Abstract: The objective of this study is to present new empirical findings about the economics of informally supplied health care with special emphasis on the labor market-related opportunity cost and to measure the burden of informal caregiving for the inpatient at Lemlem Karl hospital, Maichew, Ethiopia. The study employs ordinary list square and ordered logit method of regression. In addition, the study also employed measurement mechanisms like; opportunity cost, proxy good and Zarit Burden Scale. The mean time spent on informal caregiving was 73.18 hours/4.1days and the mean cost of informal caregiving for the inpatient at Lemlem Care Hospital by using the opportunity cost and proxy good valuation method is 689.56birr (23.74$) and 724.653 birr (24.5$) per 4.1 days respectively. The study also measures caregiver’s burden level by using Zarit Burden Scale and the result depict that of the total respondents 51 (38.06%) affected by moderate caregiving burden and followed by 41 (30.60%) of the respondents with little caregiving burden. To reduce the cost and burden of principal informal caregivers and to fill this gap the following policy recommendations are made based on the findings of the study and the experience of the rest of the world. Enable informal caregivers to balance personal and social life with care responsibilities through respite care, develop and deploy a national caregiving strategy and the strategy should at a minimum include three policies; (a) Policy Related to Workplace Accommodation; (b) Financial Assistance policy; (c) Investment in informal caregiving research and development related projects.

Keywords: Economic Cost, Informal Care, Burden, Opportunity Cost, Inpatient, Proxy Good and Ethiopia

1. Introduction

Caregivers can be formal and informal. Formal caregivers are health-care professionals (HCPs) including nurses, personal support workers, rehabilitation specialists, and physicians who, are paid for the care and support they provide to the patients or clients. Informal caregivers are relatives, friends, or neighbors who provide unpaid practical support for those in need of assistance [1]. Unlike professional, informal caregivers, typically family members or friends, provide care to individuals with a variety of conditions including advanced age, dementia, and cancer. This experience is commonly perceived as a chronic stressor, and caregivers often experience negative psychological, behavioral, and physiological effects on their daily lives and health [2].

Caregiving is a complex and multidimensional activity, the nature and determinants of which evolve over time [3]. Different researchers and institutions define the term informal care and the people who provide informal care for those in need of assistance differently. [4] defines caregiving as “the provision of personal services to meet the physical and mental needs that allow a person to function at a socially
Informal caregivers have an important, yet ambiguous, role in economic evaluation but minimizing the negative economic and health consequences of caregiving for caregivers requires a multidisciplinary approach that integrates the tools of both economics and health sciences to conduct research that informs the development, implementation, and evaluation of appropriate and effective social policy [8].

The general objective of this study is to present new empirical findings of the economics of informally supplied health care with special emphasis on the labor market-related opportunity cost and to measure the burden of informal caregiving for the inpatient at Lemlem Karl hospital, Maichew, Ethiopia. Having the above general objective; this research has also the following specific objectives like: to measure the cost and burden of informal caregiving, to analyze the impact of gender on the cost and burden of informal caregiving, to investigate the impact of socioeconomic status on the cost and burden of informal caregiving and to investigate the relationship between the cost and burden of informal caregiving.

Information about the cost and burden of informal caregiving is important because strategies directed at caregivers are likely to be more successful if they target modifiable determinants of the caregiving burden and address specific caregiver needs. Knowledge of these determinants would also help to identify caregivers most at risk of poor outcomes and deliver specific interventions at the appropriate time [3].

Research which focuses on informal caregiver’s opportunity cost and the burden is useful for health, social and labor policy of the given country under study. It is important for the health policy because a decline in the supply of informal care would increase the demand for alternatives that are costlier (require a huge expenditure) from a health care budget perspective. It is important for social policy because knowledge of the determinants of the supply of informal care is crucial for the development of effective social policy programs [7]. It is also important for labor policy because such research will have a positive effect on the development of incentives for informal caregivers such as care leave facilities. Thus, the immediate outcome of this study provides pertinent result and policy implication to policymakers. Besides, we believe that the study will add something to the existing stock of knowledge and provoke or initiate for further study in the area as it reveals the difficulty in resolving the empirical question about the cost of informal caregivers for the inpatient.

2. Materials and Methods

The type of data employed in this research is cross-sectional data and all the respondents are principal informal caregivers i.e. they are likely to provide most hours of informal care and to coordinate the care provided by other informal caregivers [7].

Specification of the Model and Description of the
Variables.

Care recipient, caregiver, and household characteristics may determine caregiver outcomes [8]. The level of care required by the care recipient is a major factor that influences the caregiver’s life and health effects [2]. In short, factors associated with caregiver outcomes can be divided into three categories: 1) characteristics of the caregiver, 2) characteristics of the patient, and 3) characteristics of the care situation [11].

Background characteristics of the caregiver that may influence caregiver outcomes include age, gender, living situation, socioeconomic status, and type and quality of the relationship between the care recipient and caregiver. Patient characteristics that have been cited in the literature as having an influence on caregiver outcomes include disease-related and treatment-related characteristics, dependency, and physical and psychologic symptoms. Care characteristics may include duration of care, intensity of care, and different types of care. The more confining the care tasks are (i.e., the less time-flexible and the more disruptive they are to the caregiver’s schedule), the more likely they are to create negative consequences. Moreover, because providing care requires time, the time available for other activities such as household chores, leisure, and visiting family and friends may be expected to decrease [11].

2.1. Specification of the Model

Model one (opportunity cost valuation method) through OLS.

\[ VIC_i = \beta_0 + \beta_1\text{APC} + \beta_2\text{EXP} + \beta_3\text{ICGHPD} + \beta_4\text{LS} + \beta_5\text{NEC} + \beta_6\text{HHS} + \beta_7\text{DSEX} + \beta_8\text{DMS} + \beta_9\text{Doutofmaichew} + \beta_{11}\text{DUR} + \beta_{12}\text{EDU} + \beta_{13}\text{SCR} + \epsilon_i \]

In this model, we calculate the value of informal care (VIC) by using the opportunity cost valuation method.

Model Two (proxy good valuation method)

\[ VIC_i = \text{Value of informal care} \]

Model two proxy good valuation Method.

In this model, we calculate the value of informal care (VIC) by using the proxy good valuation method.

Model Three (through Ordinal logistic regression)

The ordinal logistic regression model can be expressed as a latent variable model [12]. Assuming a latent variable model exists, \( y_i \sim x\beta + \epsilon \), can be defined where \( x \) is a row vector (1* k) containing no constant, \( \beta \) is a column vector (k*1) of structural coefficients, and \( \epsilon \) is random error with standard normal distribution: \( \epsilon \sim N (0,1) \).

\[ y_i \sim x\beta + \epsilon, \epsilon \sim N (0,1) \]

\[ ICGBi = \beta_0 + \beta_1\text{ICGHPD} + \beta_2\text{LS} + \beta_3\text{NEC} + \beta_4\text{APC} + \beta_5\text{D SEX} + \beta_6\text{D Area} + \beta_7\text{D employment} + \beta_8\text{D Satisfaction} + \beta_9\text{D Ability} + \epsilon_i \]

2.2. Description of the Variable

| Name            | Description of the variable                                                                 |
|-----------------|---------------------------------------------------------------------------------------------|
| VICi            | is the value of informal care of the principal informal caregiver i per 4.1 days, because the average length of stay at Lemlem Karl Hospital is 4.1 days. The VIC will be calculated by using the two revealed preference valuation methods (opportunity cost and proxy good valuation method). \( VIC = \beta_iW_i \). Where, \( \beta_i \) is the number of hours spent on informal caregiving task by the principal caregivers i and \( W_i \) is wage per hour of the given person or the proxy for wage. |
| APC             | is for the age of the principal caregiver                                                    |
| EXP             | is for the Job experience of principal caregiver                                              |
| ICGHPD          | Average Informal caregiving hours per day                                                     |
| LS              | Length of stay in the hospital with the inpatient                                             |
| NEC             | is number of external caregivers                                                            |
| HHS             | stands for the household size of the inpatient                                               |
| DSEX            | is dummy variable which stands for the gender of principal caregivers                        |
| DMS             | is categorical variable which stands for the marital status of principal informal caregivers |
| D out of maichew| is dummy variable which stands for principal caregivers who are from out of maichew town   |
| D out of maichew| D out of maichew=1 if they are not from maichew                                              |
| D out of maichew| D out of maichew=0 otherwise                                                                 |
| D out of maichew| D out of maichew=1 if they are not from maichew                                              |
| D out of maichew| D out of maichew=0 otherwise                                                                 |
is dummy variable which stands for principal caregivers from urban area

\[ DUR = 1 \text{ if the principal informal caregiver is from urban area} \]
\[ DUR = 0 \text{ otherwise (if the principal informal caregiver is from rural area)} \]

stands for the educational level of principal caregivers (categorical variable)

\[ D \text{ illiterates} \] dummy variable, which stands for illiterate principal informal caregivers
\[ D \text{ primary} \] is dummy variable for principal informal caregivers with primary education level
\[ D \text{ secondary} \] is dummy variable for principal informal caregivers with secondary education level
\[ D \text{ certificate} \] dummy variable for certificate/diploma holder principal informal caregivers
\[ D \text{ degree} \] is base group, which stands for Degree and above Degree holder principal informal caregivers

is dummy variable which stands for the sex of informal care recipient

\[ D\text{fcr} = 1 \text{ if the informal care recipient is female} \]
\[ D\text{fcr} = 0 \text{ otherwise (if the informal care recipient is female)} \]

is dummy variable, which stands to indicate the informal care recipient ability

\[ D \text{ disable} = 1 \text{ if the informal care recipient is not able move (walk)} \]
\[ D \text{ disable} = 0 \text{ otherwise} \]

dummy, which stands for informal caregiver’s area

\[ D \text{ rural} = 1 \text{ if the informal care giver is from rural area of southern Tigray} \]
\[ D \text{ rural} = 0 \text{ otherwise} \]

dummy, which stands for the employment status of the principal informal caregivers

\[ D \text{ employed} = 1 \text{ if the respondent is employed} \]
\[ D \text{ employed} = 0 \text{ if not (unemployed)} \]

dummy, which stands for respondent’s satisfaction by the service of Lemlem Karl hospital for principal informal caregivers

\[ D \text{ satisfied} = 1 \text{ if the respondent is satisfied by the service of the hospital} \]
\[ D \text{ satisfied} = 0 \text{ otherwise} \]

3. Data Presentation and Analysis

3.1. Descriptive Statistics

Using survey method one hundred thirty-four (134) informal caregivers and informal care recipient were studied about their personal socioeconomic background. Out of the total respondents (principal informal caregivers) 41 (30.60%) are from the rural area while 93 (69.40%) are from the urban areas of the study area. Of the total respondents 80 (59.7%) are female, the rest 54 (40.3%) are male. The survey result depicts that 71 (52.98%) of the respondents are between the age of 31 to 45 years. The remaining 45 (33.58%) and 18 (13.42%) of the respondents fallen below 30 years and above 45 years respectively.

With regards to the educational level of principal informal caregivers, the majority 64 (47.7%) of the respondents are illiterate while 13 (9.7%), 16 (11.9%) of the respondents attended primary and secondary school education respectively. The remaining respondents 19 (14.7%) and 22 (16.4%) attended certificate and degree/above degree educational level respectively. On the other hand, the data shows that the majority, which is 97 (72.38%), are married followed by single principal informal caregivers 29 (21.64%) and the remaining 5 (3.73%) and 3 (2.23%) respondents are divorced and widowed respectively.

When we see the health status of informal care recipient, 32.83% of respondents are with slight health problem, 23.88% have moderate health problem, 39.55% of respondents have sever health problem and the rest 3.73% are with extreme health problem. Concerning the movement ability of informal care recipient, the majority which is 74 (55.22%) of them are movable and the rest 60 (44.77%) are disable.

The study also measures caregiver’s burden level by using Zarit Burden Scale and the result depict that of the total respondents the majority which is 51 (38.06%) affected by moderate caregiving burden and followed by 41 (30.60%) of the respondents with little caregiving burden. The remaining 30 (22.39%) and 12 (8.96%) of the respondents are affected by sever and mild informal caregiving burden respectively.

The mean time spent on informal caregiving was 73.18 hours/4.1days and the mean cost of informal caregiving for the inpatient at Lemlem Care Hospital by using the opportunity cost and proxy good valuation method is 689.56birr (23.74$) and 724.653 birr (24.5$) per 4.1 days respectively. From gender perspective the mean cost of informal caregiving by female respondent is 605.9 (20.89$) and 760.13 (26.17$) as calculated with opportunity cost and proxy good valuation method. Whereas the mean value of informal caregiving by male respondents is 685.33 (23.59$) and 567.06 (19.52$) as calculated with opportunity cost and proxy good valuation method.

3.2. Econometric Result and Interpretation

3.2.1. OLS Regression Result Interpretation

Out of the total independent variables age (APC), length of stay (LS), number of external caregivers (NEC), household size (HHS), marital status, area dummy (D rural) of the
respondent are not significant. However, the remaining variables like paid job experience, informal caregiving hours per day, gender dummy (DF), area dummy (informal variables like paid job experience, informal caregiving hours * indicates statistical significance at 1%, 5% and 10% respectively. 

The dummy for sex of the informal caregivers is found negative and significant at 5%. That is, other things remain constant; if the informal caregiver is female respondent then her cost of informal care will be lower from that of male respondents by 23%.

### Table 1. OLS regression result.

| Invic (Robust) | Coef. | Std. Err. | t | P>|t| | [95% Conf. Interval] |
|----------------|-------|-----------|---|-----|-----------------|

* ** *** indicates statistical significance at 1%, 5% and 10% respectively.

This means, the cost of informal caregiving of male respondent is higher than female respondent does. Other things remain constant as the paid job experience of the respondent increase by one year on average his/her informal caregiving cost will increase by 7.81%. Concerning informal caregiving hour, the variable (ICGHPD) is significant at 1% and as the daily informal caregiving hour increase by an hour, on average the value of informal care will increase by 9.55%.

As it is presented in the description of the study area parts Lemlem Karl Hospital, provide its service for both the Maichew and the surrounding southern Tigray catchment area population. This study found that the area of principal informal caregiver is statistically significant at 10%. Other things remain constant if the principal informal caregiver is from Maichew city his/her value of informal care will be higher than from that of principal caregivers from the surrounding southern Tigray by 27.61%.

When we see the impact of educational level on informal caregiving cost, it is statistically significant at 1%. Within the educational level, we have five categories, which include illiterate, primary educational level, secondary educational level, certificate/diploma level and principal informal caregivers with a degree and above degree educational level. In the above OLS regression degree and above degree holder principal informal caregivers are considered as the base group and all other principal caregivers with the remaining educational level are compared with them. The above OLS regression result depict that if the principal informal caregiver is illiterate then his/her value of informal care will be lower than with that of the degree holder principal caregiver by 79%, if the principal informal caregiver is with primary educational level then his/her cost of informal care per 4.1 days will be lower than with that of the degree holder principal caregiver by 104.2%, if the principal informal caregiver is with secondary educational level then his/her value of informal care will be lower from degree and above degree holder principal informal caregiver by 71% and if the principal informal caregiver is with certificate/diploma level then his/her value of informal care will be lower from degree and above holder principal informal caregiver by 47%.

Concerning the relationship between the movement ability of informal care recipient and the cost of informal care incurred by principal informal caregivers it is statistically significant at 10%. Other things remain constant principal informal caregivers who provide informal care for disable inpatient will incur 14% higher informal care giving cost compared to informal caregivers who provide informal care for inpatients with movement ability.
3.2.2. Estimation of Order Logit Regression Model and Analysis

In this part of the study, we gave a great emphasis for informal caregiving burden level through our order logit regression models with statistically significant variables and interpreting them by taking their simple logit coefficient initially and then odds ratio and marginal effects of the outcomes categorical variables respectively.

### Table 2. Ordered logistic regression.

|       | Coef.  | Std. Err. | z      | P>|z|  | [95% Conf. Interval] |
|-------|--------|-----------|--------|------|---------------------|
| ICGHPD| .0243325 | .020754 | 1.21   | .225 | -.0150144 to .0636795 |
| LS    | -.0413076 | .0285777 | -1.45 | .148 | -.097319 to .0147038 |
| NEC   | .0997862 | .1557533 | .64   | .522 | -.2054846 to .405071 |
| APC   | -.104395* | .0210805 | -4.95 | .000 | -.1457121 to .0630779 |
| Df    | .1644412 | .364629 | 0.45   | .652 | -.5502185 to .8791008 |
| D rural | .7649112*** | .4019318 | 1.90 | .057 | -.0228606 to 1.552683 |
| D employed | 1.386791* | .4251019 | 3.26 | .001 | .5536063 to 2.219975 |
| D satisfied | -.8316471** | .3615734 | -2.30 | .021 | -1.540318 to -1.129762 |
| D disable | .4313643 | .357204 | 1.21 | .227 | -.2688728 to 1.131601 |
| /cut1 | -.3.25593 | .8338596 | -4.95 | .000 | -.4.900664 to -.1.611795 |
| /cut2 | -.2.747142 | .8267062 | -2.30 | .021 | -4.367457 to -1.126828 |
| /cut3 | -.5.812665 | .7900235 | -2.30 | .021 | -2.129684 to .967151 |

In the above ordered logistic regression, we first see the iteration log. At iteration 0, Stata fits a null model, i.e., the intercept-only model. It then moves on to fit the full model and stops the iteration process once the difference in log likelihood between successive iteration becomes sufficiently small. The final log likelihood (-147.18315) is displayed again. Also at the top of the output, we see that all 134 observations in our data set were used in the analysis. The likelihood ratio chi-square of 48.99 with a p-value of 0.0000 tells us that our model as a whole is statistically significant, as compared to the null model with no predictors. The pseudo R-squared of 0.1427 is also given.

Out of the total independent variables, age of principal informal caregivers (APC), dummy, which stands for respondents from rural area (Drural), dummy, which stands for employed respondents (Demployed) and dummy, which stands for respondents who are satisfied by the service of Lemlem Karl hospital for principal informal caregivers (Dsatisfied) are statistically significant at 1%, 10%, 1% and 5% respectively.

For age of principal informal caregivers (APC), we would say that for a one-year increase in age, we expect 0.104395 decrease in the log odds of being in higher level of informal caregiving burden, given all of the other variables in the model are held constant. If the respondent is from rural area (Drural), we expect 0.7649112 increase in log odds of being in higher level of informal caregiving burden compared to informal caregivers from urban parts of southern Tigray. If the respondent is employed (Demployed), we expect 1.386791 increase in log odds of being in higher level of informal caregiving burden compared to unemployed respondents. If the respondent is satisfied by the service of Lemlem Karl Hospital for principal informal caregivers (Dsatisfied), the regression result depicts 0.8316471 decrease in log odds of being in higher level of informal caregiving burden compared to unsatisfied respondents.

### Table 3. Ordered logistic regression (odds ratio).

|       | Odds Ratio | Std. Err. | z     | P>|z|  | [95% Conf. Interval] |
|-------|------------|-----------|-------|------|---------------------|

In the output above the results are displayed as proportional odds ratios. For age of principal informal caregivers (APC), we would say that for a one-year increase in age, the odds of being in the sever level of informal caregiving burden versus the combined moderate, mild and little categories are 0.9008 greater, given that all of other variables in the model remain constant. Likewise, the odds of the combined mild moderate and sever burden level versus little burden level is 0.9008 times greater compared to unemployed respondents, given that other variables in the model held constant. If the respondent is satisfied with the service of Lemlem Karl Hospital for principal informal caregivers (Dsatisfied), we can expect that the odds of the sever burden level versus the little, mild and moderate burden level are 4.001986 times greater compared to unsatisfied respondents, given that other variables in the model held constant. If the respondent is employed (Demployed), the regression result depicts the odds of the sever burden level versus the little, mild and moderate burden level are 4.001986 times greater compared to unemployed respondents, given that other variables in the model held constant. If the respondent is from rural area (Drural), the regression result depicts the odds of the sever burden level versus the little, mild and moderate burden level are 2.148804 times greater compared to informal caregivers from urban parts of southern Tigray, given that other variables in the model held constant. If the respondent is employed (Demployed), the regression result depicts the odds of the sever burden level versus the little, mild and moderate burden level are 4.001986 times greater compared to unemployed respondents, given that other variables in the model held constant. If the respondent is from rural area (Drural), the regression result depicts the odds of the sever burden level versus the little, mild and moderate burden level are 4.001986 times greater compared to unemployed respondents, given that other variables in the model held constant.

Informal caregiving is routine and ongoing. It arises out of a relationship with the informal care recipient in response to the demand for support which is greater than normally expected level due to their inability. Informal caregivers support with the tasks that recipients are unable to do for themselves. These may involve undertaking personal care household, financial and administrative tasks, helping with mobility, along with emotional support and companionship. Caregiving may also include some nursing activities. The caregiver role varies with the age and nature of the impairment of the care recipient (in our case the inpatient), as compared to urban informal caregivers, respondents from rural area of south Tigray,1395398 (13.95%) less likely to be affected by little informal caregiving burden, 0.0205324 (2.05%) more likely to be in little informal caregiving burden level, 0.0882816 (8.82%) less likely to be affected by sever informal caregiving level, 0.0450868 (4.5%) less likely to be in mild informal caregiving burden level, 0.0172515 (1.72%) less likely to be affected by sever informal caregiving level and 0.0024993 (0.25%) less likely to be in severe informal caregiving burden level.

Comparing to urban informal caregivers, respondents from rural area of south Tigray,1395398 (13.95%) less likely to be affected by little informal caregiving burden, 0.0205324 (2.05%) more likely to be in little informal caregiving burden level, 0.0882816 (8.82%) less likely to be affected by sever informal caregiving level, 0.0450868 (4.5%) less likely to be in mild informal caregiving burden level, 0.0172515 (1.72%) less likely to be affected by sever informal caregiving level and 0.0024993 (0.25%) less likely to be in severe informal caregiving burden level.
attending to any shortfall not provided by paid health care workers from the health care institutions [13].

In most countries, informal care forms a major share of the healthcare and serves as a basis of many community-based healthcare services and is a major aspect of their feasibility it is not reflected in social statistics or little economic information exists about such care because informal care is a less visible part of care both in terms of costs and effects. Even though informal caregivers mostly serve without any payment, care provision can still come at a certain cost and burden. Moreover, it has often been ignored in economic evaluations and policymaking [14, 7].

Using conservative assumptions, this paper suggests that the effort made by informal carers is considerable with great value. In size, its value is comparable to, or exceeds, the value of care provided formally by the health care institutions. Beside the burdens of informal caregiving, the time spent on caring can reduce labor supply and, thus, can reduce output. Nonetheless, attempts to measure this cost are at a primitive stage specifically in Africa where Ethiopia belongs. Further research is needed [15].

4.2. Recommendation

Reducing the cost and burden of informal caregiving for the inpatients should be a critical agenda for the government as the increased cost and burden on caregivers is likely to lead to the costlier institutionalization of care recipients [16]. In the case of Ethiopia, there is no formal policy intended to support informal caregivers and to reduce the cost and burden of principal informal caregivers and to fill this gap the following policy recommendations are made based on the findings of the study and the experience of the rest of the world.

Enable informal caregivers to balance personal and social life with care responsibilities: To reduce the burden of principal caregivers we need to introduce a temporary institutional care for the inpatients, providing relief for their usual informal caregivers (respite care) and through this system there is a possibility to care for the caregivers. In short respite care services provide a break for caregivers.

Develop and deploy a national informal caregiving strategy: This strategy should explicitly and systematically focus on the reduction of the cost and burdens of principal informal caregivers or it should have details on how to exploit the nation’s systems for health care, workplaces, and long-term services aspects of the informal caregivers and to support the principal informal caregivers health, values, and social and economic well-being, as well as to address the needs of the increasingly culturally and ethnically diverse caregiver population. Besides, the strategy should at a minimum include the following three policies:

A. Policy Related to Workplace Accommodation: Enable work-life balance for employed caregivers by flexible scheduling and this can be achieved through Leave for caregivers (short & long term or paid & unpaid care leave), Flexible work arrangements (providing careers sufficient income and a social network through work).

B. Financial Assistance policy: adopt federal policies that provide economic support for working and nonworking caregivers to offset the costs of caregiving, lost wages, and other related costs of the principal informal caregivers. This support may be given through caregiver’s allowance (Payments to people from low-income groups who are looking for a person who needs support), cash for care benefit to inpatients (for those in-patients who do not have families) or through unemployment benefit for caregivers (If the principal informal caregiver decides to stop working to provide informal care). The cost of funding more services and supports for caregivers is minute compared to the value of their contributions.

C. Investment in informal caregiving research and development related projects.
