}}{\mu_{v}k_{i}(\mu_{v} + I_{H}\beta_{v})},
\end{align*}
$$

The endemic equilibria Eq (5) satisfies

$$I_{H}(aI_{H}^2 + bI_{H} + c) = 0,$$

where

$$\begin{align*}
a &= \rho\beta_{H}\beta_{v}\mu_{v}k_{i}k_{j}k_{s}, \\
b &= \beta_{H}\beta_{v}(k_{i}k_{j}k_{s}\Lambda_{v} - k_{i}\rho\Lambda_{H}\mu_{v} + k_{i}k_{j}k_{s}\mu_{v}(\rho\beta_{H}\mu_{v} + \mu_{H}\beta_{v})), \\
c &= \mu_{H}\mu_{v}k_{i}k_{j}k_{s}(1 - R_{0})
\end{align*}$$

where $R_{0}^{*} = R_{0}^{*} + 2R_{1}(1 - R_{0})$. The coefficient $a$ in Eq (7) is obviously positive and $c$ is positive whenever $R_{0} < 1$ and negative if $R_{0} > 1$. It is the sign of $b$ and $c$ will decide about the positive solution of Eq (7). Let $R_{0} > 1$, then there exists two roots for Eq (7), one is positive and the other is negative. $c = 0$ if $R_{0} = 1$, then a unique non-zero solution exists i.e., $I_{H} = -b/a$, for $b < 0$. Equilibria depend continually on $R_{0}$ changes which shows that there exists an interval to the left of $R_{0}$ on which there are two positive equilibria

$$I_{H}^1 = \frac{-b - \sqrt{b^2 - 4ac}}{2a} \quad \text{and} \quad I_{H}^2 = \frac{-b + \sqrt{b^2 - 4ac}}{2a}.$$

There is no positive solution of Eq (7) if $c > 0$ and either $b \geq 0$ or $b^2 < 4ac$ and hence no endemic equilibria. We establish the following:

**Theorem 4.1.** The system (1) has:

1. if $c < 0$ if and only if $R_{0} > 1$ then a unique endemic equilibrium exists;
2. if $b < 0$ and $c = 0$ or $b^2 - 4ac = 0$ then a unique endemic equilibrium exists;
3. if $c > 0$ and $b < 0$ and $b^2 - 4ac > 0$ then two equilibria exists;
4. otherwise no endemic equilibrium.
Case (iii) of (4.1) shows the possibility of a backward bifurcation in system (1) when $R_0 < 1$. The backward bifurcation can be obtained by setting $b^2 - 4ac = 0$ and solved for the critical value of $R_0$, shown by $R_c$ is given by

$$R_c = 1 - \frac{b^2}{4a\mu_H^2 k_1 k_2 k_3}.$$

Thus, $R_c < R_0$ is equivalent to $b^2 - 4ac > 0$ and therefore, backward bifurcation would occur for values of $R_0$ such that $R_c < R_0 < 1$. This fact can be seen for choosing the parameters values of the model (1): $\chi_H = 0.0022$, $\beta_H = 0.0002$, $\beta_V = 0.0009$, $\mu_H = 0.01$, $\delta_V = 0.3$, $\mu_V = 0.003$, $\Lambda_V = 1.3$, $\Lambda_H = 0.4$, $\eta = 0.11$, $\rho = 0.029$, $\gamma = 0.0614799$. The bifurcation diagram is presented in Fig 1, which demonstrate the existence of two locally asymptotically stable equilibria whenever $R_0 < 1$, which confirm the occupancy of a backward bifurcation in system (1).

4.1 Existence of bifurcation

In order to establish the backward bifurcation phenomenon, we use the centre manifold theory [9, 28]. We take into account the transmission rate, $\beta_H$ as bifurcation parameter so that $R_c^* = 1$ if and only if $\beta_H^* = \beta_H = \frac{k_1 k_2 k_3 a_H^2}{a_H a_V + \delta_V a_V + a_V}$. The following variations are made in the variables of the system (1) so that $S_H = x_1$, $E_H = x_2$, $I_H = x_3$, $R_H = x_4$, $S_V = x_5$, $E_V = x_6$, $I_V = x_7$. Also, further adopting vector notation $x = (x_1, x_2, x_3, x_4, x_5, x_6, x_7)^T$. Zika model can then be formulated in
the form \( \frac{dx}{dt} = F(x) \), with \( F = (f_1, f_2, f_3, f_4, f_5, f_6, f_7)^T \) as indicated below:

\[
\frac{dx_1}{dt} = \Lambda_H - \beta_{H}x_1(x_7 + \rho x_6) - \mu_Hx_1 \\
\frac{dx_2}{dt} = \beta_{H}x_1(x_7 + \rho x_6) - k_1x_2 \\
\frac{dx_3}{dt} = Z_Hx_2 - k_2x_3 \\
\frac{dx_4}{dt} = \gamma x_3 - \mu_Hx_4 \\
\frac{dx_5}{dt} = \Lambda_V - \beta_Vx_5x_6 - \mu_Vx_5 \\
\frac{dx_6}{dt} = \beta_Vx_5x_6 - k_3x_6 \\
\frac{dx_7}{dt} = \delta_Vx_6 - \mu_Vx_7
\]  

(8)

The system (8) is evaluated at the Jacobian matrix for the disease free endemic state (DFE) \( E_0 \) denoted by \( J(E_0) \) gives

\[
J(E_0) = 
\begin{pmatrix}
-\mu_H & 0 & -\frac{\rho \mu_H \Lambda_H}{\mu_H} & 0 & 0 & 0 & -\frac{\beta_H \Lambda_H}{\mu_H} \\
0 & -k_1 & \frac{\rho \mu_H \Lambda_H}{\mu_H} & 0 & 0 & \frac{\beta_H \Lambda_H}{\mu_H} \\
0 & Z_H & -k_2 & 0 & 0 & 0 & 0 \\
0 & 0 & \gamma & -\mu_H & 0 & 0 & 0 \\
0 & 0 & \frac{\mu_H k_3 (\gamma \rho \mu_H \Lambda_H - \mu_H k_1 k_2)}{\beta_H \Lambda_H \delta_V} & 0 & -\mu_V & 0 & 0 \\
0 & 0 & \frac{\mu_H k_3 (\gamma \rho \mu_H \Lambda_H - \mu_H k_1 k_2)}{\beta_H \Lambda_H \delta_V} & 0 & 0 & -k_3 & 0 \\
0 & 0 & 0 & 0 & 0 & \delta_V & -\mu_V \\
\end{pmatrix}
\]

has a simple zero eigenvalue, at the other eigenvalues having negative real parts. Hence, the Center Manifold theorem [28] can be applied. For this we need to calculate \( a \) and \( b \). We first start by calculating the right and the left eigenvector of \( J(E_0) \) denoted respectively by \( W = [w_1, w_2, w_3, w_4, w_5, w_6, w_7]^T \) and \( V = [v_1, v_2, v_3, v_4, v_5, v_6, v_7]^T \). We obtain

\[
w_1 = -\frac{w_1 k_2}{\mu_H}, \quad w_2 > 0, \quad w_3 = \frac{w_3 Z_H}{k k_2}, \quad w_4 = \frac{\gamma w_3 Z_H}{k k_2}, \quad w_5 = \frac{w_5 k_3 (\rho \beta_H \Lambda_H k_1 k_2 - \mu_H k_1 k_2)}{\beta_H \Lambda_H \delta_V k_2}, \\
w_6 = -\frac{w_6 k_2}{\mu_H}, \quad w_7 = -\frac{w_7 k_2}{\delta_V}
\]
and

\[ v_1 = v_4 = v_5 = 0, \quad v_6 > 0, \quad v_2 = \frac{v_2 \mu_H (\delta v \mu_v + \mu_v^2)}{\beta_H \Lambda_H \delta_v}, \]

\[ v_3 = \frac{v_3 \mu_H k_v (k_v + \mu_v^2)}{\beta_H \Lambda_H \delta_v}, \quad v_7 = \frac{v_6 k_v}{\delta_v}. \]

After some rigorous algebra computations, it can be shown that

\[ a = -\frac{2v_2 w_2^2 \left( -\frac{\beta_H^2 k_1}{\beta_H k_2} \left( \frac{\mu_H k_1}{\beta_H k_2} - \frac{\mu_H k_1}{\beta_H} \right) + \frac{\rho \beta_H^2 k_3 k_1}{\mu_H k_2} + \frac{v_3 \mu_H k_1^2 (\rho \beta_H^2 \Lambda_H \delta_v - \mu_H k_1 k_1) k_1}{\Lambda_H^2 \delta_v \Lambda_v k_2^2} \right)}{\beta_H^2} \]

and

\[ b = \frac{v_2 w_2 \Lambda_H \left( \frac{\rho \mu_H k_1}{\beta_H \Lambda_H} \frac{(\rho^2 - 1) \Lambda_H}{k_2} \right)}{\mu_H}. \]

Here, the coefficient \( b \) is positive, it is the sign of \( b \) will determine the occurrence of backward bifurcation in the given model. It follows from Theorem [28] that the system (1) will undergo backward bifurcation if the coefficient \( a \) is positive. This is implying that the disease free is not globally stable.

4.2 Local stability endemic equilibrium

**Theorem 4.2.** The endemic equilibrium of the model (1) is locally asymptotically stable, if \( R_0 > 1 \).

**Proof:** At \( E_1 \) without \( R_H \) the jacobian matrix evaluated as

\[
J(E_1) = \begin{pmatrix}
-k_4 - \mu_H & 0 & -k_5 & 0 & 0 & -k_8 \\
k_4 & -k_1 & k_5 & 0 & 0 & k_8 \\
0 & \kappa & -k_2 & 0 & 0 & 0 \\
0 & 0 & -k_6 & -k_7 - \mu_v & 0 & 0 \\
0 & 0 & k_6 & k_7 & -k_3 & 0 \\
0 & 0 & 0 & 0 & \delta_v & -\mu_v
\end{pmatrix},
\]

where \( k_4 = \beta_H (\rho r_1 + \Gamma_v), \quad k_5 = \rho \beta_H S_H, \quad k_6 = S_v \beta_v, \quad k_7 = I_v \beta_v, \quad k_8 = \beta_H S_H \).

The associate characteristic equation of \( J(E_1) \) is

\[ \lambda^6 + c_1 \lambda^5 + c_2 \lambda^4 + c_3 \lambda^3 + c_4 \lambda^2 + c_5 \lambda + c_6 = 0, \quad (9) \]

\[ \begin{aligned}
\frac{d}{dt} &= \frac{d}{dt}
\end{aligned} \]
where

\[
\begin{align*}
    c_1 &= \mu_H + k_1 + k_2 + k_3 + k_4 + k_5 + 2 \mu_V, \\
    c_2 &= k_1k_4 + (k_3 + k_4)k_7 + k_2(k_5 + k_6 + k_7) + k_2(k_5 + k_8 + k_9 + k_10 + k_11) + k_2(k_9 + k_10 + k_11), \\
    c_3 &= k_3k_7 + k_2 + k_4 + k_6 + k_7 + k_5, \\
    c_4 &= k_2k_4 + k_2 + k_5 + k_6 + k_7 + 2 \mu_V + \mu_V(2 \mu_H + \mu_V) + k_2 + k_5 + k_6 + k_7 + k_9, \\
    c_5 &= k_2(k_2k_4 + k_2 + k_5 + k_6 + 2 \mu_V) + k_2(k_2k_4 + k_2 + k_5 + k_6 + 2 \mu_V) + k_2(k_2k_4 + k_2 + k_5 + k_6 + 2 \mu_V), \\
    c_6 &= \mu_V(2 \mu_H + 2 \mu_V).
\end{align*}
\]

where \( k_0 = (\mu_H + k_3 + k_5 + 2 \mu_V), k_{10} = (2 \mu_H + k_4 + k_7), k_11 = (\mu_H + k_4 + k_7 + 2 \mu_V), k_{12} = (\mu_H + k_3 + k_9), k_13 = (\mu_H + k_4), k_{14} = (k_5 + \mu_V) \).

The Routh-Hurwitz criteria for Polynomial Eq (9) will give six negative eigenvalues if the conditions given below are satisfied: \( C_i > 0 \), for \( i = 1, 2, 3, \ldots, 6 \). The relevant Routh Hurwitz criteria in [29] could be used to show that the model (1) is stable locally asymptotically when \( R_0 > 1 \).

### 5 Global stability

This section investigates the global results for the model (1) at \( E_0 \) and \( E_1 \). First, we give the proof of the disease free global stability.

#### 5.1 Global stability disease free equilibrium

**Theorem 5.1.** For \( R_0 < 1 \), the disease free equilibrium \( E_0 \) of the system (1) is globally asymptotically stable.

**Proof:** To show this result, we define the following lyapunov function

\[
L(t) = w_1(S_H - S_H^*) - S_H^* \log S_H - S_H^* \frac{S_H}{S_H^*} + w_2S_H + w_3I_H + w_4(S_V - S_V^* - S_V^* \log S_V - S_V^* \frac{S_V}{S_V^*}) + w_5E_V + w_6I_V.
\]

Taking the time derivative of \( L(t) \), we have

\[
L(t) = w_1 \left(1 - \frac{S_H}{S_H^*}\right) S_H + w_2S_H + w_3I_H + w_4 \left(1 - \frac{S_V}{S_V^*}\right) S_V + w_5E_V + w_6I_V.
\]
Using system (1), we have

\[
L(t) = w_1 \left(1 - \frac{S_H}{S_H^0}\right) \left[\Lambda_H - \beta_H S_H (I_V + \rho I_H) - \mu_H S_H \right]
+ w_2 \left[\beta_H S_H (I_V + \rho I_H) - (\mu_H + \chi_H) E_H \right]
+ w_3 \left[\Lambda_H E_H - (\mu_H + \gamma + \eta) I_H \right] + w_4 \left(1 - \frac{S_V}{S_V^0}\right) \left[\Lambda_V - \beta_V S_V I_H - \mu_V S_V \right]
+ w_5 \left[\beta_V S_V I_H - (\mu_V + \delta_V) E_V \right] + w_6 [\delta_V E_V - \mu_V I_V].
\]

Using \(S_H^0 = \frac{\Delta_H}{\mu_H} S_H\) and \(S_V^0 = \frac{\Lambda_V}{\mu_V}\), and after simplifications, we obtain

\[
L(t) = -\mu_H w_1 \frac{(S_H - S_H^0)^2}{S_H^0} + [w_2 - w_1] \beta_H S_H (I_V + \rho I_H)
+ [w_3 w_4 w_5] \beta_V S_V I_H - \mu_V w_4 \frac{(S_V - S_V^0)^2}{S_V^0}
+ [w_5 - w_1] \beta_V S_V I_H - \mu_V w_4 \frac{(S_V - S_V^0)^2}{S_V^0}
+ [w_5 - w_1] \beta_V S_V I_H - \mu_V w_4 \frac{(S_V - S_V^0)^2}{S_V^0}
+ \left[ w_1 \beta_H \frac{\Lambda_H}{\mu_H} - w_3 (\mu_H + \gamma + \eta) \right] I_H
+ \left[ w_2 \beta_H \frac{\Lambda_H}{\mu_H} - w_3 (\mu_H + \gamma + \eta) \right] I_H
+ \left[ w_5 \beta_V \frac{\Lambda_V}{\mu_V} - w_6 \mu_V \right] I_V.
\]

Let’s choose the constants: \(w_1 = w_2 = \chi_H\), \(w_4 = \frac{\delta_V \beta_H \Lambda_H}{\mu_H (\mu_H + \gamma + \eta)}\), \(w_3 = (\mu_H + \chi_H)\), \(w_6 = \frac{\delta_V \beta_H \Lambda_H}{\mu_V (\mu_H + \gamma + \eta)}\). We get

\[
L'(t) = -\chi_H \mu_H \frac{(S_H - S_H^0)^2}{S_H^0} - \frac{\delta_V \beta_H \Lambda_H (S_V - S_V^0)^2}{\mu_V (\mu_H + \gamma + \eta)}
+ (\mu_H + \chi_H) (\mu_H + \gamma + \eta)(1 - R_0) I_H.
\]

Thus, \(L'(t)\) is negative for \(R_0 \leq 1\) and zero if and only if \(S_H = S_H^0\), \(S_V = S_V^0\), \(E_H = I_H = R_H = 0\) and \(E_V = I_V = 0\). Therefore the largest compact invariant set in \(\Pi\) is the singleton set \(E_0\). So, the model (1) is globally asymptotically stable.
5.2 Global stability endemic equilibrium

Before we proceed to obtain the global stability of the model (1) at endemic equilibrium $E_1$, first, at endemic steady state we obtain:

\[
\begin{align*}
\Lambda_H &= \beta_H S_H^* (I^*_H + \rho I^*_H) + \mu_H S_H^* \\
(\mu_H + \chi_H) E_H^* &= \beta_H S_H^* (I^*_H + \rho I^*_H) \\
\chi_H E_H^* &= (\mu_H + \gamma + \eta) I^*_H \\
\sum_{H} \left( \frac{(\chi_H + \mu_H)(\mu_H + \gamma + \eta)}{\chi_H} \right) I_H^* &= \beta_H S_H^* (I^*_H + \rho I^*_H) \\
\Lambda_V &= \beta_V S_V^* I_H^* + \mu_V S_V^* \\
\beta_V S_V^* I_H^* &= (\mu_V + \delta_V) E_V^* \\
\delta_V E_V^* &= \mu_V I_V^* \\
\beta_V S_V^* I_H^* &= \frac{(\mu_V + \delta_V) \mu_v I_V^*}{\delta_V}
\end{align*}
\]

Now, we prove the global stability of the model (1) at endemic equilibrium $E_1$ by following [30–32].

**Theorem 5.2** If $R_0 > 1$, then the endemic equilibrium $E_1$ is globally asymptotically stable.

**Proof:** Consider the Lyapunov function:

\[
L = \int_{S_H}^{E_H} \left( 1 - \frac{S_H}{x} \right) dx + \int_{E_H}^{I_H} \left( 1 - \frac{E_H}{x} \right) dx + \int_{I_H}^{\infty} \left( 1 - \frac{E_H}{x} \right) dx + \int_{S_V}^{E_V} \left( 1 - \frac{S_V}{x} \right) dx + \int_{E_H}^{I_H} \left( 1 - \frac{E_H}{x} \right) dx + \int_{I_H}^{\infty} \left( 1 - \frac{E_H}{x} \right) dx.
\]

The derivative of $L$ along the solutions of system (1) is

\[
\dot{L} = \left( 1 - \frac{S_H}{S_H^*} \right) S_H^* + \left( 1 - \frac{E_H}{E_H^*} \right) E_H^* + \frac{(\mu_H + \chi_H)}{\chi_H} \int_{I_H}^{\infty} \left( 1 - \frac{I_H}{x} \right) dx + \left( 1 - \frac{S_V}{S_V^*} \right) S_V^* + \left( 1 - \frac{E_V}{E_V^*} \right) E_V^* + \frac{(\mu_V + \delta_V)}{\delta_V} \left( 1 - \frac{I_V}{I_V^*} \right) I_V^*.
\]

By direct calculations, we have that:

\[
\left( 1 - \frac{S_H}{S_H^*} \right) S_H^* = \left( 1 - \frac{S_H}{S_H^*} \right) \left[ \Lambda_H - \beta_H S_H (I_V^* + \rho I_H^*) - \mu_H S_H \right]
\]

\[
= \left( 1 - \frac{S_H}{S_H^*} \right) \left[ \beta_H S_H^* (I_V^* + \rho I_H^*) - \beta_H S_H (I_V^* + \rho I_H^*) + \mu_H S_H - \mu_H S_H \right]
\]

\[
= \mu_H S_H^* \left( 2 - \frac{S_H}{S_H^*} \right) + \left( 1 - \frac{S_H}{S_H^*} \right) \beta_H S_H (I_V^* + \rho I_H^*) - \beta_H S_H (I_V^* + \rho I_H^*) + \mu_H S_H - \mu_H S_H.
\]
\[
(1 - \frac{E_h}{E_h}) E_{h} = \left( 1 - \frac{E_h}{E_h} \right) \left[ \beta h S_h(I_h + \rho I_h) - (\mu h + \chi h)E_h \right] \\
= \beta h S_h(I_h + \rho I_h) - \beta h S_h(I_v + \rho I_v) \frac{E_h}{E_h} \\
- (\mu h + \chi h)E_h + (\mu h + \chi h)E_h \\
= \beta h S_i(I_v + \rho I_v) - \beta h S_h(I_v + \rho I_v) \frac{E_h}{E_h} - (\mu h + \chi h)E_h \\
+ \beta h S_i(I_v + \rho I_v), \\
\tag{11}
\]

\[
(1 - \frac{I_h}{I_h}) \left( \frac{\mu h + \chi h}{I_h} \right) I_h = \left( 1 - \frac{I_h}{I_h} \right) \left( \frac{\mu h + \chi h}{I_h} \right) \left[ \chi h E_h - (\mu h + \gamma + \eta)I_h \right] \\
= (\mu h + \chi h)E_h - (\mu h + \chi h)E_h \frac{I_h}{I_h} \\
- \frac{(\mu h + \chi h)(\mu h + \gamma + \eta)}{I_h} I_h \\
+ \frac{(\mu h + \chi h)(\mu h + \gamma + \eta)}{I_h} I_h \\
= (\mu h + \chi h)E_h - \beta h S_h(I_v + \rho I_v) \frac{E_h I_h}{I_h I_h} - \\
\beta h S_i(I_v + \rho I_v) \frac{E_h I_h}{E_h I_h} \\
+ \beta h S_i(I_v + \rho I_v), \\
\tag{12}
\]

\[
(1 - \frac{S_v}{S_v}) S_v = \left( 1 - \frac{S_v}{S_v} \right) \left[ \Lambda_v - \beta v S_v I_h - \mu v S_v \right] \\
= \left( 1 - \frac{S_v}{S_v} \right) \left[ \beta v S_v I_h + \mu v S_v - \beta v S_v I_h - \mu v S_v \right] \\
= \mu v S_v \left( 2 - \frac{S_v}{S_v} \right) + \left( 1 - \frac{S_v}{S_v} \right) \beta v S_v I_h - \beta v S_v I_h \\
+ \beta v S_v I_h, \\
\tag{13}
\]

\[
(1 - \frac{E_v}{E_v}) E_v = \left( 1 - \frac{E_v}{E_v} \right) \left[ \beta v S_v I_h - (\mu v + \delta v)E_v \right] \\
= \beta v S_v I_h - \beta v S_v I_h \frac{E_v}{E_v} - (\mu v + \delta v)E_v + (\mu v + \delta v)E_v \\
= \beta v S_v I_h - \beta v S_v I_h \frac{E_v}{E_v} - (\mu v + \delta v)E_v + \beta v S_v I_h, \\
\tag{14}
\]
(1 - \frac{I_v'}{I_v}) \frac{\mu_v + \delta_v}{\delta_v} I_v' = \left(1 - \frac{I_v'}{I_v}\right) \frac{\mu_v + \delta_v}{\delta_v} [\delta_v E_v - \mu_v I_v]

= (\mu_v + \delta_v) E_v - (\mu_v + \delta_v) E_v \frac{I_v'}{I_v} = \frac{(\mu_v + \delta_v) \mu_v I_v}{\delta_v}

+ \frac{(\mu_v + \delta_v) \mu_v I_v}{\delta_v}

= (\mu_v + \delta_v) E_v - \frac{\beta_v S_v I_H}{E_v} E_v \frac{I_v'}{I_v} = \frac{\beta_v S_v I_H}{E_v} I_v' + \beta_v S_v I_H.

It follows from Eqs (10)–(15)

L = \mu_H S_H \left(2 - \frac{S_H}{S'} - \frac{S_H}{S_H'}\right) + \mu_v S_v \left(2 - \frac{S_v}{S_v'} - \frac{S_v}{S_v''}\right)

+ \beta_H S_H (I_v' + \rho I_H') \left(3 - \frac{S_H}{S_H'} - \frac{I_H}{I_H' - E_v I_H} + \frac{(I_v' + \rho I_H')}{(I_v' + \rho I_H')} \left(1 - \frac{S_H E_H}{S_H' E_H}\right) \right)

+ \beta_v S_v I_H' \left(3 - \frac{S_v}{S_v'} - \frac{I_v'}{E_v I_v} - E_v I_v' + \frac{I_H}{I_H' - E_v I_H} \left(1 - \frac{S_v E_v}{E_v S_v'}\right) \right)

In Eq (16),

\left(2 - \frac{S_H}{S_H'} - \frac{S_H}{S_H'}\right) \leq 0,

\left(2 - \frac{S_v}{S_v'} - \frac{S_v}{S_v''}\right) \leq 0,

\left(3 - \frac{S_H}{S_H'} - \frac{I_H}{I_H' - E_v I_H} + \frac{(I_v' + \rho I_H')}{(I_v' + \rho I_H')} \left(1 - \frac{S_H E_H}{S_H' E_H}\right) \right) \leq 0,

\left(3 - \frac{S_v}{S_v'} - \frac{I_v'}{E_v I_v} - E_v I_v' + \frac{I_H}{I_H' - E_v I_H} \left(1 - \frac{S_v E_v}{E_v S_v'}\right) \right) \leq 0.

One can see that the largest invariant subset, L = 0 is E_v. So, by LaSalle’s invariance Principle [33], E_v is globally asymptotically stable whenever \( R_0 > 1 \).

6 Sensitivity analysis of \( R_0 \)

We performed sensitivity analysis to explore the model robustness to parameter values used. This is to provide information on the parameters that have significant impact of theoretical model for Zika virus transmission in relation to the reproduction number \( R_0 \). In order to undertake this activity we made use of normalised forward sensitivity index of a variable to a parameter approach vividly described in [34, 35] this technique is expressed as the ratio of the relative variation in the variable to the relative variation in the parameter. It can also be viewed as a differentiable function of the parameter.
Definition 6.1. The normalized forward sensitivity index of a variable $h$, that depends differentially on a parameter $l$, is defined as:

$$\Upsilon_l^h = \frac{\partial h}{\partial l} \times \frac{l}{h} = 1$$

(17)

The detailed sensitivity indices of $R_0$ based on the evaluation to the other parameters of the model are presented in Table 1. The parameters are organized in such way that it begins from the most sensitive to the least sensitive one. The most sensitive ones from the Table 1 are the human infected treatment rate, natural death in humans, recruitment rate of humans, the rate of exposed humans moving into infectious class, probability of mosquitoes getting infected, mosquitoes recruitment rate, the rate flow from $E_V$ to $I_V$, human recovery rate due to treatment ($\eta$, $\mu_H$, $\Lambda_H$, $\chi_H$, $\beta_H$, $\Lambda_V$, $\delta_V$ and $\gamma$, respectively) and the least parameter is the human modification parameter $\rho$.

For instance, increasing (or decreasing) the human infected treatment rate $\eta$ by 10% decreases (or increases) $R_0$ by 9.004%; similarly, increasing (or decreasing) the natural death in humans, $\mu_H$, by 10% increases (or decreases) $R_0$ by 5.710%. In the same way, increasing (or decreasing) the proportion of recruitment rate of humans, $\Lambda_H$, by 10% increases (or decreases) $R_0$ by 5.5009%. Further, increasing (or decreasing) the rate of exposed humans moving into infectious class $\chi_H$ by 10% increases (or decreases) $R_0$ by 5.508%. In addition, increasing (or decreasing) the probability of mosquitoes getting infected, $\beta_H$, by 10% increases (or decreases) $R_0$ by 4.630%. While increasing (or decreasing) the mosquitoes recruitment rate, $\Lambda_V$, by 10% increases (or decreases) $R_0$ by 4.490%. Furthermore, increasing (or decreasing) the rate flow from $E_V$ to $I_V$, $\delta_V$, by 10% increases (or decreases) $R_0$ by 2.641%. On the other hand, increasing (or decreasing) the human recovery rate due to treatment, $\gamma$ by 10% increases (or decreases) $R_0$ by 1.809%.

### 7 Analysis of optimal control

In this section, we make uses of Pontryagin’s Maximum Principle in order to come out with the necessary conditions that establishes the presence of optimal control of the Zika virus SEIR model. We include time dependent controls in the Zika SEIR model and endeavour to explore the appropriate optimal strategy for putting the Zika virus under control. We use three control variables, the control $u_1(t)$ represents the efforts on preventing zika infections through bed-nets, the control on treatment of zika infected individuals $u_2(t)$ and the third control $u_3(t)$.

| Parameter | Description | Sensitivity |
|-----------|-------------|-------------|
| 1 $\eta$ | Human infected treatment rate | -0.9004 |
| 2 $\mu_H$ | Natural death rate in human | -0.5710 |
| 3 $\Lambda_H$ | Recruitment rate of humans | -0.5509 |
| 4 $\chi_H$ | The rate of exposed humans moving into infectious class | 0.5508 |
| 5 $\beta_H$ | Probability of humans getting infected | 0.4630 |
| 6 $\beta_V$ | Probability of mosquitoes getting infected | 0.4490 |
| 7 $\Lambda_V$ | Mosquito recruitment rate | 0.4490 |
| 8 $\delta_V$ | The rate flow from $E_V$ to $I_V$ | 0.2641 |
| 9 $\gamma$ | Human recovery rate due to treatment | -0.1809 |
| 10 $\rho$ | Human modification parameter | 0.0146 |

https://doi.org/10.1371/journal.pone.0185540.t001
represents the efforts through insecticides spray against mosquito. In this regard, the following objective functional are taking into consideration our objective functional is similar to what is in the literature [9, 36, 37],

$$J(u_1, u_2, u_3) = \int_0^T \left( B E_{Ht} + C I_{Ht} + D E_{Vt} + E I_{Vt} + \frac{a_1}{2} u_1^2 + \frac{a_2}{2} u_2^2 + \frac{a_3}{2} u_3^2 \right) dt,$$ \hspace{1cm} (18)

where $B, C, D, E$ are the balancing cost factors due to scales and $a_1, a_2$ and $a_3$ denote the weighting constants for making uses of bednets which has the potential of reducing the spread of the disease(prevention), effective treatment activities which include the efficacy of the drugs and encouraging patients to take their drugs timely and effective and availability of insecticide spraying against all stages of mosquitoes. The costs associated with prevention, treatment and insecticide are taken be of the form of nonlinear. Thus, we endeavour to anticipate an optimal control $u_1^*, u_2^*, u_3^*$ such that,

$$J(u_1^*, u_2^*, u_3^*) = \min J(u_1, u_2, u_3), \Gamma = \{(u_1, u_2, u_3)|0 \leq u_i \leq 1, i = 1, 2, 3\}.$$

The necessary conditions that an optimal solution must conform is emanated from the Pontryagin Maximum Principle [38]. This concept translates Eqs (18) and (19) into a kind of problem characterised with minimizing pointwise a Hamiltonian $H$, with respect to $u_1, u_2$ and $u_3$

$$H = B E_{Ht} + C I_{Ht} + D E_{Vt} + E I_{Vt} + a_1 u_1^2 + a_2 u_2^2 + a_3 u_3^2 + \lambda_{S_H}(\Lambda_H - (1 - u_1)\beta_H S_H (I_V + \rho I_H) - \mu_H S_H) + \lambda_{E_H}((1 - u_1)\beta_H S_H (I_V + \rho I_H) - (\mu_H + \chi_H) E_H) + \lambda_{I_H}(\chi_H E_H - (\mu_H + u_2^* + \eta) I_H) + \lambda_{R_H}(u_3^*\gamma I_H - \mu_H R_H) + \lambda_{S_V}(\Lambda_V - (1 - u_1)\beta_V S_V I_H - u_3\mu_V S_V) + \lambda_{E_V}((1 - u_1)\beta_V S_V I_H - (\delta_V + u_3 \mu_V) E_V) + \lambda_{I_V}(\delta_V E_V - u_3 \mu_V I_V)$$ \hspace{1cm} (20)

where $\lambda_{S_H}, \lambda_{E_H}, \lambda_{I_H}, \lambda_{R_H}, \lambda_{S_V}, \lambda_{E_V}, \lambda_{I_V}$ and $\lambda_{I_V}$ constitute the adjoint variables or co-state variables. The system solution is attained by appropriately taking partial derivatives of the Hamiltonian Eq (20) with respect to the associated state variable.
Theorem 7.1. Given optimal controls $u_1^*, u_2^*, u_3^*$ and solutions $S_{H}, E_{H}, I_{H}, R_{H}, S_{V}, E_{V}, I_{V}$ of the corresponding state system (18) and (19) that minimize $J(u_1, u_2, u_3)$ over $\Gamma$. Then there exists adjoint variables $\lambda_{S_{H}}, \lambda_{E_{H}}, \lambda_{I_{H}}, \lambda_{R_{H}}, \lambda_{S_{V}}, \lambda_{E_{V}}, \lambda_{I_{V}}$ satisfying

$$-\frac{d\lambda_{i}}{dt} = \frac{\partial H}{\partial \lambda_{i}}$$

where $i = S_{H}, E_{H}, I_{H}, V, S_{V}, E_{V}, I_{V}$ and with transversality conditions

$$\lambda_{S_{H}}(t_f) = \lambda_{E_{H}}(t_f) = \lambda_{I_{H}}(t_f) = \lambda_{R_{H}}(t_f) = \lambda_{S_{V}}(t_f) = \lambda_{E_{V}}(t_f) = \lambda_{I_{V}}(t_f) = 0$$

and

$$u_1^* = \min \left\{ 1, \max \left( 0, \frac{S_{H}B_{H}I_{V}(\lambda_{E_{H}} - \lambda_{S_{H}}) + S_{V}B_{V}I_{H}(\lambda_{E_{V}} - \lambda_{S_{V}})}{a_1} \right) \right\},$$

$$u_2^* = \min \left\{ 1, \max \left( 0, \frac{\gamma_{IH}(\lambda_{I_{H}} - \lambda_{E_{H}})}{a_2} \right) \right\},$$

$$u_3^* = \min \left\{ 1, \max \left( 0, \frac{\mu_{V}S_{V}\lambda_{S_{V}} + \mu_{V}E_{V}\lambda_{E_{V}} + \mu_{V}I_{V}\lambda_{I_{V}}}{a_3} \right) \right\}.$$  

Proof: Corollary 4.1 of Fleming and Rishel [39] provides the condition of possible existence of an optimal control based on the convexity of the integrand of $J$ with respect to $u_1, u_2$ and $u_3$, a priori boundedness of the state solutions, and the Lipschitz characteristics of the state system in line with the state variables. The Hamiltonian function determines at the optimal control level leads to the governing adjoint variables. Thus, the adjoint equations can be rearranged as

$$-\frac{d\lambda_{S_{H}}}{dt} = \mu_{H}\lambda_{S_{H}} + (1 - u_1)B_{H}(\lambda_{S_{H}} - \lambda_{E_{H}})(I_{V} + \rho I_{H})$$

$$-\frac{d\lambda_{E_{H}}}{dt} = -B + (\mu_{H} + \gamma_{IH})\lambda_{E_{H}} - \lambda_{H}\lambda_{I_{H}}$$

$$-\frac{d\lambda_{I_{H}}}{dt} = -C + (\mu_{H} + \nu_{H} + \eta)\lambda_{I_{H}} - (u_{2}\gamma)\lambda_{E_{H}} + \rho(1 - u_1)B_{H}S_{H}(\lambda_{S_{H}} - \lambda_{E_{H}})$$

$$+ (1 - u_1)\beta_{V}S_{V}(\lambda_{S_{V}} - \lambda_{E_{V}})$$

$$-\frac{d\lambda_{S_{V}}}{dt} = \mu_{H}\lambda_{S_{V}}$$

$$-\frac{d\lambda_{E_{V}}}{dt} = \mu_{V}\lambda_{E_{V}} + (1 - u_3)\beta_{V}I_{V}(\lambda_{S_{V}} - \lambda_{E_{V}}) + \mu_{V}u_{3}\lambda_{S_{V}}$$

$$-\frac{d\lambda_{I_{V}}}{dt} = -D - (\delta_{V} + u_{3}\mu_{V})\lambda_{E_{V}} - \delta_{V}\lambda_{I_{V}}$$

$$-\frac{d\lambda_{I_{V}}}{dt} = -E + (1 - u_3)\beta_{H}S_{H}(\lambda_{S_{H}} - \lambda_{E_{H}}) + \mu_{V}u_{3}\lambda_{I_{V}}.$$
8 Numerical simulations

In this section, we present numerical simulation solutions as illustration which is obtained using MATLAB program. The Table 2 presents the parameter values used for the simulations.

8.1 Prevention (u_1) and treatment (u_2) control only

In this strategy, prevention measure of providing bednets u_1 and the treatment efforts u_2 are employed to optimize the objective function J, and at same time the insecticide spray control (u_3) is set to zero. It is obvious in Fig 2(a) that there is a substantial difference between the number of exposed individuals E_H under control, compare to cases without control. Without the presence of the two controls the number of exposed humans appear to be increasing. The result depicted in Fig 2(b) clearly shows that the control strategy activated is effective to reduce the infected humans I_H under control, as not the case without control. The number of infected humans increases without the control strategies. Fig 2(c) showed that there is no significant different between the presence of control and without control in the number of exposed mosquitoes. The obvious pattern is observed in Fig 2(d) that without control the infected mosquitoes are reducing than the presence of control. The Zika prevention control u_1 should be maintained at a maximum effort in the entire duration of the intervention at the same time control u_2 which deals with prevention should be kept about 6% during the 120 days.

8.2 Prevention (u_1) and insecticide control (u_3) only

In this strategy, prevention effort targeting at making effective uses of bednets u_1 and the insecticide spray control (u_3) are explored while control u_2 is set to zero is employed to optimized the objective function J. We can infer from Fig 3(a) that there is no difference between the presence of the two controls activated and without the controls in the number of exposed humans E_H bednet u_1. In Fig 3(b) the number of infected humans is increased despite the activation of controls u_1 and u_2 and this indicated that just provision of bednet and treatment of humans would not reduce the spread of Zika virus. The control strategy in Fig 3(c) is effective as there is a substantial difference between the presence of control and without control. in the number of exposed mosquitoes E_V. It can be infer that if effective mechanisms of praying mosquitoes are put in place little attention can be put in the provision of bednets in humans. significant difference is also shown in Fig 3(b) which suggest that this control strategy. There is a

https://doi.org/10.1371/journal.pone.0185540.g003
significant difference between the presence of the two controls and without the control as seen in Fig 3(d). The use of bednets and insecticide spray reduces the number of infected mosquitoes $I_V$ and would eventually reduce the spread of the disease. The control profile in Fig 3(e) stipulates that this strategy would require that control $u_1$ must be maintained for a maximum effort of 120 days throughout the process while control $u_2$ must be kept constant for maximum effort 100% for 40 days and gradually reduce to 22% within the rest of the 120 days. The control $u_3$ is kept zero throughout the process.

8.3 Treatment ($u_2$) and insecticide ($u_3$) only

In this strategy, treatment efforts $u_2$ and the insecticide spray control ($u_3$) are employed to optimize the objective function $J$, at the same time the prevention control $u_1$ is set to zero. We can infer from Fig 4(a) that there no significant difference between the number of exposed humans $E_H$ in the presence of control strategy and without control strategy. This indicates that the strategy is not the best way to reduce the number of humans getting exposed to the zika virus disease. The result in Fig 4(b) shows that the control strategy is not the best way to reduce the number of infected humans. The control strategy is more effective in Fig 4(c) as the number of exposed mosquitoes $E_V$ are substantially minimized. In fact, without the presence of control in Fig 4(c) the number of exposed mosquitoes $E_V$ is increasing. It is clear that in Fig 4(d) there is vast different between the number of infected mosquitoes $I_V$, the presence of control and without control strategy. There presence of control strategy is capable of minimizing the number of infected mosquitoes $I_V$ in the communities. The control profile in Fig 4(c) indicates that the Zika prevention control $u_3$ should be maintained at maximum effort 100% for 16 days and finally decreasing till the end of 120 days while control $u_2$ must be kept at a maximum effort 5% for 5 days and immediately decreasing zero in the entire 120 days intervention.

8.4 Prevention, treatment and insecticide ($u_1$, $u_2$, $u_3$)

In this strategy, all the three controls are explored in order to optimize ($u_1$, $u_2$, $u_3$). It obvious in Fig 5(a) that a vast significant difference between number of exposed humans $E_H$ in the presence of control and without control. The activation of all the controls has the a greater effect of minimizing the number of exposed humans in the communities. The in Fig 5(b) further indicates that there substantial difference between the presence of control and without control. This shows that the control mechanisms are able to reduce the number of infected humans $I_H$ within the communities. In the absence control the the infection will be spreading at a faster rate. There is relatively significant difference between the presence of control and without control as in Fig 5(c). In fact communities where zika virus are presence should be to take precaution measures to avoid exposure to the infected virus. Fig 5(d) suggest that the there is substantial different between the the presence of control and without control. This further suggests that the application of all the three control is the best strategy to minimize the number of infected mosquitoes $V_I$ which will eventually can lead to the reduction of the spread of zika virus. The control profile in Fig 5(c) suggests that control $u_1$ ought to be kept at a maximum 100% for about 40 days and gradually reduce to 25% and kept same within the entire 120 days period. The control $u_2$ is just maintain at 8% and then gradually decrease and maintain in the entire 120 days. The control $u_3$ is kept at a maximum 100% for 20 days then decrease to 25% which is maintain throughout the entire 120 days.
Fig 4. Simulations of the model showing the effect of Zika prevention and treatment only on transmission. Fig 4(a)-(e) respectively represent the behavior of exposed human, infected human, exposed mosquitoes, infected mosquitoes and control profile. $u_1 = u_2 = u_3 = 0$ represents system without control while $u_2 = u_3 \neq 0, u_1 = 0$, shows control system. Fig 4(a) $u_1 = u_2 = u_3 = 0$-without control system and $u_2 = u_3 \neq 0, u_1 = 0$ control system, Fig 4(b) $u_1 = u_2 = u_3 = 0$-without control system and $u_2 = u_3 \neq 0, u_1 = 0$ control system, Fig 4(c) $u_1 = u_2 = u_3 = 0$-without control system and $u_2 = u_3 \neq 0, u_1 = 0$ control system, Fig 4(d) $u_1 = u_2 = u_3 = 0$-without control system and $u_2 = u_3 \neq 0, u_1 = 0$ control system, Fig 4(e) $u_1 = u_2 = u_3 = 0$-without control system and $u_2 = u_3 \neq 0, u_1 = 0$ control system.

9 Conclusion

In this work, we studied a deterministic Zika virus model. The basic properties of the proposed model is investigated in addition to the basic reproduction \( R_0 \) without control. The steady states of the model is studied and both disease free and endemic equilibrium is locally asymptotically stable. The disease free equilibrium is found to be globally asymptotically is stable. The central manifold theory is employed to study the stability of endemic equilibrium and also found to be asymptotically stable. Optimal time control is incorporated into the proposed model namely bednets, treatment and spraying of insecticide. The Pontryagin’s Maximum Principle is explored and used to determine the essential conditions usually necessary for effective control of zika virus. The numerical simulation results obtained suggest that the best strategy to minimize the the spread of zika virus is to optimize all the three controls. The reduction of the disease can only be attained when needed attention of all the thee controls are taken into account. The results presented are clear and the public health implications are provided.
