We consider the definition of unpolarized transverse-momentum-dependent parton distribution functions while staying on-the-light-cone. By imposing a requirement of identical treatment of two collinear sectors, our approach, compatible with a generic factorization theorem with the soft function included, is valid for all non-ultra-violet regulators (as it should), an issue which causes much confusion in the whole field. We explain how large logarithms can be resummed in a way which can be considered as an alternative to the use of Collins-Soper evolution equation. The evolution properties are also discussed and the gauge-invariance, in both classes of gauges, regular and singular, is emphasized.

QCD Evolution Workshop  
May 14 - 17, 2012  
Thomas Jefferson National Accelerator Facility, Newport News, VA (USA)

∗Speaker.  
†Speaker.
1. Introduction

In high-energy physics, transverse-momentum-dependent parton distribution functions (TMD-PDFs), with or without spin dependence, have proved to be an essential quantities for unraveling the internal structure of protons, as well as being an ingredients representing hadronic physics in a wide class of factorized physical observables. In this effort we will consider the unpolarized TMDPDF and how it should (or could) be defined in a way compatible with a generic factorization theorem of a transverse-momentum-dependent (TMD) physical observable. To properly define such quantities one needs to consider the following issues combined:

1. The role of the soft function, to be defined below, as a crucial part of the factorized hadronic tensor.
2. The distinction between pure and naively calculated collinear matrix elements.
3. How a definition of a TMDPDF should be independent of the use of any regulator of the non-ultra-violet divergences (nUV). By definition, “nUV divergences” include the physical infra-red (IR) ones of perturbative QCD (pQCD) and the un-physical ones like rapidity divergences.

Consider the Drell-Yan heavy lepton pair production process where the lepton pair is produced with transverse momentum \( q_T \) much larger than \( \Lambda_{\text{QCD}} \). Assuming that the soft and collinear modes completely capture the IR of full QCD, which is a highly nontrivial statement, then, at leading twist, one can establish the following factorization theorem for \( q_T \)-dependent cross section:

\[
\sigma = H \left( \frac{Q^2}{\mu^2} \right) \frac{J_n J_{\pi} S}{}, \tag{1.1}
\]

where the \( q_T \)-dependence is implicit in the pure collinear matrix elements \( J_n \), \( J_{\pi} \) and the soft function \( S \). By “pure” collinear contribution we mean that the soft (zero-bin) contamination has to be subtracted out. In the remainder of this section we refer to all quantities in Eq. (1.1) as the partonic version of the physical matrix elements unless otherwise stated. To explain in simple terms how the TMDPDF should be defined we emphasize the following:

1. In pQCD the extraction of the hard part is performed by considering a generic Feynman diagram contributing to \( \sigma \) and then “subtracting” all the physics contributing to the relevant lower scales. In the effective field theory (EFT) methodology this is equivalent to a multiple matching procedure starting from full QCD and the appropriate effective theories. In both approaches it is obvious that the hard part should depend only on the hard scale and the renormalization one as well. Thus, \( H \) is a polynomial of only one quantity: \( \log(\frac{Q^2}{\mu^2}) \). Any dependence on nUV regulators needed to calculate \( \sigma \) is prohibited.
2. The un-canceled nUV divergences in \( \sigma \), no matter how they are regulated, are completely a genuine IR ones that has to be generated by similar ones from the right-hand side of Eq. (1.1). This is the ultimate check (at least pertubatively) for either the subtraction philosophy or the EFT matching procedure to work! The immediate conclusion is that the product \( J_n J_{\pi} S \) has to include only the IR of QCD. Again we emphasize that this simple observation is (or should be, if perturbative calculations are performed properly) independent of any regulator(s) of the nUV divergences.
Given the factorization theorem of $\sigma$, where $\sigma$ is calculated in full QCD, with the above two observations and combined with the requirement of identical treatment among the two collinear sectors $n$ and $\overline{n}$, one can easily conclude that each quantity, $J_n \sqrt{S}$ and $J_{\overline{n}} \sqrt{S}$, has to be a well-defined quantity in the sense that it is free of any nUV divergences that do not exist in the full pQCD calculation of $\sigma$ (a calculation that is needed in order to extract the hard part $H$). Again we mention that this line of reasoning is valid no matter which set of regulators is used for the nUV as long as one uses the same set for both collinear sectors. Thus we define the quantity $F_{n,\overline{n}} = J_{n,\overline{n}} \sqrt{S}$ as the “TMDPDF”. For two identical partons in the initial states one simply has: $F_n = F_{\overline{n}}$.

Notice that no attempt to go “off-the-light-cone” has been made. There are mainly two reasons for that. First is that one is completely free to regularize the nUV divergences with any set of regulators and moreover there is also no need to even distinguish between the different kinds of divergences in that set. This is definitely true if one believes that the factorized result of $\sigma$ holds to all orders in perturbation theory. The second reason is that large logarithms can be resummed (and one should be able to resum them) without any reference to a specific set of regulators. We believe this observation is simple enough and it should be undisputed.

We finally remark that if one insists on introducing different regulators for the two collinear directions (like different off-shellnesses, $\Delta$’s, etc.), as it is done in \cite{3}, then certain logarithms of the ratio of those different $n, \overline{n}$-regulators will still appear in each one of the TMDPDFs, $F_n$ and $F_{\overline{n}}$. Those logarithms are intimately related to the existence of the Wilson lines in the collinear and soft matrix elements. However those logarithms will cancel when one combines the two collinear contributions and the soft function to $\sigma$. Thus we find it completely harmless to use identical parameters as long as one can still resum large logarithms and extract each TMDPDF from the relevant experimental data.

We start by briefly reviewing Collins definition of the TMDPDF \cite{4} and then compare it with the “on-the-light-cone” one \cite{5}. Some phenomenological applications of the definition and evolution of TMDs as defined in \cite{5} can be found in Ref. \cite{6}.

## 2. Collins Approach

In impact parameter space, Collins defines the TMDPDF as:

$$F_n(x, b; Q_n, y_n) = \hat{J}_n(x, b; Q^2) \sqrt{\tilde{S}(b; +\infty, y_n) \tilde{S}(b; -\infty, -\infty) / \tilde{S}(b; +\infty, -\infty) \tilde{S}(b; y_n, -\infty)}.$$  

(2.1)

The first factor in the last term is exactly the definition of the TMDPDF where all Wilson lines are still on-the-light-cone. However it should be noted that this definition relies on the hypothesis that soft contamination in the naively calculated collinear contribution $\hat{J}_n$ can be removed by soft function subtraction. This issue is a subtle one and its validity depends on the consistent use of the nUV regulators of the naive collinear, its soft limit (or its zero-bin) and the soft function built from soft Wilson lines. More discussion on this can be found in \cite{7, 8, 9}. Hereafter we will not
discuss this issue further. The aim of the second term, is not canceling the rapidity divergencies as one might naively think (especially when going off-the-light-cone) but to introduce a new parameter \( y_n \) that allows the derivation of a “Collins-Soper” like evolution equation to resum large logarithms of \( Q/k_T \). The dependence of Collins’ TMDPDF on this arbitrary parameter will cancel only when two TMDPDFs (or, more generally, two “collinear” hadronic contributions like one TMDPDF and one fragmentation function in the case of SIDIS) are combined since the two sectors are tilted asymmetrically (notice the \( e^{\pm 2y_n} \) in the two tilted collinear directions) so as to achieve this cancelation. We want now to raise two important points:

1. The second factor in the last term of Eq. (2.1) introduces an arbitrary dependence on \( y_n \) of a single TMDPDF. In all existing literature using Collins formalism (e.g.,[12, 13, 14, 15]) for single sector, this dependence is canceled when \( y_n \) is set to zero, which is to say that we are back on-the-light-cone since that factor reduces to unity.

2. If that factor is exactly 1 on-the-light-cone, and one can still resum large logarithms by simply noticing that the first factor in the last term of Eq. (2.1) is free from all un-physical \( n \)UV divergencies (under the requirement of identical treatment of two collinear sectors) then why one needs to consider the \( y_n \)-dependent factor in the first place? Life is much simpler without it!

Given all the considerations above, we now show more explicitly how Collins approach reduces to ours when one chooses \( y_n = 0 \). In that approach the master equation for quark TMDPDF, denoted by \( \tilde{F}^C_{f/p} \), is

\[
\tilde{F}^C_{f/p}(x, b; \xi_F, \mu_f = Q_f) = \sum_{j=q,g} \int_x^1 dx' \tilde{C}^C_{f/j}(x', b; \xi_F, \mu_f = \mu_i^2, \mu_f) \phi_{j/p}(x'; \mu_f) \\
\times \exp \left\{ \tilde{K}(b; \mu_f) \ln \frac{\sqrt{\xi_{F,i}}}{\mu_f} + \int_{\mu_f}^{\mu_f = Q_f} \frac{d\mu'}{\mu'} \left[ \gamma_F\left( \frac{\alpha_s(\mu')}{\ln \frac{Q_f}{\mu'^2}} \right) \right] \right\}.
\]

where the matching of the quark TMDPDF onto the standard PDF is

\[
\tilde{F}_{f/p}(x, b; \xi_F, \mu) = \sum_{j=q,g} \int_x^1 dx' \tilde{C}^C_{f/j}(x', b; \xi_F, \mu) \phi_{j/p}(x'; \mu) + \mathcal{O}\left((\Lambda_{QCD}^a)^a\right).
\]

(2.2)

On the other hand, our master equation for the TMDPDF on-the-light-cone is

\[
\tilde{F}_{f/p}(x, b; Q_f^2, \mu_f = Q_f) = \sum_{j=q,g} \int_x^1 dx' \tilde{C}^C_{f/j}(x', b; \mu_f) \phi_{j/p}(x'; \mu_f) \\
\times \exp \left\{ -D(b; \mu_f) \ln \frac{Q_f^2}{\mu_f^2} + \int_{\mu_f}^{\mu_f = Q_f} \frac{d\mu'}{\mu'} \left[ \gamma_F\left( \frac{\alpha_s(\mu')}{\ln \frac{Q_f^2}{\mu'^2}} \right) \right] \right\}.
\]

where the matching of the quark TMDPDF onto the standard PDF is given by

\[
\tilde{F}_{f/p}(x, b; Q_f^2, \mu) = \sum_{j=q,g} \int_x^1 dx' \tilde{C}^C_{f/j}(x', b; Q_f^2, \mu) \phi_{j/p}(x'; \mu) + \mathcal{O}\left((\Lambda_{QCD}^a)^a\right).
\]

(2.3)
The fact that the TMDPDF $\tilde{F}_{f/p}$ is free from all un-physical nUV divergencies allows us to write

$$\tilde{C}_{f/j}(x,b;Q^2,\mu) = \left(\frac{Q^2 b^2}{4e^{-2\gamma_E}}\right)^{-D(b,\mu)} \tilde{C}_{f/j}^\Theta(x,b;\mu).$$  \hfill (2.4)

In both cases $\mu_T$ should be chosen so that the large logarithms in the matching coefficients $\tilde{C}$ are canceled. This choice can follow the well-known CSS approach \[10\], where one relates $\mu$ with $b$ and has to deal with the issue of Landau pole. However one can also follow the work of \[11\] and transform back to momentum space before setting the scale $\mu_I$, which is related finally to $k_T$.

When setting $y_n = 0$ one gets the following relations:

$$\tilde{K}(b;\mu) \rightarrow -2D(b;\mu), \quad \gamma_F^\prime(\zeta,\mu) \rightarrow \gamma_F(Q^2,\mu), \quad C_{f/j}^C(x,b;\zeta,\mu) \rightarrow \tilde{C}_{f/j}(x,b;Q^2,\mu).$$  \hfill (2.5)

The above relations hold to all orders in perturbation theory. Thus we see that Collins formalism reduces to the “on-the-light-cone” one.

3. The TMDPDF On-The-Light-Cone

For many years, the two main issues that people have tried to resolve in order to get the correct definition of the TMDPDF are the following:

- On one hand, the TMDPDF should be free from rapidity divergencies. In the case of the PDF, as it is shown in Sec. 4, these divergencies cancel when one combines virtual and real diagrams. But when we allow the collinear matrix element to depend also on the transverse coordinate, such cancelation does not hold anymore.

- On the other hand, the TMDPDF is a quantity that depends on two different scales: the hard probe $Q$ and the transverse momentum $k_T$. When these scales are widely separated, one needs to resum the large logarithms appearing in perturbative expression of the TMDPDF.

In the following we give a consistent definition of the TMDPDF, while staying on-the-light-cone that addresses the issues mentioned above. More details can be found in \[5\].

An intermediate step towards getting the factorization theorem of the hadronic tensor $M$ is given by

$$M = H(Q^2/\mu^2) \int d^4y e^{-iyq} J_n(0^+,y^-;\vec{y}_\perp) J_\pi(y^+,0^-,\vec{y}_\perp) S(0^+,0^-,\vec{y}_\perp),$$  \hfill (3.1)

where $H$ is the hard matching coefficient, $J_{n(\pi)}$ are the pure-collinear matrix elements and $S$ is the soft function. The collinear pieces $J_{n(\pi)}$ are intended to contain just collinear modes, however in actual calculation we integrate over all momentum space thus collecting a contribution from soft modes as well. Below we denote the “naive collinear” as: $\hat{J}_{n(\pi)}$.

The fact that the soft function depends just on the transverse coordinate was derived in \[5\] based on power counting arguments of the soft and collinear modes.
Based on Eq. (3.1), by symmetry, we define the TMDPDF as

$$F_n(x; \vec{k}_{n\perp}) = \frac{1}{2} \int \frac{d r}{(2\pi)^3} e^{-i \left( \frac{1}{2} r^+ x^+ - \vec{r}_\perp \cdot \vec{k}_{n\perp} \right)} J_n(0^+, r^-, \vec{r}_{\perp}) \sqrt{S(0^+, 0^-, \vec{r}_{\perp})}$$

where the second equality holds only if the subtraction of soft contamination is equivalent to dividing by the soft function.

We can use any regulator to regularize the nUV, however one has to be consistent. A factorization theorem can be understood from the effective field theory point of view as a multiple steps of matching between different effective theories. In this sense it is a must that one regularizes the “IR” consistently in the theory above and below the relevant scale. Then, the matching coefficients ($H$ and $\tilde{C}$ in our case) can never depend on the set of the nUV regulators.

We choose a frame where $p = (p^+, 0^-, 0_{\perp})$ and $\overline{p} = (0^+, p^-, 0_{\perp})$ with $p^+ = p^- = Q$, and write the poles of fermion propagators with a real and positive parameter $\Delta$:

$$\frac{i(p + k)}{(p + k)^2 + i0} \rightarrow \frac{i(p + k)}{(p + k)^2 + i\Delta}, \quad \frac{i(\overline{p} + k)}{(\overline{p} + k)^2 + i0} \rightarrow \frac{i(\overline{p} + k)}{((\overline{p} + k)^2 + i\Delta}. \quad (3.3)$$

The above prescription applies as well to the fermion propagators. The corresponding pole-shifting for collinear and soft Wilson lines goes as follows

$$\frac{1}{k^+ + i0} \rightarrow \frac{1}{k^+ + i\delta}, \quad \frac{1}{k^- + i0} \rightarrow \frac{1}{k^- + i\delta}, \quad (3.4)$$

where $\delta$ is related to $\Delta$ through the large components of the collinear fields,

$$\delta = \frac{\Delta}{p^+} = \frac{\Delta}{\overline{p}^+}. \quad (3.5)$$

This relation comes from the fact that in order to recover the correct IR structure of QCD, the contributions of collinear and soft Wilson lines have to be consistent with the collinear and soft limits, respectively, of full QCD.
Figure 2: Virtual corrections for the soft function. Double lines represent the soft Wilson lines, $S_{n(\bar{n})}$. “h.c.” stands for Hermitian conjugate.

3.1 Virtual Diagrams

The diagrams in figs. (1) and (2) give collinear and soft virtual contributions respectively to $F_n$. The Wave Function Renormalization (WFR) diagram (1a) and its Hermitian conjugate give

$$f_{n1}^{(1a)} + (1a)^* n_1 = \frac{\alpha_s C_F}{2\pi} \delta(1-x) \delta^{(2)}(\vec{k}_{n,\perp}) \left[ \frac{1}{\epsilon_{UV}} - \frac{\ln \mu^2}{\Delta} + \frac{1}{2} \right]$$

(3.6)

The W Wilson line tadpole diagram, (1b), is identically 0, since $n_2 = 0$. Diagram (1c) and its Hermitian conjugate give

$$f_{n1}^{(1c)} + (1c)^* n_1 = \frac{\alpha_s C_F}{2\pi} \delta(1-x) \delta^{(2)}(\vec{k}_{n,\perp}) \left[ \frac{2}{\epsilon_{UV}} \ln \frac{\delta}{p^+} + \frac{2}{\epsilon_{UV}} \ln^2 \frac{\delta \Delta}{p^+ \mu^2} - 2 \ln \frac{\Delta}{\mu^2} + \ln^2 \frac{\Delta}{\mu^2} + 2 - \frac{7\pi^2}{12} \right].$$

(3.7)

The contribution of diagrams (2a) and (2b) is zero, since (2a) is proportional to $n_2 = 0$ and (2b) to $\vec{n}^2 = 0$. The diagram (2c) and its Hermitian conjugate give

$$S_{n1}^{(2c)} + (2c)^* 1 = -\frac{\alpha_s C_F}{2\pi} \delta^{(2)}(\vec{k}_{n,\perp}) \left[ \frac{2}{\epsilon_{UV}} \ln \frac{\delta^2}{\mu^2} + \ln^2 \frac{\delta^2}{\mu^2} + \frac{\pi^2}{2} \right].$$

(3.8)

The virtual part of the TMDPDF at $O(\alpha_s)$ while using the relation in Eq. (3.5) is

$$F_{n1}^v = -\frac{1}{2} f_{n1}^{(3a)} + (3a)^* + J_{n1}^{(3)} + (3)^* - \frac{1}{2} \delta(1-x) S_{n1}^{(3c)} + (3c)^*$$

$$= \frac{\alpha_s C_F}{2\pi} \delta(1-x) \delta^{(2)}(\vec{k}_{n,\perp}) \left[ \frac{1}{\epsilon_{UV}} + \frac{1}{\epsilon_{UV}} \left( \frac{3}{2} + \ln \frac{\mu^2}{Q^2} \right) - \frac{3}{2} \ln \frac{\Delta}{\mu^2} - \frac{1}{2} \ln^2 \frac{\Delta}{Q^2 \mu^2} + \ln^2 \frac{\Delta}{\mu^2} + \frac{7}{4} - \frac{\pi^2}{3} \right].$$

(3.9)

As mentioned earlier, individual contributions to $F_{n1}^v$ have mixed divergences, however $F_{n1}^v$ itself is free from them. The $\Delta$-dependence that remains is pure IR, as can be seen from the matching with full QCD in Sec. 6.

3.2 Real Diagrams

The relevant diagrams for the real part of $F_n$ are shown in figs. (3) and (4). Diagram (3a) gives

$$f_{n1}^{(3a)} = \frac{\alpha_s C_F}{2\pi^2} (1-\varepsilon)(1-x) \frac{k_{n1T}^2}{|k_{n1T}^2 - i\Delta(1-x)|^2},$$

(3.10)
The sum of diagram (3b) and its Hermitian conjugate (3c) is
\[ \hat{J}_n^{(3b) + (3c)} = \alpha_s C_F \frac{2}{\pi^2} \frac{x}{(1-x) + i\delta/p^+} \left( \frac{1}{k_{nT}^2 - i\Delta(1-x)} \right) + h.c., \] (3.11)

Diagram (3d) is zero, since it is proportional to \( n^2 = 0 \).

For the real emission of soft gluons, diagrams (4a) and (4d) are zero, since they are proportional to \( n^2 = 0 \) and \( \pi^2 = 0 \) respectively. Diagram (4b) and its Hermitian conjugate (4c) give
\[ S^{(4b) + (4c)} = -\frac{\alpha_s C_F}{\pi^2} \frac{1}{k_{nT}^2 - \delta^2} \ln \frac{\delta^2}{k_{nT}^2}. \] (3.12)

Combining the above contributions according to Eq. (3.2), one gets the real part of the TMDPDF \( F_{n1} \) at \( \mathcal{O}(\alpha_s) \), which is free from rapidity divergencies. A detailed discussion about the remaining pure IR \( \Delta \)-dependence can be found in \([5]\).

4. Integrated PDF

In this section we briefly report the calculation of the integrated PDF at first order in \( \alpha_s \) with the \( \Delta \)-regulator. As it is shown below, the mixed divergencies will cancel when we combine virtual and real contributions, leading to the well-known IR collinear divergence of the PDF.

The virtual diagrams for the PDF are the same as for the naive collinear matrix element that enters into the definition of the TMDPDF, Fig. (1). Then we have
\[ \Phi^{(1)}_{n1} = \frac{\alpha_s C_F}{2\pi} \delta(1-x) \left[ \frac{1}{\epsilon_{UV}^2} + \frac{(3/2 + \ln \mu^2)}{\epsilon_{UV} Q^2} \right] - \frac{3}{2} \ln \frac{\Delta}{\mu^2} - \frac{1}{2} \ln^2 \frac{\Delta}{Q^2} + \ln^2 \frac{\Delta}{\mu^2} + \frac{7}{4} - \frac{\pi^2}{3} \]. (4.1)
The real diagrams are the same as in Fig. (3), from which we get

\[
\phi_{n^1}(\vec{p}) = \frac{\alpha_s C_F}{2\pi} (1-x) \left[ \frac{1}{\epsilon_{UV}} + \ln \frac{\mu^2}{\Delta} - 1 - \ln (1-x) \right],
\]

and

\[
\phi_{n^1}(\vec{p}, \vec{q}) = \frac{\alpha_s C_F}{2\pi} \left[ \left( \frac{1}{\epsilon_{UV}} + \ln \frac{\mu^2}{\Delta} \right) \left( \frac{2x}{(1-x)_+} - 2\delta (1-x) \ln \frac{\Delta}{Q^2} \right) - 2\delta (1-x) \left( 1 - \frac{\pi^2}{24} - \frac{1}{2} \ln \frac{\Delta}{Q^2} \right) + \frac{\pi^2}{2} \delta (1-x) \right] ,
\]

Diagram (3d) is zero since it is proportional to \( \pi^2 \).

Mixed divergencies \( \frac{1}{\epsilon_{UV}} \ln \frac{\Delta}{Q^2} \) (and also double IR poles \( \ln^2 \frac{\Delta}{Q^2} \)) are cancelled when we combine virtual and real contributions. The PDF to first order in \( \alpha_s \) is finally

\[
\phi_{n^1}(x; \mu) = \delta (1-x) + \frac{\alpha_s C_F}{2\pi} \left[ \mathcal{P}_{q/q} \left( \frac{1}{\epsilon_{UV}} - \ln \frac{\Delta}{\mu^2} \right) - \frac{1}{4} \delta (1-x) + (1-x) \right],
\]

where \( \mathcal{P}_{q/q} \) is the one-loop quark splitting function of a quark in a quark,

\[
\mathcal{P}_{q/q} = \left( 1 + \frac{x^2}{1-x} \right) = \frac{1 + x^2}{(1-x)_+} + \frac{3}{2} \delta (1-x) = \frac{2x}{(1-x)_+} + (1-x) + \frac{3}{2} \delta (1-x).
\]

The IR collinear divergence is encoded in the single logarithm \( \ln (\Delta/\mu^2) \), while the rest is a function of \( x \) that in general depends on the regulator used.

5. \( Q^2 \)-Dependence and Resummation

When \( k_T \gg \Lambda_{QCD} \) we can perform an operator product expansion (OPE) of the TMDPDF onto the integrated PDF,

\[
\tilde{F}_n(x; b, Q, \mu) = \int_x^1 \frac{dx'}{x'} \tilde{C}_n \left( \frac{x'}{x} ; b, Q, \mu \right) \phi_n(x' ; \mu) ,
\]

where

\[
\phi_n(x; \mu) = \frac{1}{2} \int \frac{dy^-}{2\pi} e^{-i\vec{y} \cdot \vec{x}} \langle p | \bar{Z}_n(0^+, y^-, \vec{0}_+) \frac{\pi}{2} \mathcal{X}_b(0^+, 0^-, \vec{0}_-) | p \rangle |_{zb \ \text{included}} ,
\]

and \( \tilde{C}_n \) is the matching coefficient that cannot depend on any IR regulator as mentioned before. In this section we compute \( \tilde{C}_n \) to first order in \( \alpha_s \).

The virtual part of the TMDPDF in momentum space was given in Eq. (4.1), and in impact parameter space it reads

\[
\tilde{F}_{n^1} = \frac{\alpha_s C_F}{2\pi} \delta (1-x) \left[ \frac{1}{\epsilon_{UV}^2} + \frac{1}{\epsilon_{UV}} \left( \frac{3}{2} + \ln \frac{\mu^2}{Q^2} \right) - \frac{3}{2} \ln \frac{\Delta}{\mu^2} - \frac{1}{2} \ln \frac{\Delta^2}{Q^2 \mu^2} + \ln \frac{\Delta}{\mu^2} + \frac{7}{4} - \frac{\pi^2}{3} \right].
\]
The Fourier transform of real-gluon emission diagrams given in Eqs. (3.10, 3.11, 3.12), while keeping the $\Delta$’s to regulate the nUV divergences, are

$$\tilde{f}_{n}^{\beta^{(h)}} = \frac{\alpha_s C_F}{2\pi} (1-x) \ln \frac{4e^{-2\gamma_E}}{\Delta (1-x) b^2},$$

(5.4)

$$\tilde{f}_{n}^{\beta^{(h)}} = \frac{\alpha_s C_F}{2\pi} \left[ \ln \frac{4e^{-2\gamma_E}}{\Delta b^2} \left( 2x \left( 1-x \right) - 2 \delta \left( 1-x \right) \ln \frac{\Delta}{Q^2} + \frac{\pi^2}{2} \delta \left( 1-x \right) ight) - 2 \delta \left( 1-x \right) \left( 1 - \frac{\pi^2}{24} - \frac{\ln^2 \frac{\Delta}{Q^2}}{2} \right) \right],$$

(5.5)

and

$$\tilde{f}_{n}^{\beta^{(h)}} = \frac{\alpha_s C_F}{2\pi} \left( \ln \frac{4e^{-2\gamma_E}}{\Delta b^2} + \frac{2\pi^2}{3} \right).$$

(5.6)

Finally, the TMDPDF in impact parameter space to first order in $\alpha_s$ is

$$\tilde{F}_n = \phi_n + \frac{\alpha_s C_F}{2\pi} \left[ - L_T \mathcal{P}_{q/q} \left( 1-x \right) - \delta \left( 1-x \right) \left( \frac{1}{2} L_T^2 - \frac{3}{2} L_T + L_T \ln \frac{Q^2}{\mu^2} + \frac{\pi^2}{12} \right) \right],$$

(5.7)

where $L_T = \ln(\mu^2 b^2 e^{2\gamma_E} / 4)$, $\phi_n$ is the PDF given in Eq. (4.4) and the remaining part is exactly the OPE matching coefficient

$$\tilde{C}_n(\alpha; b, Q, \mu) = \delta \left( 1-x \right) + \frac{\alpha_s C_F}{2\pi} \left[ - \mathcal{P}_{q/q} L_T \left( 1-x \right) - \delta \left( 1-x \right) \left( \frac{1}{2} L_T^2 - \frac{3}{2} L_T + \ln \frac{Q^2}{\mu^2} L_T + \frac{\pi^2}{12} \right) \right].$$

(5.8)

In the integrated PDF the mixed divergencies are canceled when we combine virtual and real diagrams. When we allow for a transverse separation also in the collinear matrix element, real diagrams do not cancel these divergencies of the virtual part. It is the soft function (square root) that does this job. Mixed divergencies in the virtual part of the collinear matrix element are canceled by the virtual part of the soft function; and the ones in the real part of the collinear are canceled by the real part of the soft function. All the remaining $\Delta$-dependence is pure IR.

The fact that the TMDPDF is free from rapidity divergencies allows us to extract and exponentiate its $Q^2$-dependence to all orders in the following way [5],

$$\tilde{F}_n(x; b, Q, \mu) = \left( \frac{Q^2 b^2}{4e^{-2\gamma_E}} \right)^{-D(\alpha_s, L_T)} \tilde{C}_n^Q(x; b, \mu) \otimes \phi_n(x; \mu),$$

(5.9)

where

$$\tilde{C}_n^Q(x; b, \mu) = \delta \left( 1-x \right) + \frac{\alpha_s C_F}{2\pi} \left[ - \mathcal{P}_{q/q} L_T + \left( 1-x \right) - \delta \left( 1-x \right) \left( \frac{1}{2} L_T^2 - \frac{3}{2} L_T + \frac{\pi^2}{12} \right) \right].$$

(5.10)

Given the renormalization group invariance of the hadronic tensor $\tilde{M}$ in impact parameter space,

$$\tilde{M} = H(Q^2/\mu^2) \tilde{F}_n(x; b, Q, \mu) \tilde{F}_n(z; b, Q, \mu),$$

(5.11)
we can establish the following relation between the anomalous dimension (AD) of the hard matching coefficient, $\gamma_H$, and the one of the TMDPDF, $\gamma_o$,

$$\gamma_o = -\frac{1}{2} \gamma_H = -\frac{1}{2} A(\alpha_s) \ln \frac{Q^2}{\mu^2} - \frac{1}{2} B(\alpha_s). \quad (5.12)$$

Notice that this relation allows us to extract the AD of the TMDPDF up to third order in $\alpha_s$ from the known $\gamma_H$ at three loops [18, 19]. And since $A(\alpha_s) = 2\Gamma_{\text{cusp}}(\alpha_s)$ to all orders in perturbation theory, we get also

$$\frac{dD(\alpha_s, L_T)}{d\ln \mu} = \Gamma_{\text{cusp}}(\alpha_s). \quad (5.13)$$

Our master equation for the quark unpolarized TMDPDF $\tilde{F}_{j/p}$ in impact parameter space is

$$\tilde{F}_{j/p}(x, b; Q^2, \mu = Q) = \sum_{q = u, d, s} \int_x^1 \frac{dx'}{x'} e_i^q \phi_{j/f}(x'; b, \mu) \phi_{j/p}(x'; \mu)$$

$$\times \exp \left\{ -D(b, \mu) \ln \frac{Q^2}{\mu^2} + \int_{\mu}^{\mu=Q} \frac{d\mu'}{\mu'} \left[ \gamma_n(\alpha_s(\mu'); \ln \frac{Q^2}{\mu'^2}) \right] \right\}. \quad (5.14)$$

6. Hard Part at $\mathcal{O}(\alpha_s)$

The hard matching coefficient for the $q_T$-dependent DY cross section is the same as the one for inclusive DY. As mentioned before, this matching coefficient at the higher scale $Q$ is obtained by matching the full QCD cross section onto the imaginary part of the product of two effective theory currents. This echoes the “subtraction method” in perturbative QCD.

We start by rewriting the cross section in a more useful way,

$$d\sigma = \frac{4\pi \alpha}{3N_c Q^2 s} \frac{dxdzdq^2}{2(2\pi)^4} \sum_q e_q^2 M(x, z; \bar{q}_\perp, Q),$$

$$M(x, z; \bar{q}_\perp, Q) = H(Q^2/\mu^2) \int d^2 k_{n\perp} d^2 \bar{k}_{\pi\perp} \delta^2(\bar{q}_\perp - \bar{k}_{n\perp} - \bar{k}_{\pi\perp}) \left[ \delta(1-x)\delta(\bar{q}_\perp) + O(\alpha_s^2) \right] + O(\alpha_s^2) \quad (6.1)$$

where $M$ is the hadronic tensor.

In QCD the virtual part of $M$ with the $\Delta$-regulator is

$$M'_{QCD} = \frac{\alpha_s C_F}{2\pi} \delta(1-x) \delta(1-z) \delta^2(\bar{q}_\perp) \left[ \left( \frac{2\ln^2 \Delta}{Q^2} - 3\ln \frac{\Delta}{Q^2} - \frac{9}{2} + \frac{\pi^2}{2} \right) \right]. \quad (6.2)$$

The above result can be simply obtained by considering the one-loop correction to the vertex diagram for $q\bar{q} \to \gamma^*$, with the inclusion of the WFR diagram while using the fermion propagators in Eq. (5.3).
The virtual part of $F_n$ at one-loop is given in Eq. (4.1), and we have an analogous result for $F_{\Pi}$. Using Eq. (6.1), the total virtual part of the hadronic tensor $M$ in the effective theory is

$$M_{\text{SCET}}' = H(Q^2/\mu^2) \frac{\alpha_s C_F}{2\pi} \delta(1-x) \delta(1-z) \delta^{(2)}(\vec{q}_\perp) \left[ \frac{2}{\epsilon_{\text{UV}}} + \frac{1}{\epsilon_{\text{UV}}} \left( 3 + 2\ln \frac{\mu^2}{Q^2} \right) - 2\ln^2 \frac{\Delta}{Q^2} - 3\ln \frac{\Delta}{Q^2} + 3\ln \frac{\mu^2}{Q^2} + \ln^2 \frac{\mu^2}{Q^2} + \frac{7}{2} - \frac{2\pi^2}{3} \right],$$

where the UV divergences are canceled by the standard renormalization process. We notice that the IR contributions in Eqs. (6.2) and (6.3) are the same, as they should, thus the matching coefficient between QCD and the effective theory at scale $Q$ is:

$$H(Q^2/\mu^2) = 1 + \frac{\alpha_s C_F}{2\pi} \left[ -3\ln \frac{\mu^2}{Q^2} - \ln^2 \frac{\mu^2}{Q^2} - 8 + \frac{7\pi^2}{6} \right].$$

The above result was first derived in [20]. We can also obtain the AD of the hard matching coefficient at $O(\alpha_s)$ and verify Eq. (5.12),

$$\gamma_H = -\frac{\alpha_s C_F}{2\pi} \left[ 6 + 4\ln \frac{\mu^2}{Q^2} \right] = -2\gamma_1.$$

It is clear that the IR divergences of full QCD are recovered in the effective theory calculation, Eq. (6.3). To get this one must use the same regulator in both theories and the way that one regulates the IR physics (or more generally, the nUV) in both sides have to be consistent. The matching coefficient at the higher scale depends only on the hard scale $Q^2$ as it should be.

**7. Gauge Invariance: $T$-Wilson Line**

One of the advantages of setting all the perturbative calculation on-the-light cone is that it is straightforward to show the gauge invariance of the relevant physical quantities. Below we derive the transverse gauge link, the $T$ Wilson line, that has to be included in the effective theory in order to accomplish the calculation of collinear and soft matrix elements in a gauge invariant way [21, 24].

First we recall some of the features of the gluon fields in QCD in light-cone gauge (LCG) [24]. To fix matters, we work in QCD with the gauge fixing condition $\pi A = 0$. The canonical quantization of the gluon field proceeds by inserting in the Lagrangian the gauge fixing term $\mathcal{L}_{gf} = \Lambda^a (\bar{\pi} A^a)$.

The $\Lambda^a$ is a field whose value on the Hilbert space of physical states is equal to zero. It is possible to write the most general solution of the equation of motion of the boson field $A^a_\mu$ by decomposing it as

$$A^a_\mu (k) = T^a_\mu (k) \delta (k^2) + \pi^a_\mu \frac{\delta (\bar{\pi} k)}{k_\perp} \Lambda^a (nk, k_\perp) + \frac{i k_\mu}{k_\perp} \delta (\bar{\pi} k) U^a (nk, k_\perp),$$

where the field $T^a_\mu$ is such that $\pi^a_\mu T^a_\mu (k) = 0$ and $k^\mu T^a_\mu (k) = 0$. Fourier transforming this expression we see that in general the field $A^a_\mu (x)$ has non-vanishing “−” and “⊥” (respectively $nA^a_\mu (x)$ and $A^{a,\perp}_\mu (x)$) components when $x^+ \to \pm \infty$. Now we define

$$A^{(\omega)} (x^+, x_\perp) \overset{\text{def}}{=} A (x^+, \infty^-, x_\perp),$$

$$\tilde{A} (x^+, x_\perp) \overset{\text{def}}{=} A (x^+, x^-, x_\perp) - A^{(\omega)} (x^+, x_\perp).$$

12
and get
\[ iD_\perp = i\partial_\perp + gA_\perp = i\partial_\perp + g\tilde{A}_\perp + gA_\perp^{(\infty)} = i\tilde{D}_\perp + g\tilde{A}_\perp^{(\infty)}. \] (7.3)
Taking into account that the fields \( \tilde{A}_\perp \) and \( A_\perp^{(\infty)} \) in Eq. (7.4) are evaluated at space-like separated points then one can show that
\[ iD_\perp = Ti\tilde{D}_\perp T^\dagger, \] (7.4)
where
\[ T^\dagger = P \exp \left[ -ig \int_0^\infty d\tau l_\perp \cdot A_\perp^{(\infty)}(x^+, x_\perp - l_\perp \tau) \right], \] (7.5)
This equation leads us automatically to include the \( T \)-Wilson line at the level of the soft-collinear effective theory (SCET) Lagrangian. Moreover \( 1/\pi\partial \) and \( T \) commute because the \( T \)-Wilson line does not depend on \( x^- \). Under gauge transformation \( \delta A_\mu^{(\infty)} = D_\mu \omega \) one has \( T(x^+, x_\perp) \rightarrow U(x^+, x_\perp)T(x^+, x_\perp)U^\dagger(x^+, x_\perp - l_\perp \infty) = U(x^+, x_\perp)T(x^+, x_\perp) \) since \( A_\mu^{(\infty)}(x^+, \infty_\perp) = 0 \). Notice also that the \( T \)-Wilson lines are independent of \( l_\perp \).
Now we split the fermion field into large and small components using the usual projectors \( \eta \pi / 4 \) and \( \pi \eta / 4 \) and eliminate the small components using the equations of motion [25]. The result of this is
\[ \mathcal{L} = \bar{\xi}_0 \left( inD + i\tilde{D}_\perp \frac{1}{imD} i\tilde{D}_\perp \right) \frac{\pi}{2\sin}. \] (7.6)
In QCD and in LCG with the gauge condition \( \pi A = 0 \) we get
\[ \mathcal{L} = \bar{\xi}_0 \left( inD + Ti\tilde{D}_\perp \frac{1}{imD} i\tilde{D}_\perp T^\dagger \right) \frac{\pi}{2\sin}. \] (7.7)
In order to get the SCET Lagrangian we must implement multipole expansion and power counting on the fields that appear in Eq. (7.5). In SCET we have also the freedom to choose a different gauge in the different sectors of the theory. We distinguish the cases of SCET-I and SCET-II. The two formulations differ essentially in the scaling of the soft sector of the theory. Here we are interested in the different sectors of the theory. We distinguish the cases of SCET-I and SCET-II. The two formulations differ essentially in the scaling of the soft sector of the theory. Here we are interested in SCET-II which is the effective theory necessary for the Drell-Yan \( q_T \)-spectrum where \( q_T \) is much larger than \( \Lambda_{\text{QCD}} \) and much smaller than \( Q \). The collinear modes we have in In SCET-II scale as \( (\pi k, nk, k_\perp) \sim Q(1, \eta^2, \eta) \) where \( \eta \ll 1 \) and the soft modes as \( (\pi k, nk, k_\perp) \sim Q(\eta, \eta, \eta) \). Collinear and soft gluon fields’ components scale accordingly.
The soft sector of SCET-II has peculiar features. In regular gauges soft partons do not interact with collinear ones because the interactions knock the collinear fields far off-shell. This is also true in light-cone gauge except when one makes the choice \( nA_\perp = 0 \) (take here a covariant gauge for collinear fields for fixing ideas). It is easy to be convinced that interactions like \( \prod_\nu \phi_\nu(x)A_\perp^{(\infty)}(x, x_\perp^\nu) \), where here “\( \infty \)” refers to the \( + \) direction and \( \phi_\nu(x) \) are generic collinear fields, preserve the on-shellness of the collinear particles. Using multipole expansion the vertex becomes \( \prod_\nu \phi_\nu(x)A_\perp^{(\infty)}(0^-, x_\perp^\nu) \) (because for collinear fields \( x^- \sim 1 \) and for the soft field \( x^- \sim 1/\eta \)). In this gauge the covariant derivative for collinear particles becomes \( iD_\mu^\nu = i\partial_\mu + gA_\mu^\nu(x) + gA_\perp^{(\infty)}(0^-, x_\perp^\nu) \). The gauge ghost \( A_\perp^{(\infty)} \) however can be decoupled from collinear gluons defining a
“soft free” collinear gluon $A_n^{(0)}(x) = T_{sn}(x_\perp) A_n^\mu(x) T_{sn}^\dagger(x_\perp)$ where

$$T_{sn} = \bar{p} \exp \left[ ig \int_0^\infty d\tau l_\perp \cdot A_{n\perp}^{(\infty)}(0^-, x_\perp - l_\perp \tau) \right].$$  \hspace{1cm} (7.8)

Defining $D_n^{(0)} = i\partial^\mu + gA_n^{(0)}\mu$ we have $i\tau l_\perp D_{n\perp} = T_{sn}(x_\perp)i\tau l_\perp D_{n\perp} T_{sn}^\dagger(x_\perp)$ and

$$\mathcal{L} = \xi_n^{(0)} \left( i n D_n^{(0)} + i p_{n\perp} W_n^{T(0)} \frac{1}{i\tau} W_n^{T(0)\dagger} i p_{n\perp} \right) \frac{\bar{p}}{2} \xi_n^{(0)},$$  \hspace{1cm} (7.9)

where $\xi_n^{(0)} = T_{sn}(x_\perp) \bar{\xi}_n(x)$ and $W_n^{T(0)} = T_n^{(0)\dagger} W^{(0)}$ are made out of soft free gluons. Thus, and thanks to $T_{sn}$ Wilson lines, the soft partons are completely decoupled from the collinear ones.

With the existence of the $T$-Wilson lines it is possible now to compare the one-loop contributions in both Feynman gauge and LCG. This comparison can be performed at the level of the integrands without the need to perform any actual calculations.

In light-cone gauge we use the ML prescription [23], which is the only one consistent with the canonical quantization of QCD in this gauge [24]. Moreover in the $n$ and $\pi$ collinear sectors the only gauge fixings compatible with the power counting of the collinear particles are respectively $\pi A_n = 0$ and $n A_n = 0$, which correspond to “killing” the highly oscillating component of the gluon field in each sector. We now compare the integrals that we have evaluated in Feynman gauge with the corresponding ones in light-cone gauge.

The interesting contribution to the collinear part of the TMDPDF in Feynman gauge is provided by the $W_n$ Wilson line and it is (cfr. Eq. (3.7))

$$f_n^{(0)}(\text{Feyn}) = -\delta(1-x)\delta^{(2)}(\bar{k}_{n\perp}) 2ig^2 C_F \mu^{2\epsilon} \int \frac{d^d k}{(2\pi)^d} \frac{1}{(k^2 + i0)(k^+ + i0)} \frac{p^+ + k^+}{(p + k)^2 + i0}. \hspace{1cm} (7.10)$$

In light-cone gauge this result is reproduced when one combines the axial part of the WFR

$$f_n^{(0)}(\text{Ax}) = \delta(1-x)\delta^{(2)}(\bar{k}_{n\perp}) 4ig^2 C_F \mu^{2\epsilon} \int \frac{d^d k}{(2\pi)^d} \frac{1}{(k^2 + i0)} \frac{p^+ + k^+}{(p + k)^2 + i0} \left[ \frac{\theta(k^-)}{k^+ + i0} + \frac{\theta(-k^-)}{k^- - i0} \right], \hspace{1cm} (7.11)$$

with the contribution of the $T$ Wilson line

$$f_n^{(0)}(T) = -\delta(1-x)\delta^{(2)}(\bar{k}_{n\perp}) 2ig^2 C_F \mu^{2\epsilon} \int \frac{d^d k}{(2\pi)^d} \frac{1}{(k^2 + i0)} \frac{p^+ + k^+}{(p + k)^2 + i0} \theta(k^-) \left[ \frac{1}{k^+ - i0} - \frac{1}{k^- + i0} \right]. \hspace{1cm} (7.12)$$

It is clear that $f_n^{(0)}(\text{Feyn}) = f_n^{(0)}(T) - f_n^{(0)}(\text{Ax}) / 2$. In SCET there is also a tadpole diagram that needs to be considered however it is null in light cone gauge since the gluon field does not propagate at infinity [21]. Similar considerations hold for Feynman diagrams with real gluon contributions and for the soft sector [8].

As a final remark, it is not so obvious how one can implement light-cone gauge calculations while going off-the-light-cone.
8. Conclusions

We have argued that to properly define the TMDPDF, one needs to include the soft factor (a square root of it). With this inclusion the TMDPDF can be renormalized and it captures all the IR of full QCD when it is introduced in a properly obtained factorization theorem. We argued that one does not need to introduce any of the “off-the-light-cone” contributions, while still being able to resum large logarithms, thus avoiding the use of the Collins-Soper evolution equation.

The evolution of the TMDPDF has been discussed and the $Q^2$-resummation at the intermediate scale was explained. That was achieved under the assumption of identical treatment of two collinear sectors and it was mainly based on the fact that the TMDPDF is free from rapidity divergences.

The conclusions above are independent of the set of regulators that one uses for the nUV. Moreover, if one is consistent with the regularization of nUV divergencies in the theories above and below a certain relevant scale, then the matching coefficients will be independent of this set of regulators.

We also discussed the relevance of the $T$-Wilson line and their contribution to render hadronic matrix elements gauge invariant. Contrary to many existing statements in the literature, those Wilson lines are crucial for the gauge invariance to hold. Finally, all this effort can be extended to the proper definition and treatment of polarized quark and gluon TMDs, which are important ingredients in order to get information about the inner structure of the nucleons.
